At maximum scale, there would be around 1x10 genetically modified Chinese Hamster Ovary cells in the extracapillary space of a single hollow-fibre culture system flowpath, in a volume of approximately 10 litres. In the event of spillage from the culture system, the area can be effectively disinfected. The culture system is contained within a process building, and the wider environment is unlikely to become contaminated.

The waste generated by the work in question falls into 3 categories:

A. Solid waste (which may also contain absorbed or residual levels of liquid) All material falling into this category (including used culture flasks, pipettes, and hollow-fibre flowpaths) are discarded into yellow hard plastic "Biohazard" bins identified as containing GMO waste which, when full, are closed using their dedicated lid and are collected by Site Services and stored in an identified locked bin until sent for incineration. Incineration has been acknowledged (ACGM Newsletter No. 29) as giving effectively 100% kill.

B. Liquid waste from all sources except that in category c (below) All material falling into this category will be chemically inactivated. Specifically, one-quarter volume of Haychlor Industrial (Hays Chemical Distribution Ltd.) - a sodium hypochlorite solution containing >5% available chlorine - will be added to every volume of liquid to be discarded, mixed thoroughly, and left at room temperature for at least 10 minutes before discarding to drain with copious quantities of water. This procedure has been validated with transfected CHO cells, under both the conditions normally expected during the majority of the work (c.1.5x10^5 viable cells/ml, c. 460g/ml protein) and under conditions beyond (i.e. more demanding than) those we would expect to encounter (c.1x10^7 viable cells/ml, > 8300g/ml protein). Under both sets of conditions, the viability of the cells was reduced below the level of detection, i.e. less than approximately 1 remaining viable cell per 1000 viable cells prior to treatment (see BPL R&D Lab. Book 642, pages 53-61). Due to the negligible environmental risk posed by the cells (see Risk Assessment section (v)) this level of inactivation is deemed sufficient.

The inactivation process will be routinely monitored to ensure the presence of free chlorine at the end of the inactivation period. Re-validation of the inactivation will not be performed, unless the conditions of use change from those under which the method was validated. In particular, the method will be revalidated if: i.) a different host cell line is used, or ii.) higher protein concentrations are used in the cell suspension to be inactivated, or iii.) the activity classification changes.

C. Liquid waste from the intracapillary circuit of hollow-fibre culture systems. The cell culture medium in the intracapillary circuit of our hollow-fibre system is separated by an ultra-filtration membrane with a 10kD pore size from the genetically-modified cells in the extracapillary space. Only molecules small enough to pass through these pores will move from the extracapillary space to the intracapillary circuit. These pores have a cross-sectional area which is around 8 orders of magnitude too small to allow passage of the cells, and thus cells could only escape into the intracapillary space if there were a catastrophic loss of membrane integrity. However recovery of our product, (Immunoglobulin G, molecular weight 150 - 160kD) which we harvest from the extracapillary space, is dependant on the integrity of the ultrafiltration membrane, so we would be rapidly aware of even a much smaller loss of membrane integrity. Thus this waste is considered not to contain GMMs, and is released to drain without further treatment.

Monitoring - Compliance with the principles of Good Microbiological Practice and Good Occupational Safety & Hygiene, as well as specific measures outlined above, will be monitored by regular internal and external safety audits.

The maximum culture volumes of bacterial cells is 250ml at any one time. Waste from such cultures is treated, following manufacturer's instructions, with 1% Virkon solution (Antec International Limited, UK). Efficacy of this treatment is tested every six months by treating a volume of viable culture in this matter and establishing percentage kill by subsequent growth on an agar plate. Records of testing are maintained by the Biological Safety Officer of OGT. Glassware used for bacterial culturing is thoroughly washed, after Virkon treatment, using an acid wash cycle in a Lancer 1300E industrial glass cleaner (designated for used glassware cleaning). Disposable laboratory solid waste is autoclaved at 121C for 20 minutes before removal to clinical waste storage. This is collected on a regular basis and incinerated by the Oxfordshire NHS Ambulance Trust. The autoclave (LTE Falcon 200L MC) is serviced and validated annually by LTE Scientific, Oldham, UK. Regular In-House testing of the autoclave is carried out using a duo-spore biological safety indicator (Propper Manufacturing Co, USA). Records of these procedures are maintained by the OGT Biological Safety Officer.

### Purposes of the contained use

CDNA libraries will be used as a source of genetic material for molecular cloning of the cell surface glycoproteins. The mammalian cell lines used for expression of the recombinant proteins are required for their ability to express high levels of correctly folded and post-translationally modified mammalian glycoproteins.

### Recipient or parental organism

The mammalian cell lines are sourced from external suppliers and are supplied free from contaminating agents. The cell lines documented here are unable to survive in the environment and have a history of safe use.

### Host/vector system

Transiently transfected cells have a finite life-span of 3-4 days after which they die due to the high number of episomally replicated plasmid molecules present within them and thus are unable to propagate indefinitely. Stably transfected cells are propagated to the desired level and then maintained for a short period to express the desired protein.

The cells eventually exhaust the media nutrients and die, after which the recombinant protein can be harvested from the supernatant.

The plasmids containing the cloned gene are non-mobilisable and therefore cannot transfer into other hosts.

### Origin & function

The cloned glycoprotein genes are of murine or human origin. The constructs to be expressed encode truncated, soluble forms of these cell surface molecules and will be cloned using commercial vector systems with a history of safe use.

The recombinant proteins expressed are non-toxic and will be purified using established methods such as affinity chromatography, ion exchange chromatography and fast protein liquid chromatography.

### Evaluation of foreseeable effects

Non-transfected cell lines are not able to infect healthy humans or animals and will be handled at class 11 containment level. Workers will not be working on any B lymphocytes derived from themselves (see RA 1).

Transiently transfected cells have a finite lifespan, as previously described, and are unable to propagate outside of laboratory conditions.

Stably transfected cells die as a consequence of the culture techniques used for protein expression and harvesting.

Naked DNA vectors are unable to replicate and are non-toxic.

All cell culture is performed in a class 11 biological safety cabinet and waste products are treated as described below. Sufficient precautions are taken to ensure the protection of the health of workers and the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste is disinfected with Virkon solution (Antec International Ltd USA) according to manufacturer's instructions. The treated waste is then disposed of as part of normal laboratory waste. Efficacy of waste management by this method is monitored routinely by treatment of a growing cell culture as detailed above. The effect of Virkon treatment on the cell culture is assessed by staining the cells with a vital dye (trypan blue) and determining the number of live cells by microscopy. Disposal plasticware is disinfected as above and then held in a closed container pending sterilisation by steam (121°C for 20 min). This waste is collected by contracted waste disposal services and incinerated. The autoclave used for this purpose is validated routinely using commercially available testing kits.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee have reviewed the risk assessments pertinent to the notification of intention to conduct individual contained use activities (attached) and find them satisfactory for work carried out on these premises.

Proimmune must ensure all staff carrying out these procedures are adequately trained to protect the safety of those working within the premises.

Project Ref 758/13.1

Date Ackn'd 04/11/2013
CU2 Project Title The transient expression of non-toxic, recombinant glycoproteins of human or mammalian origin in HEK293T cells (Human embryonic kidney cells transfected with the SV40 large T antigen) and other mammalian cells
Date Project Ceased

Class CultureVol
Class2 CultureVolume
Class3-4
Class 2 1-50 Litres
Non-GMM Consent Granted
Project Additional Information

Purposes of the contained use

cDNA libraries will be used as a source of genetic material for molecular cloning. The use of HEK293 cells is for their ability to express high levels of non-toxic recombinant proteins. The use of Adenoviral expression system is for its ability to transduce primary human or mammalian cells in order to transiently express non-toxic human or mammalian proteins.

Recipient or parental organism

HEK293T cells are sourced from a commercial supplier
293A cells are sourced from a commercial supplier
Primary human PBMC’s are sourced from the national Blood Service.

Host/vector system

Transiently transfected cells have a finite life-span of 3 – 4 days after which they die due to the high number of episomally replicated plasmid molecules present within them and thus are unable to propagate indefinitely.
Stably transfected cells are propagated to the desired level and then maintained for a short period to express the desired protein. The cells eventually exhaust the media nutrients and die, after which the recombinant protein can be harvested from the supernatant.
The plasmids containing the cloned gene are non-mobilisable and therefore cannot transfer into other hosts.
Replication incompetent Adenovirus infected cells are maintained for a short period to express the desired protein.

Origin & function

1) The HEK293T cells will be used to express cloned genes of mammalian or human origin and are designed express high levels of recombinant human or mammalian antibodies or other recombinant non-toxic proteins. The non-hazardous, soluble proteins will be purified using well documented techniques.
2) The replication deficient adenovirus transduced cells will be used to express non-toxic genes of human or mammalian origin for research purposes.

Evaluation of foreseeable effects

Non-transfected cell lines are not able to infect healthy humans or animals and will be handled at class II containment level. Workers will not be working on any peripheral blood mononuclear cells derived from themselves (see RA 1)

Transiently transfected cells have a finite lifespan, as previously described, and are unable to propagate outside of laboratory conditions.

Stably transfected cells die as a consequence of the culture techniques used for protein expression and harvesting.
Naked DNA vectors are unable to replicate and are non-toxic. The Adenoviral vector is replication incompetent so cannot replicate without specialised culture conditions.

All cell culture is performed in a class I biological safety cabinet and waste products are treated as described below. Sufficient precautions are taken to ensure the protection of the health of workers and the organisms and the genetic material is non-transmissible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Standard laboratory containment level 2. Control measures as stated in the risk assessment table 1.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is disinfected with Virkon solution (Antec International Ltd. USA) according to manufacturer’s instructions. The treated waste is then disposed of as part of normal laboratory waste.

Efficacy of waste management by this method is monitored routinely by treatment of a growing cell culture as detailed above. The effect of Virkon treatment on the cell culture is assessed by staining the cells with a vital dye (trypan blue) and determining the number of live cells by microscopy.

02/03/2022
Of all our projects the cloning and protein expression projects using E.coli seems to be most relevant concerning efficient inactivation as mammalian and insect cell cultures are extremely sensitive to decontamination reagents and unlikely to grow outside the incubation units. The maximum culture volumes are normally 500-600mL in 3L Erlenmeyer flasks and fermented in a special E.coli shaking incubator, which is sealed and additionally surrounded by a barrier. After cell harvest by centrifugation the remaining broth is decontaminated over night with hazard tabs and disposed into the sink afterwards. Any other waste including the cell debris from protein extraction are collected in bags and disposed by a professional and licenced company. For validation of the decontamination procedure of liquid bacterial waste we have designed following test, which will be performed in our labs in the week of 22nd to 26th of January 2001; results may certainly be forwarded to the Health & Safety Executive on request. Transformed E.coli cells will be grown overnight in 500ml volumes to maximal OD. To increase the value of the results we will instead of harvesting cells combine the untouched cultures to 2L total volume and decontaminate overnight by a hazard tablet according to our standard protocol. Next day then, samples of the supernatant will be spread on LB-agar plates and eventually surviving cell numbers will be determined. If any germs survive the procedure, I would advise the responsible staff to add an additional autoclaving step or better to increase the incubation time or the concentration of the decontamination reagent. The cell survival assay for process validation would be repeated according to the proposed alteration(s).
Solid waste is inactivated by autoclaving.

Maximum volumes of 1.5L. Expected volumes usually <50 ml. Cultures in glass or plastic tubes. Agar plates maximum 50 per batch. The waste will be made safe by large laboratory autoclave with a cycle of 126°C for 30 minutes at the standard cycle for waste. The autoclaves have been validated at commissioning by a full "worst case" scenario test under the supervision of the "authorised person" for the hospital autoclave. The autoclaves undergo regular checks at 3 month intervals with multipoint thermocouples carried out by the specialist hospital autoclave engineer. Each individual run is recorded and the cycle checked before the door of the autoclave is released. If there is a run failure the machine is automatically locked and the engineer rectifies the problem and the makesafe cycle is repeated for that load. Records for each cycle are kept and are available for inspection.

Liquid waste from cultures will be disinfected with overnight treatment with vircon disinfectant, used in accordance with a manufacturer's instructions. This treatment has been independently assessed for efficacy against a wide range of bacteria, fungi and viruses (details can be found at http://www.antecint.co.uk/) A kill rate of 100% has been claimed against E.Coli and 99.99% against M.smegmatis in 10 minutes exposure test using 1% vircon. Solid waste generated by Regma Bio-Technologies will be disposed of by incineration on site at the DERA incineration facility. Waste will at no stage be transported off site. Liquid waste containing GMOs will be inactivated by treatment with 2% Vircon over a 24 hour period. This inactivation will be carried out within the laboratory before disposal as inactivated waste. At no stage will GMO or unmodified organisms leave the laboratory in a live state.

Solid waste will be collected and inactivated by incineration using existing procedures and equipment at the DERA establishment at Porton Down. Liquid waste will be collected and also disposed of using DERA establishment facilities.

Laboratory surfaces will be disinfected with either vircon on a daily basis. Monitoring for contamination will be carried out on a weekly basis using swab tests to detect the presence of contamination.

Date of Significant Change

Project Additional Information

Purposes of the contained use

Generation and proagation of ACGM class 2 recombinant E.coli and M.smegmatis.

Recipient or parental organism

Non-infectious, non-pathogenic organisms with a history of safe use.

Host/vector system

The host organisms will be either non-infectious lab strains of Escherichia coli (K-12 derivatives) or non-pathogenic Mycobacterium species (eg Mycobacterium smegmatis). Various non-mobilisation or mobilisation defective E.coli and M.smegmatis vectors will be employed.

Origin & function

Many of the genetic elements will be novel in construction, with some sequences based on human protein sequences, but optimised for bacterial expression.

Evaluation of foreseeable effects

The possible effects of the genetic modifications described in detail in the confidential section of this submission have been assessed and minimised wherever possible. Genetic modification is carried out in non-pathogenic and non-infectious hosts. Gene sequence encoding human proteins or sections thereof are optimised for expression in bacterial hosts, and as a result are significantly different to their human counterpart, thus minimising the possibility of human genetic disruption. The vectors involved are not able to be sustained in other organisms in the environment, and therefore carry little risk of environmental damage. Moreover, the majority of the hosts, vectors, genetic elements and expressed proteins have a history of safe use.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from cultures will be disinfected with overnight treatment with Virkon disinfectant, used in accordance with the manufacturer's instructions. This treatment has been independently assessed for efficacy against a wide range of bacteria, fungi and viruses (details can be found at http://www.antecint.co.uk/). A kill rate of 100% has been claimed against E.coli and 99.99% against M.smegmatis in 10 minute exposure tests using 1% Virkon.

Solid waste will be collected and inactivated by incineration using existing procedures and equipment at the DERA establishment at Porton Down. Liquid waste will be...
collected and also disposed of using DERA establishment facilities.

Laboratory surfaces will be disinfected with either Virkon on a daily basis. Monitoring for contamination will be carried out on a weekly basis using 'swab tests' to detect the presence of contamination.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste cell culture medium will be sterilised in an autoclave on a minimum cycle of 121 for 30min. Expected degree of kill is 100% to be validated by Trypan Blue assay. It will then be disposed of down a designated drain. Waste plastic cell culture plates will be immersed in a 1% solution of commercially available disinfectant "Virkon" for a minimum of 30 mins. Expected degree of kill is 100% to be validated by Trypan Blue assay. Plates will be placed in clinical waste bags for removal and incineration by a licenced contractor.

The Committee have discussed the proposed GM work and have approved the attached Risk Assessment.

Project Ref 762/00.1

CU2 Project Title

02/03/2022  Page 11036 of 15326
**Project Additional Information**

**Purposes of the contained use**

Assays provide receptor affinity and efficacy estimates for novel, potential drug candidates.

**Recipient or parental organism**

All the cell lines are well characterised and are commercially available from either the American Tissue Collection or the European Culture Collection.

**Host/vector system**

The hosts are all well characterised cell lines. The vectors are all non-viral, synthetic, plasmid constructs.

**Origin & function**

The cell lines used are commercially available and are of human mammalian origin. They are genetically modified using plasmid constructs to express various types of receptors.

**Evaluation of foreseeable effects**

The cell lines are assigned to biosafety level 1 by their commercial supplier. Some have been shown to be tumorigenic in mice but this is not a foreseeable effect in humans. The cell are unable to survive outside the culture medium and have no foreseeable effect on humans or the environment.

Genetic Modification of the cells is unlikely to increase their ability to survive outside the culture, or to increase their pathogenicity. The vectors used are non-mobilisable and prevent no risk to the environment.

The receptor proteins expressed by the cells may be allergenic or immunogenic in humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste cell culture medium will be sterilised in an autoclave on a minimum cycle of 121 for 30 min. Expected degree of kill is 100% to be validated by Trypan Blue assay. It will then be disposed of down a designated drain. Waste plastic cell culture plates will be immersed in a 1% solution of commercially available disinfectant "Virkon" for a minimum of 30 mins. Expected degree of kill is 100% to be validated by Trypan Blue assay. Plates will be placed in clinical waste bags for removal and incineration by a licenced contractor.

For activities involving GMMs, describe the waste management measures which will apply to the activity

<table>
<thead>
<tr>
<th>Waste management</th>
</tr>
</thead>
</table>
| **Solid waste:**  Solid waste will be in the form of agar plates.  
Solid waste will be collected in biohazard bags which will be located by each bench involved in work using GMMs. This material will then be transferred to an autoclave in a nearby room. The material will be inactivated by autoclaving at 121°C for 20 minutes under pressure to give 100% kill. The autoclave is serviced every 6 months and temperature verified using autoclave tape.  
Liquid waste: This will take the form of small scale liquid cultures (overnights), the supernatants of larger scale cultures which have had the cell pellet removed by centrifugation, lysed cell pellet debris which may contain some non-lysed cells.  
For this type of waste disinfectants such as clearsol (1%), or tegodyne (0.5%) will be used. These are commercially available disinfectants and are used in accordance with the manufacturers instructions. These disinfectants have been validated by the manufacturers as 100% effective if used under the recommended conditions. This will yield a 100% kill.  
Spillages: disinfectants will be used at higher doses: clearsol (5%) and tegodyne (3%). 100% kill. Validation see above.  
Ultimate fate: inactivated material will be disposed of by normal methods - liquid waste in the sink, solid waste as non-hazardous waste.  
Monitoring and testing: The Biological Safety Committee will conduct a safety inspection of all laboratories working with GMMs every 6 months. This is to ensure that all the appropriate safety measures are in use and that GMP (good microbiological practice) and GOSH (good operational safety and hygiene). |

Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Well-characterised standard laboratory strains of E. coli strains are to be used. These are all disabled and not known to be pathogenic. Inserts are unlikely to increase pathogenicity. The vectors are, at least, mobilisation-defective, if not non-mobilisable. Proteins to be expressed are not known to be toxic, nor are their sequences known to be oncogenic. Use of T7-based promoter systems means that expression levels in anything other than the engineered DE3 strains will be minimal.  
There is a negligible hazard with respect to human health and the environment therefore the assessment of Class 1 (containment level 1) is appropriate for these hosts/vector systems.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

- **Yes**

**Laboratory work will commence at the beginning of January. This is when the research staff will arrive.**

At present, the Safety Committee consists of the project leader and the company Chief Executive. In January, a senior scientist with 6 years post-doctorate experience will be appointed as biological safety officer. The committee will spend some days at the beginning of January to consider the vectors to be used in the stated expression systems. The lab operating procedures will also be finalised at this time. After this, the committee will meet on a monthly basis to consider current practices and how to act on any proposed changes to procedures.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Personal - hands will be washed in 'Lab Guard' soap before leaving laboratory. General - work surfaces swabbed with Savlon daily. Spills - Virkon granules onto spills, use tissue to remove to autoclave bag. Liquid - presept 10,000 ppm overnight in container before disposal to drain with copious amounts of water. Glassware - presept 10,000ppm overnight then washed in dishwasher. Waste - solid - dispose as biohazard into autoclave bag for kill run in autoclave. Sharps - into sharps box for incineration. Ugar plates - dispose as biohazard into autoclave for kill run. All autoclaved solid waste sealed in autoclave bags. After kill run sealed into waste bags and disposed in the general bins.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

In the preliminary meeting of the GMSC (team leader and chief executive), it was decided that the above waste management measures were sufficient. Once the staff and work start in January, the biological safety officer and his deputy (to be appointed) will assess teh procedures being used, carry out monitoring of the work area, and set up the inventories of safe storage and records of biological agents in use.

<td>≤ 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
We wish to use recombinant disabled adenovirus and lentivirus to transduce a variety of cell lines and primary cell cultures in order to achieve a high level expression of our genes of interest.

We will use the viral vectors to insert genes of interest into several standard mammalian cell lines, including but not exclusively, HEK 293, PC12, RH7777, A549 and primary cells such as myocytes, monocytes, neurites and adult and embryonic stem cells.

We will use the Invitrogen lentivirus and adenovirus systems.

The genes we will subclone to generate our recombinant viral vectors have been isolated from animal and human origin. We will use these genes to investigate their involvement in cellular signalling processes. Using the viral vector protocol we plan to generate a range of cell lines stably expressing our genes of interest. This will provide us with a means of studying the function of our target genes. We wish to use the adenoviral and lentiviral systems as these are the most efficient and in some cases the only method available to insert our target genes into difficult to work with cells.

The adenoviral vectors and virus generated is disabled to prevent replication of live virus outside of the packaging cell lines such as HEK 293 which supply the missing adenoviral genes. The lentiviral vectors and virus are disabled to prevent replication. Generation of live virus can only be achieved by co-transfection with plasmids containing the packaging genes (e.g. gag, pol, rev and env) so that none of the HIV structural genes are present in the packaging viral genome.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Personal - all work involving the use of recombinant viruses will take place in class 2 laminar flow hoods. Labcoats, gloves, mask and safety glasses are worn by all users. Hands are washed in "LabGuard" soap before leaving laboratory.

General - Work surfaces are washed with Virkon then 70% ethanol after each experiment and at the end of the week. All procedures will be performed in class 2 laminar flow cabinets contained in a room designated for this purpose. Spills are absorbed using Virkon granules, removed using tissue and autoclaved.

Waste - Solid waste is disposed as biohazard into autoclave bags for a kill run in the autoclave. All autoclaved solid waste is sealed in autoclave bags. All contaminated plasticware will be soaked in virkon for at least 6 hours before being autoclaved. After the kill run, sealed solid waste is disposed of in the general waste bins. Liquid waste is treated with virkon before disposal.

The autoclave is on a service contract and frequently checked for correct operation.

Please enter comments on the GM safety committee on the risk assessment

The company Genetic Modification Safety Committee has passed the attached risk assessment and associated plan of work as being suitable for the handling of these biological agents. The proposed procedures were assessed as being class 2 activities. The standard cleaning, waste disposal and decontamination procedures were also assessed as being sufficient for the purposes of this protocol.

Give brief details of the genetic modification safety committee

The genetic modification safety committee and the company safety committee are synonymous. The committee is composed of, chief scientific office, department head supplies - laboratory manager, research assistant, senior scientist, dept. head tissue pharmacology, human resources and facilities officer, therapeutics and information/IT assistant. The Committee meet once a month. The BSO updates the H&S Committee at these meetings.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste is made up to 10% with microsol 3 and left for a minimum of 20 minutes all "contaminated" equipment is either soaked or wiped down with 10% microsol 3 then cleaned with 70% etanol. Disposable plastic and any solid waste are then placed in autoclave bags and sealed in clinical yellow ridged one way burn bins for incineration. Kill rate is 100%

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

A risk assessment has been completed. Any hazards identified containment has been identified and documented with all the safety procedures in place. The work is considered low risk to staff and the environment.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Screening to measure the affinity of test substances for cell surface human receptors.

**Recipient or parental organism**

Transfected cell lines which propagate under controlled conditions in vitro, but not outside the controlled laboratory environment. Cells are transfected with non-mobilisable vectors. Single cells will be dealt with in Class II cabinets and destroyed prior to disposal there are no foreseeable effect.

**Host/vector system**

Host cells will be CHO-K1 and HEK 293-EBNA supplied commercially by Euroscreen and Invitrogen, respectively.

CHO-K1 cells are transfected with the PC DNA 03 vector (Invitrogen)

HEK 293 EBNA cells are transfected with PCEP4 (Invitrogen) vector.

**Origin & function**

Cell lines (transfected with vectors encoding specific human proteins) will be sourced from commercial suppliers eg. Euroscreen. In general, these companies obtain the CDNA of interest from a human cell or tissue library and then subclone into a suitable vector for expression in a suitable mammalian cell line. Under appropriate conditions, these cell lines then express the target human protein. Pharmagenen intend to purchase these cells and use them to assess the ability of test agents to bind the target human protein of interest.

**Evaluation of foreseeable effects**

This is routine assay work with no foreseeable adverse effect. All cells will be handled in Class II biosafety cabinets and will be destroyed after each assay.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For studies using whole cells, post-assay, cells are destroyed in situ in assay plates by addition of disinfectant (Virvsol). Plates are then sealed, placed in autoclave bags and incinerated. Therefore, degree of kill = 100%.

Similarly, for studies where membrane preparations have been produced from transfected cells, post-assay, plates or filters containing membranes will be sealed in autoclave bags and incinerated.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N
A risk assessment has been completed. Any hazards have been identified. Containment has been identified and documented.

With all safety procedures in place the work is considered low risk to staff the environment.

The GMM will only be cultured on a small scale (10-200ml maximum). Work areas will be disinfected after every use with Virkon. Any spill will be treated with disinfection (Virkon) according to manufacturers' instructions immediately after spillage. All waste, solid and liquid, will be autoclaved at 121 degrees C, 15 psi for 20 minutes and then disposed by normal routes. The normal functioning of the autoclave will be monitored to estimate the "degree of kill" on a regular basis (sterilisation indicator strips/temperature recorder). External contractors (S.W. Scientific) service the autoclave annually.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

LTHT has a well established multi-disciplinary committee, chaired by a consultant virologist, and representing infection prevention and control, occupational health, pharmacy, oncology, basic science, nursing and medicine.

The committee convenes quarterly, and more recently has introduced responsive review to improve study approval timelines in line with NIHR targets. Formal application forms are used to review risk assessment and standard operating procedures are also scrutinised as part of the authorisation process.

The committee operates within a terms of reference and reports into and is accountable to the organisation's Risk Management Board.

### Level 1 (GMMs)

### Level 2 (GMMs)

### Level 3 (GMMs)

### Level 4 (GMMs)
L2 GMMs prep. for clinical use by pharmacy aseptics and admin. on oncology wards in clin. trials

Waste management is managed through a single process to ensure consistency and compliance irrespective of Cat 1 or Cat 2 status. Specific deactivation of residual agent or delivery equipment, if necessary, is stipulated in the study specific SOP for the trial, which includes compliance with local trust policies and procedures.

All preparation materials and clinical waste derived from the procedure of administration of the agent is contained within a newly configured waste disposal clinical sharps container for each individual procedure carried out. If chemical deactivation is necessary this is achieved by means of a virucidal agent. Biohazard spillage kits are in use and immediately available to staff prior to any procedure. Occlusive dressings are used in some instances where viral shedding is a concern, based on the agent under use, and patients are provided with non-sterile gloves and clinical sharps containers to appropriately dispose of used dressings. These containers are returned to the hospital for safe disposal.

All waste relating to viral or GM activities is labelled appropriately and sent for incineration (external contract with White Rose) as per trust policy for safe disposal of biological and cytotoxic clinical waste.

All staff are trained and assessed in safe and appropriate waste disposal, as well as study specific requirements prior to authorisation to carry out treatment in these studies.

Study specific SOPs include an assessment of risk to patients, staff and the environment and include the process of receipt of the agent, handling, preparation, administration, waste containment and management and incident management (spillage/needlestick injury) of the agent under investigation.

A summary of the agents and clinical trials currently being conducted within LTHT is appended.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The risk assessment for the ONYX-015 virus was duly noted. The safety committee were satisfied that appropriate procedures are in place, in both the pharmacy and ward environments, to minimise the risk to human health and the environment.

**Project Ref 767/01.1**

**Date Ackn’d** 14/02/2001

**CU2 Project Title** A PHASE 1 DOSE-ESCALATION TRIAL OF ONYX-O15 (CI-1042, PFIZER PHARMACEUTICALS), AN E1B-ATTENUATED ADENOVIRUS, AS AN INTRA-VESICAL GENE THERAPY FOR RECURRENT SUPERFICIAL/MUSCLE-INVASIVE BLADDER CANCER

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use** Clinical trial

**Recipient or parental organism**

Human subjects (patients with superficial or muscle-invasive bladder cancer, selected according to strict criteria, as set out in clinical trial protocol). Approval has already been obtained from the Department of Health's Gene Therapy Advisory Committee (GTAC).

**Host/vector system**

ONYX-015 is a chimeric Group C adenovirus (Barker DD and Berk AJ (1987) Virology 156 (1), 107-121), which is selectively replication-competent. It contains no oncogenic nor immune-modifying genes. Rather, as a result of a deletion in the E1B region of the viral genome, it is incapable of replication in normal host cells i.e. those with wild-type p53 gene. In cancer cells with defective p53 function, however, it can undergo replication.

**Origin & function**

Adenovirus is obtained by propagation in 293 human embryonic kidney cells in cell culture. Clinical-grade virus, free of cellular material, will be supplied by Pfizer.
Viral stock solution will be diluted on-site (see Section 12) in sterile saline and instilled into patients' bladders via a urethral catheter on 5 consecutive days, according to a dose-escalation schedule, as set out in the clinical trial protocol, to assess the safety and potential toxicity of intra-vesical administration.

**Evaluation of foreseeable effects**

Extensive previous clinical experience with the ONYX-015 virus has already demonstrated its safety, when administered via a variety of routes, including intravenous and intra-arterial routes. This previous experience suggests that effects of the micro-organism on the individual to whom it is administered are minimal. Toxicities observed have included 'flu-like symptoms, abnormal liver function, mild hypotension, abnormal bleeding and pain at the site of injection. There have been no treatment-related deaths with this virus.

The vast majority of the human population will have been previously exposed to wild-type adenovirus. There is a theoretical possibility that, in individuals still harbouring viable wild-type virus, recombination between ONYX-015 and wild-type viruses may occur. However, the absence of any exogenous genes in the ONYX-015 genome means that the consequences for the individual concerned, those with whom the individual comes in contact, and the environment would be no more than those for wild-type (i.e. possible short-lived, self-limiting upper respiratory tract infection, bronchitis, gastro-enteritis, conjunctivitis or cystitis in humans; the virus has extremely narrow host range, and is extremely unlikely to infect other exposed species).

Wild-type adenoviruses are Hazard Group 2 biological agents (as defined by the Advisory Committee on Dangerous Pathogens), and thus containment level 2 should be adequate for this virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Schedule 8, Part II, Table 1a (8) Autoclave required in the building

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Medium-term storage of viral stocks will be in a dedicated freezer in the hospital pharmacy. Viral stocks will be diluted immediately prior to administration into sterile bags of normal saline within a dedicated vented negative pressure biological safety cabinet with separate air handling plant in a dedicated area of the hospital pharmacy. Waste sharps and other contaminated materials will be autoclaved (124oC, 11 mins) and then incinerated with an anticipated 100% kill. Diluted virus will be transported from Pharmacy to the Oncology Wards in sealed plastic bags inside a sealed plastic box. Short-term storage (no more than a few hours) on the ward will be in a dedicated refrigerator. On the oncology wards, virus will be administered via a urethral catheter in a side-room. Solid waste will be kept separate from other ward waste, then autoclaved and incinerated, with 100% kill expected. Patients will be clinically monitored until 24 hours after final administration of virus, and voided urine will be collected in hypochlorite solution (to a final concentration of 1% for 30 mins), autoclaved (anticipated 100% kill), then disposed of into hospital drains.

Effectiveness of safety cabinets and autoclaves will be monitored by weekly testing of the autoclave and annual testing of safety cabinets in accordance with existing local policy.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y
The risk assessment for the ONYX-015 virus was duly noted. The safety committee were satisfied that appropriate procedures are in place, in both the pharmacy and ward environments, to minimise the risk to human health and the environment.

NHS patients with 'Asymptomatic or Minimally Symptomatic Metastatic, Castrate-Resistant Prostate Cancer

Host/vector system

PROSTVAC-V/F is comprised of two component viral vectors: a recombinant vaccinia virus (PROSTVAC-V) and a recombinant fowlpox virus (PROSTVAC-F) to be used sequentially in a heterologous prime-boost vaccination regimen. Both viruses contain four human genes: prostate-specific antigen (PSA) and three genes encoding human immunological costimulatory molecules: B7.1, intercellular adhesion molecule-1 (ICAM-1), and leukocyte function-associated antigen-3 (LFA-3) (designated TRIad of COstimulatory Molecules or TRICOM). The simultaneous expression of PSA and TRICOM enhances the immune response. The PSA transgene is modified at one amino acid (I155L), to enhance binding and immunogenicity of a particular peptide epitope in HLA-A2-expressing subjects.

PROSTVAC-V: The parental vaccinia virus used for the generation of PROSTVAC-V was derived from a plaque isolate (designated TBC-Wy) from the seed stock of virus used by Wyeth Pharmaceuticals to produce the licensed Dryvax® Smallpox Vaccine. Dryvax was the vaccine used in the USA during the world-wide smallpox eradication campaign, which ended in the early 1970’s. The vaccinia virus is a replicating virus and therefore can shed from the vaccination site.

PROSTVAC-F: The parental fowlpox virus (TBC-FPV) was plaque-purified from a USDA-licensed poultry vaccine, POXVAC-TC, which was manufactured by Schering-Plough Corporation. The fowlpox viral vector is an avipox virus that does not replicate in mammalian cells.

Origin & function

The intent of vaccination with PROSTVAC is to induce an immune response to prostate-specific antigen (PSA), and other prostate- and tumor-specific antigens. This response may provide anti-tumor activity and slow the overall progression of disease.

Evaluation of foreseeable effects

Vaccinia virus (used as a vector in PROSTVAC-V) causes a transient infection, with elimination of viral components over several weeks. Host cells infected with vaccinia virus are short lived (days) and die by a mixed form of apoptosis/necrosis. Vaccinia replicates in the cytoplasm of infected cells, and viral DNA does not integrate into the host cell DNA. Vaccinia virus is known to be shed from the wound site in traditional dermal scarification based vaccination. It is important to note that PROSTVAC-V will be administered via subcutaneous administration in patients who were previously vaccinated with a small-pox vaccine, factors which serve to minimize shedding. Nevertheless, because the vaccinia virus is a replicating virus, there is still a risk for inadvertent inoculation or contact transmission. Thus, there are specific procedures/precautions applied to PROSTVAC-V that may not apply to PROSTVAC-F or the Placebo because the fowlpox virus does not replicate in humans.

Inadvertent sharps injuries (needle-stick, etc.), contact with skin, eyes or genitals inhalation or ingestion.

RISKS FROM EXPOSURE. Adverse reactions attributable to the administration of PROSTVAC-V/F based on the results of the randomized Phase II trial include injection site reactions experienced by 98% of patients (pain, swelling, induration, and redness). More than 10% of patients experienced gastrointestinal disorders (constipation, diarrhea, nausea), arthralgia and dizziness. The majority of events were of Grade 1 and 2 in severity. These side effects are related to both PROSTVAC-V and PROSTVAC-F. As already noted, viral shedding is minimal with PROSTVAC-V, however, there are still risks of inadvertent infection of other body sites (through scratching), or transfer of infection to others. There is no risk with PROSTVAC-F or Placebo for inadvertent infection of other body sites or transfer of infection to others. There are rare risks of severe and possibly life-threatening adverse reactions associated with PROSTVAC-V. These include eczema vaccinatum (~1/25,000, usually with history of underlying skin disorder) or progressive vaccinia (~1/1 000.000, usually with underlying immunodeficiency), or post vaccinial encephalitis (~1/500.000, usually infants or small children). These were observed after the administration of conventional smallpox vaccines, and have not been seen in prior studies of PROSTVAC or related PSA (or other tumor antigen)-containing vaccinia virus vaccines administered to vaccinia pre-immune cancer patients.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Management and containment of agent and potential hazards are detailed in the LTHT SOP for the study and the sponsors Biosafety Process guidance document for Principal Investigators and site personnel. (Attached)

Patients are treated and monitored in restricted access clinical areas. Appropriate use of biohazard signs highlight activity to others in the vicinity. Although PROSTOVAC has been registered with HSE as a deliberate release study, the requirements for handling, treatment delivery and patient management are consistent with our contained

Page 11061 of 15326
use protocols. Therefore this study is highlighted as an example of category 2 activity.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Study registered with HSE by sponsor under deliberate release regulations.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

LTHT BSC risk assessment form attached.

Staff involved in the handling or delivery of the agent, as well as those who may come into contact with patients will be made aware of the risks and necessary precautions required. Staff who may be immunocompromised, pregnant or planning pregnancy will be excluded from drug handling or administration and monitoring activities relating to this study.

Please enter comments on the GM safety committee on the risk assessment

PROSTVAC Trial – Presented by Dr SJ and Research Nurse, JC
SJ presented an overview of this study for castration resistant metastatic prostate cancer patients. She explained the objectives, inclusion/exclusion criteria and method of delivery of the vaccine. In 2 arms of the study patients will have the vaccine with or without GSF. SJ anticipated 1 patient recruited every couple of months. JC or a member of the LCRF team would administer the injection and all would have training to give this type of agent if not done so before. It was being considered that the GSF could be administered at home if patients wish to be taught how to do this. SJ mentioned the expected side effects and the preventative measures they would employ for staff and patients; such as screening patients carefully to find out who they may be in contact with, advising staff of the potential risks should they be pregnant or on immunosuppressant medication.
On discussion ST reported the new biological aseptic rooms are being commissioned in Pharmacy. She stipulated that the injection site should be covered with an occlusive dressing to prevent leakage. This vaccine was in the biosafety level 2 risk group. ST informed the meeting that a different licence would probably be required if patients gave the GSF at home, as the GSF was administered so close to the vaccine injection site and would fall under ‘deliberate release’ guidelines and this could prove extremely difficult for the licence holder to ensure compliance. BSC members and SJ all agreed it would be better for participants to have their treatments at the hospital under the contained use licence and where appropriate disposal of dressings etc can be evidenced. JC explained that they may have difficulties block booking the LCRF beds on Ward 97 for all the days of administering treatment. SJ to confirm if study is to be notified under “deliberate release” regulations (to be consistent with other study sites)
SJ will check with the Sponsor if the blinding code can be broken should there be a needlestick injury. In such cases staff would be referred to Occupational Health. It was agreed that SJ should contact the Infectious Diseases Department to make them aware of this study and so aware of any potential referral. MP had reviewed the study SOP and sent comments back to JC. JC to update the SOP and email back to the BSC Chair.
On review the BSC members agreed this study could go ahead. It was agreed that a letter/email of support from Dr Jane Minton in the Infectious Disease Department should be seen by TH. Corrections to the SOP should be sent back to the Chair. Timing of the start of the study would hinge on the Trust’s application to the HSE for a level 2 licence for these types of vaccines. SJ to be informed when this is available.
Project Ref 767/13.2

A planned programme of Early Clinical Trials using Oncolytic Viruses (OV) in cancer patients. These trials all involve the administration of OV by an intravenous (i.v.) route including genetically modified strains of vaccinia (GL-ONC1 & JX-594) and Herpes Simplex Virus (HSV1716).

Recipient or parental organism

JX-594 & GL-ONC1 are derived from different strains of vaccinia virus derived from the commonly used Wyeth vaccine strain (Dryvax®, Wyeth Laboratories). It was designed to selectively replicate in and destroy cancer cells, while at the same time stimulating a systemic anti-tumour immune response through the expression of its transgene, hGM-CSF, in the context of tumour lysis. Three genetic modifications are included in JX-594: 1) thymidine kinase gene inactivation, 2) GM-CSF gene insertion.
under the control of the synthetic early-late promoter, and 3) lac-Z gene insertion under control of the p7.5 promoter.

GL-ONC1 is a vaccinia virus genetically engineered by Genelux Corporation, designated as GLV-1h68 (laboratory name for GL-ONC1). GLV-1h68 was derived from the LIVP strain (Lister strain obtained from the Institute of Viral Preparations, Moscow) by inserting ruc-gfp (a fusion gene of Renilla luciferase and green fluorescent protein), LacZ (beta-galactosidase), and gusA (beta-glucuronidase) expression cassettes into F14.5L (located between F14L and F15L), thymidine kinase (TK), and hemagglutinin (HA) loci, respectively. Disruption of these nonessential genes and expression of the foregin gene expression cassettes not only attenuated the virus but also enhanced its tumour-specific targeting. GLV-1h68 was used in most of the in vitro cytototoxicity studies and the efficacy studies in animals.

Herpes Simplex Virus (HSV) is a member of the Herpes group of viruses, the Herpesviridae. HSV1716 (JS134.5-/w) is a genetically modified strain of HSV1 incorporating a single deletion of the RL1 gene (ICP34.5).

As a result of the above genetic modifications to the viral backbones, the risk of replication & spread of these viruses in any tissues, other than tumour, is negligible.

Origin & function

Disruption of the Thymidine Kinase (TK) gene in both GL-ONC1 & JX-594 ensures tumour-restrictive replication. GL-ONC1 has also lost several ORFs including genes for virulence (such as the cytokine response modified E protein). These changes also contribute to tumour selectivity as do the engineered deletions of F14.5L and haemagglutinin. Other modifications include insertion of proteins to enable/enhance virus detection & replication in vivo:

- LacZ (encodes β-glucuronidase which allows histological detection of viral replication in tissues & visual detection in cells) - GL-ONC1 & JX-594
- gusA (a reporter gene which results in expression of β-glucuronidase to allow detection of virus) - GL-ONC1
- Green fluorescent protein (GFP) (to enable visualisation of viral infection) - GL-ONC1
- GMCSF (to promote immune cell activation against tumour) - JX-594.

HSV1716 Has only a single deletion of the RL1 gene (ICP34.5), causing a loss of virulence & the ability to establish latency, together with confining viral replication to tumour cells. In a wild-type HSV-1 infection, ICP34.5 plays a key role by mediating escape from a major host defence to mechanism involving the PKR pathway which, if activated, will prevent protein translation and viral replication. In contrast, HSV1716 which lacks functional ICP34.5 proteins, is not able to overcome the host PKR defence and thus HSV1716 is highly attenuated in non-dividing, normal, cells.

Evaluation of foreseeable effects

Risks to human health

All of the above OV are considered a Biosafety Level 2 (BSL-2) infectious substance. The BSL-2 designation and associated guidelines apply to agents of moderate potential hazard to personnel and the environment.

All OV will be administered to patients via an i.v. route, which is low-risk strategy in comparison to other routes, e.g. intralesional.

Vaccinia viruses

Both GL-ONC & JX-594 have been used previously in clinical trials and their safety well-documented. The most extreme risks to human health are the possibility of patients developing infection following treatment which may result in viral spread to others through close contact. Humans are not a natural host of vaccinia virus & exposure of normal, healthy humans to these viruses is unlikely to result in toxicity as immune recognition & activation would control viral pathogenesis. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous infection. However, rescue drugs (e.g. vaccinia immunoglobulin, cidofovir, etc) are available to effectively treat any potential vaccinia infections, which usually manifests itself as a clinically mild rash. Neither GL-ONC1 nor JX-594 are known to produce latent infection.

HSV1716

HSV has been widely investigated for several decades with no instances or evidence of oncogenicity or vertical transmission having been reported. Exposure to HSV1716 is highly unlikely to result in toxicity as it is a non-pathogenic virus.

All OV

The risk of viral shedding has been documented in previous trials to be negligible or non-existent. In addition, to date there have been no reported secondary transmission...
events to healthcare workers or close contacts of treated patients. Despite previous safety data for all the above viruses, containment strategies will minimise the potential risk of infection/transmission. People in at-risk groups (those with skin rashes, the immunocompromised, pregnant women & infants) will be excluded from treatment & advice will be given to patients to avoid direct contact with family members in these groups for duration of treatment. No immunocompromised, pregnant or breastfeeding staff will be involved in pharmacy or patient care.

Environmental Hazards

The environmental impact is likely to be low. All the above GM viruses are not naturally found in the environment. In addition, they are replication attenuated &/or disabled and are unlikely to survive in the environment. Outside of the host, the viruses are fragile & easily inactivated by UV irradiation or with standard hospital disinfectants, e.g. Chloroclean. Shedding of the viruses in treated patients has been shown to be negligible to non-existent, therefore would not pose a risk to anything or anyone. As an additional precaution, the administration site will be swabbed with alcohol and an occlusive dressing will be used following administration if delivered via the subcutaneous route. Due to the nature of the release site, the method of administration and the fact that the viruses are replication attenuated/disabled, no other organisms are likely to be exposed to the GMO.

Risks of recombination.

Vaccinia virus is not naturally found in the environment & has no natural host reservoir. As such, there is no danger of recombination of any of the attenuated vaccinia strains with the wild-type virus. Vaccinia is capable of recombination with homologous DNA sequences. However, there was no specific concern raised during the smallpox vaccination campaigns where hundreds of millions of people were administered with the w/t virus. Despite worldwide use of the live virus vaccine, no reported adverse events due to mutation to a more aggressive phenotype has ever been reported. Various strains of vaccinia virus (such as NYCBH) have been detected in humans shortly after receiving vaccinia-based vaccines. Therefore, to avoid the risk of any potential recombination events, the protocols exclude from the proposed clinical studies patients who have been vaccinated within the past 10 years.

Recombination of orthopoxviruses with other DNA/RNA-viruses have been reported very rarely and appears to be very unusual. In addition, since poxviruses use unique promoters, gene activation by inserted foreign promoters also seems very unlikely.

GL-ONC1 - The risk that GL-ONC1 will revert into more virulent mutants is very low, as the parental LIVP strain, a descendant of the Lister strain, was attenuated by frequent passages on calf skin (more than 500 times). Furthermore, stability testing showed some variation in expression of GFP but consistent expression of the other marker genes 100% of the time. In vivo studies showed equal safety & efficacy in the absence of ruc-gfp expression.

JX-594 - JX-594 could revert its genome to its parental structure by eliminating the expression cassette inserted into the TK gene. Current genetic stability studies have not detected spontaneous revertants. Despite this, even if it was to revert back to wild-type, there would still be no environmental concern, as stated above.

HSV1716 - HSV has been widely investigated for several decades with no instances or evidence of oncogenicity or vertical transmission have been reported.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management is managed through a single process to ensure consistency and compliance irrespective of Cat 1 or Cat 2 status. Specific deactivation of residual agent or delivery equipment, if necessary, is stipulated in the study specific SOP for the trial, which includes compliance with local trust policies & procedures.

All preparation materials and clinical waste derived from the procedure of administration of the the agent is contained within a newly configured waste disposal clinical sharps container for each individual procedure carried out. If chemical deactivation is necessary this is achieved by means of a virucidal agent. Biohazard spillage kits are in use and immediately available to staff prior to any procedure. Occlusive dressings are used in some instances where viral shedding is a concern, based on the agent.
under use, and patients are provided with non-sterile gloves and clinical sharps containers to appropriately dispose of used dressings. These containers are returned to the hospital for safe disposal.

All waste relating to viral or GM activities is labelled appropriately and sent for incineration (external contract with White Rose) as per trust policy for safe disposal of biological & cytotoxic clinical waste.

All staff are trained and assessed in safe & appropriate waste disposal, as well as study-specific requirements prior to authorisation to carry out treatment in these studies.

Study-specific SOPs include an assessment of risk to patients, staff & the environment and include the process of receipt of the agent, handling, preparation, administration, waste containment and management, and incident management (spillage/needlestick injury) of the agent under investigation.

A summary of the agents & clinical trials, either approved or in development, are outlined as follows:

Clinical trials with 2 of these agents already have an approved protocol:
• An open label non-randomised Phase 1b translational study to investigate the effect of the oncolytic virus GL-ONC1 administered intravenously prior to surgery on liver metastases in patients with metastatic colorectal cancer.
  
  PROTOCOL NUMBER: GL-ONC1-008
  
  SPONSOR: Genelux GmbH, Am Neuland1, D-82347 Bernried, Germany.

• A clinical study to evaluate the biological effects of pre-operative intravenous administration of JX-594 (thymidine kinase-deactivated Vaccinia virus plus GM-CSF) prior to planned surgical resection of locally advanced/poor prognosis or metastatic cancers.
  
  PROTOCOL NUMBER: CO12/10151
  
  SPONSOR: University of Leeds, Leeds, West Yorkshire

Future clinical trials in development
• A Phase 1 trial of intravenous herpes HSV1716 in solid tumours - this trial protocol is currently in development & is expected to open within the next year.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
Biological Safety Committee meeting on 11 June 212 - Study discussed at the BSC meeting held on 11 June 2012 and was approved in principle subject to:

i) Finalised SOPs for both studies
ii) An infection lead identified
iii) Ensure staff are informed of the possible risks of exposure before working with this virus.

Biological Safety Committee Minutes - 4 March 2013 - The study involves one dose of the GM with a 28 day follow up.

The virus is attenuated by the TK deactivation.
No toxicities are expected with paracetamol.
Vaccination history of the patients is unknown
Patients will stay overnight in hospital following their drug administration
PI to discuss this study with a specialist infectious diseases consultant to ensure a pathway is in place for advice and referral if required. SOP reviewed and amendments to be incorporated.

HSV1716
The planned HSV1716 clinical trial does not yet have a finalised & approved protocol, but is intended to be presented to the Biological Safety Committee later in the year.
Due to the nature of its genetic modification, i.e. only a single deletion & no insertions, we anticipate the risk assessment & containment strategies to be consistent with the other viral agents previously described.

**Project Additional Information**

**Purposes of the contained use**

Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed contained use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival. Among them, 300 patients (Le. approximately 100 patients in EU) will receive Pexa-Vec by IT injections.

**Recipient or parental organism**

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, DryvaxTM.

W is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of W exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988).

W has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As W contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. W may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination to smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexa-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes replication in normal cells more difficult than the smallpox vaccine. Rare complications included eczema vaccinatum (patients with eczema), disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) (Fields B.N., 1996). Recent studies of smallpox vaccines have identified cardiac injury including pericarditis and myocarditis as a potential risk (Halsell J.S. et al., 2003).

W replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host genome (Moss B., 2007).
In terms of classification of hazard, W is considered as a Group 2 biological agent as per Directive (2000/54/EC). W is also classified as a Biosafety Level 2 (BSL-2) infectious substance by the US Centers for Disease Control and Prevention (CDC) (CDC, 2009) and as a risk group 2 organism by the US NIH Guidelines (NIH).

**Host/vector system**

Pexa-Vec was generated by co-transfection of CV-1 cells (Monkey kidney cells) with W (Wyeth strain obtained from the Center for Disease Control, Atlanta, Georgia) and the plasmid pSC65/hGM-CSF. The vector pSC65/hGM-CSF contains DNA sequences coding for the hGM-CSF and β3-galactosidase proteins and for their respective promoters. In addition, the transgene sequences are flanked by two W genomic regions (TKL and TKR) that allow homologous recombination between the transfer plasmid and W.

The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland (Chakrabarti 1997).

The plasmid pSC65/hGM-CSF is inserted into W. The insertion of pSC65/hGM-CSF into W can be detected by using colorimetric identification of plaques containing recombinants expressing β3-galactosidase.

The pSC65 vector when provided by Dr. B. Moss contains the LacZ gene. The LacZ gene is a reporter gene, under control of the W p7.5 early/late promoter. The additional donor gene (i.e. gene coding for hGM-CSF) is inserted in pSC65 as follows.

The plasmid pCSF-1 (No. 39754) was obtained from American Type Culture Collection and comprises the full-length cDNA for hGM-CSF (Wong 1985). The hGM-CSF gene was cloned first into the EcoR1 site of pBLUESCRIPTII SK (Stratagene, La Jolla, California), generating plasmid pBLUE/hGM-CSF, and providing restriction enzyme sites to allow cloning of the hGM-CSF gene into the Sail and Bgi II sites of pSC65. This positioned the hGM-CSF gene downstream of a synthetic promoter (PsE/L) designed by Dr Moss' laboratory to give maximal levels of transcription during both the early and late phases of vaccinia infection (Chakrabarti 1997).

**Origin & function**

Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGMCSF) gene and 3) insertion of the LacZ gene.

Due to the insertion of the transgenes, the TK gene is inactivated. This decreases W virulence (Buller R. et al., 1985) by restricting viral replication to proliferating cells. This also targets dissemination of the virus to tumors (Puhlmann M. et al., 2000).

The plasmid pCSF-1 (No. 39754, American Type Tissue Culture Collection, Rockville, Maryland) contains the full-length cDNA for hGM-CSF (Wong G.G. et al., 1985). The cDNA for the hGM-CSF gene was inserted into the TK gene to help elicit an immune response to tumor cells both at the site of viral replication and in distant metastases. The cytokine hGM-CSF was chosen because it was the most potent stimulator of systemic anti-tumor immunity among many tested (Dranoff G. et al., 1993), probably due to its unique ability to promote differentiation of hematopoietic precursors into dendritic cells (Pardoll D.M., 1995). Dendritic cells are professional antigen presenting cells that may take up and present released tumor antigens as the tumor cells are killed by the W.

The LacZ gene is contained in the pSC65 plasmid which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland.

The LacZ gene encodes for β3-galactosidase which is a hydrolase enzyme that catalyzes the hydrolysis of 13-galactosides into monosaccharides.

Of note, following recombination between the W and pSC65/hGM-CSF, the antibiotic resistance gene contained in pSC65 is not part of the insert. The final GMO does thus not contain any genes conferring resistance to antibiotics.
Evaluation of foreseeable effects

Pexa-Vec is non-integrative, and replicative and propagative characteristics of W have been attenuated in Pexa-Vec, which makes the virus replication dependent on actively dividing cells such as cancer cells. Therapy with a replicating virus can theoretically lead to shedding of the virus into the environment, and potentially to the public, although controls are used in this trial to minimize this occurrence. The clinical information available to date suggests that Pexa-Vec is safe at the clinical dose of 1 x 10^9 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 35 will likely have been previously immunized with vaccinia. In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. Therefore, public health risks with this virus are extremely low and in fact should be lower than with standard vaccination procedures. To date, no reports of transmission to health care personnel from vaccinia recipients have been published. Routine barriers nursing approaches should be used per institutional guidelines for infectious organisms (e.g. such as for M. tuberculosis, Pseudomonas).

The information regarding the risk to patient contacts and guidelines for reducing the risk of viral transmission is contained within the Participant Information Sheet and Consent Form (PISCF) and the Pexastimogene Devacirepvec (Pexa-Vec) Guidelines (provided in Appendix B of Pexa-Vec Investigator's Brochure). The PISCF will be reviewed with the patients, and their written consent will be obtained, before they undergo any study-specific procedures. A signed copy of the PISCF will be given to the patients so that they can come back to the guidelines at any time. Pexastimogene Devacirepvec (Pexa-Vec) Guidelines will be given to investigators, pharmacists, and all personnel involved in the handling of the product.

The genetic modification of the virus is not expected to result in any post-release shift in biological interactions or host range or in any known or predictable effects on non-target organisms in the environment. It is also not expected that the release of the recombinant virus would result in any increase in pathogenicity as compared to the parental virus strain and/or in any increase in the capacity to recombine with other related viruses. Therefore, under the conditions for use in the proposed clinical trial, Pexa-Vec is not considered to represent a risk for the environment and for the public health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials and devices (vials, stoppers, needles, gauze, disposable protective clothing etc) that come into contact with the vaccine will be discarded into a screw-capped jar containing approximately 150 mls Chlorclean solution. The jar will be sealed, rotated to disperse the Chlorclean solution, then placed inside a purple lidded sharps container to be disposed of in the designated Genetically Modified (GM) waste bin which will be provided. This will be disposed of as per L THT Standard Infection Prevention and Control Precautions Policy, L THT Waste Stream)
The GMSC discussed the risk assessment and noted that Pexa-Vec is a replicative oncolytic recombitant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, DryvaxTM. Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain, as below.

1. Disruption of the viral thymidine kinase (TK) gene
2. Insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF)
3. Insertion of the LacZ gene

Pexa-Vec is designed to selectively replicate in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response through the expression of its transgene, hGM-CSF, in the context of tumour lysis.

Pexa-Vec is currently in clinical development for the treatment of Hepatocellular carcinoma. The proposed release will be the administration of the investigational product by intratumoural (IT) injections to patients as part of an international, multicentre clinical trial. Results from this pivotal trial will determine whether Pexa-Vec followed by Sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

A small proportion of patients develop up to about 5 pustular lesions typical of vaccinia, however control procedures are in place and include covering any lesions with dressings.

The committee also reviewed the Standard Operating Procedure Document for the handling of JX-594 (Vaccinia GM-CSF / TK-deactivated virus) provided by the oncology clinical research department at St James's. Pregnant and breastfeeding women, individuals with exfoliative skin conditions and those who are immunocompromised should avoid direct contact with JX-594 and also patients being treated with such.

It was also acknowledged that the Trust has experience of handling GMO reagents. Dr Alan Anthoney (CoInvestigator) has previous experience ( albeit not handling) of JX-594

Dr Antony Hale, Consultant Virologist, as chair of the biological committee, confirmed on the 26 August 2016 that the required documentation, including GTAC approval had been reviewed and the study could proceed. Regular updates, usually on a quarterly basis, will be required by the committee.

Additional information covering 1) patient management of pustules & safe disposal of dressings, and 2) control of virus shedding is contained in the following three documents accompanying this notification:

ICF v2.5
Management of PV toxicities
Appendix S: Pexa-Vec Guidelines.

Project Containment
Project Additional Information

Purposes of the contained use

RP1 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. RP1 has a particular utility in combination with immune co-inhibitory pathway blockade. Intended indications to study include soft tissue sarcoma, breast cancer including triple negative breast cancer (TNBC), lung cancer including non-small cell lung cancer (NSCLC), melanoma, non-melanoma skin cancers, head and neck cancer, primary liver and kidney cancer and colorectal cancer. The initial clinical trial protocol intends to test RP1 in several indications as a monotherapy and in combination with anti-PD-1 therapy.

Recipient or parental organism

RP1 (rHSV-1hGM-CSF/GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R- [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells.
through binding to the constitutively expressed Pit-1 receptor for GALV. This results in the death of the cells by
membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1
selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic
destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an antitumour
immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced
through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly
immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may
then lead to immune destruction of distant, un injected tumours, and/or delay the progression of distant disease,
and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

### Host/vector system

RP1 (rHSV-1hGM-CSF/ GALV-GP) is derived from the RH018A strain of Herpes Simplex Virus-1. RP1 is produced in the
Vero cell and released into the culture media during cell lysis, prior to purification.

### Origin & function

RP1 was constructed using a new strain of HSV-1 (strain RH018A). Replimune obtained and compared 30 clinical
strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018A) for
further development.

RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity.

GALV-GP-R- binds to the Pit1 receptor, which is widely expressed on mammalian cells including human tumour
cells. Pit1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in
response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without
GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as
compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell
fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing
exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune
mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immunemediated
approaches to cancer therapy such as immune co-inhibitory pathway blockade.

### Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon
transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour
immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified
through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly
immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may
then lead to immune destruction of distant, un injected tumours, and/or delay the progression of distant disease,
and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| No derogation is requested |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1% Virkon solution).

**Phase 1**

As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol, (i.e. day 1, day 2, day 3, day 15, day 16, day 17, day 29, day 30, day 31, , day 43, day 57, day 71, day 85, day 99 and as part of the follow up, 30 days and 60 days after the last dose of RP1).

- Blood, saliva/oral mucosa, urine samples and injection site dressing swabs will be collected at the first, second and third RP1 injections at the following time points: pre-dose, 6 (+/-2hr) hours, 21 hours (+/-3hr) and 48 hours (+/-6hr) and also immediately prior to dosing at fourth and fifth dose.
- Specimens (swabs) will be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection. Samples should be obtained as soon as possible after symptoms arise to maximize the possibility of detection of virus, optimally within 24 hours, but samples may be collected later if collection within 24hrs is not possible. Subjects will be asked to take swabs at home for the subsequent 7 days after the initial test.

**Phase 2**

As part of phase 2 portion of the clinical trial, biodistribution and shedding will be also monitored.

- RP1 DNA levels in Blood, Saliva/oral mucosa, urine samples and injection site dressing swabs will be collected pre-dose at the first through last RP1 injections (cycles 1 to 8). Additionally, for each of the tumour types enrolled, the first six patients the following additional time points will be required: Doses 1, 2 and 3: 6 (+/-2hr) hours, 21 (+/-3hr) and 48 (+/-6hr) hours and also immediately prior to dosing at the fourth through eighth injections. Samples on injection days will be collected prior to any injections and handling of RP1.
- Samples will also be collected at the 30 and 60 day follow-up visits.
- Specimens (swabs) will also be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection.

In phases 1 and 2 of the study, samples on injection days will be done prior to any injections and handling of RP1.

02/03/2022
Genetically modified vaccinia virus (VV TK-RR-/FCU1) used as advanced therapy medicinal product for the treatment of colorectal cancer

Recipient or parental organism

The recipient is the vaccinia virus (VV) Copenhagen strain, which was selected for TRANSGENE’s oncolytic virus program as one of the most lytic strains. The virus was previously used for smallpox vaccination in Denmark and the Netherlands.

VV is considered a minor pathogen for humans (Dumbell K.R., 1985) and is classified as a biological agent of risk group 2 as per Directive 2000/54/EC. VV has the ability to infect a wide range of human tissues, but do not cause any known human disease. VV replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host genome (Moss B., 2007). VV does not produce a latent infection, so once the infection arises, the virus is rapidly cleared from the host.

Vaccination with VV was associated with mild to severe adverse events. Mild vaccine reactions included skin lesions, fever, myalgia, local lymphadenopathy, fatigue, headache, nausea, rashes, and soreness at the vaccination site (Belongia E.A. and Naleway A.L., 2003). Severe vaccination complications were extremely rare and
included death (1 per million), progressive vaccinia (1.5 per million), postvaccinal encephalitis (12 per million), eczema vaccinatum (39 per million), and generalized vaccinia (241 per million vaccinated) (Lane J.M. et al., 1970). A statistically significant increased risk of myo/pericarditis (1-2 per 10,000 vaccinees) was reported more recently (Arness M.K. et al., 2004). The great majority of the severe AEs occurred in “at risk” subjects including children <12 months of age, severely immunocompromised individuals (e.g. organ transplant recipients, HIV-positive individuals, or those receiving chronic immunosuppressive medication) and people with inflammatory skin conditions (e.g. eczema requiring previous treatment, atopic dermatitis, etc.). In addition, very rare cases of fetal vaccinia were reported during pregnancy and there is theoretical risk of transmission from breastfeeding women to their nursing infant. People from these “at risk” groups will be excluded from study participation as patients and as healthcare and housekeeping workers.

There are 2 deletions in VV genome to produce TG6002 (i.e. deletions of TK and RR genes). The deletion of the TK and RR activities conditions TG6002 replication to highly dividing cells such as cancer cells and considerably reduces the pathogenicity of the recombinant virus compared to its parental virus in mice. Therefore, the use of an attenuated recombinant VV such as TG6002 for treatment of advanced cancer in humans is expected to show an equal or better safety profile than the one of the non-attenuated parental virus during smallpox vaccination campaigns.

No environmental concern was raised during the smallpox eradication program during which hundreds of millions of people were administered with the non-attenuated parental virus of TG6002. The proposed contained use will be the administration of TG6002, in a hospital or clinic setting, by intrahepatic artery infusions to patients with colorectal cancer. Dispositions have been taken in the proposed clinical trial to avoid dissemination and inadvertent transmission of TG6002 and the hospital study staff is experienced in measures/precautions with infectious agents. It is therefore not expected that the use of TG6002 within the proposed clinical trial conditions would result in any environmental effect.

**Host/vector system**

TG6002 dsDNA virus (VV TK-RR-IFCU1) is derived from the VV Copenhagen strain (modifications include the deletions of TK and RR genes as well as the insertion of chimeric FCU1 gene).

**Origin & function**

TG6002 is the vaccinia virus Copenhagen strain in which three genetic modifications have been performed: 1) deletion of the thymidine kinase (TK) gene, 2) deletion of the ribonucleotide reductase (RR) gene, and 3) insertion of the chimeric yeast FCU1 gene in the TK locus. The vaccinia TK and RR genes were deleted to allow selective replication in cancer cells in vivo. The FCU1 gene results from the fusion of two Saccharomyces cerevisiae loci, FCY1 and FUR1 which encode for the cytosine deaminase (CDase) and uracilphosphoribosyltransferase (UPRTase) proteins, respectively. The FCU1 protein expressed by the FCU1 gene is a bifunctional enzyme with CDase and UPRTase activities. FCU1 catalyzes the conversion of the prodrug flucytosine (5-FC) into the toxic chemotherapeutic 5-fluorouracil (5-FU) and 5-fluorouridine monophosphate (5-FUMP) agents.

**Evaluation of foreseeable effects**

TG6002 is designed to have a multi-mechanistic mode of action consisting of infection and selective lysis of tumour cells through direct viral replication (oncolysis), targeted chemotherapy through in situ conversion of 5-FC into 5-FU and 5-FUMP and regression of local and distant tumours by systemic immune response. Some of the VV inherent biological properties (e.g. natural tropism for cancer cells, high efficiency at spreading to distant tumours) have been improved through genetic engineering in TG6002 which makes TG6002 a treatment candidate for tumours with high systemic spread, short doubling time and remote metastases. TG6002 is going to be administered as a viral suspension by a local route (intrahepatic artery (IHA) route) in combination with the oral 5-FC prodrug in patients with advanced and metastatic colorectal cancer refractory to standard treatments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation is requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Disposable material and equipment contaminated by TG6002 (e.g. used and unused vials, injected and non-injected infusion bags/syringes, catheters, needles, tubing, gauze, dressings, gloves) will be discarded into a ‘sweet jar’ containing 150mL of a chlorine releasing solution at a minimum of 6000ppm, sealed and rotated to disperse the chlorine solution and denature the virus. The ‘sweet jar’ is disposed of inside a large, purple lidded sharps container (double seal) and placed in a designated Genetically Modified (GM) waste bin prior to LTHT waste incineration process. NB: All waste arising from the preparation and treatment delivery within this study will be managed as above.

Non-disposable material contaminated by TG6002 (e.g. labcoat, goggles, patient gown, bedding, linens, towels) will be cleaned/treated according to regular hospital procedure for infectious material. All equipment in the pharmacy biosafety cabinet not dedicated for study use will be sterilised or cleaned with an active disinfectant (i.e. a chlorine solution at 0.6% of active chlorine) before using it for other purposes. All non-critical patient-care equipment and medical devices will be cleaned with a hospital-grade disinfectant solution before use on another patient, as per universal precautions/routine practices.

Accidental spillage - In the case of accidental spillage, all liquid will be soaked up using absorbent granules (e.g. Sochlor or equivalent granules) found within the Biohazard Spillage Kits. A chlorine solution at a concentration of 10,000 parts per million (ppm) (e.g. HazTab or Sochlor tab or equivalent) will be used on contaminated surfaces to denature the virus.

Please enter comments on the GM safety committee on the risk assessment

This study has been reviewed by Leeds Teaching Hospitals NHS Trust Biological Safety Group and approved on 22/08/2019. The completed documentation is appended to this form for information and confirmation of review.

Date of Significant Change

Project Additional Information

Purpose of the contained use

The product will be given to subjects as part of a Phase Ib clinical trial evaluating the biological effects of intravenous administration of VCN-01 in patients prior to surgical resection of high-grade brain tumours. Taking into account the naturally lytic replication cycle of adenoviruses together with the genetic modifications inserted in VCN-01 backbone, its biological activity is considered to offer a novel mechanism of action in the field of anticancer therapies, and is claimed to be based on two factors: (1) the selective killing of tumour cells by effect of its replication, which results in a self-amplification of the initial inoculum that is released after cell lysis and spread through the tumour mass, and (2) the expression of hyaluronidase, which degrades partially the extracellular matrix of the tumour facilitating the diffusion of the virus progeny and increasing the accessibility of chemotherapy and other drugs such as therapeutic antibodies.

The primary objectives of the trial are to assess the presence of VCN-01 within the resected surgical specimen and to determine the safety of VCN-01 administration.

Recipient or parental organism

VCN-01 is derived from the wild-type human adenovirus serotype 5 (HAd5). VCN-01 is produced in lung adenocarcinoma cell line A549 and released into the medium by cell lysis after 48h after infection. The cell lysate is purified throughout several steps to obtain VCN-01 at the defined concentration and formulated using a storage buffer (20mM Tris, 25mM NaCl, 2.5% glycerol).

Host/vector system

VCN-01 was constructed using wild type human adenovirus serotype 5 (HAd5).

Origin & function

VCN-01 expresses human sperm hyaluronidase (PH20), a matrix-degrading enzyme that allows reducing interstitial fluid pressure within the tumour mass (thus enabling unique tumour remodelling properties, that improve intratumoural viral spreading, immune system infiltration, and tumour uptake of drugs). The other modifications include:

1) the insertion of a tumour-specific synthetic promoter (corresponding to the E1A endogenous promoter region) that restricts the expression of viral proteins to tumoral
cells;
2) the partial deletion of the E1A gene that inhibits the viral replication in normal cells;
3) modification of adenovirus fiber protein (RGDK substitution of KKTK) that results in improved tumour infectivity and lower liver infection.

**Evaluation of foreseeable effects**

VCN-01 is designed to have a multi-mechanistic mode of action consisting of selective infection and lysis of tumour cells through direct viral replication and expression of PH20 hyaluronidase - the enzyme enabling unique tumour remodelling properties that improve viral spreading, infiltration of immune system and tumour uptake of drugs. Once the virus reaches and infects the tumour cells, its lytic nature enables the efficient generation of tumour neoantigens that can boost the innate immune response. In addition, the capsid of VCN-01 has been modified to ensure the virus evades liver tropism and selectively targets the tumour.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Derogation in respect of initial requirement to apply containment measure pursuant to the Regulation 24 of Genetically Modified Organisms (contained use) Regulations 2014 The request concerns derogation from applying the containment measure: autoclave - required in the building where GMO agents will be administered at LTHT premises.

We are conducting a number of clinical trials with use of viruses classified at level 2 containment, but we do not have direct access to autoclave facilities in our clinical locations. We would like to request an exemption from having the autoclave in the building due to the type of activities performed and the low amount of waste generated. None of the current and future studies would require culturing, concentration or modification of the viruses at our site. We are solely involved in the final preparation and administration of GMO products already pre-packaged by the supplier and the main risk is due to direct contact (vials, needles, study drug bag containing virus, swabs, etc.) following virus administration. We would like to continue to use chemical inactivation methods at Leeds Teaching Hospitals NHS Trust for all the activities involving GMOs classified at level 2 of containment.

The virus inactivation procedure itself does not require the use of, or access to, an autoclave, but does ensure that material contaminated with GM Virus is inactivated in a consistently safe and effective way. All GMO trials conducted at our site are considered carefully, and the appropriate chemical GMO inactivation method is established by ATMP Oversight and Assurance Group based on the available scientific data provided by suppliers. Arrangements for handling and disposal of waste are always clearly defined for each clinical trial in our local standard operating procedures.

Referring to the notification we developed the adenovirus inactivation procedure with use of chlorine releasing solution as per SOP- DH-20.1.0 submitted with notification. We believe this proposal shows methodology, which is safe and adequate from a risk management perspective.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Disposable material and equipment contaminated with VCN-01 agent (e.g. used and unused vials, injected and non-injected infusion bags/syringes, needles, dressings, gloves) will be discarded into a "sweet jar" containing chlorine solution at a minimum of 10000ppm, sealed and rotated to disperse the chlorine solution and denature the virus. The jar is to be disposed of inside a large, purple lidded sharps container (double seal) and to be disposed of according to current LTHT Waste Policy NB: All waste arising from the preparation and treatment delivery within this study will be managed as above (LTHT Standard Infection Prevention and Control Precautions Policy, LTHT Waste Stream).

Non-disposable material contaminated with VCN-01 (e.g. labcoat, googles, patient gown, bedding, towels) will be cleaned/treated according to regular hospital procedure for infectious material. All equipment in the pharmacy biosafety cabinet not dedicated for study use will be sterilised or cleaned with an active disinfectant (i.e. chlorine solution at 0.6% of active chlorine) before using it for other purposes. All non-critical patient care equipment and medical devices will be cleaned with a hospital-grade disinfectant before use on another patient, as per universal precautions/routine practices.
Accidental spillage— in the case of accidental spillage, all liquid will be soaked up using absorbent granules (e.g. Sochlor or equivalent) found in the Biohazard Spillage Kits. A chlorine solution at a concentration of 10000 ppm will be used on contaminated surfaces to denature the virus (e.g. Haz Tabs, Sochlor or equivalent).

Project Additional Information

Purposes of the contained use

T3P-Y058-739 (T3P), a genetically-modified strain of the bacterium Yersinia enterocolitica, will be used to treat patients with cancer (advanced solid tumours) within an open-label, phase I/II clinical trial. T3P is a live attenuated bacterium that has been modified to abrogate pathogenicity and to enable the bacterium to micro-inject surrounding eukaryotic cells with two human immunomodulatory proteins: retinoic acid-inducible gene-1 caspase recruitment domain (RIG-I CARD) and cyclic GMP-AMP synthase (cGAS). These stimulate the production of type I interferons and other cytokines. In addition to delivery of the cargo proteins, the T3P bacteria themselves stimulates the production of potent pro-inflammatory cytokines, especially tumour necrosis factor-α (TNFα). Thus, the presence of T3P in tumours is anticipated to result in stimulation of a strong immune response to the tumour. T3P will be administered either by intratumoural injection or intravenously by infusion over 2 hours.

Recipient or parental organism

T3P-Y058-739 has been derived by genetic engineering from the parental strain Yersinia enterocolitica E40. This strain was isolated in the early 1990s in Belgium from a human patient. Y. enterocolitica E40 belongs to a low-virulent subspecies of Yersinia enterocolitica, called “Palearctica”, which lacks the high pathogenicity island (HPI) coding for the siderophore Yersiniabactin (Ybt).

Host/vector system

The host range is described to be limited to E. coli, selected members of the family Enterobacteriaceae and few other organisms including Serratia marcescens and Yersinia. T3P-Y058-739 has been derived by genetic engineering from the parental strain Yersiniaenterocolitica E40. Y. enterocolitica E40 belongs to a low-virulent subspecies of Y.enterocolitica Palearctica that are characterised by deficient iron acquisition. This deficiency is maintained in T3P-Y058-739. In addition, the following genetic modifications have been introduced to further reduce virulence and to confer the strain with its therapeutic activity.

Due to the deletion of all six effector proteins, the virulence of T3P-Y058-739 is dramatically reduced compared to its parental strain Y. enterocolitica E40.

Evaluation of foreseeable effects

Therapy with T3P is expected to be well tolerated. The main side effects are expected to be local inflammation following intra-tumoural (IT) injection, and transient pyrexia and ‘flu-like’ symptoms related to systemic endotoxin exposure following intravenous (IV) administration.
It is anticipated that T3P will result in anti-tumour activity when administered as monotherapy by IT injection or by IV infusion (IT injection will be evaluated initially). T3P is also predicted to have additivity or synergy with checkpoint inhibitors (CPIs), and evaluation of T3P in combination with the CPI pembrolizumab is also planned.

T3P is a live attenuated bacterium that has been modified to remove pathogenicity and to enable the bacterium to micro-inject surrounding human cells with two human immunomodulatory proteins (RIG-I CARD and cGAS). These proteins stimulate the production of type I interferons and other cytokines which attract and activate cells of the immune system. Microinjection of the cargo proteins by T3P takes place via the naturally occurring bacterial type 3 secretion system (T3SS). The T3SS looks and acts like minute syringes (sometimes called nano-syringes or injectisomes) on the surface of the bacteria. Microinjection of cargo proteins may occur very rapidly (within minutes) of T3P being introduced into a tumour by local intra-tumoural (IT) injection. It can also occur more slowly, as tumours become colonised by T3P following intravenous (IV) administration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation in respect of initial requirement to apply containment measure pursuant to the Regulation 24 of Genetically Modified Organisms (contained use) Regulations 2014 The request concerns derogation from applying the containment measure: autoclave - required in the building where GMO agents will be administered at LTHT premises.

While we have not conducted studies using a GMO bacteria before, are delivering a number of clinical trials which use viruses classified at level 2 containment. We do not have direct access to autoclave facilities in our clinical locations. We would like to request an exemption from having the autoclave in the building due to the type of activities performed and the low amount of waste generated. None of the current and future studies would require culturing, concentration or modification of the viruses at our site. We are solely involved in the final preparation and administration of GMO products already pre-packaged by the supplier and the main risk is due to direct contact (vials, needles, study drug bag containing virus, swabs, etc.) following virus administration. We would like to continue to use chemical inactivation methods at Leeds Teaching Hospitals NHS Trust for all the activities involving GMOs classified at level 2 of containment.

The virus inactivation procedure itself does not require the use of, or access to, an autoclave, but does ensure that material contaminated with GM Virus is inactivated in a consistently safe and effective way. All GMO trials conducted at our site are considered carefully, and the appropriate chemical GMO inactivation method is established by ATMP Oversight and Assurance Group based on the available scientific data provided by suppliers. Arrangements for handling and disposal of waste are always clearly defined for each clinical trial in our local standard operating procedures.

Referring to the notification we developed the GMO Bacteria inactivation procedure with use of chlorine releasing solution as per the T3P IMP handling SOP submitted with notification. We believe this proposal shows methodology, which is safe and adequate from a risk management perspective.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable material and equipment contaminated with the T3P agent (e.g. used and unused vials, injected and non-injected infusion bags/syringes, needles, dressings, gloves) will be discarded into a “sweet jar” containing chlorine solution at a minimum of 10000ppm, sealed and rotated to disperse the chlorine solution and denature the virus. The jar is to be disposed of inside a large, purple lidded sharps container (double seal) and to be disposed of according to current LTHT Waste Policy NB: All waste arising from the preparation and treatment delivery within this study will be managed as above (LTHT Standard Infection Prevention and Control Precautions Policy, LTHT Waste Stream).

Non-disposable material contaminated with T3P(e.g. labcoat, googles, patient gown, bedding, towels) will be cleaned/treated according to regular hospital procedure for infectious material. All equipment in the pharmacy biosafety cabinet not dedicated for study use will be sterilised or cleaned with an active disinfectant (i.e. chlorine solution at 0.6% of active chlorine) before using it for other purposes. All non-critical patient care equipment and medical devices will be cleaned with a hospital-grade disinfectant before use on another patient, as per universal precautions/routine practices.
Accidental spillage—In the case of accidental spillage, all liquid will be soaked up using absorbent granules (e.g., Sochlor or equivalent) found in the Biohazard Spillage Kits. A chlorine solution at a concentration of 10000 ppm will be used on contaminated surfaces to denature the virus (e.g., Haz Tabs, Sochlor or equivalent).

Is an emergency plan required according to regulation 20? N

Give brief details of the genetic modification safety committee

Central Manchester University Hospitals NHS Foundation Trust (CMFT) has incorporated the Genetic Modification Safety Committee into its “Early Phase Safety Committee (EPSC)” co-opting appropriate specialists onto the committee when a GM trial is being reviewed. The risk assessment has been expanded to include a Genetic Modification section encompassing GMM pathway, Patient pathway and Waste pathway according to guidance in the SACGM Compendium:

Give brief details of the genetic modification safety committee

GMSC will meet a minimum of twice per year to review existing risk assessments and arrange for audits of the laboratories. Meetings to approve new risk assessments will be held as required. The GMSC activities are reported to the main Health and Safety Committee.

GMSC made up of:
- Chairman and Health and Safety Committee representative
- Biological Safety Officer (Safety Consultant to company)
- Deputy Biological Safety officer (local)
- Scientific/technical staff representative (Molecular Biologist)
- Management representative (Director of R&D)
- Advisory persons (not committee members)
- Supervisory Medical Officer
- Occupational Health Advisor

Inactivation of GMMs in contaminated material will be as follows:

**Liquid Discharge:** Waste to be treated with 1:1 Trigene (Halogenated tertiary amine compound) to a final concentration of 1% v/v. Trigene is MAFF approved and conforms with British and European Standards (CE93/42/EEC) with a 99.999% degree of kill.

**Solid Waste:** Solid waste will be sealed, retained in Biohazard waste sacks (double bagged) and further contained in UN approved rigid containers. Solid waste will be removed for incineration off-site by a nominated commercial 'clinical waste' carrier in accordance with all relevant legislation and guidelines. Degree of inactivation is 100%.

Please enter comments of the GM safety committee on the risk assessment

The GMSC has reviewed the company's GM procedures and the risk assessments performed. The GMSC confirmed the work to be carried out is Class 1 and were satisfied with the assessment of risks to both human health and the environment. The control and containment measures in place are appropriate for Class 1 activities.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The GMSC found no real problems with the risk assessment. They asked for more information on the genetic insertion. This has been included in section 17.
**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To produce adenovirus bank to cGMP.

**Recipient or parental organism**

Human adenovirus type S, which has 1 gene deletion and 1 gene insertin. These genetic modifications impair the ability of the adenovirus to infect normal human cells.

**Host/vector system**

Fully validated NCI-HS20 cells and SW620 cells. These cell lines are tumour-forming in nude mice in vivo. They are cells of human origin.

**Origin & function**

There is an insertion of a cell-cycle regulated promoter which renders replication of the virus specific to tumour cells. The material will be used in Phase 1 clinical trials.

**Evaluation of foreseeable effects**

The pathogenicity of this virus has been reduced more than 100x by the genetic modification. It is highly unlikely that this virus could establish a productive in vivo infection in humans. There are no zoonoses for human adenovirus, and no vectors, so environmental spread would be limited in the event of an escape.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- **CU2 Project Title**: GMP PRODUCTION OF AN ADENOVIRUS VECTOR IN 293 CELLS.
- **Class**: Class 2
- **Culture Volume Class 2**: < 1 litre
- **Non-GMM**: not applicable
- **Consent Granted**: N

- **Date Project Ceased**: 01/08/2006
- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

- **Historical Date of Additional Info**: 29/04/2002

**Project Additional Information**

- **Purposes of the contained use**: Production of material for a clinical trial.

- **Recipient or parental organism**: Adenovirus construct with E1 and E3 region deletions. The adenovirus vector contains an insert coding for the expression of an immuno-conjugate (Icon) molecule. The Icon molecule is composed of a mutated mouse factor VII (mfVII) targeting domain and the Fc domain of a human IgG1 molecule. The vector is constructed using the Q

02/03/2022
biogene Ad-easy system.

**Host/vector system**

Host cell: 293A cells (transformed human embryonic kidney cell line). Vials to be used sourced from ATCC originally and GMP bank prepared by BioReliance, Rockville, Maryland, USA. This bank is a fully validated cell bank and is regarded as being non-pathogenic to humans.

**Origin & function**

Direct injection of the adenoviral vector into tumour causes tumour cells infected by the vector to synthesize and secrete the icon into the blood. The blood-borne icon binds with high affinity to tissue factor expressed on endothelial cells lining the lumen of the tumour vasculature. The Fc domain of the icon activates a cytolytic immune attack against the tumour vasculature causing regression and death of the tumour cells.

The purified replication-deficient adenovirus vector is to be produced as a GMP virus bank and it is intended for use in a clinical trial.

**Evaluation of foreseeable effects**

The virus will be handled under full class II containment in a GMP clean room environment.

No foreseeable effects in case of escape. As the virus is a replication-deficient vector and adenoviruses have no zoonoses or vectors which would limit any environmental spread in the unlikely event of an escape. All contaminated or potentially contaminated material will be autoclaved at 121 degrees C for at least 15 minutes prior to disposal. Adenovirus is shown to be completely inactivated by autoclaving under these conditions. Also, the disinfectants routinely used by Excell laboratory staff during production procedures are all known to be virucidal with respect to adenovirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Virus will be handled under Class II containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Although wild-type adenovirus may be able to survive for sometime in the environment, any reversion of the vector to the wild-type is unlikely. There are no zoonoses for human adenovirus and no vectors which would therefore limit environmental spread in the unlikely event of an escape.

All handling of the adenovirus vector and 293 cells infected with the vector will be performed under Class II containment conditions in a validated GMP clean room.

Adenovirus is susceptible to all disinfectants used routinely by staff during production (e.g. Kericide A or B, 2% Virkon, 2% Trigene, 1% Sodium Hypochlorite followed by 70% IPA). All contaminated and potentially contaminated material will be autoclaved at 121 degrees C for at least 15 minutes prior to disposal. Decontamination procedures are documented in the Company Standard Operating Procedures.

Autoclave efficiency is regularly monitored using a combination of chemical and biological indicators. Each run performed on the autoclave is checked to ensure that the correct temperature has been reached. All disinfectants used have full validation certificates on their action on adenoviruses.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
To follow: Risk assessment forwarded to the Moredun GM Safety Committee. Internal Safety Committee at Excell Biotech see no problem for Excell employees in using this product as a result of their training and the facility they will be working in.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**
### Purposes of the contained use

Growth of a non pathogenic vibrio species up to 50L fermentation volume expressing the non toxic B subunit of E. coli enterotoxin and recovery of the expressed protein from the cell culture supernatant.

### Recipient or parental organism

Marine vibrio strain (considered non pathogenic to humans)

### Host/vector system

An IPTG induced expression vector carrying the gene for the non-toxic B subunit of E. coli enterotoxin.

### Origin & function

E. coli Enterotoxin B subunit expressed in a vibrio species.

Therapeutic uses,
- Allergy eg Allergic Rhinitis
- Autoimmune Disease eg Rheumatoid Arthritis
- Vaccine Adjuvant

### Evaluation of foreseeable effects

No hazards have been identified.

The introduction of the B subunit genes of the E. coli enterotoxin into the vibrio organism is unlikely to alter any existing pathogenic traits.

The host cell line is considered non pathogenic to humans.

The B subunit of E. coli enterotoxin has been extensively evaluated in vaccine trials without any adverse effects.

As all vibrio species are assigned as biological hazard class 2 organisms by ACDP all project work (cell culture, primary recovery and purification) with the organism will be carried out at Excell Biotech's category II facility, Antigen Production Unit, Pentlands Science Park.

Although the risk is effectively zero cell culture samples for assay will be manipulated in a Cat II microbiological safety cabinet.

All potentially contaminated waste will be autoclaved prior to disposal.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Following fermentation and primary recovery the culture supernatant will be 0.22um filtered and a sterility assay will be carried out. No viable GMO will be present following this stage.

It is unlikely that the vibrio organism would survive in the environment and as the organism is already present in the wider marine environment the consequence of release of the organism into the environment is negligible.

The fermenter vessel will be cleaned and flushed with 0.5M sodium hydroxide, rinsed and steam sterilised.

Membranes and equipment used for primary recovery will be cleaned with 0.5M sodium hydroxide. Cell paste will be held in 0.5M sodium hydroxide to kill cells. No viable GMO will be present following this treatment. Killed cell paste (liquid waste) will be uplifted from the site for disposal by an approved contractor.
All potentially contaminated waste will be autoclaved prior to disposal and uplifted from the site by an approved contractor.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

No hazard was identified.

Review of the GMO risk assessment reviewed at the monthly meeting and communicated to the staff via the meeting minutes, which are circulated to staff, and made available on the H&S notice board.

The GMO RA was submitted for review to the Moredun Institute, Pentlands Science Park, GMO committee. No comments or response has been received at the time of submission of this form to the HSE.

Give brief details of the genetic modification safety committee

The Joint Genetic Modification Committee for the Royal Free site meets three times a year to discuss GM matters pertaining to the Royal Free Campus of the Medical School [GM 99], The Royal Free NHS Trust and The Anthony Nolan Research Centre.  
The committee composition is that outlined for the RF and UC Medical School GM99.  
The Anthony Nolan has a representative on the above committee and the ANBMT senior scientists and Research Director meet at similar times following the meetings at the RFH for dissemination of information from the main committee, and for discussion of new matters arising thereof they also meet to discuss new work prior to submission.

Please enter comments of the GM safety committee on the risk assessment

For the risk assessment example sent in Section 7 the Committee expressed concern with aerosol production resulting from vaccine release during the filling of syringes prior to injection. The workers were required to draw up a Standard Operating Procedure which is attached.

It was also noted that the workers were not experienced with GM work. The committee thought as the workers were only handling a prepared GMM for the purposes of injection inexperience in GM work was not a cause for concern.

For activities involving GMMs, describe the waste management measures which will apply to the activity

- with 70% ethanol.
- Waste is clearly labelled biohazard double bags will be incinerated as clinical waste.
- Hazard conditions consist of possible spillages, aerosol spray when opening cryovials or during the use of needles when working with animals.
- Work is restricted to determined areas, disinfecting solutions will always be available, working guidelines are clearly posted, unauthorised personnel is not permitted. Strict adherence to Category II working practices. Reporting in case of accident is according to College procedures.
- Training to work with GMM's category II. Guidelines regarding dressing code, how to treat spillages and disinfection with 1% Virkon and 70% ethanol. Medical records held by occupational health advisor.
- Documented spillage procedures are clearly established. In case of accident with sharps, College procedure with blood borne viruses will be followed.
- Autoclaves are regularly serviced and checked. Autoclaved material is checked using autoclaving tape to assess has reached appropriate temperature for disinfection.

Project Additional Information

Purposes of the contained use

The aim of this project is to use lentiviruses as an expression system for investigating mechanisms of molecular regulation of a family of ion channels expressed in neuronal cells. A commercially available lentivirus expression kit from Invitrogen will be used. We will make recombinant lentiviruses encoding membrane proteins which we are interested in: eg. heteromeric G proteins of the Gi/o family (THESE G PROTEINS ARE NOT MEMBERS OF THE SMALL G PROTEIN FAMILY) and fluorescent reporter proteins such as PLCdelta-PH-CFP and PSD95-GFP. The cDNA inserts themselves are very unlikely to have any harmful effects and they are currently used in our research into mechanisms of cellular signalling. The cDNAs encoding these proteins will be subcloned into a viral expression construct (pLenti6, Invitrogen). This will be transfected into HEK293FT cells (producer cells) to generate recombinant virus. The recombinant virus will then be used to infect cultured rat or mouse central neurones in vitro. The neurones will then be used in electrophysiological studies where the effects of the heterologous membrane proteins on the neuronal ion channels will be assessed. These experiments will allow the investigation of specific single proteins (eg Gi/o proteins) on the activity of ion channels in their native neuronal environment.

Recipient or parental organism

The commercially available kit from Invitrogen is a third generation system based on HIV-1 (see Dull et al., 1998: J. Virol. 72, 8463-71) which allows the construction of a recombinant replication-incompetent, HIV-1-based lentivirus. There are a number of biosafety features which have been introduced to minimise risks. These are as follows: (1) All HIV sequences required for encapsidation and reverse transcription are absent. (2) There is a deletion in the 3' UTR resulting in self-inactivation of viral genome. (3) None of the HIV-1 structural genes contain LTRs and are thus never expressed in the target cell. (4) It contains the minimal number of HIV-1 genes required to generate an efficient vector (only three of the nine are used: gag, pol, and rev). (5) The removal genes are those which are pathogenic therefore no recombinant vector can acquire the pathogenetic features of the parental virus. (6) The tat gene, which is important for replication, has been removed. (7) The packaging genes are contained on 4 separate plasmids and thus the system relies on 4 separate plasmids for the production of transducing particles. (8) These plasmids contain no regions of homology thus preventing any recombination which could occur. (9) The virus is replication incompetent and as a replication-deficient vector it poses significantly reduced risks. Thus these viruses may infect cells and integrate DNA into the target cell but they are incapable of further replication.

Host/vector system

Vectors: HIV-based lentivirus expression vector (pLenti6) into which the gene of interest will be cloned. This vector also contains the elements needed for packaging of the expression construct. Kit also contains viral packaging mix of vectors: this is an optimised mixture of three packaging plasmids which supply the structural and replication proteins required for production of lentivirus.

Hosts: HEK293FT cells will be used to produce the virus. Recombinant proteins will then be expressed in primary neuronal cells.

Origin & function

Recombinant lentivirus will be used to transduce primary central neurones in vitro which have been isolated and cultured from rat or mouse. The intention of this project is to study the effects of the signalling proteins (described in Section 6) on ion channel activity in these neurones by using electrophysiological techniques.

Evaluation of foreseeable effects

Recombinant virus is produced in the HEK293FT producer cells. In these cells the virus can replicate. The potential risk which may arise from this is direct exposure of the viral supernatant produced to the operator. This could arise through the use of sharps and a direct needlestick injury, or if viral supernatant is accidentally splashed onto exposed areas of skin which are cut or scratched. This will be prevented by total avoidance of use of glass and sharps (including needles and forceps) since only sterile, disposable plasticware will be used. The plastic pipettes and pipette tips used are blunt and are also aerosol-resistant and contain a filter thus reducing any aerosol formation. Furthermore labcoats and gloves (and overshoes) are worn at all times. In addition, there is virtually no risk to the environment because retroviruses exhibit poor survival in the general environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All surfaces are swabbed before and after use with 10% Virkon and 70% IMS. Sharps (rarely used) and Pipetman pipettes are placed in specified sharps bins. Waste media, pipette tips and plasticware are doused in Virkon prior to autoclaving in sealed and double-bagged plastic autoclave bags. These procedures will ensure an anticipated 100% kill of virus.

Please enter comments on the GM safety committee on the risk assessment

The proposal has been reviewed by a representative panel of the Genetic Modification Safety Committee, which agreed with the proposer’s classification of Class 2. The notification will be submitted to the next meeting of the full Committee on 10 April 2003. The laboratories were last inspected in December 2002 and conditions were found to be satisfactory.

Project Additional Information

Purposes of the contained use
- Molecular cloning and expression, of Porphyromonas gingivalis genes encoding extracellular protease, enzymes involved in protein modifications, lipopolysaccharide biosynthesis, and outer membrane proteins in Escherichia coli.
- Manipulate the above constructs for insertional mutagenesis of genes putatively involved in protease and outer membrane protein expression, and post-translational modification and re-introduce into Porphyromonas gingivalis.

Recipient or parental organism
The origin of DNA will be the oral-gram negative anaerobe, Porphyromonas gingivalis ATCC 53978 (W50). The bacterium is extremely sensitive to oxygen and is unlikely to survive outside the anaerobic cabinet after a prolonged exposure to air. The population of Porphyromonas gingivalis is elevated in periodontal diseases of the teeth supporting tissues but otherwise present in low numbers in healthy sites. The proteases and outer membrane proteins are recognised virulence factors. Additionally, the genome of Porphyromonas gingivalis has been sequenced by TiGR (http://www.tigr.org/).

Host/vector system
Escherichia coli K12 derivitives (XL-1 Blue, XL10 Gold, SCS110, SURE, Stratagene), general cloning hosts, will be used. The strains are attenuated, sensitive to bile salts and are unable to survive in the alimentary canal. Porphyromonas gingivalis (see above) will be used for complementation of mutated genes.

E. coli - Plasmids pUC18 - derived (Amp(r), LacZa - pUC18, pUC18notl, pK18) will be the general cloning and manipulating vectors. For expression of poly his-tagged recombinant proteins JFQ- derivitives (commercially known as pQE80, Qiagen) will be used to direct controlled (inducible by Isopropyl -D thiogalactoside, IPTG) expression under ptac or pT5 promoter, respectively.

Porphyromonas gingivalis - pNJR12 (tet(r) Bacteroides/Porphyromonas - E.coli) shuttle plasmid will be used; the plasmid is known to replicate autonomously as a low copy number (<10 copies per bacterium). Alternatively, manipulated genes will be integrated into the genome via the homologous recombination using erythromycin encoding cassette (from pVA2198).

Origin & function
Chromosomal DNA will originate from Porphyromonas gingivalis and will encode orthologues of: Proteases specific for extracellular arginine - peptide bonds (Lys-gingipain) Proteases specific for extracellular lysine peptide bonds (Arg-gingipain) Outer membrane proteins . Enzymes involved in lipopolysaccharide (LPS) biosynthesis, glycan transferases.

The open reading frames (orfs) will be amplified, cloned and manipulated (by insertion of a specialised macrolide-lincosamide cassette, erm) in E. coli with the main intention of inactivating the corresponding gene in Porphyromonas gingivalis via homologous recombination. These mutants will be assessed, biochemically and genetically, to ascertain their contribution to the metabolism, survival and pathogenicity of Porphyromonas gingivalis.

Some of these orfs will be specially cloned for controlled expression in E. coli for subsequent production of antiserum for studies of protein expression in Porphyromonas gingivalis.

Another set of orfs will be cloned into pNJR12 and introduced into Porphyromonas gingivalis to compliment corresponding mutations to assess interconnecting metabolic pathways.

Evaluation of foreseeable effects
The genome of Porphyromonas gingivalis W83 has been sequenced by The Institute of Genomic Research (http://www.tigr.org/) and annotated (http://www.tigr.org/tigr-scripts/CMR2/GenomePage3.spl?database=gpg) so only known orfs will be cloned. Protease gene constructs have previously been shown not to yield active enzyme in E.coli. However, expression of active enzymes from some constructs cannot be ruled out. Expression of Porphyromonas gingivalis proteins in E. coli is unlikely to make the host more pathogenic than Porphyromonas gingivalis itself. Inactivation of Porphyromonas gingivalis genes is expected to lead to metabolic defects that should result in attenuated and poor viability of the bacterium. Complementation of Porphyromonas gingivalis should lead to restoration of normal activities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All relevant containments are in place to minimise the potential of any risk. All materials (pipette tips, plates, glassware, tissues, gloves, etc) that are contaminated with bacteria or nucleic acids will be thoroughly soaked in 5% Hycolin then autoclaved, or autoclaved directly, and disposed via the College in accordance with departmental containment level 2 safety regulations.

Project Ref 174/01.2

Date Ackn’d 30/09/2009

Date Project Ceased

CU2 Project Title USE OF REVERSE GENETICS TO CREATE AN ATTENUATED INFLUENZA VIRUS

Class 2

Culture Vol Class 2 < 1 Litre

Consent Granted Not Applicable

Date Project Ceased

02/03/2022
Purposes of the contained use

To produce an attenuated influenza virus that could be used as a live attenuated vaccine against current strains of influenza virus. Current influenza virus vaccines are only about 70% effective, live attenuated virus vaccines like those we are trying to develop may be more effective.

Recipient or parental organism

The extensively studied PR8 strain of the influenza virus will be used as the recipient influenza strain. The PR8 strain of influenza virus is highly attenuated and does not cause disease in humans. Influenza viruses are classified as ACDP category 2 pathogens.

Host/vector system

Plasmids containing the cloned genes of influenza virus strain PR8 are being generously donated by Professor Brownlee (Sir William Dunn School of Pathology, University of Oxford). The plasmids are pPOLI-PB2-PR8, pPOLI-PB1-PR8, pPOLI-PA-PR8, pPOLI-HA-PR8, pPOLI-NP-PR8, pPOLI-NA-PR8, pPOLI-M-PR8, pPOLI-NS-PR8, pPOLI-Sapl-Rib, pcDNA-PB1-PR8, pcDNA-PB2-PR8, pcDNA-PA-PR8, pcDNA-NP-PR8. These plasmids are all pUC18 derivatives. These will be transfected into either Vero (African Green Monkey) cells or 293T (Human kidney) cells. Recombinant virus will then be retrieved from these transfected cells (see Fodor E, et al. Rescue of influenza A virus from recombinant DNA, J Virol 1999; 7.3.9679-9682).

Origin & function

The introduced genetic material will be the influenza virus neuraminidase and haemagglutinin genes cloned from recent strains of the influenza virus such as A/New Caledonia/11/99. Mutations will be added to these cloned genes to attenuate the virus. Alterations to the neuraminidase gene have been shown to lead to a reduction of virulence (see Solarzano et al. Reduced levels of neuraminidase of influenza A viruses correlate with attenuated phenotypes in mice, J. Gen Virol 2000: 81 Pt3: 737-742). The recombinant virus will thus contain all the PR8 gene segments except those encoding the neuraminidase and haemagglutinin which will come from a recent strain of the influenza virus. The introduced gene products will be expressed on the surface of the recombinant influenza virus and are intended to act as antigens to provoke a protective immune response to any later challenge by the wild type influenza virus.

Evaluation of foreseeable effects

The influenza virus normally causes an upper respiratory infection in humans, however, the attenuated PR8 strain is non-pathogenic in humans. The mutations we add to the influenza virus genome are intended to be stable and to attenuate the virus. The haemagglutinin and neuraminidase proteins have been shown to be non-toxic to humans and have been used extensively in vaccines. Vaccines are available to protect against influenza virus infection and there are antiflu drugs such as Tamiflu and Relenza.

Influenza viruses pose limited environmental risk as they are degraded quickly in the environment (UV, desiccation), the genetic modifications we perform will not change this.
Work with the mutated influenza virus being conducted in Microflow Biological Safety Cabinets in a category 2 GLP laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste produced containing recombinant influenza virus will be treated with Basol a quaternary ammonia compound based detergent. This detergent is known to very rapidly destroy lipid encapsulated viruses such as influenza. To ensure a one hundred per cent kill the waste containing the recombinant virus will be left in the basol for 24 hours. The waste will then be disposed of down the sink. This is a standard technique for disposing of influenza waste.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Both the parent virus and the neuraminidase and haemagglutinin proteins from recent strains have a history of safe use in humans.

Project Additional Information

Purposes of the contained use

Molecular cloning of Pseudomonas aeruginosa genes encoding metalloproteases, serine proteases, genes involved in type III secretion systems and genes involved in cobalamin (vitamin B12) biosynthesis in Escherichia coli.

Construction of insertion mutants of the genes mentioned above in Pseudomonas aeruginosa.

Recipient or parental organism

The origin of DNA will be the gram-negative bacterium Pseudomonas aeruginosa.

The genome of P. aeruginosa has been sequenced in a collaboration among the Cystic Fibrosis Foundation, the University of Washington Genome Center and Pathogenesis Corporation (http://www.pseudomonas.com/).

In P. aeruginosa the mutated genes are unlikely to confirm any advantage relative to the wild type strain; complemented strains are expected to restore wild type gene activities.

Host/vector system

Escherichia coli JM109 strain a K12 derivative will be used as a cloning host.

This strain is attenuated, sensitive to bile salts and unable to survive in the gut.

E. coli S17-1 a mobilising strain that carries the transfer function of the plasmid RP4 integrated in its chromosome will be used as the host for the plasmid pEX100T carrying the disrupted P. aeruginosa genes.

The vectors used in this project are:

- pUC18, pUC18NotI. Non-mobilisable vectors
- pUCP18-Escherichia-Pseudomonas shuttle vector. Non-mobilisable
- pEX100T-gene replacement vector, mobilisable. The P. aeruginosa genes cloned in this vector are interrupted by the insertion of a gentamicin resistance cassette.
- pUCGm-source of the gentamicin resistance, GM R cassette.

Origin & function

02/03/2022
Chromosomal DNA will originate from Pseudomonas aeruginosa and will encode orthologues of:

- Metalloproteases
- Serine proteases
- Genes involved in Pseudomonas aeruginosa type III secretion system
- Genes involved in cobalamin (vitamin B12) biosynthesis

The open reading frames will be amplified, cloned and manipulated (by insertion of a gentamicin resistance cassette) in E. coli with the main intention of inactivating the corresponding gene in P. aeruginosa via homologous recombination. These mutants will be assessed, biochemically and genetically, to ascertain their contribution to the survival and pathogenicity of P. aeruginosa.

The above open reading frames will be cloned into pUCP18 and introduced into P. aeruginosa in order to complement the corresponding mutations.

**Evaluation of foreseeable effects**

The E. coli JM109 strains carrying the cloned P. aeruginosa genes should not be more hazardous than the P. aeruginosa host. In P. aeruginosa the mutated genes are unlikely to confer any advantage relative to the wild type strain. Complementation of P. aeruginosa should lead to restoration of normal activities.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All relevant containments are in place to minimise the potential of any risk.

All materials (pipette tips, plates, glassware, tissues, gloves) that are contaminated with bacteria or nucleic acid will be thoroughly soaked in 5% Hycolin autoclaved and disposed via the college in accordance with the safety regulations.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Molecular cloning of Helicobacter pylori genes encoding proteolytic enzymes of H. pylori identified using a number of bioinformatic approaches.

Construction of insertion mutants of the genes mentioned above in Helicobacter pylori.

Recipient or parental organism

a) Escherichia coli DH5a (or similar K12 derivative) (supE44 (lacZYA-argF)U169 (80lacZ M15) hsdR17 (rk-, mk+) recA1 endA1 gyrA96 thi-1) that is recognised as a non-colonising and disabled. It may be considered equivalent to ACDP category 1. It has limited survivability in the environment. Over expression strain: ER2566 Genotype: F- fhuA2 [lon] ompT lacZ::T7 gene1 gal sulA11. (mcrC-mrr)114::IS10 R(mcr-73::miniTn10-TetS)2 R(2gb-210::TN10)(TetS) endA1 [dcm].

E. coli DH5a carrying cloned genes from H. pylori should not be more hazardous than the H. pylori host. The cloned genes will be under controlled promoters (lacZ). This will increase the potential virulence of the E. coli but should not be anymore hazardous than the Wild-type H. pylori. The E. coli strains are attenuated and are unable to survive in the gut.
b) Helicobacter pylori SS1, 26695, J99 and NCTC 11637. All strains carry the Cag pathogenicity island and do not carry any virulence plasmids. 26695 and J99 are the 2 sequenced Helicobacter pylori strains. SS1 is the adapted mouse colonising strain and NCTC 11637 is the adapted Mongolian Gerbil colonising strain. All strains are ACDP category 2 and have very limited survivability in the environment. H. pylori must be ingested in large quantities (>10^8 cfu/mL) with acid suppressive drugs to enable successful colonisation, and infection (Marshall, B., et al (1985). Attempt to fulfil Koch’s postulates for pyloric Campylobacter. Med J Aust 142, 436-439. and Morris, A & Nicholson, G. (1987). Ingestion of Campylobacter pyloridis causes gastritis and raised fasting gastric pH. Am J Gastroenterol 82, 192-194). H. pylori is a micro-aerophile. It has a maximum life span of 1 hr if left in an oxygenic. It has poor survivability in the environment.

Helicobacter pylori: The disruption of a gene with either cat or apahA3 is unlikely to confer any advantage to the wild type strain, apart from the introduction of the antibiotic resistance genes. Neither of these antibiotics have ever been and are never likely to be part of treatment regimens for H. pylori infection. If strain cans be complemented, it will restore the Wild-type activities. Further, Large quantities of H. pylori must be ingested along with acid suppressive drugs to allow colonisation.

**Host/vector system**

- **pUC19**: High copy number cloning vector
- **pGem**: High copy number cloning vector
- **pTyb**: H. pylori is a protein fusion vector with a T7 RNA polymerase expressed off a Lac Promoter
  - Overexpression of recombinant proteins will only occur upon addition of IPTG
- **p KatA**: pGem with katA cloned into lacZ. katA::aphA3 (originating from Campylobacter coli)
- **pucCat20**: puc19 vector containing cat originating from Campylobacter coli

None of the above vectors are replicated in H. pylori and will be used as suicide vectors.

**Hosts**

- *Escherichia coli* DH5α (or similar K12 derivative) (supE44 (lacZYA-argF)U169 (80lacZ M15) hsdR17 (rk-, mk+) recA1 endA1 gyrA96 thi-1 relA1)

**Genotype**

- F- -fhuA2 [lon] ompT lacZ::T7 gene1 gas sulA11 (mcrC-mrr)114::IS10 R(mcr-73::miniTn10-TetS)2 R(zgb-210::Tn10)(TetS) endA1 [dcm].

**Origin & function**

All genes identified as potentially encoding proteolytic enzymes of *H. pylori* will be cloned from the sequenced strain *H. pylori* 26695. These genes will be cloned into a vector and disrupted using an antibiotic resistance cassette, such as aphA3 or cat encoding kanamycin and chloramphenicol resistance, respectively (originating from Campylobacter coli). Once the genes have been disrupted in the vector, they will be introduced to *H. pylori* by transformation and incorporated into the genome by allelic exchange. Kanamycin and Chloramphenicol are not currently used and are unlikely to ever be used in therapeutic regimes for the treatment of *H. pylori* infection.

**Evaluation of foreseeable effects**

Creating protease deficient mutants of *H. pylori* are unlikely to confer any advantage to the organism. It is more likely to compromise the pathogenicity of the bacterium.

Introducing virulence factors into the attenuated derivatives of *E. coli* K12 is likely to increase the potential virulence of the *E. coli*. The potential virulence of the *E. coli* will not exceed that of the Wild-type *H. pylori*.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All relevant containments are in place to minimise the potential of any risk.
All materials (pipette tips, plates, glassware and gloves) that are contaminated with bacteria or nucleic acid will be thoroughly soaked in 5% (v/v) hycolin, autoclaved and disposed by incineration via the college in accordance with safety regulations, currently in use for ACDP hazard group 2 organisms.

### Project Additional Information

#### Purposes of the contained use

A marker plasmid will be constructed to allow the monitoring of bacteria either by bioluminescence or fluorescence in the presence of a fluorescent substrate.

#### Recipient or parental organism

Recipient organisms: *Escherichia coli K12, Salmonella typhimurium SAL1, Legionella pneumophila NCTC11191, Bacillus cereus NCT2599, Pseudomonas aeruginosa PAK and Burkholderia cepacia NCIMB9091; all are wild type identified laboratory strains. E. coli is ACDP cat. 1 all other organisms are cat. 2.

#### Host/vector system

Plasmid vector (pBBR1MCS4) confers ampicillin resistance and is only mobilisable when the RK2 transfer functions are provided in trans. Plasmid will be modified to also confer chloramphenicol resistance.

#### Origin & function

Firefly luciferase (luc+) from the commercially available plasmid pSR-luc+ or β-galactosidase (lacZ) amplified from the E. coli K12 chromosome will be cloned into the plasmid pBBR1-MCS4. These will allow us to determine the amount of bacteria adhered to eukaryotic cells either by luminescence (luc+) or fluorescent (lacZ).

#### Evaluation of foreseeable effects

Since the plasmid being constructed is only for use as a marker it is not expected to change the virulence properties of the recipients. Therefore a release of the GM organism would result in the same effect as a release of the unmodified organism.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials contaminated with GM bacteria will be soaked in 5% (w/v) hycolin (if not directly autoclaved), autoclaved and disposed of by incineration via the college in accordance with the safety regulations currently in use for ACDP hazard group 2 organisms.

Project Additional Information

Purposes of the contained use
To investigate function of DNA replication, recombination and repair genes, and their role in antibiotic resistance acquisition.

Recipient or parental organism
Clinical and laboratory isolates of Streptococcus pneumoniae and other mitis group streptococci.

Host/vector system
Genes will either be cloned in E. coli vectors unable to replicate in streptococci in order to mediate incorporation into the pneumococcal/streptococcal genome, or cloned in shuttle vectors such as pVA838 and pVA981 which can replicate in pneumococci/streptococci. In some cases genes will be cloned to allow expression: pMSP3535 allows regulated expression in streptococci.

Origin & function

The intention is either to inactivate or to overexpress the genes in streptococci. In some cases genes will be inactivated by insertion of antibiotic resistance cassettes, and reporter genes will be inserted downstream of promoters to assess regulation of expression.

Evaluation of foreseeable effects
Modified S. pneumoniae and mitis group streptococci may have an increased mutation rate and some will carry additional antibiotic resistance genes. Hypermutable organisms are generally at a disadvantage due to the accumulation of errors. Clinical isolates known to have a wide range of mutation frequencies are not thought to be associated with increased virulence. There is potential for an increase in mutation to antibiotic resistance. Penicillin is usually the drug of choice for treating infection - penicillin resistance cannot be gained by point mutation, and none of the resistance cassettes to be used confer penicillin resistance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All cultures and contaminated materials are autoclaved (effective 100% kill, monitored by regular servicing of autoclave and integrated chart recorder). After autoclaving, disposable solids are removed as clinical waste for incineration, and liquids are disposed of to drain.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Please enter comments on the GM safety committee on the risk assessment

Project Ref 174/06.2

Date Ackn'd 30/09/2009

CU2 Project Title

Investigation of interactions of enterohaemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) and cells of the organised lymphoid tissue of the human gut.

Class 2

Consent Granted Not Applicable

Project notified under transitional arrangements N

Purposes of the contained use

Investigation of enterohaemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) can affect and modulate immune cells of the human gut by injecting proteins via a type III secretion system.
Laboratory derivatives of the E. coli strain EHEC 0157:H7. All strains are Shigatoxin-negative.

Laboratory derivatives of the E. coli strain EPEC 0127:H6. All strains are negative for the EspC enterotoxin.

Host/vector system

The strains to be used carry a plasmid (pFPV25.1) with the gene that encodes for green fluorescent protein (GFP) or the plasmid pCX340 with a gene that encodes with NleD ("Non LEE Encoded effector", an EHEC effector protein) fused to TEM-1 β-lactamase which serves as a reporter protein to directly show that a cell has received a signal via type III secretion.

Origin & function

pFPV25.1 expressing the green fluorescent protein (GFP) allows direct visualisation of EHEC and EPEC by fluorescent microscopy. pCX340 expressing NleD or TccP fused to TEM-1 β-lactamase serves as a fluorescent-based reporter for cells which have received a signal via type III secretion.

Evaluation of foreseeable effects

Modification involves introduction of marker genes. These are expected to have no effect on the virulence of the host.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures and contaminated materials are autoclaved (effective 100% kill, monitored by regular servicing of autoclave and integrated chart recorder). After autoclaving, disposable solids are removed as clinical waste for incineration, and liquids are disposed of through the drain.

Project Containment

The comments were that if a member of staff suffers from diarrhea, the PI and the Health and Safety Officer will be notified. A restriction was made on the volume of media in which the organism was cultured (maximum 20 ml).
Project Ref 174/06.3

Date Ackn'd 30/09/2009

CU2 Project Title To make single base changes by site directed mutagenesis in 10 genes involved in replication of the live attenuated Oka Varicella-zoster vaccine virus.

Class 2

Cultivation Class < 1 Litre

Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use
To determine the biological significance of wildtype alleles present in genes involved in replication that occur at significantly lower frequency in the original Oka vaccine preparation but appear to have been selected for in Oka Varicella vaccine viruses that cause rashes.

Recipient or parental organism
Attenuated Oka varicella vaccine virus present in Cosmids and in a BAC.

Host/vector system
Cosmids and BAC are already assembled containing the entire Oka varicella vaccine virus and will be transfected into E. coli to obtain sufficient titres.

Origin & function
Genes to be manipulated are involved in either DNA replication, gene expression or are of unknown function but are known to be expressed during latency and may include: Ie10 AND ie62 (transactivator proteins), Membrane protein (ORF1), Stearoylated membrane protein (ORF 9), glycoprotein C (ORF14), latency expressed protein (ORF21), glycoprotein B (ORF31), ORF39 (unknown function), 50 (unknown function), Origin of re0plication binding protein (ORF51), Components of DNA helicase/primase complex (ORFs 6, 52, 55) ORF54 (unknown function), Uracil-DNA glycosylase (ORF59).

Mutated cosmids will be transfected into melanoma cells to produce transmissible recombinant virus.

**Evaluation of foreseeable effects**

Recombinant Oka vaccine virus from cosmids or BAC may have increased virulence compared to original Oka vaccine virus but are highly likely to remain attenuated compared to wildtype virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cultures and contaminated materials are autoclaved (effective 100% kill, monitored by regular servicing of autoclave and integrated chart recorder). After autoclaving, disposable solids are removed as clinical waste for incineration, and liquids are disposed of to drain.

This connected programme of work aims to investigate the neutralisation and tropism properties of different retroviruses. Both ACDP 2 and ACDP 3 retroviruses will be used including HIV 1 and 2, HTLV 1 and 2, SIV and MLV. Retroviral genes will be amplified from infected cell cultures or patient DNA and either full length molecular clones or plasmids containing different retroviral genes will be generated. Transfections into mammalian cell lines will result in either fully infectious or defective virus particles that are not transmissible.

Recipient or parental organism

Retroviral full length molecular clones will be propagated in E. coli K12 derivatives and in human cells. E. coli K12 derivatives are disabled and non-colonising. Mammalian cell lines will be used but these will not come from worker. Fully infectious virus will be made following transfection of these plasmids into mammalian cell lines. The foreseeable risk for work with these full length molecular clones is the production of infectious virus. Transfections and all subsequent work with these retroviruses will be done in a CL3 laboratory.

Host/vector system

Host cell lines and primary cells including: T-cells, fibroblasts, epithelial cell lines, primary peripheral blood mononuclear cells and macrophages. All cell lines and primary cells will not be from any authorised workers. The bacterial hosts for expression vectors will be disabled E. coli K12 derivatives. The cloning plasmid vectors will include TOPO vectors, pcDNA3.1, pCAGGS, pNL4.3 delta env, pMDG (VSV-G envelope vector) pCNCG (packaging plasmids) and pHIT60 (MLV gag/pol vectors). Vaccinia virus expressing T7 RNA polymerase: VR2153.

Origin & function

Retroviral genes amplified from DNA from patients will be cloned into mammalian expression vectors following cotransfection into mammalian cell lines either fully
infectious virus will be made of defective, non-transmissible virus capable of only a single round of infection will be made. The intended function is to study the neutralisation and tropism properties of these chimeric infectious or pseudotyped viruses.

The vectors to be used include pCGNCG (Sonoeka et al 1995), PCSGW, pSVIII, pCAGGS, PCR-Blunt II and pCR 2.1. Packaging vectors include p8.3, p8.91. Full length molecular clone vectors include pNL4.3, p89.6 and pHXB2. The envelope deleted plasmid can be pNL4.3 delta env. These retrovirus vector systems are standard laboratory reagents.

The intended functions of the plasmid expression vectors, retroviral expression vectors and the general material inserted in them is to change the level of expression of viral and/or host proteins in the cell. This will result in the production of cells and viruses with altered properties.

Evaluation of foreseeable effects

The bacterial strains used for all plasmid propagations are disabled in key bacterial functions and are unable to survive in the environment or pass genetic material onto host bacterial flora following a breach in containment. Expression of the retroviral full length molecular clones could cause infection if injected intra muscularly in sufficient quantities. These clones will only be grown in a maximum culture volume of 100ml and sharps will be forbidden in this laboratory area in order to minimise the above risk. PPE in the form of Howie lab coats, goggles and disposable gloves will also be worn. The plasmids used for the generation of pseudotyped retroviruses split the retroviral genome into separate plasmids such that virus production is only initiated when all plasmids are present in a mammalian cell line. These plasmids are always propagated separately to minimise the risk. No mammalian cell culture is present in the CL2 molecular biology laboratory where this work is carried out. The risk of naked DNA is considered to be negligible.

The recipient cell lines and primary cells which are not from person who work in the laboratory are known to be free from human pathogens ACDP2-4 groups. These cells have limited survivability in the environment and have serum and nutrient requirements that would not likely be met outside laboratory tissue culture. Transfection of the full length molecular clones results in fully infectious virus that is capable of infecting a worker. Recombination between the plasmids for the pseudotyped viruses could also result in infectious virus though this is very unlikely. The risk is managed by carrying out transfections into mammalian cells and all subsequent work in a CL3 laboratory.

A Code of Practice details all working practices for this laboratory. All staff must be fully trained by an experienced worker and copies of all training records kept. All work with cell cultures is carried out in a Class 1 microbiological safety cabinet which is tested every 6 months. Access to the laboratory is controlled by card. Sharps are forbidden. Vaccinia virus is used to boost the expression of retroviral envelopes. In order to limit the exposure of workers to those only involved in the work directly, it will be handled in the CL3 laboratory where access is controlled and a separate class 1 microbiological safety cabinet and CO2 incubator can be dedicated to this work. Workers with vaccinia virus will be fully apprised of the risks prior to working with the virus as per the attached risk assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment Level 2:
Bacterial waste: All GMMs are inactivated in 5% Trigene for at least 16 hours before disposal or autoclaved followed by incineration as per college practice.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMSC required that laboratory workers would not work with plasmids containing full length viral genomes until containment level 2 training has been completed.

- **Culture Vol:** < 1 Litre
- **Consent Granted:** Yes
- **Withdrawn:** N
- **Historical Significant Changes:**
  - N
- **Historical Date of Additional Info:**
- **Significant Change ID:**
- **Date of Significant Change:**

### Project Additional Information

**Purposes of the contained use:**

Chronic infection with the hepatitis viruses is an important cause of morbidity and mortality. This connected programme of work aims to investigate the biology of the viruses and potential agents useful in treatment and prevention of infection. Both HBV and HCV will be investigated as will co-infection of HCV and HIV and the effect of HCV infection on HIV virus production and other properties. Viral genes from infectious clones or patient samples transfected into cell lines will result in either fully infectious virus or non-transmissible defective virus particles.
Recipient or parental organism

Full-length or partial viral DNA will be cloned into Ecoli. Transfection of full-length RNA or plasmid DNA, or partial length DNA co-transfected with a defective retroviral plasmid construct into mammalian cell lines or primary cells will be used. These will not come from any laboratory worker. The foreseeable risk for work with these full length molecular clones is the production of infectious virus. Viral RNA will be produced and stored in the CL3 laboratory as will transfections and all subsequent work with these constructs.

Host/vector system

Host cell lines and primary cells including: fibroblasts, hepatoma cell lines, and primary cell, T-cells, peripheral blood mononuclear cells and macrophages. All cell lines and primary cells will not be from any authorised workers. The bacterial hosts for expression vectors will be disabled E.coli K12 derivatives. The cloning plasmid vectors will include TOPO vectors, pGEM, pcDNA31, pCAGGS, pNL4.3 delta env, and pSVIII.

Origin & function

The intended function of the genetic material is to introduce it into mammalian cells so that it becomes possible to study the neutralisation of the hepatitis viruses and their effect on the functions of the cell. Hepatitis genes will be amplified from infected patients and will be cloned into mammalian expression vectors and following cotransfection into mammalian cells defective, non-transmissible virus capable of only a single round of infection will be made. The vectors to be used include the mammalian expression vectors pSVIII, pCAGGS and pNL 4.3 delta env. Other vectors include pGEM Teasy and the TOPO vectors pCR-Blunt land pCR2.1. Full-length RNA from a plasmid containing cloned JFH1 will be used to transfect mammalian hepatoma cell lines (Wakita et al, 2005). This is known to transfect successfully and produce infectious virus particles. Mutations of this construct or constructs from other genotypes or of mixed genotype will also be used. Further, these HCV expressing cell lines will be infected with HIV and other retroviruses to study the effects on HIV biology. These experiments will result in the production of cells and viruses with altered properties. A well characterised hepatoma cell line which is already transfected with the hepatitis B virus, and produces viral particles into the tissue culture medium, will also be used (Sells et al, 1987)

Evaluation of foreseeable effects

The bacterial strains used for all plasmid propagations are disabled in key bacterial functions and are unable to survive in the environment or pass genetic material onto host bacterial flora following a breach in containment. The plasmids used for the generation of pseudotyped retroviruses split the retroviral genome into separate plasmids such that virus production is only initiated when all plasmids are present in a mammalian cell line. These plasmids are always propagated separately in disabled E. coli K12 derivatives to minimize this risk. No mammalian cell culture is present in the CL2 molecular biology laboratory where this work is carried out. The risk of naked DNA is considered to be negligible.

Co-transfection of the envelope deleted retroviral plasmid, a plasmid containing a marker gene and the cloned envelope genes into a mammalian cell can result in a single cycle infectious virus which is not transmissible. To mitigate the risk of infection co-transfection and all subsequent work will only be carried out in a CL3 laboratory covered by a code of practice which details all working practices for this laboratory. All staff must be fully trained by an experienced worker and copies of all training records kept. All work with cell cultures is carried out in a Class 1 microbiological safety cabinet which is tested every 6 months. Access to the laboratory is controlled by card, Sharps are forbidden.

Cell lines expressing full length clones of the hepatitis viruses produce small quantities of infectious virus. All such culture and the subsequent experiments will be carried out in a dedicated CL3 laboratory under its code of practice as described above. All work with HIV viruses will be carried out in a CL3 laboratory with a COP detailing all work practices.

[The recipient cell lines and primary cells which are not from persons who work in the laboratory are known to be free from human pathogens ACDP2-4 groups. These cells have limited survivability in the environment and have serum nutrient requirements that would not likely be met outside laboratory tissue culture.]

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment Level 2:
Bacterial waste: All GMMs are inactivated in 1% Virkon or 5% Trigene for at least 16 hours before disposal. Plates will be autoclaved followed by disposal in the clinical waste as per college practice.

Containment Level 3:
All fluid waste is inactivated in 1% Virkon or 5% Trigene for 16 hours prior to disposal. All disposable plasticware is placed in double autoclave bags and autoclaved within the CL3 laboratory prior to disposal in the clinical waste as per college practice. The performance of the autoclave is tested every 6 months under a service contract. The autoclave is also monitored for each run through its printout and the inclusion of Thermolog chemical integrator strips (Bennett Scientific) to the load.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The GMSC were satisfied with the classification as Class 2 or as Class 3 for the risk assessments attached.

Project Ref 424/02.1

TO CONSTRUCT RETROVIRAL VECTORS, CAPABLE OF INFECTING HUMAN CELLS THAT EXPRESS GENES ENCODED BY CULTANEOS AND OTHER HUMAN PAPILLOMAVIRUSES (HPV)

Class 2

Non-GMM Consent Granted

Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

transferred from centre 424 on 12/7/06.
## Project Additional Information

### Purposes of the contained use
We aim to investigate the effects of expressing HPV genes in human epidermal keratinocytes. We will investigate cellular responses to viral gene expression in the context of ultra-violet radiation. The main purpose of these experiments is to determine whether the viral encoded activities could account for effects in skin cancer.

### Recipient or parental organism
HPV genes will be propagated in bacteria (E. coli K12 strains HB101 and Sure). DNA will then be introduced into suitable mammalian retroviral packaging cell lines (murine) for virus production. Recombinant viruses will then be used to transduce human cells.

### Host/vector system
- pBabe Puro/pBabe-bsd retroviral vectors, propagated in recombination deficient bacteria (E coli HB101/Sure).
- Phoenix cells: murine retro viral packaging cell line.

### Origin & function
All HPV DNA sequences used are previously cloned in plasmid vectors and freely available.
Likely that the HPV encoded sequences will modify the cell cycle, differentiation status and apoptotic responses of the infected human cell.

### Evaluation of foreseeable effects
Recombinant virus is potentially hazardous. Contact will therefore be minimised. Work will be carried out in a safety cabinet thereby reducing the risk of aerosol. Sharps will be avoided. If contact does occur, recombinant virus is replication defective, effect thereby localised; immune rejection of virally infected cells of human/murine origin; handling only one virus at a time will minimise changes of recombination.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All work will be carried out in purpose built and equipped laboratory space designated and reserved for such experiments.
All liquid waste will be decontaminated with 1% Virkon or 5% sodium hypochlorite. Solid waste will be autoclaved. A 100% kill will result.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste - decontaminated with 1% Virkon or 5% Sodium Hypochlorite. Then to drains.
Solid waste - autoclaved followed by incineration.
100% kill is expected in both cases.

**Historical Significant Changes**

TRANSFERRED FROM GM CENTRE 424 - 12/7/06.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to generate immortalised human cell lines derived from the skin that can be used for research and drug screening.
Recipient or parental organism

Recipient cells will include human oral, anogenital and cutaneous keratinocytes. Hair follicle, germinative epithelium, matrix, outer root sheath keratinocytes, dermal papilla and connective tissue sheath fibroblasts as well as sebocytes from sebaceous glands.

Host/vector system

The pBABE retroviral vector consists of the long terminal repeat (LTR) packaging sequence from the Moloney murine leukemia virus (MoMuLV). Because the env and reverse transcriptase genes have been deleted and as there is no origin of replication this vector is considered by the ACGM to be non-mobilisable and incapable of further replication in the target cell.

Origin & function

It is intended that infecting cultured human cells with hTERT and SV40LT inserts will result in the production of immortalised cell lines. Therefore, the foreseeable effects of this activity are the generation of immortalised human cell lines.

Evaluation of foreseeable effects

Foreseeable effects will be the immortalisation of skin derived cell lines.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

PT67 packaging cells are considered to be disabled hosts and are not considered to be pathogenic to humans or animals and would have a very limited ability to survive in the environment.

pBabe will be used to express hTERT and SV40LT in human primary cell lines. The human cell lines in both their primary and transformed state are unable to survive outside of the tissue culture flask and are therefore, unlikely to spread or cause damage to the environment. If a human or animal were to be infected by one of these transformed human cell lines, these cells would be rejected by the normal immune system.

All work will be carried out in purpose built and equipped laboratory space designated and reserved for such experiments.

All liquid waste will be decontaminated with 1% Virkon or 5% Sodium Hypochlorite. Solid waste will be autoclaved. A 100% kill will result.

Retroviral supernatants for infection of cell cultures will be produced in volumes of <(less than) 100 ml.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Retroviral vectors to be used in this study are considered by the ACGM to be non-mobilisable and incapable of further replication in the target cell.

Human cell lines in both their primary and transformed state are unable to survive outside of the tissue culture flask and are therefore, unlikely to spread or cause damage to the environment. If a human or animal were to be infected by one of these transformed human cell lines, these cells would be rejected by the normal immune system.

As sharps will not be used in these studies the risk of inoculation into humans is negligible. All work with retroviral supernatants will be carried out by the worker wearing laboratory coat, facemask and double gloves. The risk of human infection is considered negligible.

All liquid waste will be decontaminated with either 1% Virkon or 5% Sodium Hypochlorite. Solid waste will be autoclaved followed by incineration. Members of the MuLV group of viruses require high titre to establish infection in immunologically competent animals and so the risk of harm to either the environment associated with accidental
release of the vector is low.

The committee considers this work to be class II and therefore all retroviral work will be carried out in our Cat II suite, Rm 1.18.

Please enter comments on the GM safety committee on the risk assessment

The committee considers this work to be class II and therefore all retroviral work will be carried out in our Cat II suite, Rm 1.18.

Significant Change ID
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Development of vectors (viral and plasmid) and molecules for the treatment of autoimmune diseases and cancer by affecting the immune system and enabling restoration of normal tissue function.

**Recipient or parental organism**

All genetically modified vectors (see attachments) are disabled and lack essential genes which prevent their autonomous replication. They need specific packaging cell types to produce a viral particle which is replication deficient and cannot multiply or produce progeny. These vectors will have no effect to the environment as they will not be released, and are maintained under strict laboratory conditions.

**Host/vector system**

Retroviral packaging cells from mouse origin (GP+E86-ecotropic also pseudotyped with VSV-G protein; GPenv-AM12 and PT67 amphotropic), human packaging cells (Bosc-23p-ecotropic; ABOSC-23-amphotropic), human 293 cells to grow adeno-associated vectors, HIV vectors, disabled E.coli such as TOP-10, DH5a, LE392. See attached forms for more details.

**Origin & function**

All GMO's we use are genetically disabled. The E.coli strains cannot survive outside the laboratory and the viruses we use cannot replicate and do not contain any viral encoded genes (retroviruses, HIV vectors and adeno-associated virus).

No culture, container or solution containing GMO's is left untreated by Virkon, autoclave or incineration. All personnel involved have been and will be properly trained in the use of category II GMO's. It is not envisaged that any of the microorganisms used will have ecologically disruptive effects as they are genetically disabled and will be used under strict laboratory conditions only.

**Evaluation of foreseeable effects**

- All GMO's we use are genetically disabled. The E.coli strains cannot survive outside the laboratory and the viruses we use cannot replicate and do not contain any viral encoded genes (retroviruses, HIV vectors and adeno-associated virus).

- It is not envisaged that any of the microorganisms used will have ecologically disruptive effects as they are genetically disabled and will be used under strict laboratory conditions only.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

i. Liquid waste will be treated with Virkon 1% for 2 hours (shown by the manufacturer as appropriate for disinfection) before disposal to main drains. Solid waste will be autoclaved and later incinerated. Sharps will be incinerated. Cryovials containing virus will be stored in specified cryofreezer and opened only in Class II cabinets. Spillages and working surfaces will be cleaned with 1% Virkon and with 70% ethanol.

ii. Waste is clearly labelled biohazard double bags will be incinerated as clinical waste.
I. Hazard conditions consist of possible spillages, aerosol spray when opening cryovials or during the use of needles when working with animals.
ii. Work is restricted to determined areas, disinfecting solutions will always be available, working guidelines are clearly posted, unauthorised personnel is not permitted.
iii. Training to work with GMM's category II. Guidelines regarding dressing code, how to treat spillages and disinfection with 1% Virkon and 70% ethanol. Medical records held by occupational health advisor.
iv. Documented spillage procedures are clearly established. In case of accident with sharps, College procedure with blood borne viruses will be followed.
v. Autoclaves are regularly serviced and checked. Autoclaved material is checked using autoclaving tapeto assess has reached appropriate temperature for disinfection.

Project Ref 774/02.1

Date Ackn'd 13/08/2002
Date Project Ceased

CU2 Project Title ANGIOPGENIC GENE THERAPY PRODUCT FOR CORONARY ARTERY DISEASE

Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

**Recipient or parental organism**

See box below

**Host/vector system**

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E 1 region; from map unit 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

**Origin & function**

The FGF-4 gene was originally isolated from a cDNA library which was constructed from nRMA of Kaposi's sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

**Evaluation of foreseeable effects**

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to nonexistent.

Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or nonexistent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (e.g. promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.
The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be transferred to the autoclave in the London Chest Hospital in a sealed leakproof autoclavable container. Inactivation of Ad5FGF-4 is by autoclaving at 121°C for 15 minutes. This results in 100% kill of the vector. The material is then transported off site and incinerated. Service contracts are in place for the autoclave. Formal inspections will be conducted with the safety officer.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee met on the 8th July 2002 to discuss this proposal. All the relevant individuals involved in the project were also present to answer any queries. Overall the committee felt that the assessment was well written, with all the key issues well documented.

A number of specific questions were raised which were answered by Melanie Preston. These included:

1. The type of patients to be selected and the criteria for inclusion to the study.
2. How consent was obtained and the information to be given to the patients.
3. Whether on balance this study would be conducted at Class 1. On balance it was agreed that class 2 would be appropriate. As more experience with these types of studies is obtained the containment level would be re-examined.

The committee was informed that a safety audit was conducted which was satisfactory.

The assessment was accepted by the committee with some minor amendments and will be sent to the HSE as soon as possible.
### Project Additional Information

**Purpose of the contained use**

To express Semaphorin 4B in cultured mammalian cells to study the uncharacterised function of this protein.

**Recipient or parental organism**

- Cultured mammalian cells
  - Primary human macrophages

**Host/vector system**
E. coli such as DH5alpha  
Bacterial plasmids including pCMV-XL4 (Origene Technologies) and pCMV-script (Stratagene)  
Adenovirus transfer vector pShuttle-CMV (Qbiogene)  
Adenoviral plasmid AdEasy(Qbiogene)

### Origin & function

Bacterial plasmids and adenoviral plasmid constructs will be obtained from Oxford Biomedica Ltd (Oxford). Cultured mammalian cells will be obtained from Cancer Research UK (London) cell services department. Primary human macrophages obtained from buffy coat samples that have been screened for pathogens and dispatched by the national blood transfusion service.

The plasmid constructs will be used to express the Semaphorin4b gene in cultured mammalian cells by transfection and by adenoviral gene transduction. Various assays for migration, invasion, proliferation and gene expression will then be done.

### Evaluation of foreseeable effects

The bacterial host strains used are disabled and so cannot survive in the gut. Non-mobilisable bacterial plasmids including pCMV-XL4 (Origene Technologies) and pCMV-script (Stratagene) capable of stable integration in eukaryotic cells but not transmissible to natural gut bacteria.

The design and production methods of the adenovirus ensure that only replication defective viruses are produced and hence spread from an initially infected cell line is very unlikely. This is achieved by virtue of the adenoviral plasmid lacking the E1/E3 region of the wildtype adenovirus serotype 5 genome from which it is originally derived.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All apparatus (disposable pipettes, pipette tips, tissue culture flasks) used will be submerged in Virkon overnight before being autoclaved and disposed of by incineration.

**Project Additional Information**

**Purposes of the contained use**

The above systems will be used to deliver reporter genes (such as GFP or LacZ) or therapeutic gene such as cytokine and chemokine receptor genes or pro-drug activation genes such as P450 and P450 reductase and cell cycle control genes.

**Recipient or parental organism**

Generation of vector particles in various widely available cell lines.

**Host/vector system**

Initially incorporation into the adenovirus transfer vector.

Adenoviral genome plasmid lacking the E1/E3 region has been created by homologous recombination in bacteria between the adenoviral genome plasmid (AdEasy1 (Qbiogenelnc, 2251 Rutherford Rd, Carisbad, CA 92008) and the aforementioned transfer vector. This system is not likely to generate replication competent adenovirus.
Retroviral systems such as pBabe-puro and murine virus packaging cell lines such as GP+E and AM12.

**Origin & function**

Reporter genes such as GFP and LacZ.
Therapeutic genes such as cytokine or chemokine genes eg IFN-γ of murine or human origin or chemokine receptor genes.
Prodrug activating genes such as P450 and P450-reductase.
Cell cycle control genes such as hTERT to immortalise normal cells to then study transformation.

**Evaluation of foreseeable effects**

The design and production methods of the adenovirus ensures that only replication defective viruses are produced, and hence spread from an initially infected cell is very unlikely. This is achieved by virtue of the adenoviral plasmid lacking the E1/E3 region of the wild type adenovirus serotype 5 genome from which it is originally derived. During viral production the packaging cell line Perc6 (Introgene) complement the deficiency in the E1/E3 region. Because the adenoviral region contained in Perc6 is designed to minimise the length of similarity with the transfected adenoviral plasmid, the generation of replication competent adenoviral particles, whereby the E1/E3 region becomes incorporated into the adenoviral genome, is greatly reduced.

The retroviral systems used do not contain the protein envelope coding sequence and therefore cannot produce any virus particles.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All reasonable precautions will be taken when working with genetically modified organisms.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All apparatus (disposable pipettes, pipette tips, tissue culture flasks) used will be submerged in 5% Virkon overnight before being autoclaved at 121°C for 20 mins and subsequently disposed of by incineration (QMW contract).

Liquid waste will be diluted in 5% Virkon (minimum 1/1000) for at least 24 hours.

Date of Significant Change

Project Additional Information

Purposes of the contained use
To generate, introduce and express in mammalian cell systems genes which have the potential for cancer therapy

Recipient or parental organism
Standard disabled bacteria strains derived from E.coli such as DH5alpha, DH10B, XL-1 and BJ183 for the 'AdEasy' system.

Host/vector system
Various well characterised non-pathogenic mammalian cell lines
Replication incompetent (E1A deleted) adenoviral vectors ('AdEasy' See He et al, Proc Natl Acad Sol USA 1998; 95: 2509-14) containing inserted transgenes. AAV helper-free system (Stratagene) Wild-type adenoviruses (no inserted transgenes)
Replication-competent adenoviruses - DL1520 and DL922-947 mutants (including some inserted transgenes as detailed).
Replication defective viruses will contain the following types of genes: tumour suppressor and apoptotic genes (PTEN, p53, p16 and members of the bcl-2/bax family, IAP, SMAC families; dominant negative mutants -P13 kinase, RAS, AKT, MAPK) produce molecules that would promote tumour cell death but have no effect on normal cells; genes for prodrug activators (cytosine deaminase, HSV thymidine kinase, CYP1A2, carboxypeptidase G2 and linamarase enzyme) would only have a toxic effect to the cells that they have been introduced to and only in the presence of the appropriate prodrug; chemokines and cytokines (TRAIL, TNFalpha,fas ligand, SF14, Fli-3) should represent no hazard to humans as the viruses that express them will be tumour-specific and should increase tumour cell death in these models either directly or indirectly by enhancing anti-tumour immunity. Reporter genes (GFP,Lac-Z) will also be used and other genes as listed in attached risk assessment.

DL1520 and DL922-947 viruses the transgenes introduced will be: Sodium Iodide Symporter gene (hNIS), the pro-drugactivators (cytosine deaminase, thymidine kinase) and cytokines/chemokines TRAIL, TNF-alpha and fas ligand.

In all viruses used only one transgene will be expressed in one construct at any one time.

Wild type adenoviruses when used will contain no additional genes.

Work with adenoviruses will be separate from work with AAV.

Constructs will be targeted to mammalian cells and models of disease.

Evaluation of foreseeable effects

Most gene products as described previously act within tumour cells to promote cell death. Replication defective viruses (E1A deleted) cannot replicate or produce virus from recombination events in normal cells as the genes would not be present to complement. DL1520 does not replicate in normal cells and DL922-947 only replicates in cells that are cycling, both are attenuated relative to wild-type virus. DL 1520 has the E1B-55k region deleted, the protein that binds and inactivates p53. If the virus infects normal cells the cells will enter apoptosis and do so therefore the virus cannot replicate. Conversely in tumour cells where p53 is inactivated, the virus is able to replicate. DL922-947 the E1A-CR2 region is deleted which binds pRB and therefore replicated only in tumour cells where the pathway is inactivated. Both viral forms are attenuated compared to the wild-type adenovirus, in normal cells the attenuated is such that the yield of the virus is 0.1% of the wild type (see Heise, C et al Nat Med 2000 Oct;6(10):1134-9) in the replication competent viruses the transgenes will be inserted into the missing E3 region, which is separate from the site of disableness. Viruses are verified by PCR to ensure no recombination has occurred. The feasibility of insertion into the deleted E1B-55k (for DL1520) and E1A(for DL922-947) regions will be explored. No transgenes used in the viruses could compliment replication in normal cells. None of the genes expressed can complement for the defective nature of the viruses: inclusion of a gene such as p53 or pRb would actually restore wild type function of the cancer cell (rather than the virus) and make the virus unable to replicate. The cytokines/chemokines used should pose no additional risk. There is an established literature on each of them and we have expert collaborators who are using gene transfer systems for them presently (Andre lieber, University of Washington, Seattle USA; Frances Balkwill, Cancer Research UK) Effects on host immune reactions to viral mutants has been explored (Liu TC et.al: Mol Therapy. Wang YH et al: Nat.Biotech 21:1328-1225). Wild type adenovirus could potentially infect humans leading to mild flu-like symptoms, however their use is contained within a Cat 2 environment and manipulated within a biological safety cabinet and protective clothing used. In case of accidental spillage spills would be immediately inactivated with Virkon powder and a breathing mask used to avoid inhalation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

"All work is carried out in approved Category 2 laboratory facilities with standard containment and control measures. All staff are fully trained and work with appropriate protective clothing. All GMO material (and material exposed to GMOs) will be autoclaved prior to disposal."

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste diluted with 1% Virkon overnight or 10 minutes minimum (which gives complete disinfection according to manufacturers tests) then discarded to the sink. Plasticware soaked in 1% Virkon then inactivated material is autoclaved or incinerated.

Contaminated glass (pasteur pipettes) are saked in 1% Virkon before incineration. Use of sharps is discouraged at all times. However where unavoidable, sharps are
discarded into sharp-bins and incinerated.

Solid waste is autoclaved prior to disposal into clinical waste destined to be incinerated by professional contractors.

No viable GMOs are discarded.

Project reviewed and approved at Local GMSC meeting on 29/03/04

Project Ref 774/04.2

Date Ackn'd 06/04/2004

CU2 Project Title

THE USE OF MAMMALIAN AND BACTERIAL EXPRESSION VECTORS IN THE STUDY OF GENES AND PROTEINS INVOLVED IN CELL SURVIVAL SIGNALLING.

Date Project Ceased

Class

Class 2

Consent Granted

Non-GMM < 1 litre

Project notified under transitional arrangements N

Withdrawn N

Tick if notifying a connected programme of work N
The aim of the project is to express various signalling proteins in mammalian cell culture to assess their effects on cell biology, i.e. apoptosis and cell cycle perturbations.

Recipient or parental organism

XL1-Blue, XL-10 Gold bacterial strains

Host/vector system

pCDNA-3, pEGFP, pBABE, pRETRO-SUPER vectors

Origin & function

p53 and family members - tumour suppressors, involved in sensing DNA damage and other stresses, function as transcription factors.
Yes-Associated Protein (YAP) - function as transcription factor co-activators, pro-apoptotic in certain conditions.
Akt - serine/threonine kinase, pro-survival factor, involved in protection from apoptosis and regulator of metabolism.
AMPK-AMP dependent kinase, senses AMP levels, regulator of metabolism in cells.
14-3-3 - phospho-adaptor protein, binds phosphorylated protein in cell, involved as scaffold for signalling.
Forkhead and family members-transcription factors involved in cell cycle and apoptosis.
Bcl-2 family members-proteins that are both pro- and anti-apoptotic.

Evaluation of foreseeable effects

The retroviral vector system contains inherent safety features to minimise the risks associated with them. The vectors themselves, pRETRO-SUPER(pRS) were generated by creating a self-inactivating murine stem cell virus (pMSCV) plasmid. The 3' LTR of the pMSCV was inactivated by an internal (NheI-XbaI) deletion to generate a self-inactivating virus(-LTR). Upon integration to the genome of the virus produced from this vector, the 3' LTR is duplicated to the 5' LTR to generate a provirus that lacks all of the LTRs enhancer-promoter activities (see Brummerkamp et al, Cancer Cekk,2(3):243-7, 29002) For proper integration, plasmid has to be transiently transfected into packaging cells, i.e: Phoenix. Otherwise plasmids will be generated, but not viruses. Packaging cells have viral protein production machinery for viral proteins (env, gag, pol) necessary for virus production-retroviral plasmid itself does not.

Replication competent virus is unlikely to be generated by recombination, three recombination events would be required for replication competent helper-virus outbreak (http://www.stanford.edu/group/nolan/tutorials/retpkg_6_repcomp.html).
Genes encode human proteins, which are all expressed intracellularly and do not have activity outside the cell. Inserted genes are human, will not affect bacterial pathology. Amphotrophic virus would be able to infect human cells if not handled correctly, downregulation of oncogenes or tumour suppressor genes locally could have deleterious effects. However, all work with amphotrophic virus will take place in a category 2 facility and with the requisite care using biological safety cabinets and personal protective clothing, rendering the risk of exposure to low. Where possible, ecotropic virus will be used. In the event of accidental spillage the spillage would occur within our laboratory would be disinfected with Virkon powder leading to the rapid destruction of live material thus eliminating the risk of genetic transfer to the environment. Waste would be treated as detailed in Section 12 to avoid transfer of genetic material to the environment.

**Project Additional Information**

**Purposes of the contained use**

To identify novel therapeutic targets related to cancer cell adhesion, migration and invasion by dissecting the molecular basis of cell adhesion in normal and cancer cells and tissues.

**Recipient or parental organism**

**Host/vector system**

Standard disabled bacteria strains mostly derived from E. coli, K12 eg DH5, TOP10, JM109. Various mammalian cell lines. Replication incompetent (due to lack of env, gag and pol(1)) retroviral plasmids (including pBabe, pRev Tet on/pRev TRE (Clontech's tetracycline/doxycyline inducible system), pLNCX2). E1a-deleted adenoviral vectors, various murine cell line strains.

**Origin & function**

Cell adhesion molecules (eg integrins, cadherins, desmosomal proteins) are not considered oncogenes but their expression varies in disease, including cancer. (In fact E-cadherin is considered a tumour suppressor). By selectively deleting or over-expressing wild-type, mutant or fragments of these molecules we will dissect the role of individual molecules in cancer.
Cell-adhesion molecules modulate cell behaviour via their interaction with both signalling and structural molecules. We shall seek to down-regulate the expression of wild-type, mutant or fragments of these molecules in order to trace the role of individual molecules on the function of cell adhesion molecules. These signalling molecules may include growth factors, tyrosine kinases, serine/threonine kinases, phosphatases, GTPases and the structural molecules may include cytoskeletal associated proteins.

We will also use siRNA to down-regulate the adhesion and adhesion-associated molecules described.

**Evaluation of foreseeable effects**

Modulating the function of adhesion molecules, by mechanisms described above, may affect the adhesive and motile behaviour of cells, which may affect tumourigenicity. Some of the relevant signalling molecules (e.g., src, Ras) have oncogenic mutant forms. Similarly, down-regulation of tumour suppressor genes with siRNA would also likely increase tumourigenic potential of cell lines. However, as all GM-active staff are given training in a strict code of practice and as all infectious vectors are replication incompetent, risk associated with such work is reduced to a minimum as described in the risk assessment.

**Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste diluted with Klorsept (to 10,000 ppm chlorine) or 1% Virkon overnight (which gives complete disinfection according to manufacturers tests) then discarded to sink (containment Level 1 activity) or autoclaved (Level 2). Plasticware is soaked overnight in Chlorox (e.g., pipettes) then autoclaved, or just autoclaved (e.g., tissue culture dishes). Transport to the autoclave is in special autoclave bags held in a leak-proof plastic, wheeled-container. Inactivated material is incinerated.

Contaminated glass is soaked in Klorsept then autoclaved before re-use. Use of sharps is discouraged at all times. However, when unavoidable, sharps are discarded into sharp-pins and incinerated.

No viable G/Ms are discarded.

**Is an emergency plan required according to regulation 20?**  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

This was reviewed by members of the local committee and no adverse comments were received.

**Project Containment**
Project Additional Information

Purposes of the contained use

The purpose of the contained use is to undertake an exploratory phase I/II trial of a replicating herpes simplex virus vector, OncoVEX-GM-CSF, in patients with locally advanced epithelial cancer of the head and neck.

Recipient or parental organism

See box below.

Host/vector system

OncoVEX-GM-CSF is a herpes simplex virus type 1 vector. It is based on the strain JS-1 that has been developed at BioVEX, the company that has generated OncoVEX-GM-CSF, rather than the lab strain 17+ that has been used in previous clinical trials. In the GMP manufacture, the virus was propagated on Vero cells (ATCC catalogue number X38) African green monkey kidney cells.

Origin & function

Not Applicable
OncoVEX-GM-CSF I contains three modifications. It is deleted in the neurovirulence factor ICP34.5. Deletion of this gene dramatically reduces the replication of this virus in normal neurons and many previous publications suggest that IPC34.5- HSV vectors are only capable of replicating within tumour cells. OncoVEX-GM-CSF is also deleted in ICP47. The normal function of ICP47 is to block antigen presentation with MHC class I and II on the cell surface by inhibiting the transporters associated with antigen processing (TAP1 and TAP2). This also allowed upregulation of US11, a gene that promotes viral growth in tumour cells without decreasing tumour selectivity. Finally, an expression cassette consisting of the CMV immediate early promoter driving expression of a human GM-CSF gene is situated in the site of both ICP34.5 genes.

OncoVEX-GM-CSF is believed to function via two separate mechanisms. Firstly, it is oncolytic, thereby destroying tumour cells directly. It is thus able to infect and destroy neighbouring, uninfected tumour cells. Secondly, the destruction of tumour cells leads to the release of tumour-associated antigens that engender an immune response, enhanced by the local expression of GM-CSF. It is hoped that this immune response may lead to further immune-mediated destruction of the injected tumour and distant metastases.

**Evaluation of foreseeable effects**

This virus has completed phase 1 trials in humans, so extensive data are available on the effects of deliberate injection into humans.

All patients in the phase 1 trials were injected with OncoVEX-GM-CSF directly into cutaneous or subcutaneous metastases from a variety of primary malignancies, including breast, head and neck and colon cancers or melanoma. HSV type 1 seronegative individuals appear to react differently to those who are seropositive. Doses of 10^6 pfu/ml are well tolerated by seronegative and positive individuals, although the single seronegative patient developed mild fever (<38°C) five days after injection. However, at doses of 10^7 pfu/ml, both seronegative patients developed fever, that was again transient and mild, and erythema around the injection site along with vesicles that took several weeks to heal. In seropositive patients, doses of 10^7 and 10^8 pfu/ml were tolerated without side effects.

However, it must be stressed that the virus was deliberately injected into tumour nodules (which had been confirmed by biopsy prior to enrolment in the trial), rather than normal tissue. Pre-clinical assessment of OncoVEX-GM-CSF and other ICP34.5 deleted HSV1 vectors has suggested that there is minimal replication of ICP34.5 deficient HSV1 vectors has suggested that there is minimal replication of ICP34.5 deficient HSV1 vectors in normal cells. Similarly, BalbC mice tolerated three subcutaneous doses of 1 x 10^9 pfu OncoVEX-GM-CSF and direct intracerebral doses of 1 x 10^7 pfu without significant toxicity, whereas the LD50 for intracerebral wild-type HSV1 in BalbC mice is <10 pfu.

At no point in the trial was recombination with wild-type virus ever detected, nor reactivation of latent wild-type HSV1 infection.

Finally, this virus remains highly susceptible to acyclovir treatment, as the thymidine kinase gene remains intact. Therefore, in the event of accidental inoculation of a health care worker, treatment with acyclovir will lead to rapid elimination of any infected virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All treatment will take place as in-patient procedures. All injections be performed in the new gene therapy and experimental medicine unit, which is equipped with double HEPA filtration. Any liquid waste will be treated with Virkon. A 1% solution of Virkon has been shown to provide effective disinfection within 10 minutes (see http://www.antechh.com/framset.html)

An autoclave is present within the gene therapy unit. All solid waste potentially contaminated with OncoVEX-GM-CSF will be autoclaved prior to disposal.

Surfaces will routinely be disinfected with 1% Virkon and 70% ethanol.

All patients will wear occlusive dressings over injected tumours: in the phase 1 trial of OncoVEX-GM-CSF, no virus was ever detected penetrating these dressings, suggesting that accidental release into the atmosphere is also unlikely.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All treatment will take place in a dedicated gene therapy unit equipped for work at containment level 2.

Any liquid waste will be treated with Virkon. A 1% solution of Virkon has been shown to provide effective disinfection within 10 minutes. (see http://www.antechh.com/framset.html)

An autoclave is present within the gene therapy unit. All solid waste potentially contaminated with OncoVEX-GM-CSF will be autoclaved prior to disposal.

Surfaces will routinely be disinfected with 1% Virkon and 70% ethanol.

All patients will wear occlusive dressings over injected tumours: in the phase 1 trial of OncoVEX-GM-CSF, no virus was ever detected penetrating these dressings, suggesting that accidental release into the atmosphere is also unlikely.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please enter comments on the GM safety committee on the risk assessment

This application was discussed at the local GM safety committee on Monday 14th February 2006. Issues raised and discussed were:

- a) provision of standard operating procedures concerning GM work in the gene therapy and experimental medicine unit, especially relating to disposal of waste.
- B) possibility of using retractable needles to minimise the risk of needle stick injuries.
- C) storage and documentation of use of OncoVEX-GM-CSF, including pharmacy records.

The local GM safety committee was satisfied that all these points were adequately addressed.

Project Ref 774/06.2
Use of viral vectors for the transfer of genes for studying the biology of adhesion for the purpose of developing novel and-cancer strategies.

Purposes of the contained use
To use lentiviral and adenoviral vectors to identify novel therapeutic targets related to cancer cell adhesion, migration and invasion of dissecting the molecular basis of cell adhesion in normal and cancer cells and tissues.

Recipient or parental organism
Standard disabled bacteria strains mostly derived from E. coli K12 including DH5a, TOP10, JM109. H293-derived packaging cell lines.

Host/vector system
Standard disabled bacteria strains mostly derived from E.coli, K12 eg DH5a, TOP10, JM109. Various mammalian cell lines. Replication incompetent 2nd generation and additionally self-inactivating 3rd generation lentiviruses. Replication-incompetent adenoviral vectors (AdEasy based Ad5 and Ad2 vectors) and replication competent adenoviruses modified to only replicate in tumour cells but not cells with normal p53 and Rb pathways.

Origin & function
Cell adhesion molecules (eg integrins, cadherins, desmosomal proteins) are not considered oncogenes but their expression varies in disease, including cancer. (in fact E-cadherin is considered a tumour suppressor). By selectively deleting or over-expressing wild-type, mutant or fragments of these molecules we will dissect the role of individual molecules in cancer.

Cell-adhesion molecules modulate cell behaviour via their interaction with both signalling and structural molecules. We shall selectively delete or over-express wild-type, mutant or fragments of these molecules in order to trace the role of individual molecules on the function of cell adhesion molecules. These signalling molecules may include growth factors, tyrosine kinases, serine/threonine kinases, phosphates, GTPases and the structural molecules may include cytoskeletal associated proteins.

Insertion of peptide sequences into coat proteins of adenovirus (particularly knob) to re-direct the adenovirus to more restrictive cancer associated targets, including over-expressed adhesion molecules, growth factor receptors and cytokine receptors. Such modifications will include removal of endogenous CAR and integrin binding site.
making to restrict tropism to specific target cells.

We will also use siRNA to down-regulate the adhesion and adhesion-associated molecules described.

Evaluation of foreseeable effects

Modulating the function of adhesion molecules, by mechanisms described above, may affect the adhesive and motile behaviour of cells, which may affect tumourigenicity. Some of the relevant signalling molecules (eg src, Ras) have oncogenic mutant forms. Similarly down-regulation of tumour suppressor genes with siRNA would also likely increase tumourigenic potential of cell lines. In addition, it is understood that the WRPE region of lentivirus is reported to have oncogenic properties. However, as all GM-active staff are given training in a strict code of practise and as all infectious vectors are replication incompetent, risks associated with such work is reduced to a minimum as described in the risk assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All facilities are at category 2 standard, with a strictly controlled environment. All rooms and laboratories are constructed so as to prevent accidental release into the environment. In the unlikely event that an escape/leak should occur the organisms concerned will not be able to survive. All waste generated will be autoclaved prior to incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste diluted with Klorsept (to 10,000 ppm chlorine) or 1% Virkon overnight (which gives complete disinfection according to manufacturer's tests) then discarded to sink (containment level 1 activity) or autoclaved (level 2). Plasticware is soaked overnight in Chloros (eg pipettes) then autoclaved, or just autoclaved (eg tissue culture dishes). Transport to the autoclave is in special autoclave bags held in a leak-proof plastic, wheeled-container. Inactivated material is incinerated.

Contaminated glass is soaked in Lorsept then autoclaved before re-use. Use of sharps is discouraged at all times. However, when unavoidable, sharps are discarded into sharp-bins and incinerated.

No viable GMOs are discarded.

Is an emergency plan required according to regulation 20? [ ]

Please enter comments on the GM safety committee on the risk assessment

The GMSC considered this proposal on the 27/10/2005
The following points were considered:
1. Environmental risk assessment was considered (attached)
2. Following current guidance from HSE the lentivirus work is deemed to be class 2.
3. Replication competent work was considered to be Class 2.
4. All other adenoviral work was considered to be Class 1.
**Project Additional Information**

**Purposes of the contained use**

The purpose of this work is to explore the ability of vaccinia virus (VV) to accumulate and preferentially replicate within solid tumours. A variety of replication-selective oncolytic VV will be constructed and their efforts on virul tissue specificity and antitumour ability will be assessed. In addition, vectors carrying therapeutic genes to enhance the antitumour potency and the reporter genes GFP and luciferase will be used to follow the location of the virus within host systems.

**Recipient or parental organism**

Vaccinia strains Western Reserve, Lister and Wyeth
All three strains are commercially available and have been widely used in several laboratories for many years. In addition, strains Lister and Wyeth have been used as smallpox vaccines in millions of people worldwide. They are classified as containment level 2 by the ACDP. In our project, we mostly focus on using lister strain.

**Host/vector system**

Host cells: E.coli DH5α, K12. The E.coli strains are widely used, highly attenuated commercial strains.

Vectors: pUC18, pUC4K, pSJH7 and pNT8, these vectors fulfill a number of criteria that make them safe to use.

**Origin & function**

DNA from wild type strains will be amplified by PCR and cloned first into standard, commercially available plasmids (pUC18, pUC4K) where deletion mutants will be constructed. The modified DNA will then be cloned into the specialist plasmid (pSJH7) for transient selection. These DNA manipulations will take place in commercially available E.coli strains, acting as as a clone vector. The plasmids will be co-transfected into the cell lines TK143 or D980R along with a second vector containing an attenuated version of the wild type VV genome, such that viral replication can only occur following recombination of the two plasmids. Virus can then be picked form plaques and successful recombination checked by PCR and Southern bloting. Genes to be targeted will be involved with crucial genes for VV replication (as described in the risk assessment, such as VGF and TK) and the evasion of the host immune system (IFN binding proteins, anti-apoptotic proteins). Inserted DNA will be heavily disrupted and so unlikely to be active and the disruption of these genes is likely to reduce the pathogenicity of the host organism.

In addition, this same techniques will be used to insert the therapeutic genes into the viral genome. These therapeutic genes have been listed in the risk assessment. Vaccinia virus containing reporter genes such as the sodium iodide Symporter, GFP, β-Galactosidaase and Luciferase will also be used as control vectors. We will inform the HSE whenever any inserts that deflect from this form are chosen to arm the viruses.

**Evaluation of foreseeable effects**

The results of genetic modification will reduce the pathogenicity of the parental organism. No adverse effects are anticipated. The inserted therapeutic genes chosen in this project are no harm to human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All reasonable precautions will be taken with genetically modified organisms. All facilities are at category 2 standard with a strictly controlled environment. All rooms and laboratories are constructed so as to prevent accidental release into the environment. In the unlikely event that an escape/leak should occur the organisms concerned would not be able to survive. All waste generated will be autoclaved prior to incineration.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste is deactivated using 1% Virkon overnight or 10 minutes minimum (which gives complete disinfection according to manufacturers tests, see www.antech.com/virindex) then discarded to the sink. Plasticware soaked in 1% Virkon then inactivated material is autoclaved or incinerated. Contaminated glass (pasteur pipettes) are soaked in 1% Virkon before incineration. Use of sharps is discouraged at all times. However where unavoidable, sharps are discarded into sharps bins and incinerated.

Solid waste is autoclaved prior to disposal into clinical waste destined to be incinerated by professional contractors. No viable GMOs are discarded.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form
Project reviewed and approved at local GMSC meeting on 27/10/05. The committee recommended that this project be classified as class 2 due to the ACDP classification of the wild type vaccina virus as containment level 2, despite the fact that created GMMs will be attenuated for virulence.

CU2 Project Title Use of human stem cells to repair neurological disease.

Class 2
Consent Granted Not Applicable

Withdrawn N

Project notified under transitional arrangements N

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Date of Significant Change
Project Additional Information

Purposes of the contained use

During the use of stem cells containment level 2 will be observed. The room will not be accessible to any persons not fully aware of the risks associated with the use of these cells. This especially relates to the risk of injury from sharps that may have been exposed to the GMO.

Recipient or parental organism

The purpose of this work is to examine the ability of modified Human stem cells to augment/recover functional loss in neurological disease.

Host/vector system

Human neural stem cells derived from the ventral mesencephalon infected with a replication defective amphotropic retrovirus carrying the mycERTAM construct. The cells do not carry replication competent retroviruses. Cells are also transduced with resistance to Neo (G418). The two transgenes, mycERTAM and neo, are cloned into a pSVX plasmid and transmitted to the cells via cell suracereceptor-viral envelope protein interaction. The site of insertion into the vector is at the BamH1 site of the pSVX plasmid. v-myc will result in an immortalization of transduced cells.

Origin & function

To ensure a homogenous and persisting population of neural stem cells in vitro, these cells were transduced with the immortilizing mycERTAM, construct, a chimeric gene encoding the c-myc proto-oncogene fused with a tamoxifen-sensitive mutant of the estrogen receptor.

Evaluation of foreseeable effects

These cells carry an oncogene and theoretically there is potential for tumourigenesis, but this is considered to be effectively zero since the oncogene is constrained entirely within the cells. Thus there is no vector to facilitate transfer of the oncogene out of the cells and into the wider environment. Moreover, in the absence of tamoxifen, the oncoprotein is entirely non-functional, so even within the cells the capacity for expression is extremely limited.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All reasonable precautions will be taken with genetically modified organisms.

All facilities are at category 2 standard within a strictly controlled environment. All rooms and laboratories are constructed so as to prevent accidental release into the environment. In the unlikely event that an escape/leak should occur the organisms concerned would not be able to survive. All waste generated will be autoclaved prior to incineration.

In the absence of a helper virus, the transgenic construct is totally constrained within the cells. The cells have no capacity for survival in the environment. Hence the threat to the environment is very small. This vector system is well established in laboratories and has a good record of environmental safety.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste products will be deactivated by overnight soaking in a 1% Virkon solution before being discarded to the sink. Plasticware will be soaked in 1% Virkon to inactivate and then incinerated or autoclaved.

Contaminated glass will be soaked in 15 virkon prior to incineration. Use of sharps will be minimised, but where used will be discarded in a sharps bin and incinerated.
Solid waste will be autoclaved and then incinerated by professional contractors.

No viable GMOs are discarded.

Project Ref 774/07.1

Date Ackn’d 13/04/2007

CU2 Project Title

The knockdown of tumour suppressor gene expression by RNA interference using amphotropic retroviral and lentiviral vectors.

Date Project Ceased

Project notified under transitional arrangements  

N

Class 2  

Consent Granted

Not Applicable

Tick if notifying a connected programme of work  

Y
Purposes of the contained use

The aim of the project is to generate replication defective amphotropic retroviruses and lentiviruses that express shRNAs against a range of tumour suppressor genes, including CDKN2A, AFR, TP53, PTCH, the telomerase components hTERC and hTERT, AKAP220, PCDH7/8, SERPINB family, LPHH2, GRM7, PLOD2, RASGRF2, OAT3, PIG38 and WDR4, which under certain circumstances can suppress tumour development. Other genes will include MYC, GL-1, GL-2, WNT-1, WNT-8A, WNT-16, WDR4, S33Y, engrailed, winged helix domain, SMO, RAS-GRF2, FOXM1.

This will allow the knockdown in expression of these genes using short hairpin RNAs that generate the stable expression of small interfering RNAs (RNAis) within the target cell. This will enable evaluation of the role of the above genes in human keratinocyte senescence.

Recipient or parental organism

The cells used will be primary cultures of human epidermal, oral, hair follicle and eccrine sweat gland keratinocytes, sebocytes, prostate epithelial cells, dermal papilla fibroblasts, dermal fibroblasts, lung fibroblasts and their immortal or neoplastic derivaties. The target cells in culture are not considered to posr any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory.

Retroviral or lentiviral infection is only transient in the target cell and it will not be able to produce the virus. The cells will therefore not exert any foreseeable effects on either human health or the environment.

Host/vector system

The system used to allow expression of small interfering RNAs against genes mediating senescence in human keratinocytes involves replication-defective amphotropic retroviruses and lentiviruses.

The retroviral (pRETOSUPER and pRETROSUPERIOR) and lentiviral (pLentLox3.7, pLKO.1 or pHR1U1-CMVGFPSin 18 will be used to transfer the shRNAs into human keratinocytes. The lentiviral vectors have the advantage of being able to infect non-diving keratinocytes. These viruses have the potential to infect human cells only when they have been packagaed in appropriately engineered packaging cells. Once packaged these infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in other non-engineered cells.

In more detail:
The pRETROSUPER and pRETROSUPERIOR vectors are derived from the Murine Embryonic Stem Cell virus (pMSCV). The vector has a specifically designed 3'LTR that has a deletion in the LTR promoter elements. This deletion results in inactivation of the LTR mediated transcription upon retroviral integration. The constructs will be grown in the excision repair-deficient E. Coli strain GT116 to avoid removal of the shRNA sequences. The resulting plasmids will then be transfected into Phoenix-E cells.
To produce ectropic retrovirus and then into PT67 cells to generate high titre amphotropic retroviruses. Alternatively the constructs will be transfected into Phoenix A cells to generate amphotropic virus directly. Each of these cell lines contains gag, pol and env genes encoded by 2 separate plasmid expression vectors both of which lack the retroviral cis-acting packaging signal to minimise the likelihood of replication competent virus arising through recombination.

The first lentiviral vector, pHR1U1-CMVGFPSin18, was created by first sub-cloning inserts into the BglII/SalI site in the pIU1-T7 vector. The PCR fragments containing both IU1 promoter and the insert were sub-cloned into the pHRCMVGFPSWsin18 vector. Lentivirus will be generated by co-transfecting 293T cells with the pMD.G, pCMVDR8.91 and pHR1U1-CMVGFPSin18 using the three plasmid lentiviral packaging system.

The second lentiviral vector to be used, pLL3.7, is the third generation system (self inactivating vectors) derived from HIV-1 incorporating many safety features. These include deletion in the enhancer region of the 3'U3 of the long terminal repeat which results in self inactivation after transduction of the target cell. Genes encoding the structural and other components are split into four plasmids which are engineered not to contain any regions of homology to prevent any recombination and none contain LTRs or psi packaging sequence. Thus none of the HIV-1 structural genes are present on the packaged viral genome and thus are never expressed in the transduced target cell. Short hairpin RNAs (shRNAs) will be cloned into the pLentLox3.7 (pLL3.7) lentiviral transfer vector and delivered to the cells in the form of an amphotropic lentivirus. The resulting infected cells will then generate a continuous supply of RNAi in the target cells. Infected cells can be identified by the co-expression of the GFP FLAG with shRNA. The expression cassette to create a vector that simultaneously produces shRNAs and a reporter gene. To facilitate the introduction of RNAi stem cell loops, a multiple cloning site was placed immediately after the U6 promoter. The pLL3.7 constructs will be grown in either DH5 alpha or the excision repair-deficient E.Coli strain to avoid removal of the shRNA sequences. The resulting plasmids will then be transfected into 293FT cells along with the packaging vectors pMD.Lg/pRRE (gag/pol elements), pRSV-REV and pMD.G (VSVG envelope glycoprotein vector) to produce high titre amphotropic lentiviruses. These are available commercially from Invitrogen as pLP1, pLP2 and pLP/VSVG vectors.

The lentiviruses will then be recovered by ultracentrifugation and resuspended in phosphate-buffered saline before titration on HeLa cells. Concentrated viruses 10 million infectious units per ml will then be used to infect the normal human keratinocytes.

pLKO.1-puro (modified third-generation HIV-derived lentiviruses)
This vector is replication incompetent and self-inactivating, and requires the co-transfection of 2 plasmids carrying the gag, pol and VSV G genes to produce lentiviral particles.

Origin & function
The genetic material to be introduced via the retroviral and lentiviral systems consists of short hairpin RNAs that target a number of genes involved in mediating senescence in human keratinocytes. These include the tumour suppressors, hTERC, hTERT, CDKN2A, ARF, TPS3, PTCH, AKAP220, PCDH7/8, SERPINB family, LPHH2, GRM7, PLOD2, RASGRF2, OAT3, PIG38 and WDR4.

It is anticipated that by knocking down the expression of these genes their role in keratinocyte senescence can be further understood.

In addition, the lentiviral vector has been engineered co-express GFP FLAG with the shRNA constructs to act as markers of infected cells.

Evaluation of foreseeable effects
The final GMO human cells will contain stably integrated DNA copies of the retroviral and lentiviral vectors encoding the transferred shRNAs against the genes listed above. The cells will be free of retrovirus or lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture.

It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses or lentiviruses which are used to transiently effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
To minimise the risk to human health it will be essential to prevent exposure to infectious retroviral or lentiviral particles. All work will therefore be carried out under Class II containment conditions. Following experimental work, all viral supernatants will be autoclaved and spent medium will be inactivated using precept tablets (10,000 ppm chlorine), 1% Virkon or 1000cpm Actichlor™ before removal from the Class II laboratory for disposal. Solid waste will be double -bagged in biohazard bags prior to removal from the Class II laboratory and then autoclaved before final consignment of waste approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by both infection of appropriate indicator cells and assays of reverse transcriptase activity. Once these criteria have been met the infected target cells will be removed from Class II containment and handled using standard tissue culture procedures.

Separate lab coats are worn within the Class II laboratory, gloves will be worn, plastic ware will be used and all use of sharps will be avoided.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The risk assessments were reviewed by the GMSC on 30th August 2006. It was agreed that a number of similar assessments would be grouped together since the basic work in each case is fundamentally the same. The committee asked in some cases for more information regarding inserts and vectors. A sub-group of the committee reviewed again (7th Feb 2007) the local risk assessments prior to sending to HSE. The local assessment by Dr The is included in this application as well as the accompanying one as it includes work using RNA silencing techniques.

(The risk assessment pertaining to a very similar notification was discussed at the CRUK Beatson Laboratories, Glasgow, Safety Committee of the 12th May 2004 and was approved with minor modification.)

02/03/2022
The aim of the project is to generate replication defective amphotropic retroviruses that express human oncogenes, in particular; RAS, MEK-EE (constitutively active), ERBB1, EPS8, MYC, GLI-1, GLI-2, WNT-FOXM1, AXL-1, Htert, Htetc, AKAP220, PCDH7/8, SERPINB family, LPHH2, GRM7, PLOD2, RASGRF2, OAT3, PIG38, WDR4, Akt, Erk1/2, EPS8. Other tyrosine kinases may be included as appropriate.

Other genes include HaRas V12, ikBaM. Other genes associated with the telomerase complex. This will enable evaluation of the role of the above genes in human cellular senescence, immortalisation transformation and telomerase regulation.

Any significant deviation from this the above will be notified to HSE.

The cells used will be primary cultures of human epidermal, oral, hair follicle and eccrine sweat gland keratinocytes, sebocytes, prostate epithelial cells, dermal papilla fibroblasts, dermal fibroblasts, lung fibroblasts and their immortal or neoplastic derivatives.

Other cells will include EBV-transduced human B cells, primary lymphoid cells, phoenix packaging cell line.

The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory.

Retroviral infection is only transient in the target cell and it will not be able to produce the virus. The cells will therefore not exert any foreseeable effects on either human health or the environment.

The system used to allow expression of human oncogenes mediating senescence in human cells involves replication-defective amphotropic retroviruses.
The retroviral vectors pBABE, pWZL, pMNDBanshee, pBloxTSH, pLCRESH, LXN and pSIN will be used to transfer the into human keratinocytes. The lentiviral vectors have the advantage of being able to infect non-dividing keratinocytes. These viruses have the potential to infect human cells only when they have been packaged in appropriately engineered packaging cells. Once packaged these infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in other non-engineered cells.

In more detail: pBabe series which is based on the Moloney murine leukaemia virus, MoMLV and contains the LTR and packaging sequences from the MoMLV. The pBabe vector lack the env and reverse transcriptase genes and there is no eukaryotic origin of replication, hence these vectors are considered to be non-mobilisable. This modified virus will be classified as Class 1. The full length hTERT cDNA was cloned in the EcoRI site of pBabe-Hygro, pBabe-Puro and pBabe-Neo downstream of the LTR promoter to create pBabe-Hygro-hTERT, pBabe-Puro-hTERT and pBabe-Neo-hTERT.

To create pBloxTSH, the 3.5-kb EcoRI-SalI fragment from pCI-Neo-hTERT was first cloned in the EcoRI and SalI sites of pBabe-Puro, to create pBabe-Puro-hTERT. The 1.7-kb HpaI-HindIII L-histidinol resistance gene (HISD) from pLXSHD into the 8.2kb SalI-HindIII fragment from pBabe-Puro-hTERT, creating pBTSH. The 5.2kb EcoRI-HindIII sits in pBabe-Puro, creating pBloxTSH.

pMND was created from Moloney Murine Leukemia Virus. The MND backbone, which has alterations to address three viral elements implicated as repressors of expression by Mo-MuLV: the enhancer, the primer binding site, and the negative-control region. pMND-Banshee was modified from pMND so that it harbours a specialised termination signal to result in non-polyadenylated transcripts. hTERC was cloned downstream of the U1 promoter in the EcoRI and HindIII sites of Bluescript II SK (+). U1-hTERC was cloned in the BglII and HindIII sites of the pMND-Banshee-Neo to create pMND-Banshee-hTERC.

pLXSH is a derivative of pLXSN that carries the hygromycin resistance gene. pLXSN contains eukaryotic expression elements: 5’ Moloney murine sarcoma virus, LTR promoter the hygromycin- resistance gene and Moloney murine leukemia virus promoter3’. To create pLCRESH the PstI-MluI fragment from pACN (Cre) was subcloned into the HpaI site of pLXSH.

PWZL

pSIN is derived from Moloney Murine Leukemia Virus and is ‘replication incompetent’ vectors through loss of the gag, pol and env genes that are provided in trans by the amphotropic Phoenix packaging cell line. In addition, pSIN is a ‘Self-Inactivating’ vector through deletion of the 3’ UTR.

Origin & function

The genetic material to be introduced via the retroviral systems consists of human genes involved in mediating senescence, immortalisation or telomerase activation in human cells. These include the oncogenes, hTERC, hTERT, RAS, MEK-EE (constitutively active) ERBB1, MYC, GLI-1, GLI-2, WNT-1, WNT-16, FOXM1, AXL-1, AKAP220, PCDH7/8, SERPINB family, LPHH2, GRM7, PLOD2, RASGRF2, OAT3, PI3 and WDR4.

It is anticipated that by ectropically expressing these genes their role in keratinocytes senescence can be further understood.

Evaluation of foreseeable effects

The final GMO human cells will contain stably integrated DNA copies of the retroviral vectors encoding the transferred oncogenes listed above.

The cells will be free of retrovirus or lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.

It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

Project Ref  774/08.1

Date Ackn'd 02/03/2022  CU2 Project Title
Purposes of the contained use

Culturing and genetic manipulation of trypanosomatid parasites.

Recipient or parental organism

Trypanosoma brucei brucei (strain MITat427, clone 221a). This organism is non-pathogenic to humans and used as a model system for human pathogenic Trypanosoma brucei sub-species.

Leishmania major (strain Friedin). This organism causes cutaneous leishmaniasis. However, infections will usually self cure, leaving a scar. This species is a model system for other, more severe forms of leishmaniasis.

Host/vector system

Vectors

The only vectors used during this work are based on standard bacterial cloning vectors (e.g., pBluescript-based plasmids). This is to allow propagation of parasite DNA sequences in E.coli.

 Inserts

The trypanosomatid genes (derived from either genomic DNA or cDNA) under study include nitroreductases, peroxidases and superoxide dismutases. Non-coding and/or partial coding genomic DNA sequences from the parasites will be used to construct gene knockout vectors. All coding and non-coding sequence under study are highly unlikely to be involved in pathogenicity/virulence.

Parasite genomic DNA and cDNA will be used to target specific loci by homologous recombination. Modified coding sequences (e.g., epitope tagged versions) will be used to complement mutant phenotypes. DNA introduced into trypanosomes is propagated by insertion into the parasite nuclear genome of non-therapeutic, drug selectable
markers. The drug selectable markers aph (3')-lib from Tn5, ShBle from Streptalloteichus hindustanus, bsd from Aspergillus terreus, pac from Streptomyces alboniger and hph from E.coli plasmids, will be used to transform T.b.brucei or L.major to G418, bleomycin, blasticidin, puromycin and/or hygromycin resistance respectively.

</thead>
</table>

Virkon for use with T.brucei has been validated experimentally for three time points. Specifically 1x106 T.brucei in 1ml of culture media were microscopically observed to be “healthy-alive and mobile”. To this culture an equal volume (1ml) of 2% Virkon was added to give a final concentration of 1% Virkon. The culture was microscopically observed (on an inverted light microscope with a 40x objective) 10 minutes later all T.brucei were found to be “totally lysed-dead and morphologically unrecognizable”. Cultures were further observed after 1 hour and overnight with the same result. Images of these were taken but independently observed (3 people) to verify the results. This experiment has been repeated using higher concentrations of T.brucei (5x106ml-1) in larger culture volumes (10ml) with the same results as described above (data provided by Dr E. Hendricks, Imperial college London).

Please enter comments on the GM safety committee on the risk assessment
The application needed to identify a backup autoclave for waste in the SBCS building.

This issue was addressed as follows:
The autoclave (room 411) in the Fogg building is opposite the containment level 2 laboratory. This autoclave is now working correctly with issues related to its maintenance and repair clarified. If the autoclave in room 411 does break down, the contractor will repair it within the week. Any containment level 2 waste generated during this time will be stored in sealed containers in room 401 until the autoclave is fixed. We anticipate that waste levels will be minimal; we will only generate 2 boxes of waste per week. If for any reason the autoclave is irreparable, work in the containment level 2 lab will cease. SBCS will replace the autoclave. We will only commence work when the new autoclave is in place. In extreme emergencies, containment level 2 waste will be double bagged and sterilized in small lab autoclaves. Thermolog indicators will be included.

Informed that the QMUL GM safety committee approved the risk assessment on 22/02/2008; local reference number 0774/0801/06. An inspection of the facility by the local GMSC was carried out on 25/02/2008.

**Purposes of the contained use**

This programme of work will use lentiviruses to deliver cDNA encoding specific genes or RNAi to knock out specific genes into various rodent and human cell lines. Established model systems will then assess the effect of these upregulated or downregulated genes in vitro or in cells.

**Recipient or parental organism**

Replication-defective 2nd and 3rd generation HIV lentiviral vectors and modified vectors constructed in house will be packaged by transient transfection of plasmids into HEK 293T cells.

Rodent and human cells will be infected with the packaged lentiviruses.

Cell lines are free of adventitious agents, and have a history of safe usage in the laboratory, equivalent to containment level 1.

**Host/vector system**

Replication-defective lentiviruses used for gene transfer in this study are 2nd and 3rd generation HIV lentiviral vectors. These lentiviruses have a wider tropism than wild-type HIV because the VSV-G Env permits entry into all cells. The virus produced is replication-defective, and all chances of recombination leading to a replicative virus is considered negligible.

**Origin & function**

We wish to use lentiviruses to express:

1. P13K isoforms and P13K signalling pathway kinases, phosphatases and other pathway components (bovine, human or mouse) and mutant oncogenic forms of these, identified in various cancers. Of the 8 catalytic subunits of the P13K family, only p11 Oalpha has so far been found to be mutated in cancer. These mutations increase the enzymatic activity of p11 Oalpha. p11 Oalpha mutations can be concurrent with mutations in other genes encoding proteins such as Ras, p53, PTEN, etc. Overexpression of p11 Oalpha in cells has recently been shown to induce p53-mediated growth arrest and mutational inactivation of p53 is required in order for cells to become transformed (Kim JS et al. 2007, MCB, 27(2):662). Ectopic overexpression of wild-type forms of the catalytic subunits p11 Obeta, p11 Odelta and p11 Ogamma can transform avian fibroblasts (Kang et al., 2006, PNAS, I 03(5):1 289), but there is no evidence for a similar effect in mammalian cells.

2. We also wish to use RNA1 to target the same classes of molecules described in 1. above.

4. Resistance Genes: Neomycin, hygromycin, zeocin resistance genes used as positive selection markers. No potential hazard, have a well-established record of safe use.

5. Gene Regulation: Proteins required for tetracycline regulated expression of genes from tetracycline responsive promoters. These include tTa, rtTA, rtTA2S-M2 and tetR-KRAB; these molecules bind DNA through variants of the tetracycline repressor and do not bind specific eukaryotic DNA sequences. Gre and FLP recombinase: Used to catalyse the site-specific recombination of DNA between loxP sites (Gre) or between FRT sites (FLP). Gre or FLP-coding lentiviruses will be used for infections of cells derived from mice bearing conditional mutations of the genes described above.

**Evaluation of foreseeable effects**

2nd generation lentiviral vectors have the genes and sequences for lentivirus formation split between 3 vectors. The backbone of the lentiviral vector only retains the packaging signal and the LTRs between which transgenes of interest are inserted (pHR or similar). Other genes required for synthesis of lentiviruses are supplied in trans on plasmid vectors and are encoded from CMV promoters. From one plasmid the VSV-G Env protein is expressed (pVSV-G or similar) and from a second plasmid Gag, Pol, Tat and Rev are encoded (pCMV 8.91 or similar). In 3rd generation lentiviruses vectors, the LTRs are also self-inactivating, such that upon reverse transcription they are also deleted. Most experiments will use the 3rd generation lentiviral vectors. A favourable system is the ViraPower Lentiviral Expression System (Invitrogen) which combines a mixture of 3 plasmids pLPi, pLP2 and pLPIVSVG encoding gag/pol and Rev response element, Rev, VSV-G env respectively. These are co-transfected with the packaging vector (four are available eg pLent64NS-DEST).
For the introduction of RNAi to knockdown specific genes, systems such as the pGIPZ from Open Biosystems will be used (http://www.openbiosystems.com/RNAi/shRNAmirLibraries/c3lpzLentiviralshRNAmir).

Lentiviruses have the capacity to infect human cells so infection of normal and HIV infected cells must be considered. Infection of normal cells will result in promoter/transgene incorporation into the genome. Harmful effects could be caused by transgene expression or due to insertional mutagenesis. The lentivirus vectors are replication defective, but there is a theoretical risk of recombination with wild-type HIV-1 or HIV-2. However, there is no report of this ever happening. In any case, recombination restoring all HIV genes — which is necessary to produce a replication - competent virus - would delete the transgene, converting the recombinant virus to wild-type. In order to reduce the risk further, the use of lentiviruses will be at ACGM Containment Level 2.

The recombinant viruses can only be packaged by cotransfecting the plasmid components of the vector system into 293T cells. Transfected cells producing the recombinant virus must be maintained in tissue culture and cannot survive outside the laboratory. Recombinant lentiviruses, are also unstable and unlikely to survive for long with survival time dependent on factors such as temperature and pH. Although theoretically the lentiviruses would be able to infect other animal species such as rodents, the likelihood of this occurring accidentally is negligible. In the event that this did occur, the recombinant virus would be unable to propagate. This programme of work does not include deliberate infection of animal species with lentivirus vectors. No harm to the environment is envisaged.

<table>
<thead>
<tr>
<th>Containment and control measures for GMOs that are not microorganisms (e.g. GM animals &amp; plants)</th>
</tr>
</thead>
<tbody>
<tr>
<td>All basic molecular biology manipulations that do not result in production of virions will be conducted on the bench at Containment Level 1 using GLP. All steps involved in production of infectious virions will be Containment level 2. Experienced staff used to work in a containment level 2 environment will conduct the experiments. Strict local rules describing protective wear, handling and disposing of infectious materials will be adhered to. All liquid waste is decontaminated with 1% Virkon overnight. Any potentially contaminated material eg plastic is also soaked in 1% Virkon overnight, double-bagged, transported in leak proof containers to an autoclave in the same building and autoclaved. All equipment that has come into contact with lentivirus will be autoclaved before cleaning or disposal. Aerosols may be produced during the preparation of lentivirus and infection of HEK 293 cells. To prevent the dispersal of aerosols, preparation and infection of the virus will be carried out in a biological safety cabinet class II. All work surfaces will be thoroughly cleaned with disinfectant solution followed by 70% ethanol. Sharps will be used with special care and disposed of into sharps bins. Needles will not be re-sheated before disposal.</td>
</tr>
</tbody>
</table>

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be decontaminated by soaking in 1% virkon, then disposed in sealed double-bags which will be autoclaved and incinerated in accordance with local and country regulations for the disposal of biohazardous waste. Inactivation of lentivirus by autoclaving at 121°C for 15 minutes, will give effectively 100% kill. Using a higher temperature, or a longer time, is permissible. Waste will be transported in leak proof containers to autoclaves by trained staff and immediately placed in the autoclave for discard.

If live cells infected with lentiviruses are to be taken out of the Containment Level 2 lab and cultivated elsewhere, they must be tested for replication-competent virus first. In addition it should be noted that live cells infected with lentivirus that are to be used for experiments outside of the isolation room must be transported inside SEALED containers that are wiped over with microsol prior to leaving the hood and then only opened in areas designated as category 2 and for use with lentiviral infected cells. Otherwise cells should be fixed or lysed prior to removal from the hood in the isolation room.
Amendments required by the GMSC have been addressed in the final version of the risk assessment. The oncogenic nature of P13K genes have been assessed, competency and training of workers has been assessed.

Project Ref 774/08.3

Date Ackn’d 08/04/2008
CU2 Project Title In vitro transfection of primary cells and cell lines for in vitro experiments to assess suitability for in vivo transplantation studies.
Class 2
Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID GM774/08.3a
**Project Additional Information**

**Purposes of the contained use**

The overall goal of the research is to improve the viability, integration and therapeutic benefits of donor cells used for transplantation into the failing heart. The first step towards this aim is to engineer donor cells (by using a lentiviral transfection system) to express a variety of either structural or secreted proteins which will enable improved connections and communication between donor and host cells as assessed in an in vitro co-culture system prior to in vivo transplantation studies.

**Recipient or parental organism**

The donor cells used will be either established cell lines (mouse skeletal C2C12, rat skeletal L6 and 293T cells) or primary cells isolated from rat or mouse (skeletal myoblasts, bone marrow cells, circulating endothelial progenitor cells, fibroblasts, cardiac myocytes). These target cells are not known to pose any hazard to human health and require precise culture conditions therefore will not survive outside the laboratory.

**Host/vector system**

The lentiviral vector plasmid will be based on pHRSIN-CSGW-dlNotl encoding EGFP from the SFFV promoter. This will be engineered to include the genes of interest and the eGFP may be replaced with luciferase. The vector system requires 3 transfer plasmids to be transiently co-transfected into 293T cells to produce the lentiviral particles to be used for subsequent transfection. This system reduces the risk of productive recombination with the vector genome. The system is also self-inactivating (SIN) which minimizes the risk of the creation of replication competent virus.

**Origin & function**

Once the cells have been transfected using the created replication defective lentiviral vectors and washed clean of free vector, they will be used in in vitro co-culture studies or for cell transplantation studies to the heart. The proposed function of the inserted genes is to improve the integration and survival of the donor cells and improve the regeneration of the damaged heart.

- **Connexins**: Structural protein responsible for cell-cell channel (gap junction) formation. Not secreted. Present in most cell types. Function to improve connectivity/communication between donor and host cells. Sequence derived from mouse or rat. Low hazard.
- **Cadherins**: Structural proteins responsible for cell adhesion. Not secreted. Present in most cell types. Function to improve adhesion between donor and host cells. Sequence derived from mouse or rat. Low hazard.
- **IL-I receptor antagonist**: Competes with IL-I for the IL-i receptor. Function is to reduce IL-i mediated effects such as inflammation. Has been administered to human subjects with no adverse effects (Cytokine 4:353, 1992). Human sequence. Low hazard.
- **Muscle specific IGF1**: Function is to aid regeneration by reducing apoptosis. This form of IGF1 has not been associated with oncogenicity. Mouse sequence. Low hazard.
- **SDF-i**: Brief up-regulation naturally occurs after MI. Prolonged expression may aid the recruitment of stem/progenitor cells to the ischaemic area and also aid cell survival.
- **SuperOxide Dismutase (SOD)**: Scavenger enzyme associated with a reduced risk of DNA damage and hence reduced oncogenesis. Function is to reduce the damage caused during reperfusion of the heart. Low hazard. Reporter genes (beta-Gal, GFP, YFP, CFP, luciferase): Used as markers. Not secreted. Expression of these proteins does not affect normal cellular processes. Low hazard.

**Evaluation of foreseeable effects**

Preparation of the lentiviral vectors will give rise to high concentrations of the final non-replicative vector to be used. As the lentiviral system is infective of non-dividing cells, there is a risk of localised infection to the operator, expression of the inserted genes of interest and possible insertional mutagenesis. This risk is reduced by the system being self-inactivating so the operator will never be exposed to replication competent virus, so if infected will not produce more virus. The genes of interest present are unlikely to be detrimental to human health. All work with the lentivirus will be carried out in a class II safety cabinet, labcoats, gloves and safety specs will be worn no sharps
will be used and all waste inactivated immediately. Hence the risk of harm to the operator will be effectively zero. The final transfected cells present a very low risk since they will be washed clean of free vector. The supernatant from the washes will be tested for infectivity of fresh cells to test for remaining virus particles and to determine if replication competent virus is present. If no infection occurs (tested for by the presence of the marker gene eGFP or luciferase — visually or for the gene of interest by PCR), then the cells will be deemed to be clear and can be transferred out of the containment 2 laboratory for further experimentation. The cells need specific conditions for survival and hence will not survive in the environment if released.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be inactivated immediately using 1% final concentration of virkon (minimum incubation of 20 minutes). Inactivated liquid waste will then be disposed via the sink. Virkon is proven to be effective against a wide range of bacteria and viruses including lentiviruses. All solid waste will be rinsed with 1% virkon and placed into autoclave bags. The waste will be double bagged and placed into a covered trolley for transportation to the autoclave. Waste will then be autoclaved prior to disposal via the clinical waste route (incineration). The autoclave is validated annually and records maintained.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Detail and degree of kill for waste control now included in section 14. Test for remaining virus particles now included in section 11. New laboratory inspected by the GMSC.

## Project Additional Information

**Purposes of the contained use**

Development of vectors (viral and plasmid) and molecules for the study of diseases of the endocrine system or lipid metabolism. This will involve transgenic over-expression, gene knockdown, cellular reprogramming and directed differentiation. All genetically modified vectors are disabled and lack essential genes which prevent their autonomous replication. All require specific packaging cell types to produce a viral particle which is replication deficient and cannot multiply or produce progeny. All vectors will have no effect to the environment as they will not be released, and are maintained under strict laboratory conditions.

**Recipient or parental organism**

**Recipient Cells**

Mammalian cell lines (for example 293T, 3T3, CHO, HepG2, Huh7, U2O-S), and primary cells (for example fetal and adult fibroblasts). Human and mouse embryonic stem cells and adult stem cells (for example; mesenchymal stem cells, adrenal stem cells, pancreatic/hepatobiliary progenitors).

Human embryonic cells and primary cells or tissues are obtained by donation after comprehensive pathogen screening at the clinic (HIV, Hepb/c). Cell lines are also subjected to the same screening process once in the laboratory context. Human primary cells are donated from unscreened patients and are quarantined pending the pathogen screening as described prior to genetic modification.

**Viral Vectors**

Retroviral vectors used are derived from Moloney murine leukaemia virus (MMLV), a mouse virus therefore chances of mobilisation by recombination with endogenous viruses in a human are practically impossible. Furthermore, the vectors contain no MoMLV coding sequences and so are completely replication disabled and the chances of recombination are minimised.
Lentiviral vectors derived from HIV1, SIV, EOAV and FIV are based on genome integrating viruses. Like retroviruses, the severely deleted genomes contain no endogenous coding sequences and the 3'-Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

Adenoviral vectors (serotypes Ad2/5) are disabled by mutations to the E1a and E3 genes that are fundamental to the early stages of viral replication. Although adenoviruses are human pathogens infection does not result in serious illness and as such are a low risk to humans. The viral genome is transient in infected cells (does not naturally integrate into the host genome) and so there is minimal risk of insertional mutagenesis.

Adeno-associated Viral vectors (AAV) are disabled by mutations to the Rep gene which is necessary and fundamental to replication. Furthermore, AAV requires the expression of adenoviral genes to facilitate its replication. Recombinant forms of AAV will integrate into the host cell genome at very low frequency and so the chances of insertional mutagenesis are low.

**Host/vector system**

<table>
<thead>

</tr>
</tbody>
</table>

These gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol II/III promoters. Reporter genes include; Fluorescent - e.g. GFP, YFP, CFP, dsRed, Luminescent - e.g. firefly and renilla Luciferase, biochemical e.g. CAT, AFP. Mammalian promoter/enhancer elements will be used to drive reporter genes as previously described.

**Evaluation of foreseeable effects**

The recombinant viral vectors are all highly disabled vectors.

Lentivirus/retrovirus: Theses self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal. Whilst the envelope pseudotyping extends the cellular tropism and confers greater stability viral vector will always be contained within a class II safety cabinet thus user exposure to liquid aerosol is impossible.

The exposure of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.
Adenoviral vectors are deleted of essential replication/packaging genes that are supplemented by an established packaging cell line (293T).

Adeno-associated Virus is defective by nature and has a replication disabled genome and is incapable of replication without helper adenovirus. In this instance the vectors used would require the provision of cap and rep genes in trans in order to replicate and disseminate. There is no significant chance of reversion to the wild-type. Furthermore, the AAV8 & 5 subtypes derived from humans are not able to replicate or cause disease in any animal species therefore it is highly unlikely that such a virus, if released into the environment, would represent a significant risk.

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion and fate. Also, most have known or suspected oncogenic or tumour suppressor properties.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Viral vector expressing potential oncogenes are a potential environmental risk as host infection could elicit a transformation event. All work is carried out in a class II cabinet and all liquid waste inactivated by virkon treatment and solid waste autoclaved.

Primary cells infected with viral vector containing potential oncogene would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| none |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid waste will be treated with Virkon 2% for 2 hours (shown by manufacturer as appropriate for disinfection) before disposal to main drains. Solid waste will be autoclaved and later incinerated. Sharps will be incinerated. Cryovials containing virus will be sorted in specified cryofreezer and openend only in Class II cabinets. Spillages and working surfaces will be cleaned with 2% Virkon and with 70% ethanol. Waste is clearly labelled biohazard double bags will be incinerated as clinical waste. Hazard conditions consist of possible spillages, aerosol spray when opening cryovials or during the use of needles when working with animals. Work is restricted to determined areas, disinfecting solutions will always be available, working guidelines are clearly posted, unauthorised personnel is not permitted. Strict adherence to Category II working practices. Reporting in case of accident is according to College procedures. Training to work with GMM's category II. Guidelines regarding dressing code, how to treat spillages and disinfection with 2% Virkon and 70% ethanol. Medical records held by occupational health advisor. Documented spillage procedures are clearly established. In case of accident with sharps, College procedure with blood borne viruses will be followed. Autoclaves are regularly serviced and checked. Autoclaved material is checked using autoclaving tape to assess has reached appropriate temperature for disinfection. |

The risk assessment was initially prepared and discussed at the QMUL local GM safety committee meeting on 29/04/2010 followed by a site inspection on the 18/05/2010. At the meeting the committee requested clarifications and amendments to all the assessments, in particular control measures, waste management and the biological activity of the inserted sequences were discussed at length. The risk assessment was finally approved at a supplementary meeting of the local GM committee and signed off on 24/05/2010.

### Project Additional Information

#### Purposes of the contained use

Genetically modified vectors and plasmids will be generated in order to study human cancers. Methods involved will include transgenic overexpression and gene-knockdown. Gene manipulation of this kind will allow us to gain an understanding of how the genes of interest affect the development and/or progress of cancer.

#### Recipient or parental organism

**Recipient Cells**

Mammalian cell lines (e.g. HEK293T, PANC02, IGROV, TOV21G) and primary cells (e.g. mouse and human epithelial cells). Established cell lines are obtained from commercial suppliers (e.g. ATCC, DSMZ) and have been screened for pathogens prior to sale. Mouse primary cells are obtained from colonies with full health screen. Human primary cells are obtained from donors after comprehensive pathogen screening at the clinic (HIV, Hep B/C etc).

**Viral Vectors**

Retroviral vectors used are derived from Moloney murine leukaemia virus (MMLV), a mouse virus therefore chances of mobilisation by recombination with endogenous viruses in a human are practically impossible. Furthermore, the vectors contain no MoMLV coding sequences and so are completely replication disabled and the chances of recombination are minimised.

Lentiviral vectors derived from HIV1, SIV, EIAV and FIV are based on genome integrating viruses. Like retroviruses, the severely deleted genomes contain no endogenous coding sequences and the 3'-Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

Adenoviral vectors (serotypes Ad2/5) are disabled by mutations to the E1a and E3 genes that are fundamental to the early stages of viral replication. Although adenoviruses are human pathogens infection does not result in serious illness and as such are a low risk to humans. The viral genome is transient in infected cells (does not naturally integrate into the host genome) and so there is minimal risk of insertional mutagenesis.

Adeno-associated Viral vectors (AAV) are disabled by mutations to the Rep gene which is necessary and fundamental to replication. Furthermore, AAV requires the expression of adenoviral genes to facilitate its replication. Recombinant forms of AAV will integrate into the host cell genome at very low frequency and so the chances of insertional mutagenesis are low.

**Host/vector system**

Bacterial hosts used are derived from E.coli strains e.g. DH5a and derivatives, JM109, INV110. Plasmid vectors used include derivatives of pcDNA3, pGL3, pGFP etc.

Viral vectors:

- Recombinant lentiviral vectors based on HIV-1, EIAV, SIV, FIV pseudotyped with VSV-G, gp64, RRV, ENTV envelopes, safer versions will be used from 2nd, 3rd or later generations.
- Retroviral vectors based on MLV, pseudotyped with MLV/VS-G will be packaged by transient transfection in 293T cells. Established adenoviral vectors (Ad2/5) will be produced by transient transfection of 293T (or derivative) cells. AAV will be produced in an established transient 293T helper system.

#### Origin & function
Once the cells have been transfected using the created replication defective viral vectors and washed clean of free vector, they will be used in in-vitro experiments in the study of the genetics of cancer.

Some of the genes involved in these studies will include:
-dlg4 and scribble (polarity genes)
-HVCN1 (encodes a voltage-gated proton)
-TNF family members, IL family members (cytokines)

These gene targets will also be subject to gene knockdown with siRNA and shRNA.

**Evaluation of foreseeable effects**

The recombinant viral vectors are all highly disabled vectors.

**Lentivirus:**
HIV-1 based. Replication defective, as five of the nine HIV-1 genes required for replication were eliminated, leaving the gag and pol reading frames, which encode for the structural and enzymatic components of the virion, respectively, and the tat and rev genes, fulfilling transcriptional and post-transcriptional functions (Zufferey et al., 1997). Viral particles express VSV-G (G-protein of vesicular stomatitis virus) as envelope protein to facilitate entry in human and mouse cells/cell lines, since its receptor is ubiquitously expressed by mammalian cells. Generation of GIPZ shRNAmir lentiviral particles requires a packaging step during which the expression construct containing the silencing sequence is enclosed in a viral capsid. Gene functions that facilitate this process (e.g., encoded by the structural genes gag, pol, env, etc.) are distributed amongst multiple helper plasmids, which do not contain significant regions of homology. This tactic further minimizes the probability of recombination events that might otherwise generate viruses capable of autonomous replication. GIPZ shRNAmir constructs contain a WPRE sequence devoid of the X protein and its promoter.

**Retrovirus:**
These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/ infection cycles. The probability of seroconversion is minimal. Whilst the envelope pseudotyping extends the cellular tropism and confers greater stability viral vector will always be contained within a class II safety cabinet thus user exposure to liquid aerosol is impossible. The exposure of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.

**Adenovirus:**
The design and production methods of the adenovirus ensures that only replication defective viruses are produced and hence spread from an initially infected cell is very unlikely. This is achieved by virtue of the adenoviral plasmid lacking the E1/E3 region of the wild type adenovirus serotype 5 genome from which it is originally derived. During viral production a packaging cell line is used which complements the deficiency in the E1/E3 region. Due to the design of these plasmids, the generation of replication competent adenoviral particles is greatly reduced.

**AAV:**
Adeno-associated virus is replication deficient by nature due to its replication disabled genome, rendering it incapable of replicating without helper adenovirus. In this instance the vectors used would require the provision of cap and rep genes in trans in order to replicate and disseminate. There is no significant chance of reversion to the wild-type. Furthermore, the AAV8 & 5 subtypes derived from humans are not able to replicate or cause disease in any animal species therefore it highly unlikely that such a virus, if released into the environment, would represent a significant risk.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Viral vector expressing potential oncogenes are a potential environmental risk as host infection could elicit a transformation event. All work is carried out in a class II microbiological cabinet within laboratories at Containment Level 2; all liquid waste inactivated by Virkon treatment; solid waste autoclaved and incinerated. Stocks checked for RCV by PCR methods before use.
Sharps use minimised and safe handling practised.

Primary cells infected with viral vector containing potential oncogenes would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plasticware will be soaked in 1% Virkon overnight before disposal and autoclaving. Any supernatant will be aspirated into a liquid waste bottle containing concentrated Virkon. Virkon is a broad spectrum disinfectant and is validated to give 5-6 log kill under typical laboratory experimental conditions by manufacturer.

All waste is then disposed of in sealed autoclave bags, which will be autoclaved and incinerated in accordance with UK regulations for the disposal of biohazardous waste. Inactivation of virus by autoclaving at 121°C for 15 minutes, will give 100% kill. Using a higher temperature or a longer time is permissible. Waste will be transported in leak proof containers to autoclaves by trained staff and immediately placed in the autoclave for discard.

All autoclaves are regularly maintained via a service contract in order to ensure instruments are working to correct temperatures and pressures. Following autoclaving, waste will be uplifted by an authorised waste contactor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Project assessed as GM Class 2 and local risk assessments peer reviewed as suitable by GMSC on 21 April 2011. Existing laboratories and facilities to be used which have been inspected by peer review inspections in the last 2-3 years.

Project Containment
Project Ref 774/11.3

Development of lentiviral vectors for the study of various cancer types, including ovarian, pancreas, prostate and colorectal cancers as well as mesothelioma and endometrial cancer

Purposes of the contained use
Genetically modified vectors and plasmids will be generated in order to study human cancers. Methods involved will include transgenic overexpression and gene-knockdown. Gene manipulation of this kind will allow us to gain an understanding of how the genes of interest affect the development and/or progress of cancer.

Recipient or parental organism
Mammalian cell lines (e.g. HEK293T, PANC02, IGROV) and primary cells (e.g. mouse and human epithelial cells). Established cell lines are obtained from commercial suppliers (e.g. ATCC, DSMZ) and have been screened for pathogens prior to sale. Lentiviral vectors derived from HIV1, SIV, EIAV and FIV are based on genome integrating viruses. They have severely deleted genomes which contain no endogenous coding sequences and the 3'-Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

Host/vector system
Plasmid vectors used include derivatives of pcDNA3, pGL3, pGFP etc.
Viral vectors: Recombinant lentiviral vectors based on HIV-1, EIAV, SIV, FIV pseudotyped with VSV-G, gp64, RRV, ENTV envelopes, safer versions will be used from 2nd, 3rd or later
Once the cells have been transfected using the created replication defective viral vectors and washed clean of free vector, they will be used in in-vitro experiments in the study of the genetics of cancer.

Some of the genes involved in these studies will include:
Rad51, BRCA1, BRCA2, P63
L4-100k, L4-33k and L4-22k, E1A (adenoviral genes)
TNF family members, IL family members (cytokines)

These gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol II/III promoters. Reporter genes include; Flourescent- e.g. GFP, YFP, CFP, dsRed, Luminescent- e.g. firefly and renilla Luciferase.

Evaluation of foreseeable effects

The recombinant viral vectors are all highly disabled vectors.

Lentivirus:
HIV-1 based. Replication defective, as five of the nine HIV-1 genes required for replication were eliminated, leaving the gag and pol reading frames, which encode for the structural and enzymatic components of the virion, respectively, and the tat and rev genes, fulfilling transcriptional and post-transcriptional functions (Zufferey et al., 1997).
Viral particles express VSV-G (G-protein of vesicular stomatitis virus) as envelope protein to facilitate entry in human and mouse cells/cell lines, since its receptor is ubiquitously expressed by mammalian cells.
Generation of GIPZ shRNAmir lentiviral particles requires a packaging step during which the expression construct containing the silencing sequence is enclosed in a viral capsid. Gene functions that facilitate this process (e.g., encoded by the structural genes gag, pol, env, etc.) are distributed amongst multiple helper plasmids, which do not contain significant regions of homology. This tactic further minimizes the probability of recombination events that might otherwise generate viruses capable of autonomous replication.
GIPZ shRNAmir constructs contain a WPRE sequence devoid of the X protein and its promoter.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Viral vector expressing potential oncogenes are a potential health / environmental risk as host infection could elicit a transformation event. All work is carried out in a class II microbiological safety cabinet within laboratories at Containment Level 2; all liquid waste inactivated by Virkon treatment; solid waste autoclaved and incinerated. Sharps will be used with special care and disposed of into sharps bins. Needles will not be re-sheathed before disposal. Cells will be tested for RCV by p24 ELISA.

Primary cells infected with viral vector containing potential oncogenes would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be likely to be rejected by the host immune system.

Insertion of an oncogene or knockdown sequence into a human host during handling of viral supernatants can poses a theoretical risk. However, insertion of an oncogene into the human cells is not enough to cause a harmful event because it needs a combination of additional alterations. The risk assessment also puts in place control measures to minimise the risk of administration of the virus to an individual, therefore the event is very unlikely.

The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist. The packaging cells and any transduced cells cannot survive outside the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Ref  774/12.1

Date Ackn'd CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4
The main focus of this project is trying to understand what role mechanical forces (e.g. strain or compression) play in cell fate. We also hope to gain insight into how mechanical forces are processed by both embryonic and adult stem cells, and what role they may play in the (re)organisation of the genetic information inside the nucleus, and how that will thereby result in changes in nuclear architecture and gene regulation.

Adult, semi- or terminally differentiated cells, such as primary mouse embryonic fibroblasts or primary (bovine, murine or human) chondrocytes or primary (adult bovine, murine or human) skin fibroblasts, HeLa cells, for example.

Recipient or parental organism

1. Lentiviruses - use of 3rd generation or higher self-inactivating (SIN) pseudolentiviral transduction particles is an efficient way to introduce genetic modifications in a broad spectrum of mammalian cell types, such as those outlined above.

For example, EF1α-STEMCCA-LoxP (OKSM) Lentivirus: (Merk/Millipore Part number CS204439/SCR531).

A 3rd generation SIN Lentiviral transduction particles, modified to deliver a Cre-Recombinase-excisable expression cassette, containing four Yamanka factors, Oct4, Klf4, Sox2 and cMyc (abbreviated hitherto as OKSM). High OKSM expression facilitated through truncated WPRE element (no X-protein produced).

These pseudolentiviral particles are used to generate induced pluripotency in primary, semi- or terminally differentiated cells are non-pathogenic and non-infectious beyond their initial use. To remove any chance that the lentiviral gene vectors would produce any competent virus, the viral genome was stripped of any packaging and envelope-producing sequences [Miyoshi et al. (1998) J. Virol. 72: 8150-8157]. Thus infectivity of these vectors depends on separate envelope production and packaging steps, which only make the initial round infectious, but leave the viruses otherwise replication-deficient. The vector backbone in the EF1α-STEMCCA-LoxP Lentivirus is the pPACKH1 system (System Biosciences), which is based on HIV and FIV lentiviruses, in order to ensure broad-spectrum mammalian expression. Secondly, SIN mutation was engineered into the long terminal repeat of the lentiviral backbone that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

2. Adenoviruses
Wild-type adenoviruses, including human adenovirus type 5, are associated with a number of mild disorders, such as respiratory infections in the elderly or children. There are approximately 2 phases of adenovirus transcription, namely early and late phases, which occur before and after replication. The early-transcribed regions are E1, E2, E3 and E4. The E1 gene products, including E1A and E1B, are involved in the replication of the virus. Most of the E3 proteins are involved in modulating the immune response of infected cells.

For example, Human Adenovirus Type 5 (dE1/E3), expressing Cre-Recombinase and Green Fluorescent Protein, (Vector Biolabs Catalogue number 1710) is used in conjunction with cells reprogrammed by the EF1α-STEMCCA-LoxP/OKSM lentiviral vector, to remove all traces of the OKSM gene cassette.

To ensure replication deficiency of adenoviral vectors, the E1 region is deleted allowing it to safely be used as a gene delivery tool. To accommodate larger recombinant genes (up to 8 Kb), 1st generation adenoviruses are both E1 and E3 deleted (E1/E3), since the E3 region is not essential for in vitro viral growth. The adenovirus vector is able to deliver genes with 100% efficiency to a wide selection of cell types including dividing or non-dividing cells, or primary cells or cell lines. This ability far surpasses the gene delivery efficiencies of lipid-based transfection approaches or other viral-based gene delivery systems.

3. Bacterial Plasmid Vectors and E. coli hosts.

Bacterial hosts derived from E. coli strains DH5a, JM109, INV110. Plasmid vectors derived from pcDNA3, pGL3, pENTR-1A, etc.

**Origin & function**

1. Genetic material introduced by lentivirus

   The EF1α-STEMCCA-LoxP/OKSM bears a poly-cistronic cassette that will result in the expression of four genes: Oct-4, Klf-4 and Sox2 are all transcription factors associated with the maintenance of the pluripotent and self-renewal phenotypes associated with embryonic stem cells. The fourth element, c-Myc, is an oncogene whose forced overexpression has lead to tumour growth in SCID mice. The infectious lentiviral particles are purchased "ready to use", and the genetic origin of the transgenes is murine.

2. Genetic material introduced by adenovirus

   Adenovirus Type 5/Cre-recombinase/GFP drives the expression of Cre-recombinase, a Type I topoisomerase from bacteriophage P1 that catalyzes the site-specific recombination of DNA between loxP sites, allowing us to to genetically modify DNA in situ, in living cells. In this case, the OKSM cassette, which is flanked by loxP sites, will be deleted from the reprogrammed cells generated by the EF1α-STEMCCA-LoxP lentivirus, restoring the original genotype of the cells.

   Additionally, adenoviruses will occasionally be used to introduce either knockdown or reporter-fusion constructs into primary cells, known to be difficult to transfect by lipid-based or electroporation methods. To assess the functional significance of certain genetic elements involved in cell fate, nuclear architecture or chromatin modification, certain gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol II/III promoters. The functional significance and sub-cellular localisation of certain genetic elements will be determined by the use of reporter genes and reporter-fusion constructs. Reporter genes include including fluorescent proteins—e.g. GFP, YFP, CFP, dsRed, mCherry, mRFP will be introduced either on their own, driven by mammalian promoter/enhancer elements, or fused to functional domains from (mammalian) non-hazardous (GM Class 1) nuclear proteins involved in chromatin organisation—e.g.Histone-H2B-GFP, photoactivatable Histone-H4-GFP, GFP-Heterochromatin Protein 1-beta, nuclear architecture—e.g. truncated (dominant negative) mutant of Sad1p/UNC-84-(SUN1)-fused to YFP, truncated (dominant negative) mutant of Nesprin1-Giant fused to GFP, for example.

3. Genetic material introduced by plasmid

   Plasmids will be used to introduce a similar range of knockdown or reporter-fusion elements as listed in the previous paragraph in established/immortalised cell lines or primary mammalian fibroblasts that are more readily transfectible by lipid-based transfection or electroporation (MEFs, mouse ES cells, mouse iPS cells, HeLa, for
Evaluation of foreseeable effects

1. Lentiviral use

The protocol for lentiviral infection is a mixture of GM Class 1 work and GM Class 2 work. As the viruses have a broad-spectrum tropism, the 24 hour period of infection presents an exposure risk to the workers. After this the cells are washed and cultured in virus-free medium, and detectable titres of free virus are reduced by the end of the second 24-hour period. During this 48-hour exposure window, even though the EF1α-STEMCCA-LoxP is self-inactivating beyond its initial infection, there remains the risk of exposure to worker infecting the cells to be reprogrammed. Though, without broken skin or direct mucous membrane contact, infection is unlikely to happen without the use of sharps, and there are no sharps are used at any point throughout this protocol. The remaining (post-infection) portion of the protocol all falls within GM Class 1 work.

Forseeable effects of infection: c-Myc is considered an oncogene, and its forced overexpression has lead to tumour growth in SCID mice. Primary cells infected with viral vector containing potential oncogene would pose minimal threat as expression of murine proteins would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

2. Adenoviral use

Cells infected with adenoviral vectors containing non-hazardous transgenes would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Adenovirally-based Cre-exision of from any induced Pluripotent Stem Cells generated in the group will restore the genotype of the iPS cells to that of the parent cell type, by removal of the OSKM expression cassette. The resulting cells bear no viral progenic sequences and have no foreseeable effects.

3. Plasmid and bacteriological work

All E. coli strains used for the propagation of plasmid vectors are standard lab strains, designed to be of none-to-minimal health risk to those using them. Plasmid-transformed strains should have no additional risk associated to their use.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We are not applying for any derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid cell culture waste, plasmid-related waste, waste biological material, especially that involved in Class 2 work is immediately collected in appropriate bags, and autoclaved (sterilised for 30 minutes at 121 degrees C, in pressurised steam) within the laboratory suite.

Autoclaved solid waste, marked as ‘autoclaved clinical waste’ is collected, awaiting disposal by a licensed contractor.

Liquid cell culture waste is treated with a disinfectant (1% of fresh Virkon for 10 minutes, as directed by the manufacturer, Dupont-Antec) prior to disposal down the drain. Information provided by Dupont-Antec ensures a 5-log degree of kill over a broad microbial and viral spectrum.
The main reason for classifying the lentiviral transfection stage as Class 2, is due to transient oncogene expression (Yamanaka factor genes and X-protein WPRE sequence) and the fact that pluripotent stem cell modification is a relatively new technology. A similar project was classified as Class 2 from another College Institute recently. It is noted however that the vector is 3rd gen, replication defective, self inactivating, that sharps are not used and that the hazardous elements are excised following the transfection period.

The labs are to be inspected by the GMSC.
### Project Additional Information

#### Purposes of the contained use

The purpose of producing recombinant retroviruses to use them to increase or suppress the expression of wildtype and mutant keratins, homeobox genes, POU domain containing proteins and wildtype and dominant negative mutant of proto-oncogenes such as c-JUN, c-FOS and other members of this family in keratinocytes in order to determine their role in differentiation, growth, apoptosis, migration and tissue invasion.

#### Recipient or parental organism

- Normal oral keratinocytes, Normal skin keratinocytes, HaCaT (spontaneously immortalised human skin keratinocytes), Neb-1 (HPV immortalised normal skin keratinocytes), T103C (HPV immortalised normal oral keratinocytes), SVK14 (SV40 immortalised normal skin keratinocytes), N-Tert (telomerase/P16 induced immortalised normal human skin keratinocytes), OKT-F6 (telomerase/P16 induced immortalised normal human skin keratinocytes). Human oral cancer cell lines derived from dysplastic, tumour and metastatic tissues.

#### Host/vector system

- pLPC_Cmyc: Derived from Moloney murine leukemia (MoMuLV) Moloney murine sarcoma viruses (MoMuSV).
- pSin-B (self inactivating retroviral vector). This vector is derived from MMLV.
- pRetrosuper-Puro (retroviral vector used to silence a gene expression). pRETRO SUPER series is based on the self inactivating Murine Stem Cell Virus, pMSCV. Bacterial hosts: E.coli K12 strains.

Lentiviral vectors (3rd generation) derived from HIV1, SIV and FIV are based on genome integrating viruses. Like other retroviruses, the severely deleted genomes contain minimal endogenous coding sequences with most harmful sequences (e.g. vpr, nif, rev, tat) removed or truncated (e.g. WPRE sequence) to cause inactivation of harmful gene expression, and the 3’ Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

#### Origin & function

- HOXA7 and other HOX proteins: These proteins are involved in embryonic development, however, in adult HOXA7 induces cell proliferation a keratinocytes. HOXA7 expression is induced in a variety of human tumours.
- C-JUN and c-FOS and other family members: These are proto-oncogenes which can be converted into oncogenes under certain defined conditions leading to genetic alterations.
- Vimentin: It is intermediate filament protein which is expressed in mesenchymal tissues. However, during cancer metastasis vimentin expression is induced in epithelial...
tissues.
SKN1a: This is a POU domain containing protein and it is known to play a role in keratinocyte differentiation.
Keratins: These are cytoskeletal proteins of keratinocytes and a large number of them are associated with cell proliferation, increased cellular migration and invasion.

Evaluation of foreseeable effects

There are no known diseases that are caused by overexpression or knock-down of keratins and vimentin, however, there are properties exhibited by some members of this superfamily of proteins that are similar to those exhibited by oncogenes.

The POU domain containing protein SKN1a is known to induce differentiation, and there is no disease caused by its overexpression or knockdown in animals. Overexpression of certain homeobox genes e.g. HOXA7, increases cell proliferation, but there is no evidence to date that they act as oncogenes in animal cells. The retroviral constructs will be packaged directly in Phoenix A (amphotropic) or Phoenix E (ecotropic) cells. These viruses will then be used to infect a variety of human cell lines but principally primary keratinocytes and cells derived from primary dysplasias, primary carcinoma and fibroblasts.

The activities relating to virus production and transduction will be carried out in a restricted entry laboratory facility. These viruses are replication deficient and some are self-inactivated, so once they are integrated into cellular genome, they can't produce replication competent virus particles. Nevertheless, each construct will be tested to ensure that the transduced cells are not producing infection competent viruses.

The viruses and the transduced cells cannot survive outside the tissue culture flask or dishes and therefore even if they are accidently released in the environment they are unlikely to spread and cause damage to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated with 1% virkon, 1000cpm Actichlor or 5% sodium hypochlorite for at least overnight. Virkon is a broad spectrum disinfectant and is validated to give 5-6 log kill under typical laboratory experimental conditions by manufacturer. Chlorine based disinfectants also give similar kill according to manufacturer information.

All waste is then disposed of in sealed autoclave bags, which will be autoclaved and incinerated in accordance with UK regulations for the disposal of biohazardous waste. Inactivation of virus by autoclaving at 121°C for 15 minutes, will give 100% kill. Using a higher temperature or a longer time is permissible (e.g. 134°C for 5 min).

All autoclaves are regularly maintained via a service contract order to ensure instruments are working to correct temperatures and pressures.

All wastes are kept in leak proof yellow bags clearly labelled with biohazard signs. These bags are transported from labs to autoclave facility on sturdy steel trolleys.

The laboratory facility is managed by a users group, which ensures that users are correctly trained in decontamination procedures. Training on GM and Biosafety is provided by the College to all users

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Demarcation of activities at Class 1 and Class 2 defined in the risk assessment. Risk assessment approved by GMSC on 26 July 2011

</tr>
<tr>
<td>Evaluation of foreseeable effects</td>
<td>The hazards to human health are low and containment level 2 is considered appropriate. The host E. coli is disabled and therefore incapable of existing in the human gut or in the environment The vectors selected are mobilisation defective minimizing the possibility of gene transfer. The system described produces the prion protein in cellular non-pathogenic isoform. The prion protein is a naturally occurring protein found express at high levels in all healthy humans and other mammals. Protein material is from the mouse or hamster sequence. A species barrier exists to potential conversion of cellular prion protein to the abnormal isoform. This barrier implies that there is a very low probability of human cellular prion protein being converted to the abnormal isoform by mouse or hamster PrP-Sc. Despite many attempts it has proved very difficult to converted recombinant prion protein into a pathogenic form and will only generate infection after cerebral injection into transgenic mice expressing 20 times the normal levels of prion protein. The recombinant prion protein lacks a GPI anchoring and glycosylation. Therefore recombinant material is probably far less dangerous than prion protein expressed by mammalian cells (present ubiquitously in the environment). There is no naturally occurring mouse or hamster transmissible spongiform encephalopathy</td>

E. coli is readily destroyed using standard methods. However, with the presence of PrP it is safer to disrupt both the protein and host by treating anything that has come into contact with either in 2M NaOH for 1 hour or 20,000 ppm available chlorine for 1 hour. After this, this waste will be autoclaved at 134°C for 20 minutes before disposal by incineration by an authorised contractor route, achieving a complete kill of recombinant host and expressed protein.

Disposable plastic ware will be used wherever possible, disposable solid waste (including E. coli plates) to be put in biohazard burn bins and sent for incineration (100% kill). Reusable contaminated solids (including E. coli growth flasks) will be soaked in 2M sodium hydroxide for at least 1 hour.

Spills would be cleaned up with paper towels which will be treated as solid waste, contaminated spill areas will be soaked in 20,000 ppm available chlorine of sodium hypochlorite for at least 1 hour, except for contaminated metal which will be soaked in 2M sodium hydroxide for at least 1 hour. Where soaking is not possible, contaminated areas will be wiped down with one of the above disinfectants (as appropriate) at least 3 times allowing drying between applications for at least 1 hour.

Project discussed by College GMASC at the 29 March 2012 meeting and project classified as GM Class 2 for part of the work which involves bacterial expression of the recombinant prion protein, with non-expression cloning and final purification steps work to be at GM Class 1. After amendments, project approved by GMSC 9 July 2012. Laboratory to be inspected by GMSC.

It should be noted that recent research has shown conversion of recombinant murine prions into abnormal pathogenic prions utilising specified biochemical protocols (Fel Wang et al Science (2010) 327;1132-35). This development must be kept under review by the Investigator.

Project Additional Information

**Purposes of the contained use**

Culturing and genetic manipulation of trypanosomatid parasites. Such manipulated lines can then be used to analyse the function and importance of a given gene/protein/enzyme to this parasite. The main goals of these studies are to identify new drug treatments to help combat Chagas Disease Vesceral Leishmaniasis and Mucocutaneous Leishmaniasis, the diseases caused by Trypanosoma cruzi, Leishmania donovani/infantum and Leishmania braziliensis, respectively.

**Recipient or parental organism**

Parental organisms: Trypanosoma cruzi, Leishmania donovani/infantum (synL. Chagas) and Leishmania braziliensis.

These organisms are all pathogenic to humans and designated as ADCP Hazard Group 3 organisms.

Trypanosoma cruzi:
Natural Host - mammals including humans.
Primary route of disease transmission is zoonotic via the faeces of triatomid insects (eg Triatoma infestans, Rhodnius prolixus, Panstrongylus megistus) into bite wounds/mucocutaneous membranes. The insects are only found in the Americas and are not present in the U.K.

Leishmania donovani/infantum and Leishmania braziliensis:
Natural host - mammals, predominantly humans and canines.
Primary route of transmission is zoonotic via the hematophagous feeding habits of female Sand fly insect vectors (Lutzomyia in the Americas; Phlebotomus in the rest of the World). Disease transmitting Sand flies are not present in the U.K.

**Host/vector system**

Host organisms: The pathogens are to be used as the host organisms and source of genomic DNA/gene inserts.

Vectors: The vectors used during this work are based on standard bacterial cloning vectors (eg pBluescript & pUC-based plasmids). This is to allow propagation of parasite
DNA sequences in E. coli. Several trypanosomatid expression vectors (episomal and intergrative) will be used in this study including pTEX, pRiboTEX, pRclNDEX and pTRIX. These are all based in the above bacterial cloning plasmids.

**Origin & function**

Experiments will generate trypanosomes/leishmania with altered levels of expression (over expression and heterozygote/null mutant) of a target gene.

Inserts: The trypanosomatid genes (derived from either genomic DNA or cDNA) under study include type 1 nitoreductases, peroxidases (eg ascorbate peroxidases and tryparedoxin peroxidases), iron superoxide dismutases, thioredoxin-like proteins (eg tryparedoxin, glutaredoxin), melinione sulphoxide reductases, trypanothione reductase, cytochrom F450 reductases, prostglindins F2alpha synthase, galactonolactone dehydrogenase, alternative oxidases and enzymes postulated to be involved in DNA repair (eg Apollo/Artemis homologues, Rad51). Complete coding sequences will be used to construct trypanosomatid expression vectors (episomal and integrative). The vectors used (including pTEX, pRiboTEX, pTcINDEX and pTRIX) are all based on the above bacterial cloning plasmids. Non-coding and/or partial coding genomic DNA sequences from the parasites will be used to construct gene knockout vectors.

Parasite genomic DNA and cDNA will be used to target specific loci by homologous recombination. Modified coding sequences (eg, epitope tagged versions) will be used to complement mutant phenotypes. DNA introduced into trypanosomes/leishmania is propagated by insertion into the parasite nuclear genome of non-therapeutic, drug selectable markers (neomycin, hygromycin, bleomycin, puromycin, and blasticidin)

**Evaluation of foreseeable effects**

E. coli - ampicillin resistance
T. cruzi, L. donovani/infantum and L. braziliensis - G418, bleomycin, blaticidin, puromycin and hygromycin resistance.

The gene manipulations to be performed are unlikely to alter the pathogenicity of the host organisms. However certain gene manipulations to be performed are unlikely to alter the pathogenicity of the host organisms. However, certain gene manipulations will generate parasite lines that have altered susceptibility to existing chemotherapies. Due to the procedures in place (eg no sharps use, staff training and rapid response to an incident) and lack of natural insect vectors in the UK. Containment Level 3 measures are deemed sufficient to protect human health (workers and others who may be affected) and the environment.

Due to the latency of Chagas disease, individuals using the CL3 facility are screened for the presence of T. cruzi before starting work with parasites, every six months, and upon ending the period of work as part of a health surveillance program. As the disease manifestation is more immediate for leishmania infections, regular screening for the presence of the parasite is not conducted.

In the unlikely event of any laboratory accident/incident where T. cruzi infection may thought to have occurred, screening will be conducted as soon as possible and suitable treatment and health monitoring will be conducted for all involved and health monitoring will be conducted as soon as possible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from full containment not sought

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste (eg spent culture medium) will be treated with an equal volume of 2% Trigene to give a final concentration of 1% (minimum contact time of 10 min). Serological pipettes, pastettes and pipette tips will be immersed in 1% Trigene for a minimum contact time of 10 min. Tissue culture flasks, including the neck and centrifuge tubes will be thoroughly washed with 1% Trigene (minimum contact time of 10 min). A5 minute exposure to 0.2% Trigene has been shown to kill 100% trypanosomes/leishmania (Wang et al 2008 Parasites & Vectors. 1.35). All liquid waste is left in a demarked area in the CL3 suite for a minimum of 24h before disposal.
down a designated sink within the CL3 suite. The worker is responsible for disposing of the waste.

All plasticware will then be treated as hazardous solid waste and inactivated as follows: Pipette tips and serological pipettes will be dispensed into dedicated sharpsafe containers. Once deemed 75% full these will be closed and tagged with a numbered bag-tie specific for CL3 waste. The remaining solid waste will be transferred to an autoclave bag contained inside a labelled autoclave box (situated next to the microbiological safety cabinet). When deemed "3/4 full", the bag will be closed, a thermolog indicator put into the autoclave box and the box lid shut. The bag will then be tagged with a numbered bag-tie specific for room 610 waste. All solid waste (bags and sharpsafe bins) are then autoclaved as soon as possible in the CL3 autoclave (located in the suite lobby). An autoclave cycle with a holding temperature of 121°C for 20 mins will be carried out. This cycle will provide a complete kill of any remaining pathogens. Non hazardous materials are not allowed to be treated or sterilised within the autoclave at the same time. After completion of the autoclave cycle, the thermolog indicator plus the readout from the autoclave will be examined to determine if sterilisation has occurred. If successful, the autoclave bag within the autoclave box or sharpsafe container will then be transferred outside of the CL3 suite via a designated leakproof and robust trolley for final incineration and disposal. The autoclave bag/sharpsafe will be transferred to a clinical waste bag, sealed with a numbered tag specific for CL3 waste then put into the clinical waste bins. Every two/three days, the autoclaved waste is transferred to a larger, locked clinical waste bin ready for collection by PHS group, who hold an Upper Tier Carrier License to transport GM waste. The final disposal step involves its incineration at the Sidcup, Kent Incinerator operated by SRCL (this is validated to incinerate GM waste).

If an autoclave run does not occur correctly, the autoclave cycle is repeated. If the failure is repeated , the tagged, bagged and boxed waste will be transferred using a designated trolley to the back up autoclave external to the CL3 suite, where the waste will be autoclaved as described above.

Any autoclave failure will be reported to the Building & Laboratory Manager, Containment Facility Manager and/or Biological Safety Officer, who will contact the designated technical support.

70% ethanol will be used to clean non-disposable materials and surfaces.

Spills and splashes treated with 1% Trigene

Transfer between CL3 rooms within the suite will be in a leak-proof, impact-resistant container

02/03/2022
The overall goal is to understand the mechanisms of chromatin regulation in C. albicans. Specific goals are to characterise:

a). The pathways responsible for centromere establishment and maintenance.
b). Regulation of gene expression by the RNAi machinery.
c). The Biology of DNA repeats

Recipient or parental organism

C. albicans strains: CAI4, ura3: CAIS, ura3, ade2: RM1000, his1 , ura3; BWP17, his1, ura3, arg4 and derivatives of these strains carrying further disabling markers

Host/vector system

Vector system: 1. Non-mobilisable E. coli vectors (including pUC18/19, pBluescript, pGEM-T; lac-based expression
plasmids such as pET vectors). 2. Specific non-mobilisable C. albicans vectors (low copy replicating and integrating vectors [pPB1, Clp10, Clp20, Clp30]; low copy replicating and integrating vectors for ectopic expression [YPB-ADHp, pACT1]; integrating expression vectors regulated by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON promoter and tet OFF promoter]. These vectors will be prepared from E. coli cultures. We will always use non-pathogenic E. coli strains such as the multiple disabled K12 derivatives, and the ree deficient BLR strain. The E. coli strain BLR is a disabled (recombination deficient) derivative of the strain BL21.

Origin & function

We are planning to generate null mutants in genes involved in:
Health and Safety

1. Centromere assembly and propagation. Null mutants will be expected to compromise centromere function resulting in lethality.
2. RNAi Null mutant will be expected to impair siRNA production of specific chromosomal loci.
3. Histone modifications. Null Mutants will be expected to alter the chromatin structures of specific chromosomal loci.
In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or tet promoter.

Evaluation of foreseeable effects

Transformations will be performed in multiple disabled C. albicans strains (ura3, ade2, arg4, or his1) to ensure that all transformants are avirulent. In none of the cases this is likely to increase virulence; instead transformants will always carry a disabling mutation, thereby rendering them completely avirulent. No null mutations have been described that increase the virulence of C. albicans.
In some experiments, the CAI4 strain will be transformed with URA3 plasmids. Insertion of the URA3 marker gene will partially restore the virulence of CAI4, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to attenuate virulence partially.
In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or tet promoter. In these experiments, the expression level is not maximised. Their ectopic expression levels will be <1% of total cell protein. The ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth. In experiments where we over-express genes, expression levels will be carefully regulated by addition of doxycycline; without doxycycline protein levels will be at or below wild type levels. The key point is that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds [1994] ASM News, 60, 313). Indeed, there is evidence that ectopic expression of factors involved in virulence traits does not increase virulence (Bailey [1997] PhD thesis, University of Aberdeen; Leng [1999] PhD thesis, University of Aberdeen; Rodaki et al. [2006]).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All yeasts will be killed by either heat treatment (all solid waste is to be autoclaved at 134 degrees C with a holding
time of 3 minutes) or addition of appropriate levels of disinfectant (all liquid medium and used consumables will be
treated with 1000 ppm Sodium hypochlorite for 8 hours - a >4 log reduction in Candida albicans viability is observed
after 15 minutes inactivation) in accordance with standard lab procedure post experimentation. All solid waste is then
collected for final incineration at hightemperature by an authorised healthcare waste contracto off site. All liquid
inactivated waste is disposed down specified laboratory drain with flushing with water.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The QMUL GMSC approved the work at GM Class 2 at its meeting on 27 Jan 2015, after discussion with the Project
Supervisor. It was noted that the partial virulence restoration noted with URA3 still made the strain attenuated below
the level of the wild type, but as the attenuations do not completely abolish virulence, work is classified as Class 2.
The GMSC noted that a transport of samples SOP be drawn up for movement of yeast samples between laboratories.
The project workers are also recommended to to arrange an allergen sensitivity test against Candida albicans. If
anyone displays sensitivity, further individual health and safety measures can be investigated.

Project Ref 774/17.1

Date Ackn’d 26/10/2017

CU2 Project Title A Phase 3 Randomized, Open-Label Study Comparing Pexa-Vec (Vaccinia GM CSF /Thymidine Kinase-Deactivated Virus) Followed by Sorafenib Versus Sorafenib in Patients with Advanced Hepatocellular Carcinoma (HCC) Without Prior Systemic Therapy.

Date Project Ceased

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted
Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (VV) derived from the commonly used vaccine Wyeth strain, Dryvax™. Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF) gene and 3) insertion of the LacZ gene. Pexa-Vec is designed to selectively replicate in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response through the expression of its transgene, hGM-CSF, in the context of tumor lysis.

Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexa Vec by IT injections. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival.

Recipient or parental organism

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (VV) derived from the commonly used vaccine Wyeth strain, Dryvax™.

Host/vector system

The transfer plasmid pSC65/hGM-CSF is used to generate Pexa-Vec. The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, USA.

Origin & function

Pexa-Vec is manufactured by Transgene (France) and labelled, QP released and shipped to investigational sites from PCI/Biotec (UK). At the investigational site, Pexa-Vec will exclusively be used for administration to patients as part of clinical study JX594-HEP024. Thus, only the GMO (Pexa-Vec), but not the wild-type host organism or the vector used to generate the GMO, will be used at the investigational site.

Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF) gene and 3) insertion of the LacZ gene. Pexa-Vec is designed to selectively replicate in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response through the expression of its transgene, hGM-CSF, in the context of tumor lysis.

02/03/2022
The GMO, Pexa-Vec is non-integrative (cytoplasmic localization), preferentially replicative in actively dividing cells (i.e. tumour cells), oncolytic (lysis of infected tumour cells) and propagative (able to spread locally to adjacent cancer cells and systematically by release into the blood stream and lymphatic system of infectious particles (Smith G.L. et al., 2002).

Over 300 adult and pediatric patients with advanced, treatment refractory cancers have received more than 1,200 doses of up to approximately 1 billion infectious units (1 x 109 pfu) of Pexa Vec via IV and/or IT administration (as of January 2014). Treatment with Pexa-Vec doses of approximately 1 billion pfu (approximately 10,000-fold more than the dose of standardized [non-attenuated] vaccinia delivered with vaccinia vaccine), has been generally well-tolerated with transient (<24 hours) flu-like symptoms (fever, chills, fatigue), nausea, hypotension and injection site pain as the most common adverse events (AEs). The overall risk of the wild type (parental) Wyeth (USA smallpox vaccination) strain indicates that out of 14 million vaccinations, there were 572 hospitalisations, 9 deaths and many less severe complications. The rate of severe adverse reactions for the wild type parental strain is approximately 1 in 50,000 vaccinations. Pexa-Vec has been even further attenuated when compared to the small pox vaccine, and therefore the safety is improved.

Secondary spread could occur by: direct contact (with a pustule, with bandages or other wastes contaminated by pustules, with expelled droplets from wound sites or liquid preparations) and indirect contact via medical devices contaminated through contact with a pustules. VV is not spread through the air (US Department of Health & Human Services, http://www.smallpox.gov/QuestionsAnswers.html). So transmission of the virus by inhalation can be assessed as negligible. The clinical information available to date suggests that Pexa-Vec is safe at the clinical dose of 1 x 109 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 42 will likely have been previously immunized with vaccinia (UK smallpox vaccination ceased in 1974). In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. To date, no reports of transmission from healthcare personnel from vaccinia recipients have been published; however at least 9 reports of infection of laboratory workers exist from the last 25 years (see safety data sheet http://www.phac-aspc.gc.ca/lab-bio/res/psds-fsfs/vaccinia-virus-eng.php). Infection control / Containment Level 2 standards and procedures and related healthcare approaches are to be implemented for worker safety.

Viral shedding data collected in a clinical study with Pexa-Vec administered by the IT route (i.e. JX-594-IT-HEP001 trial) demonstrated that the virus is not shed to the environment via urination. The virus could also not be detected in throat swab samples. There are no known or predicted environmental conditions which may increase survival, multiplication and dissemination of the Pexa-Vec. It is commonly thought that VV is not naturally found in the environment; however human to cattle (and vice versa) transmission have been reported via broken skin.

Recombination events of the wild type VV with the GMO are not thought likely, as current genetic stability studies on Pexa-Vec have not detected spontaneous revertants of Pexa-Vec.
Non–sharp solid clinical waste in an autoclave bag will be autoclaved at 121 degrees C for a holding time of 15 min, followed by high temperature incineration.

In the hospital, occlusive bandages will be used around site of wounds until shedding ceases to collect any shed particles, and such bandages autoclaved and incinerated.

Patients will be supplied with biohazard bags and gloves to secure all the waste from changing their bandages at home. They will be asked to return the sealed biohazard bags to the hospital at their next visit or arrangements will be made to collect if necessary. All biohazard bags will be placed into an autoclave bag, autoclaved and then incinerated.

Liquid hazardous waste will be inactivated by an effective disinfectant (currently, trade name ‘Chlor-Clean’, supplier Guest Medical Ltd, active ingredient dichloroisocyanurate, also known as troclosene sodium (i.e., chlorine-releasing component), at a final concentration of 1000 ppm chlorine for a minimum contact time of 5 min) before disposal down ward or pharmacy sink (subject to Thames Water trade effluent permits for site).

Chlor-clean has been validated by the supplier to pass the BS EN 14476 (virucidal) Standard covering non-enveloped and enveloped virus types as well as murine norovirus with an effective kill of > 5 log.

Any spillage of contaminated liquids will be inactivated with Chlor-Clean disinfectant at 10,000 ppm for a minimum contact time of 5 min, solidified with an inert absorbent, scooped into an autoclave bag and waste autoclaved and then incinerated as noted above.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment
1. The QMUL BGMSC peer reviewed the risk assessment at its meeting of 19 Oct 2016 and agreed with the classification of GM Class 2. As the vaccine strain is conditionally replicative and can cause human disease, it cannot be classified any lower in risk level (in line with the SACGM / Approved List of Biological Agents classification criteria).

2. The Committee noted that details on management (sections 1, 2), location/s of work (section 3), and waste (section 14), training (section 15), additional assessments (section 17) must be completed before full approval is given. This has been completed and added to risk assessment 21/09/2017.

3. All GMO work areas (wards / pharmacy / waste areas) must achieve the minimum Containment Level 2 standards required for clinical areas, as per Part 6 of the SACGM Compendium of Guidance – see pp 39-42, and consult with the QMUL Biological Safety Adviser to ensure measures are adequate. An Inspection is to be scheduled for Nov 2017.

4. The BGMSC noted that some information was noted to be patient specific and not relevant to worker and public safety, and should be re-worded or removed. This has been completed.

5. The types and rates of adverse reactions from historical vaccinia virus vaccine administrations are now noted and evaluated in the risk assessment.

6. Training course attendance recommended for GM workers and risk assessment sign off on master version.

Understanding the effects of host jumps and climate change on the spread and virulence of infections is of practical and theoretical interest. Recent results have suggested that some ranavirus strains propagate more rapidly at higher temperatures: both in cell lines, in experiments infecting amphibians in the lab and the field. A major goal of this project will be to establish the changes in the expression of genes and miRNAs associated with temperature, viral genotype, and their interactions.

In detail, the project will involve analysis of transcriptomes and miRNAs expression levels of cell lines, before and after infection with the virus, at different temperatures (and probably in cell lines from different species). Then, the differences in the expression of genes and miRNAs encoded by both host and ranaviruses would be detected to probably explain the change in propagation rate with temperature and why it differs between viral strains.

One GMM is to be used in this project, and the GMM is described as below: a FV3 strain RUK13 was modified by targeting loci considered non-essential since they represent genes where presence/absence varies across the virus phylogeny. Puro-EGFP cassette was inserted into RUK13 to generate a GMM RUK13-KOUS22. Puro-EGFP cassette is a dual selection marker consisting of the puromycin resistance gene fused in frame with the enhanced green fluorescent protein (EGFP) reporter under the control of the FV3 immediate-early (IE) 18k promoter. Therefore this GMM is very important for identifying the result of ranavirus infection.

### Recipient or parental organism

**Fish Cell Line**

### Host/vector system

**Ranavirus RUK13 strain**

### Origin & function

Wild-type ranavirus strains – No members of this virus genus (or family) are known to infect mammals and they cannot grow in cell culture at temperatures above approximately 30°C. Neither the wild type viruses nor the GMMs are therefore considered a threat to human health. Virus is cultured in a fish cell line (EPC). Puromycin (antibiotic) resistance marker forms part of the inserted cassette in addition to green fluorescent protein (GFP, not considered hazardous to health). Puromycin is an antibiotic used in laboratory cell culture and does not have medical uses meaning that any theoretical impact of release into the environment should be small.

### Evaluation of foreseeable effects

Wild type ranaviruses may pose an important risk to amphibian hosts and may also infect reptiles and fish. Amphibian ranavirus infections are notifiable to the OIE. For the
GMM RUK13-KOUS22, no revertants have been observed till now.
Puromycin (antibiotic) resistance marker forms part of the inserted cassette in addition to green fluorescent protein (GFP, not considered hazardous to health). Neither the puromycin resistance marker itself nor the GFP are known to have any toxic effects.
Puromycin is an antibiotic used in laboratory cell culture and does not have medical uses meaning that any theoretical impact of release into the environment should be small.
There is a possibility that the inserted cassette could be disseminated and maintained in the outside environment however the inserted genetic materials is innocuous and the risk of dissemination is very small and can be limited further through standard containment protocols.
Ranaviruses may persist for weeks or months in water and soil (Nazir et al., 2012) but they are obligate parasites of poikilothermic vertebrates that elicit infections in a dose-dependent fashion. Virus inactivation with routinely used disinfectants (bleach, virkon) is highly effective (Bryan et al., 2009) and autoclaving of waste provides a second layer of containment. The importance of adhering thoroughly to aseptic procedures to prevent contamination of virus cultures simultaneously serves as a prerequisite barrier to dissemination of virus to the outside environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

An open-topped container of >1% Virkon (final concentration 1% w/v) would be kept in the safety cabinet when manipulating the virus and infected cells. Pipets would be filled with Virkon before being ejected, then the pipets and pipet tips would be ejected into the container with >1% Virkon for 30 minutes >99.99% viruses would be killed. Wash the disinfected solids using fresh cell culture medium, and the medium would be used to infect the cells to test the disinfection efficiency. Then the solids would be properly labelled, identified and deposited into designated yellow collection bin for offsite high temperature incineration by an authorised hazardous waste contractor (currently PHS) at St Mary’s Hospital Incinerator, Sidcup, Kent.

Solid waste: plastic consumables, gloves. Plastic, gloves and other consumables will undergo one autoclave cycle with 15 min holding time at 121℃, prior to off-site high temperature incineration (yellow bag clinical waste).

Liquid waste: cultures. Final concentration of 1% (w/v) RelyOn+ Virkon solution with minimum contact time of 1 minute before disposal down designated laboratory drain with copious amounts of tap water. Supplier efficacy data notes test pass achieved (>4 log) with a suspension test (EN14476) with a model test virus Adenovirus Type 5 at 1:100 dilution. Efficacy testing noted by Bryan, 2009 achieved 8 log kill by 1 minute inactivation with Virkon S (a similar active ingredient (perxygen) disinfectant to RelyOn+ Virkon).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This virus is not infectious to humans but is infectious and very severely harmful to amphibians, fish, and reptiles. The genetic modification (non-hazardous gene insert - GFP) to this virus has been already made in the Institute of Zoology so the risk to the environment is not from the expressed non-hazardous gene expression but from the virus itself.

A key question put the researchers was what GM Class / Containment level work this modified virus had been assigned to at the Institute of Zoology. If a precedent was set as Class 2 / Containment Level 2, then this classification may need to be followed. This has been confirmed as Class 2 / Containment Level 2 by the lead researcher.

Further risk assessment detail was required as the assessment was patchy in places, and the disinfection and waste disposal procedures need to be set stringently to ensure 100% kill within the laboratory. These amendments have been completed in the revised document.

This virus is currently not on any UK controlled micro-organism listings (DEFRA or any other).

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

Biotin metabolism and fatty acid biosynthesis are essential pathways for survival of Mycobacterium tuberculosis (Mtb) and therefore they have been targeted for tuberculosis drug development. Biotin protein ligase (BPL) is the terminal gene in biotin metabolism pathway. My previous research has shown that BPL is essential for survival of Mtb in cultures as well as in mice. Silencing BPL expression in Mtb results in rapid death of bacteria and clearance of bacteria from mouse lungs. We have previously also identified a BPL inhibitor that works synergistically with the first line drugs used for TB treatment in the clinics.

In my proposed research work at Queen Mary, I plan to study the role of BPL silencing using genetic tools and chemical inhibition on Mtb interaction with the host immune system. My work will involve:
1. Infection of murine and human derived macrophages with genetically modified Mtb strains where the chromosomal copy of BPL gene has been replaced with tetracycline regulated BPL. I will follow up the course of infection by plating in 7H10 agar plates to enumerate the number of bacteria and study the impact on macrophage biology by microscopy, ELISA and pathway inhibitor studies.
2. Generation of new Mtb mutants in fatty acid biosynthesis pathway using genetic tools for mechanistic studies.
3. Generation of gentically modified Mtb strains with GFP and luciferase reporter genes to be used in microscopy.
4. Treatment of wild type and genetically modified Mtb strains with novel inhibitors in BPL and fatty acid biosynthesis pathways using first line drugs as experimental controls.
5. Extraction of lipids from wild type and genetically modified Mtb strains using organic solvents for use in lipidomics studies.

Recipient or parental organism

Mycobacterium tuberculosis H37Rv
Mycobacterium tuberculosis Erdman

Host/vector system

pTEMCS, pTEMCK, pTEMCZ, pGMCtK series and other similar plasmid vectors commonly used in tuberculosis research.

Origin & function

Foreign inserts:
Antibiotic resistance cassettes: These plasmids contain Hygromycin, Kanamycin, Streptomycin or Zeocin resistance cassettes for screening transformants.
Reporter genes: m-cherry, GFP and Luciferase reporter genes will be occasionally used,
recombinase expression,
Gene deletions: biotin, fattyacid biosynthesis pathway gene deletions, some under the control of a tetracycline regulated expression plasmid

Evaluation of foreseeable effects

The Genetically modified organisms generated/imported for the proposed study have deletions in genes involved in fatty acid/biotin metabolism and other similar pathways in M. tuberculosis. These pathways have been demonstrated to be essential for survival of M. tuberculosis in vitro and inside the hosts. Therefore, any changes in these pathways is expected to results in a GMM strain that may be attenuated in growth and virulence compared to the parental strain.Indeed, we have tested some of the GMMs for survival in mice and our data (PMID: 29695454; bioRxiv 2021.02.08.430271) indicate that silencing the gene expression of genes in these pathways results in an enhanced clearance of Mtb from the lungs and other organs. We therefore do not anticipate any additional risks posed by the GMM strains we propose to work with.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMMs will be inactivated and disposed using the same CL3 practices as the parent Mtb strain.

1. Liquid waste: Liquid waste generated during the experiments will be deactivated by overnight treatment with freshly prepared 5% surfanios following which it will be drained in the sink with copious amounts of water to dilute the disinfectant (validation 4 log kill achieved with 5% surfanios(EN14348 compliant) treatment for a minimum contact time of 60 min)
In addition, in-house testing performed at Blizard Institute in 2015 indicated that 5% Surfaniös does inactivate more than 5 logs Mtb culture within one hour of exposure. Additionally, to re-confirm the efficacy of Surfaniös against Mtb, an in-house testing will be performed before commencing the research related experiments.

2. Solid waste: All solid waste (biological as well as non-biological) generated will be autoclaved at 134 deg C for a holding time of 40 min before it leaves the CL3 suite.
The efficacy of every autoclave cycle will be confirmed by the use of thermocouple strips. The autoclave will be annually serviced for maintenance.

3. Sharps: Plastic tips will be collected in designated sharps waste container. Plastic pipettes will be rinsed with 5% surfanios for decontamination and stored in a designated sharps storage container. Use of needles will be minimized and if required blunt needles will be used and disposed in specific sharps container. All sharps waste will be autoclaved at 134 deg C for a holding time of 40 min before it leaves the CL3 suite.

4. Emergency spill – fumigation using formaldehyde vapour (details specified within CL3 Code of Practice)

Please enter comments on the GM safety committee on the risk assessment

The Queen Mary BGMSC approved the work at GM Class 3 at the meeting held on 25 Feb 2021.

Residual clarifications required in the risk assessment on (1) Surfanios validation (2) autoclave temperature of cycle / holding time and efficacy (3) occupational health surveillance details including follow up upon an exposure, effect on any exposure to vulnerable persons (4) Summary of exposure outcomes / incidence (5) any foreseeable downstream / off target effects (6) any foreseeable changes in drug or therapeutic agent susceptibility or resistance properties.

01 April 2021- Residual clarifications completed by Lead Researcher. Risk Assessment document completed along with CU2 and sent to HSE with cover letter.

- Microbiology Research
Solid waste will be autoclaved on a waste-processing cycle that reaches 135°C for 5 mins in a fully maintained and validated autoclave. The autoclave is sited in a building adjacent and connected to the Incubator building with direct internal access via a service corridor. It will be transported in autoclave bags inside closed metal containers, which are placed directly into the autoclave. Medium aspirated from cell cultures will be suctioned directly into a closed container supplied with Virkon to a final concentration of not less than 1% (wt/vol) for a minimum of 8 hours. Residual cells within the waste medium are already defined as especially disabled and genetic modification will not alter this status. In addition, Virkon is a disinfectant with an independent testing programme proven to inactivate known adventitious organisms that could be contained in these cells. In the event of a spillage of a large volume (up to 1 litre) of cultured GMOs a mixture of 50% (vol/vol) Virkon / vermiculite (Labelled "GM spill kit") will be spread onto the spill and left to absorb and disinfect for at least 2 hours. After this time the mixture is scraped into an incineration bag (yellow plastic bag) and sent for supervised incineration.

SINCE MOVING PREMISES WHERE PREVIOUSLY WE TRANSPORTED OUR NOTIFIABLE WASTE TO FACILITIES IN AN ADJOINED BUILDING, WE HAVE CONTRACTED FOR THE REMOVAL OF NOTIFIABLE WASTE BY WHITE ROSE ENVIRONMENTAL LIMITED. IN ACCORDANCE WITH HSE GUIDELINES AND NOTIFICATIONS (GM779) PROCEDURES ENCLOSED WITH CHANGE OF CONTACT DETAILS.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
1/ INTERCYTEX Disinfection SOP specific to GMOs (Level 2) should be appended to the proposal. This was duly appended.
2/ The committee reminded INTERCYTEX that the University Proposal form is no longer acceptable to the HSE in isolation and additional information would often be required (e.g. the waste disposal SOP). Also additional hazard and risk assessment information would be useful (e.g. Use of Human Tissues and Cultured Cells SOP). These were duly noted and included in the proposal.
3/ INTERCYTEX needs to cover all procedures, including transport of waste for autoclaving and contingencies for major spillages. These are covered in INTERCYTEX SOPs and are included in the proposal.
4/ The origin of the cell lines should be stated i.e. "established human cells" or "primary mouse cells". This was duly amended.
5/ Host cells to be listed individually together with the organism of origin. Within the limits of claimed confidentiality, the cell lines proposed for use have been listed.
6/ Vector access factors to be considered in the risk assessment apply only to mammalian cells. Since no use of E. coli hosts is indicated, access factors for this organism are irrelevant. The appropriate amendments to the risk assessment have been made.
7/ For human cell lines, the question of "adventitious agents" must be addressed. The question has been addressed as an issue for GM risk assessment and also with consideration to COSHH guidelines and this is now reflected in the risk assessment and notification documents.
8/ Antibiotic resistances conferred by the vectors proposed for use under "known biological activity" Noted and duly amended.
9/ Under ‘Expression Factor’ specify the “strong promoter” to be used. Noted and duly amended.
10/ The committee carried out an inspection of the proposed laboratories areas and provided INTERCYTEX with a report. The report suggested that specific signage be applied to reflect the use of GM Level 2 organisms. The premises and equipment were deemed to be consistent with Level 2 GMO activities and approval for the proposed use of premises for specified GMO activities was granted. This was duly noted and signage will be applied once GM work is approved.

Give brief details of the genetic modification safety committee

Risk assessment for GMM is carried out by a subcommittee of the company Health and Safety Committee, Company's biological safety officer, company health and safety officer, radiation protection advisor, Executive Director Research and Development, Executive Director Business and Development (responsible for company H&S policy). Routine matters covered in regular quarterly H&S meetings. Subcommitte meet as required to discuss GMM and radiation issues.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The plants would be uplifted by Healthcare Environmental Services, and delivered to Crosshouse Waste Energy plant by a specialist vehicle. All waste will be packaged in 300 gauge bags inside a lockable wheeled bin/eurocants. Upon arrival at Crosshouse Waste energy plant the material would be lifted by hydraulic lift for tipping directly into the waste incinerator. During discharge the load would be held at negative pressure whilst loading into the incinerator. The incinerator is tested weekly by continual monitoring and is regularly tested by the environment agency.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC considered the risk assessment for the transport and incineration of genetically modified tobacco plants by Healthcare Environmental Services Limited. The committee agreed that:

1. the risks to the environment would be adequately controlled by double bagging the plants in 300 gauge black sacks, placing the full sacks into a lockable bin on wheels and transporting the bin in an enclosed vehicle to the incinerator;
2. in the event of a major accident resulting in a loss of the triple containment the extremely low risk of harm to the environment would be minimised by collecting the released plants and soil into plastic bags.

E. coli K12 derivatives are killed using virkon at a concentration indicated by the manufacturer. Effectiveness of killing is indicated by overnight culture of treated material. Class 1 facilities have virkon, bleach and 70% ethanol available for cleaning and inactivating GMM. Mammalian cell culture waste is treated immediately with bleach. All cell culture waste is autoclaved on site (BMM Weston autoclaves - fully serviced, calibrated). Autoclaved material is subsequently incinerated off site (Cambridge Pet Crematorium). Effectively 100% kill.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The level 2 containment represents the upper limit of containment for GMO work to be performed. The use of level 2 arises mainly from the possibility of adventitious agents in human primary cell cultures. The introduction of immunoprotective genes will increase the resistance of cells if they enter the body. This is a very unlikely event. The risk to human health is significantly less than the use of oncogenes for example. The risk to the environment is extremely low.

Historical Date of Additional Info

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
The aim is to develop therapies including cell based therapies for the treatment of diabetes and pancreatic cancers.

**Recipient or parental organism**
GMOs include 1) Replication defective retroviral virions based on murine retrovirus. Standard retroviral vectors to be used with both ecotropic and amphotropic host ranges. 2) Genetically modified mammalian cell lines. 3) Genetically modified mammalian primary cell cultures, including human.

**Host/vector system**
- non mobilisable plasmids containing mammalian expression signals, typically puc-based. Transfected into mammalian cells.
- Replication defective retroviral vectors in primary mammalian cell cultures.

**Origin & function**
Genetic material is either derived from the mammalian genome or from mammalian expressed mRNA. Specific genes may also be derived from mammalian viral genomes, obtained as sub-clones with no viral replication potential.

Intended function is
1) to control the growth and differentiation of pancreatic cells
2) to produce human cell based therapies for diabetes that require reduced immunosuppression by pharmaceuticals.

**Evaluation of foreseeable effects**
Primary human cells will be cultured at containment level 2. To account for the possibility of adventitious agents.
Genetic modification will reduce the immunogenicity of human cells. If introduced into the human body these cells will survive longer than wild type cells. However this event is extremely low probability and no harmful consequences would be expected.

All human tissue is pre-screened for HIV and hepatitis B before entering this facility.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
None used.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Culture media will be treated with bleach. All materials will be autoclaved on site in a BMM Weston that is fully calibrated and serviced. Following autoclaving material will be incinerated at Cambridge Pet Crematorium.
The final material will not contain living organisms.
The level 2 containment represents the upper limit of containment for GMO work to be performed. The use of level 2 arises mainly from the possibility of adventitious agents in human primary cell cultures. The introduction of immunoprotective genes will increase the resistance of cells if they enter the body. This is a very unlikely event. The risk to human health is significantly less than the use of oncogenes for example. The risk to the environment is extremely low.

**Premises Conditions**

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Date: 02/03/2022
The notified premises are all operated by SRCL Ltd, as specialist healthcare waste premises. All facilities operated by SRCL are authorised under the Environmental Permitting Regulations 2010. Of these facilities 9 of these are Healthcare waste incinerators capable of incinerating all types of clinical waste and related wastes.

For the incineration facilities the clinical waste is mechanically loaded into the Primary Chamber where it is burned at a temperature of 900 to 1000 degrees centigrade for sufficient time to produce an inert sterile ash. The gases and other combustion products then pass into the Decondary Chamber where a minimum temperature of 1000 degrees centigrade is maintained for a minimum of two seconds in an oxygen-rich atmosphere to completely oxidase the combustion products. The flue gas is then cooled to around 130 degrees Centigrade by means of a steam boiler before being treated with powdered activated carbon and hydrated lime in a bag-house to remove any remaining impurities.

For the remaining facilities, GMO and GMM waste collected will be stored at the facility pending transfer to an incineration site in the same containers as collected in.

All the facilities have a designated waste storage area with separate facilities for the storage of all permitted categories of hazardous and non-hazardous wastes. There are well developed tagging systems, paperwork systems and written procedures for the handling of the different types of waste, including GMM and GMO.

For activities involving GMMs, describe the waste management measures which will apply to the activity
The plants are operated around the clock by teams of Shift Leaders and Shift Operators, who are under the management of experienced and highly competent site management in the form of General and Plant Managers.

To satisfy the CDG regulations, clinical waste has to be packaged in UN approved containers, which include yellow bags, sealed units and sharps bins. The sealed units are specifically made for the containment of higher risk materials such as human tissue and body parts, microbiological cultures and outdated medicines. They come in various sizes typically around 30, 50 and 60 litres - and are fitted with a lid which forms a very strong hermetic seal when pushed into place. The whole bin is designed to be incinerated along with its contents, with no manual handling involved. Sharps bins are similar containers, but designed to contain hypodermic syringes, scalpels etc.

SRCL Ltd specialises in the collection, transport and disposal of clinical waste in 770 litre wheeled bins constructed of high density polyethylene with a lockable plastic lid. The wheeled bins are themselves UN approved as a large package, so that in conjunction with the smaller packages they form a UN approved combination package ideal for the transport of infectious waste.

The wheeled bins are transported in purpose-built, twin deck vehicles fitted with straps and tail-lift barriers to secure the waste during transport and during loading/unloading operations. All the vehicles are driven by ADR trained drivers; the company has its own qualified driver trainer and also has a full time, qualified Dangerous Goods Safety Advisor. The bins are mechanically loaded into the incinerators by means of hydraulic lifts, which eliminate any manual handling of waste containers within the bins. Every bin is washed for 4 minutes in a heated bin-washer after it is emptied, using a sanitiser/detergent to clean both the inside and outside of the bin.

Each bin has a unique bar code attached, which is used to track bin movements from waste producer to final disposal on a computerised system, and therefore to satisfy Duty of Care requirements.

Every facility has a spillage kit containing all the equipment needed to clean up a spillage of clinical waste, and staff who are well trained in spillage procedures. Fortunately, because of the mechanical handling systems used, spillages are very rare occurrences and the kits and training are more of a precautionary measure.

In addition, there is a GMO Safety Committee that meet at least annually.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The risk assessment was carried out to assess all the types of GM material that could possibly be sent for disposal. The requirements for inactivation or biological barriers are the responsibility of the waste producer(s).
### Project Additional Information

#### Purposes of the contained use
The storage, transport and disposal by incineration of GMOs up to Risk Class 2.

#### Recipient or parental organism
The characteristics and evaluation of foreseeable effects will be determined by the individual waste producers.

#### Host/vector system
Determined by individual waste producers.

#### Origin & function
Determined by individual waste producers.

#### Evaluation of foreseeable effects
Determined by individual waste products.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Waste must be inactivated, or the waste producer must be able to demonstrate that the waste will pose no threat to human health or the environment.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The GMM waste will be transported and stored in UN approved hermetically sealed containers used for the transport of infectious clinical waste. The whole sealed container is incinerated along with its contents with no manual handling involved.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
The GMO waste will be packaged in UN approved sealed packages, transported in lockable 820 litre wheeled bins, mechanically loaded into clinical waste incinerators operated at a minimum temperature of 100 centigrade. This will give 100% kill of GMOs. The incinerators are approved for infectious clinical waste (including risk group 4 pathogens; for special waste, radioactive waste and hazardous waste. The final product is a sterile ash which goes to a landfill site.

The risk assessment shows the activities as posing no significant risk to the environment due to the appropriate control measures that are in place.

For activities involving GMMs, describe the waste management measures which will apply to the activity

For work involving Class 1 GMM's; all waste is heat or chemically inactivated prior to discharge to drain.
The conditions during inactivation are well in excess of those required to kill the organisms (based upon considerable experience and numerous viability/growth/survival studies on the cell line).
In addition to routine inactivation of waste; process equipment is located within suites which are designed to retain spillages.
All production equipment is also disposable or subjected to validated Steam-in-Place or autoclaving procedures.
All disposables are autoclaved prior to removal from site in validated cycles.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

This project was initially discussed at a meeting of the Speke site GMSC on 11/06/92 at which it was concluded that CL1 along with Good large Scale Practice was appropriate. Subsequent meetings confirmed the controls that were to be routinely employed.
Comments of relevant personnel to the updated risk assessment (attached) include the following:-
The production area can be effectively disinfected and fumigated and is designed to retain spillages.
Equipment waste is routinely autoclaved and waste liquid streams are inactivated prior to discharge to drain.
Containment Level 1 is considered sufficient to control the risks to human health and environment although many of the controls listed for CL2 are routinely applied.
The risk of any environmental hazard is considered effectively zero.
## Project Additional Information

**Purposes of the contained use**
To generate pandemic Influenza vaccine which will contribute to stockpiles of vaccine.

**Recipient or parental organism**
A/Puerto Rico/8/1934 (PR8) Flu virus strain has been routinely used as a basis of flu vaccines with an extensive history of use. This has been combined with A/Vietnam/1203/2004 (H5N1) to produce the reverse genetics seed: rg A/Vietnam/1203/2004 X A/PR/8/34 6:2 will be used in these activities.

**Host/vector system**
See above ... generated by reverse genetics.

**Origin & function**
A/Puerto Rico/8/1934 (PR8) & A/Vietnam/1203/2004 (H5N1)

**Evaluation of foreseeable effects**
Extremely remote possibility of reassortment during simultaneous "infection" with rg A/Vietnam/1203/2004 X A/PR/8/34 6:2 and a circulating human flu virus generating a new pathogenic strain.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from the following measures specified in Table 2, Schedule 8 is applied for :-

* Items 1, 2, 3, 4, 5 & 7 relate to closed systems, such as fermenters. This process is fundamentally NOT a closed system.
* Item 6 relates to seals (there are no significant seals in the Fluvirin manufacturing process (except post viral inactivation steps when seals are in-place to ensure product integrity).
* Item 13. Negative pressure is not appropriate for cGMP activities. Containment arrangements are by alternative means which includes sealing of entrances/exits and use of pressure cascades within new staff changing rooms.
* Item 21. The final discharge for this process for all bulk egg waste will be at Onyx, Southampton (via incineration). Other waste materials eg disposable PPE and potentially contaminated consumables will be incinerated in sealed drums at Cleanaway, Ellesmere Port, Cheshire.

Note: Items 1, 3, 4, 5 & 6 of the above are the only items listed as being required for CL2 activities.

For QC activities listed as part of this application, derogation from the following measure specified in Table 1a, Schedule 8 is applied for :-

* Item 17, requires validated inactivation of GMMs in waste. Such wastes will be incinerated at Cleanaway, Ellesmere Port, Cheshire within sealed drums (as clinical waste).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Use of downward sealing packaging heads (supplied by Hosokawa Micron Ltd) plus Laminar Flow Extract Booth & HEPA Filters. Sealed loading of bulk waste into IBCs and container sided transport to Onyx incineration facility at Fawley, Southampton (covered by separate licence). Single stacking of IBCs is planned during transit. IBCs will be incinerated (not reused).

Low risk waste (disposable PPE, silicone tubing, used HEPA filters etc) will be incinerated at Cleanaway facility in Ellesmere Port within sealed drums.

Note: An emergency plan is not required due to controls being put in-place throughout the project & the submission of a separate notification from Onyx UK (waste handling contractors).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

No concerns have been raised by the local GMSC on this project. Discussed at GMSC on 28th July 2005. Next meeting is scheduled for Dec 12th 2005 when the project will be close to commencement. Issues relating to this project on site have been fully discussed with relevant parties during a series of staff briefing sessions. Trade Union reps have also been fully briefed on the project and have had an opportunity to discuss the project with HSE BAU personnel.

Project Additional Information

Purposes of the contained use

To fulfill government contract orders (typically US or UK) for Working seeds and bulk material for pandemic stock piling. Working seed production for pandemic preparedness. Candidate viruses received from WHO which have been reassorted via reverse genetics (not generated on site) are used. Testing of Seed and bulk material performed by QC and external labs.

Recipient or parental organism

A/Puerto Rico/8/1934 (PR8) Flu virus strain has been routinely used as a
basis of flu vaccines with an extensive history of use. This has been combined with various pre-pandemic and pandemic strains (H5N1, H7N9, H1N1 etc) to produce the reverse genetics candidate vaccine virus: e.g NIBRG 23 A/TURKEY/TURKEY/1/2005. Next project will be ID CDC RG56B A/Hong Kong/125/2017 H7N9, A/Duck Bangladesh/ Any other viruses will be evaluated by the biosafety committee.

Host/vector system

Candidate vaccine virus generated by reverse genetics at a WHO lab prior to receipt - The haemagglutinin (HA) and neuraminidase (NA) genome segments of the wild-type virus are cloned into ‘rescue’ plasmids under the control of an RNA polymerase I promoter. During cloning, the HA segment is modified to delete the stretch of basic amino acids that confer the highly pathogenic phenotype of the virus. These are transfected into Vero cells together with rescue plasmids containing the remaining six viral genome segments from and four expression plasmids that encode the viral replicase machinery of the PR8 virus. Genetically, the rescued RG virus is a reassortant containing six segments from PR8 and two from the wild-type virus, with the HA segment containing a deletion compared with its parent virus. The phenotype of the RG reassorted virus is expression of the wild type coat proteins, good growth in eggs (a PR8 trait), likelihood of attenuation for humans (another PR8 trait) and lack of pathogenicity (owing to the HA deletion).

Safety testing performed prior to receipt - The tests performed to demonstrate that a virus derived by reverse genetics is no longer pathogenic as per WHO guidelines and include a chick embryo lethality test, a chicken pathogenicity test, a ferret pathogenicity test and sequencing. Hazard classification BSL2 enhanced given.

Viruses prepared and received from WHO laboratory. No bacterial plasmid or vero cells are present or handled on site.

Origin & function

Avian, swine, porcine wild type viruses of pandemic potential are reassorted onto PR8 backbone via reverse genetics (see host/vector system section above). Which is historically well known virus with a strong safety record which grows well in embryonated hens eggs (but does not kill them) but is there is very low infectious risk to humans. The reassorted virus generated, safety tested an supplied by approved WHO laboratories

Evaluation of foreseeable effects

Small theoretical risk of reassortment during simultaneous "infection" with RG reassortant (A/Puerto Rico/8/1934 (PR8)) and a circulating human flu virus generating a new pathogenic strain. Risk is further reduced through application of control measures throughout use on site. Biosafety committee views this as a BSL2 hazard however due to this risk enhanced controls area

Pandemic vaccine reassortants have been produced on the human strain A/PR/8/34 (PR8) as recipient virus. PR8 has had over 100 passages in each of mice, ferrets and embryonated chicken eggs. The result of such a passage history is complete attenuation of the virus and its inability to replicate in humans.

Although it is considered that, for example, an H5N1/PR8 reassortant will be either attenuated or possibly non-infectious to humans, an indirect hazard may exist through secondary reassortment with a human or animal influenza virus as influenza viruses are known to exchange genes by the process of reassortment. For secondary reassortants to be generated, several events need to occur; firstly infection of the production staff with the reassortant strain; secondly, for an infected worker to have a mixed infection with a wild type influenza virus, and thirdly for a reassortment event to take place. In practice, manufacturers have 30 years of experience with large scale production of vaccines based on PR8 reassortants and there have been no reported cases of human illness.

Biological Risk assessments for the live areas handling GMO and strains with hazard group 2 enhanced classification for the proposed HHS contract are attached - Seed Manufacturing and QC bioassay.

Control measures for other areas detailed in section 12. Risk assessment currently under review and update for UM, ETA and TD in preparation for possible bulk order.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. No larger GMM's used or present on site.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable. Refer to risk assessments included or detail provided below

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Non-Autoclavable waste (including White safety shoes from Upstream Manufacturing Areas) must be surface decontaminated, collected in clinical waste containers placed in the change rooms, and sent for disposal via incineration.

Effluent Treatment Area -
Solid waste treatment from UM harvest:
Macerated egg waste is transferred from the Upstream Manufacturing (UM) area via a holding tank and integral transfer pipework into the Effluent Treatment Area (ETA). The waste is stored when in ETA in 40,000 liter holding vessel. This vessel is HEPA filtered and linked the ETA scrubber system. The waste is continuously feed from the vessel into the Gouda Driers, these are paddle driers that heat the material to above 100c for a total of 7 hours. The Driers are steam heated through the Paddles and jacket, temperature probes throughout the drier monitor the temperature of the material being
processed. All gas generated by the drying process are pulled into the LEV scrubber system.

LEV Scrubber system:
All gas generated from the drying system and the post HEPA filtered vessel gas is treated through the LEV scrubber system. This system consists of an acid scrubber, carbon filter and a Caustic scrubber before the gas can be released through the stack to atmosphere.

Virally active waste liquid:
All waste water and cleaning materials from the Upstream area are treated in the ETA facility. The drains in the UM area direct all waste to the external sump which is sealed and HEPA filtered. This material is transferred into the ETA holding vessel via integral pipework, the vessel is HEPA filtered and the extract air is processed through the LEV scrubber system. The waste liquid is continuously feed from the vessel into the waste liquid treatment skid (Actini). The Actini is a thermal decontamination unit which inactivates the virus at 100c and is held for 1 minute. The Actini unit is controlled by temperature control system which directs the material back to the holding vessel if the temperature drops below the 100c limit. After treatment the waste liquid is transferred to the external sewer sump where it is pH adjusted checked to be within temperature specified for release into the sewer system.
The ETA area is contained and all drains are directed to internal ETA sumps which are then put through the waste treatment processes to prevent any waste material being released without treatment.

All waste treatment temperatures have assessed and justified through technical documents which have been reviewed and approved by the HSE.

During Pandemic processing all ETA staff are vaccinated and in the event of a spillage all staff will wear a 3M face mask or Jupiter hood as outlined by the ETA gowning procedure.

Technical Development - small scale, low volumes of virally active material generated. Waste eggs, gowns and contaminated waste from pilot plant, containment labs and lab consumables are treated with approved disinfectants and sealed contaminated waste bins. Decontaminated egg waste and contaminated waste bins are incinerated at approved off site location. Adherence with APHA import licence. No drains. Negative pressure pilot plant and single HEPA filter. Use of MBSCs with double HEPA filtration of extract air (cabinet and containment labs). The drains in the Pilot plant area direct all waste to the external sump which is sealed and HEPA filtered.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
GMSC initially met and risk assessed the current proposed GMO work 24Apr17. It was concluded current controls and practices are sufficient with some preparation activities to complete including submission of this form and notification to HSE being required. Risk assessment and procedures in place were reviewed by all impacted parties. Following satisfactory completion of the safety testing by CDC of the virus (ID CDC RG-56B A/Hong Kong/125/2017 it was confirmed the site is ready to receive the virus to plan in Seed Manufacture to meet the HHS (Health and Human Services USA) contract. Currently the order is for Seed production only. Control measures and communications captured confirmed appropriate. Further meetings held to review progression of actions as per site procedures and GMSC requirements held. Further meetings will also be held should the contract be granted for bulk manufacturing.

### Project Additional Information

**Purposes of the contained use**
To store and transport GM Waste prior to incineration

**Recipient or parental organism**
All characteristics of the GMO will be fully described by the Waste producer

**Host/vector system**
All characteristics of the GMO will be fully described by the Waste producer

**Origin & function**
All GM's will be incinerated

**Evaluation of foreseeable effects**
Forseeable affects will be different depending on the individual GM Waste to be accepted.

All information on effects will be supplied via the waste producer.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
All GM Waste must be contained in either a UN approved clinical waste sack or a one-way burn bin depending on the nature of the waste. It is the waste producers responsibility to adequately package their waste to prevent its escape, under their Duty of Care.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
We request a derogation from everything written in Schedule 8. The reason for this is that we operate a Hazardous Waste Incinerator plant and the control measures listed are not appropriate to our operation. The control measures stated within the notification should be sufficient to control the risks.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All GM Waste will be destroyed by High Temperature Incineration in temperatures of +1000C. 100% Kill.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid biological waste: inactivated by autoclaving prior to removal from premises and incineration.
Liquid biological waste: inactivated with 1% w/v Virkon solution for a minimum of 30 minutes.

Please enter comments of the GM safety committee on the risk assessment

The GM Safety Committee have no comments on this notification.
Project Additional Information

Purposes of the contained use

To determine the sterility status of recombinant ovine adenovirus using the steritest system within a half suit isolator.

Recipient or parental organism

OAV623 is an OAV that contains the full viral genome and a transgene of human origin. OAVs are capable of infecting human cells but have been shown to be unable to complete their full cycle of replication (Khatri, A et al [1997]: Virology 239 226-237), resulting in an abortive infection. Infection is still abortive in the presence of co-infected human adenovirus suggesting minimal risk to the worker when propagating this virus. It is expected however that there will be an immune response in humans on exposure to this virus.

Host/vector system

A plasmid that contains the whole OAV623 viral genome and is therefore a GMM, though of similar or lower risk to the parental virus.

The host cells and viral vector are both ovine and the virus is incapable of effective replication in humans. In addition, the expression of the transgene is under the control of a tissue specific promoter.

Origin & function

Virus and cell line are ovine. The cell line is to allow efficient propagation of the recombinant ovine virus. The virus carried a human transgene and is intended to deliver the transgene to human cells via an infective but non-replicative action. Expression of the transgene is under the control of a tissue specific promoter. The gene product is a human enzyme that will only be expressed in target tissues and will be capable of generating a toxic product from a prodrug that is administered separately.

Evaluation of foreseeable effects

OAV623 is a recombinant adenovirus, which contains the full viral genome and a transgene containing a tissue-specific promoter and a human gene encoding an enzyme that can act on a pro-drug to produce a toxic agent. OAV is capable of infecting human cells, but it has been shown to be unable to complete its full replication cycle (khatri, A et al [1997]: Virology 239 p.226-237), resulting in an abortive infection. OAV has also been shown to replicate abortively in human cells, which are co-infected with human adenoviruses. The abortive replication cycle of these viruses suggests that there is minimal risk to the worker when propagating these viruses. However, due to the lack of pre-existing immunity of the worker to OAV, there will be limited immunity on first exposure to the virus. Subsequent exposure would result in a strong immune response to the virus.
The plasmid DNA containing the full genome of OAV 623 will be used to rescue the virus under segregated conditions. As the plasmid contains the same genetic material as the intact virus, it is highly unlikely that the plasmid would be of greater risk to the worker than the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The virus will only be handled in class II microbiological safety cabinets and half suit isolators that will be swabbed with a viricide (eg Virkon or Klearcide) after use.

All equipment will be swabbed with a viricide (eg Virkon or Klearcide) after use.

All contaminated materials will be treated by chemical means (eg 1% Virkon solution, which is proven to destroy both Mastadenoviruses and Aviadenoviruses) and/or autoclaving at 121 degrees C for a minimum of 15 mins prior to removal by a contractor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agree that class 1 would normally have been appropriate for the protection of human health, but as this virus can cause mild infection in sheep it becomes a class 2 activity to ensure protection of sheep in the environment.

Other (please specify): Tick if confidential
All GMM waste material will be subject to autoclaving in a 400-litre autoclave at 121 degrees C for 15-30 min dependent upon volume of material. The autoclave is housed in specifically designed facility within an enclosed area. Floors are sealed and the flooring is extended up onto the walls to a height of 10 cm. This provides a high level of containment for any spillage and easy cleaning of spilled material.

The efficiency of the autoclave procedure is monitored using thermal strips and Bacillus spore ampoules on a routine basis. The autoclave is validated annually using multi-probe Kaye-validator, to which the thermal strips and ampoules are also validated. The autoclave also has a load-probe, which is validated annually.

The facility consists os separate laboratories for growth, handling and purification of GMMs or heterologous protein purified from the GMMs. This facility is separated from the rest of the environment by a locked (coded) door with limited access. Each laboratory has been designed to a standard of containment equivalent to class 2. This includes filtered air and negative, or positive, air pressure as appropriate. Transport of waste material to the autoclave takes place entirely within this facility and would include a maximum distance travelled of 10 metres.

_Filtration and separation of micro organisms_
The use of recombinant viral vectors is increasing in scope for clinical gene therapy applications due to the demonstration of long term transgene expression from viral vectors with little associated toxicity and good overall safety profiles in both preclinical and clinical trials. A major requirement for the development and eventual marketing of a gene therapy drug is the ability to produce the gene delivery vector at a sufficient scale. The purpose of the contained use activity is to enable fast track process development to pilot-scale ensuring a robust upstream process with satisfactory virus productivity. Recombinant viral vectors will be produced in ‘development projects’ for a number of Pall’s customers. The work will involve culturing a range of immortalised mammalian cell lines which will be transfected with a replication incompetent viral transfer plasmid encoding the gene insert of interest, plus viral packaging and envelope plasmids. Plasmids and DNA constructs will have been produced in well characterised bacterial expression systems and supplied to Pall. Transfected mammalian cells will produce high-titre recombinant virus particles intended for cell and gene based therapeutic applications.

Vectors based on adeno-associated virus (AAV), adenovirus, lentivirus and v-retrovirus will be used; these have gained importance in somatic gene therapy approaches in recent years, with use of AAV and lentiviral vectors being the most common. Inserted genes will include therapeutic genes, including genes known to be mutated in disease conditions, genes known to ameliorate pathology and genes used to manipulate cells for ex vivo therapies. Recombinant virus particles will be harvested from either the cell culture supernatant or from lysed cells using purification techniques such as chromatography or centrifugation. The viral vector systems to be used have been developed for these applications, are commercially available and/or have a long history of safe use, with good overall safety profiles in trials. Each development project will be specific to each customer in terms of the cell lines/types used, and the viral vector and gene of interest used.

Manipulations will be performed under aseptic conditions, in class II microbiological safety cabinets. Cells will be grown in adherent mode using a range of single use vessels, including T-flasks, cell factories, or in suspension mode using microcarriers in spinner flasks, or shake flasks, or in fixed-bed bioreactors, such as Pall’s iCELLis Nano. Working volumes will range from 10 - 100mL in T-flask to 1 L in the iCELLis Nano, and then up to a surface area of 500m2 in the iCELLis, with a 500L perfusion capability.
Two example risk assessment reports are submitted in support of this notification: MeiraGTx (GMM no. 002); and Adaptimmune (GMM no. 004). These risk assessments are representative of the contained use work to be performed under this notification. Any subsequent projects will be assessed to determine whether they fall within the scope of this notification. In the event that the assessment determines that future projects fall out of scope, subsequent notification to the Competent Authority will be made.

**Recipient or parental organism**

Cell lines will include:
- HEK293/293T - fully characterised cell lines from commercial source (ATCC/ECACC);
- PG13 - derived from NIH3T3
- Other, similarly well characterised cell lines may also be used.

**Host/vector system**

Viral vectors will include:
- Adeno-Associated Virus
- Adenovirus
- Lentivirus
- Gamma retrovirus
- Herpes-Simplex virus

**Origin & function**

Therapeutic genes include genes known to be mutated in disease conditions and genes known to ameliorate pathology.
- Marker genes such as GFP, RFP, LacZ, dsRED, luciferase
- Vision related genes such as Rho, Prph2, Aipl1, Mertk, RPGR, RPGRIP, RPE65
- Neuroprotective genes such as CNTF, GDNF
- Immunomodulatory genes such as IL 1, IL 10, IL 1Ra, IL4, TGF13
- Angiostatic genes such as sFlt, Endostatin, Angiostatin
- Transcription factors (ocular development) such as Crx, Pax6, NeuroD, Nrl, N2E3
- Cell cycle genes: E2F2, YAP1
- T cell receptor genes specific for cancer peptide/HLA antigens including but not limited to peptides of NY-ESO, gp100 and MAGE A3
- TCR genes specific for viral epitopes, including but not limited to human immunodeficiency virus (HIV), cytomegalovirus (CMV), Epstein Barr virus (EBV) and human papillomavirus (HPV)
- TCR genes specific for putative auto-antigens or self-antigens thought to play a role in auto-immune disease processes or in graft rejection. The auto-immune diseases include but are not linked to diabetes mellitus, type 1, rheumatoid arthritis, autoimmune hepatitis and multiple sclerosis.
- HLA genes for the production of antigen presentation cells (APC)
- AA V viral genes: Rep, Cap
- Lentiviral production genes such as GAG, POL, vesicular stomatitis virus envelope
- Vectors:
  - Cloning vectors such as pGEM-T Easy
  - Expression vectors such as pcDNA3.1, pCMV
  - Viral vector backbones, such as pD10 (AA V), pHRSIN (HIV)
Viral vector helper plasmids such as pHAV7.3 (AAV), p8.91 and pMDG (HIV1) Virapower (Invitrogen Ltd), Lenti-X (Clontech Laboratories Inc).

Recipient (Host) organisms:
Escherichia coli: DH5α, JM109
Mammalian Cells: 293T, ARPE19, HeLa, BHK, human and mouse embryonic stem cells.

Evaluation of foreseeable effects

The viral particles produced in these systems are replication-incompetent, only carrying the genes of interest. Recipient cells fall into the category of 'Especially disabled hosts' as defined by the HSE. Commercially available cloning and expression vectors have a long history of safe use, with no evidence of harm to health or environment. Viral helper plasmids for AAV and lentivirus produce the proteins required for the production of viral vectors. These plasmids have been designed to have minimal homology with wild type and recombinant viral genomes to avoid mobilization. There is no evidence of harm to health or environment. Genes of interest and other components of the viral packaging mix will not be constructed on-site but will be supplied to Pall on plasmids provided by the customer requesting the process development work. Gene sequences will vary and be specific to the customer and the application of the product. AAV: cells with plasmid vector containing the cell cycle gene E2F2 will be the most hazardous GMM produced, as persistent expression of the gene is potentially tumourigenic.

LV: no plasmid contains long terminal repeats (LTRs) or the packaging sequence. This enables the viral genome to be generated in the producer cell line but results in self-inactivation of the lentivirus after transduction into the target cell and so the lentiviral particles produced are replication-incompetent.

The likelihood of exposure or release to the environment is considered low due to the containment procedures that will be employed. Infected mammalian cells will be unable to establish themselves in nature. It is very unlikely that genetic inserts would be transferred in the environment if a breach were to occur. If such a transfer did occur, persistence in the recipient is very unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A derogation is applied for in respect of containment measure 5 in table 2 of Schedule 8; inactivation of bulk culture fluids before removal from the closed system required by validated means. For the large scale (up to 500 L) element of the contained use activity, bulk culture fluid must be removed from the bioreactor in order to harvest the vector virus products. The justification for the derogation is that recombinant viral vectors will be harvested from the bulk culture fluids using closed systems. Spent growth medium will be transferred aseptically to an intermediate bulk container, which will be sealed and taken for incineration by a licenced waste contractor. Sections D and E of the risk assessments submitted in support of this notification describe these measures.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Small volumes of liquid waste and any solid waste generated in the contained use activities will be autoclaved within the laboratory suite for a minimum of 20 minutes at 134°C in a validated discard cycle.
Small volumes of liquid waste may also be chemically inactivated using 2% (v/v) sodium hypochlorite solution or 1% (w/v) Virkon solution.
An approximate 100% kill will be achieved using either chemical or physical waste treatment methods. The autoclave is subject to quarterly servicing and annual 12-point thermocouple testing.
Large volumes of liquid waste will be transferred aseptically to intermediate bulk containers, sealed and sent for incineration by a licenced waste contractor.

Pall's GMSC has reviewed the risk assessments relating to this notification and agreed a classification of class 2 for the contained use activities.

Please enter comments on the GM safety committee on the risk assessment

Pall's GMSC has reviewed the risk assessments relating to this notification and agreed a classification of class 2 for the contained use activities.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

- **Bacteria** - E.Coli, trigene disinfectant, soaked for at least 30 minutes.
- **Viruses** - HSV, adenovirus, adeno-associated virus - Virkon disinfectant, soaked for at least 10 minutes.

After inactivating GMMs, all disposed as clinical waste and burnt off-site.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

The GMSC opinion is that the viruses to be used are probably Class 2, although as risks are low, Class 1 could be considered appropriate.

**CultureVol** < 1 litre

**History of Additional Info**

**Historical Date of Additional Info**

**Historical Significant Changes** PROJECT TITLE AMENDED 9/1/07 (FROM CONSTRUCTION AND PRE-
**Project Additional Information**

**Purposes of the contained use**

Construction and pre-clinical testing of modified forms of herpes simplex virus for vaccination purposes.

**Recipient or parental organism**

Herpes simplex virus strains with attenuating mutations but in which replication competence is retained. Attenuating mutations remove HSV genes, which usually inhibit immune responses and also render the virus non-pathogenic. These genes are VHS and/or ICP47 and may additionally include further mutations in ICP34.5, UL43, U35 and/or vmw65. The modified HSV strains also have genes encoding non-HSV antigens inserted (from infectious disease causing agents or which are selectively expressed in tumour cells) and may additionally have inserted genes encoding immune modulatory molecules such as cytokines and chemokines.

The work aims to include immune responses to the delivered antigens and to untoward effects are anticipated. The mutations to the virus have previously been shown to render the virus non-pathogenic and the genes to be delivered are not anticipated to be harmful according to previous work published in the literature.

**Host/vector system**

Herpes simplex virus 1 or 2

**Origin & function**

Inserted genetic material is of either human or rodent origin and has been cloned by PCR or obtained from collaborators in plasmid form. Genes to be inserted include tumour antigens such as MART-1, MAGE-1, tyrosinase, gp100, Her2neu, Muc-1, PS1, CEA for the development of anit-tumour vaccines. Antigens from a variety of infectious agents for vaccine development purposes will also be used as will human or rodent forms of various immunomodulatory molecules eg GM-CSF, IL12, CD40L, B7.1, RANTES. The immunomodulatory genes are aimed at the enhancement of the immune response to delivered antigens.

**Evaluation of foreseeable effects**

None of the genes to be inserted are anticipated to result in harmful effects.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste generated during the activity that has been in contact with the GMM will be treated with a Virkon solution. This broad spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact.

After treatment with the above disinfectant, the waste will then be placed into clinical waste bags and burnt offsite.
The GMSC opinion is that the viruses to be used are probably Class 2, although as the risks are low, Class 1 could be considered appropriate.

Project Additional Information

Purposes of the contained use

The primary objective of the clinical study is to assess how well the vaccine is tolerated following subcutaneous administration of three doses six weeks apart. It is planned that the vaccine will be given at three dose levels, with a safety review being carried out between each cohort. The secondary objectives of the study are: 1) to assess biodistribution of the virus in blood and urine; 2) to assess the induction of immune responses following administration of the vaccine; and 3) to determine a dose schedule for evaluation in later phase II efficacy trials.

Recipient or parental organism

HSV-2 strain HG52 (GenBank database accession number NC_001798)

Host/vector system

Strain HG52 disabled by the deletion of the vhs, 1CP47, 1CP34.5, UL43 and US5 genes (HG52 vhs AICP47 AUL43 A34.5 AUS5, ImmunoVEX HSV2). The deletions were introduced into the viral genome by homologous recombination using shuttle plasmids containing the gene of interest, which had been appropriately modified to achieve the deletion required.

Origin & function

There are no exogenous non-HSV coding sequences inserted into ImmunoVEXHSV2.

Evaluation of foreseeable effects

HSV-2 is the major cause of genital herpes, which even in its wild type form rarely causes severe systemic problems unless the virus somehow manages to get to the brain or the eye where it causes encephalitis and retinopathy respectively. Usual symptoms are genital lesions, which are routinely treated with acyclovir, famciclovir and valacyclovir. It is only transmissible through direct contact.

ImmunoVEXHSV2 has been disabled by the inclusion of mutations known to prevent pathogenicity. The vaccine contains a combination of deletions in the vhs, 1CP47 and 1CP34.5 genes, each of which are known to reduce the pathogenicity of HSV in animal models (Goldsmith et al., J.Exp.Med 187:341; Strelow and Leib, J. Virol. 69:6779; Rampling et al., Gene Therapy 7:859). ImmunoVEXHSV2 has been shown in several preclinical studies to be non-pathogenic in guinea pigs, mice and rats using doses of up to 1.00E6 pfu (the top planned clinical dose) by the subcutaneous, intranasal and intracranial routes. In addition, ImmunoVEXHSV2 has been shown to be unable to establish detectable levels of latency in mice (as measured by qPCR) following administration by the subcutaneous and intranasal routes.

The deleted gene sequences cannot be repaired during vaccine production, as the deleted genes sequences have not been inserted into the genome of the cell line used for virus growth, and thus there is no potential for recombination of the vaccine virus genome with the DNA of the production cell line. There is a small possibility of reversion of the deleted sequences to a wild-type sequence if the vaccine virus was undergoing replication in the same cell as a Wild-type virus. Under these circumstances it would be possible for recombination between the vaccine and the wild type virus DNA to occur. However, bearing in mind the intended subcutaneous administration route (in the upper arm), this is very unlikely to occur in practice. In the unlikely event that this were to occur, recombination with a wild type virus would result only in a mixture of progeny virions that either contain one or more of the deletions in the vaccine virus (i.e. a disabled virus), or wild type virus. As there are no exogenous genes inserted into the vaccine, a wild type virus containing an exogenous gene sequence could not be generated following recombination with the vaccine virus DNA. Non-homologous recombination (i.e. between different regions of two viral genomes) has not been shown to occur at detectable levels.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chelsea and Westminster Trust Pharmacy: All plastic ware (syringes and female-to-female Luer lock adaptors) will be disassembled and soaked in a 1% Virkon solution for a minimum of 10 minutes. The plastics will then be placed in a clinical waste bin for incineration. The liquid waste generated during dose preparation will be treated with a 1% solution of Virkon before disposal in the dirty utility room.

St Stephen’s Centre: After use, all sharps will be immediately placed in a specific, clearly labeled sharps bin. The disposable drape used to cover the injection site will also be placed in the sharps bin for disposal. All other clinical waste will be placed in clinical waste bag. These will then be transferred to the St Stephen’s Centre 5th Floor laboratories for autoclaving before being transferred for incineration. All dirty bed linen will be treated in accordance with infected linen procedures and will be washed using a high temperature cycle. If a vaccine or specimen spill occurs, the bed linen will be autoclaved in St Stephen’s Centre 5th Floor laboratories before being sent for washing.

Autoclave: The waste will be autoclaved before disposal as described in HIV/GUM Sop-al 3, ‘Disposal of Clinical Waste’. Any retained samples will be disposed of as described in HIV/GUM SOP-024, ‘Disposal of Retained Samples’. The autoclave is operated as described in NV/GUM SOP-034, ‘Use of the 1SOL Boxer Autoclave’. The autoclave will be pre-booked before it is required to ensure that it is available and that the waste can be autoclaved as soon as possible after each subject visit. The waste will be stored in a defined area (please add) and will be transported to the autoclave area when the autoclave becomes available. The sharps bins used for the study will be clearly labelled to indicate they contain GM waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The draft risk assessment was considered by two independent clinical GMO safety advisors who passed their comments onto the BioVex GMSC. These comments mainly requested clarification on the procedures described in the draft RA and no new procedures or procedural changes were recommended. These comments have been used to modify the RA so that all procedures are clearly explained.

The notification was then considered by the GMSC and the panel agrees that the work should be carried out at containment level 2 with no additional measures required.

## Project Additional Information

### Purposes of the contained use

Prevention of class 2 GMOs being a hazard to workers.

### Recipient or parental organism

HSV1 vectors deleted for the neurovirulence factor ICP34.5 will be engineered to express human and mouse forms of GM-CSF and other immune modulators such as RANTES, B7.1 and CD40L. These viruses are designed to replicate in tumours but not surrounding tissue (considerable literature demonstrates such a phenotype for HSV1 and 2 ICP34.5 deleted viruses) with the additional delivery of immuno-stimulatory factors. Some viruses will be additionally modified such that HSV genes that usually minimise immune responses to HSV infection are also deleted. Such genes are UL43, vhs and ICP47. Each of the deletions in ICP34.5, vhs or ICP47 has been shown individually to generate a non-pathogenic, though still replication competent virus. Deletion of UL43 alone probably does not significantly reduce pathogenicity, but this deletion will only be included in viruses already deleted for the other gene(s) above.

### Host/vector system

Herpes simples virus 1 or 2.

### Origin & function

Inserted genetic material is of either human or rodent origin and has been cloned by pcr or obtained from collaborators in plasmid form. Genes to be inserted include GM-CSF, RANTES, B7.1, and CD40L.

### Evaluation of foreseeable effects

None of the genes to be inserted are anticipated to result in harmful effects.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref  785/01.2

Date Ackn'd  21/09/2001

CU2 Project Title  ICP34.5 DELETED HERPES SIMPLEX VIRUS 1 EXPRESSING TRUNCATED

Class  2

CultureVolClass2  1-50 litres

CultureVolumeClass3-4

02/03/2022  Page 11278 of 15326
**Project Additional Information**

**Purposes of the contained use**

ICP34.5 deleted herpes simplex virus 1 expressing truncated fusogenic retroviral glycoprotein for cancer treatment.

**Recipient or parental organism**

Herpes simplex viruses deleted for the neurovirulence factor ICP34.5 have been shown in considerable literature to replicate only in dividing cells and not in surrounding tissue. Some viruses will have additional deletions of ICP47, vhs and/or UL43 genes. Deletions in ICP47 and vhs have been shown to further disable HSV.

ICP34.5: Toxicity evaluation of replication competent herpes simplex virus (ICP34.5 null mutant) in patients with malignant melanoma. (2000) Rampling, R et al, Gene Therapy (7), 859-866

**Host/vector system**

HSV1 with deletions as stated above.

**Origin & function**

Genes to be inserted are for retroviral glycoproteins. The genes will come from Moloney leukaemia virus (MLV) and Gibbon ape leukaemia virus (GALV) which are each artificially truncated in the transmembrane protein and Human Endogenous Retrovirus HERV-W which is naturally truncated in the transmembrane protein. When inserted into the ICP34.5- HSV they are expected to give viruses with additional cytotoxic killing of tumour cells due to the truncated retroviral glycoproteins. These are truncated by 16 amino acids in the transmembrane R-peptide of the wild-type protein, which normally serves to restrict fusion of the envelope until it is cleaved during viral infection. This alteration renders the protein constitutively highly fusogenic and therefore cytotoxic to human tumour cells.

The loss or mutation of the R peptide sequence which limits the titre of retroviral production together with the fact that these retroviral glycoproteins have no packaging...
sequences should limit any interaction with other HERVs.

Evaluation of foreseeable effects

HSV1 is a universally prevalent virus that even in its wild type form rarely causes severe problems. Usual symptoms are cold sores. The viruses to be used will be disabled by the inclusion of mutations known to prevent pathogenicity.

HSV is not normally transmitted through the aerosol route. Infection is by contact, which attests to the instability of the virus outside the host. HSV is rapidly inactivated by desiccation, lipid solvents and mild detergents. Humans are the only natural host for HSV. It is unlikely, if working at containment level 2 that the viruses would reach the environment, if it did it could cause no harm to humans or animals that it came into contact with.

Gene sequences will be inserted into the disabling sites so that transfer to non-disabled versions of HSV will not occur. In the unlikely event that transfer were to occur, the resulting virus would then itself be disabled. Genes cannot be repaired, as there is no potential for recombination with DNA in the cells used for growth.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during the activity that has been in contact or potential contact with the GMM will be treated with a Virkon solution. vhs: Role of the virion host shutoff of HSV1 in latency and pathogenesis (1995) Strelow, L. & Leib, D., J. Virol (69), 6779-6786

ICP47: (1) Construction and properties of a viable herpes simplex virus 1 recombinant lacking coding sequences of the alpha 47 gene. (1991) Mavromara et al., J. Virol

Host/vector system

HSV 1 with deletions as stated above.

Origin & function

Genes to be inserted are for enzyme prodrug activators. A number of different enzyme/prodrug systems has been designed, these include:

These enzyme/prodrug systems may be used in combination with truncated fusogenic retroviral glycoprotein (GM785/01.2)

Evaluation of foreseeable effects

HSV1 is a universally prevalent virus that even in its wild type form rarely causes severe problems. Usual symptoms are cold sores. The viruses to be used will be disabled by the inclusion of mutations known to prevent pathogenicity.

HSV is not normally transmitted through the aerosol route. Infection is by contact, which attests to the instability of the virus outside the host. HSV is rapidly inactivated by desiccation, lipid solvents and mild detergents. Humans are the only natural host for HSV. It is unlikely, if working at containment level 2 that the viruses would reach the environment, if it did it could cause no harm to humans or animals that it came into contact with.

Gene sequences will be inserted into the disabling sites so that transfer to non-disabled versions of HSV will not occur. In the unlikely event that transfer were to occur, the resulting virus would then itself be disabled. Genes cannot be repaired, as there is no potential for recombination with DNA in the cells used for growth.

<td>Vaccinia virus is an orthopoxvirus that has been extensively used in the past for vaccination leading to immunity to smallpox. Inoculation of non-immune individuals leads to a papule that resolves in 14-21 days. There are only very occasional complications in young children. The vector will be replication competent and accidental infection of non-immune workers with vector also encoding an exogenous protein may induce an immune response to such an encoded protein. There is, however, no evidence that the products of the genes to be inserted could be harmful to human health.</td>

- **CU2 Project Title**: GENERATION OF HSV-1 BASED HIV IN VIVO VACCINES.
- **Class**: Class 2
- **CultureVolClass2**: 1-50 litres
- **Non-GMM**: not applicable

**Project Additional Information**

Purposes of the contained use:

It is planned to generate vectors for the delivery of HIV antigens to antigen presenting cells in vivo using multiple disabled HSV1 vectors deleted for genes involved in the avoidance of host immune responses (ICP47, vhs, UL43) and/or with deletions in genes preventing replication (ICP4, ICP22, vmw65, ICP34.5).
### Recipient or parental organism

HSV1 disabled by deletion of combination of the UL43, ICP4, ICP22, ICP47, vmw65, ICP34.5 and vhs genes.

### Host/vector system

HSV1 as described above.

Hosts are:
- BHK Cells
- Vero Cells

### Origin & function

It is planned to generate HSV1 vectors which express Human Immunodeficiency Virus (HIV) gp120 (env) and a gag-pol or gag-pol-nef fusion protein. Vectors may additionally contain sequences encoding human GM-CSF.

HIV sequences will be inserted into the vhs region of HSV1 either under the control of the hCMV immediate-early promoter or the rous sarcoma virus (RSV) promoter.

Where vectors contain human GM-CSF this will be under the control of the Moloney murine sarcoma virus (MMSV) promoter.

### Evaluation of foreseeable effects

The vectors will contain a combination of disabling deletions of the UL43, ICP4, ICP22, ICP47, vmw65, ICP34.5 and vhs genes. There is a small possibility of reversion of these deleted sequences to wild-type sequence if recombination of these vectors with wild-type virus were to occur. However, the vectors will contain multiple disabling deletions. Furthermore, the transgenes encoding HIV gp120 (env) and the gag-pol-nef fusion will be inserted into the site of the deleted vhs gene. Recombination of the viral vector with wild-type HSV would therefore result in deletion of vhs from the progeny virus. Deletion of vhs has previously been shown to generate a non-pathogenic virus.

Genes to be inserted are aimed at generating immune responses. There is no evidence that the products of these genes could be harmful to human health.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during the activity that has been in contact or potential contact with the GMM will be treated with a Virkon solution. This broad-spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration, giving terminal disinfection after 10 minutes of contact.

After treatment with the above disinfectant, the waste will then be placed into clinical waste bags and burnt offsite.

### Project Additional Information

**Purposes of the contained use**

Multiply disabled HSV2 vectors deleted for genes involved in the avoidance of hot immune responses (ICP47, vhs, UL43) and/or with deletions in genes preventing replication (ICP4, ICP22, wmw65, ICP34.5) will be used to generate vectors for the delivery of HPV antigens to antigen presenting cells (APC) in vivo.
HSV2 (e.g. strain HG52) disabled by deletion of combinations of the UL43, ICP4, ICP22, ICP47, vwm65, ICP34.5 and vhs genes. Trangenes will only be inserted into viruses that contain at least two disabling mutations.

Host/vector system

HSV2 as described above.

Hosts are:
BHK cells
Vero cells

Origin & function

Sequences encoding varius Human Papillomavirus type 16 (HPV16) genes including those for L1, L2, E2 and E7 will be inserted into either the vhs or ICP34.5 region of HSV2 under the control of the human cytomegalovirus (cmv) immediate-early promoter, the rous sarcoma virus (RSV promoter, anS SV40-HTL (human T-cell lymphotrophic viurs) fusion promoter or the Moloney murine sarcoma virus (MMSV) LTR promoter.

Vectors may additionally contain human GM-CSF under the control of the SV40-HTLV fusion promoter, or the moloney murine sarcoma viruses (MMSV) LTR promoter.

Evaluation of foreseeable effects

HSV2 is the primary cause of genital herpes. It is a prevalent virus, which evin in its wild type form rarely causes severe problems unless the virus somehow manages to get to the brain or the eye causing encephalitis and retinopathy respectively.

The HSV2 vectors will contain a combination of disabling deletions of the UL43, ICP4, ICP22, ICP47, vwm65, ICP34.5 and vhs genes. There is a small possibility of reversion of these deleted sequences to wild-type sequence if recombination of these vectors with wild-type virus were to occur. However, the vectors will contain multiple disabling deletions. Furthermore, the transgenes encoding HPV16 E2, E6 and E7 will be inserted into the site of the deleted vhs or ICP34.5 genes. Recombination of the viral vector with wild-type HSV2 would therefore result in deletion of vhs or ICP34.5 from the progeny virus. Deletion of vhs or ICP34.5 has previously been shown to generate a non-pathogenic virus.

The genes to be inserted are aimed at generating immune responses. The wild type HPV16 E6 and E7 sequences are oncogenic and implicated in cervical tumorigenesis. The sequences for these genes that will be inserted into the HSV2 vector have been modified to ensure that a) they are non-oncogenic and b) there is no possibility of these disabling mutations being repaired following recombination with wild type HPV16 sequences.

The HPV 16 E protein interacts with p53 leading to its degradation. The E6 p53 binding site has been identified and previously modified to eliminate this interaction (Slebos et al. 1995 Virology 208:111-120). This mutation has been incorporated into the E6 sequence to be inserted. The sequence has also been rearranged to prevent repair of this mutation by recombinatin with wild-type HPV16 sequence. In the re-arranged HPV16 E6, the coding sequences for amino acids 73-151 was moved to the 5' terminus followed by coding sequences for amino acids 2-69.

The HPV 16 protein interacts with pRb leading to deregulation of cell cycle control. The E7 pRb binding site has been identified and previously modified to eliminate this interaction (Smahel et al. 1995 Virology 281: 231-238). This mutation has been incorporated into the E7 sequence to be inserted. The sequence has also been rearranged to prevent repair of this mutation by recombinatin with wild type HPV15 sequence. In the rearranged HPV16 E7, the coding sequences for amino acids 27-98 are located at the 5' terminus followed by the coding sequences for amino acids 2-23.

Project Ref 785/05.1

Date Ackn’ed 12/10/2005  
CU2 Project Title Expression of antigens from recombinant lentivirus vectors.

Date Project Ceased  

Date  

Class CultureVolClass2 CultureVolumeClass3-4  
Class 2 < 1 L  
Non-GMM Consent Granted

02/03/2022 Page 11289 of 15326
The project aims to use lentiviral vectors to direct expression of exogenous genes in different cell types. Specifically, expression in EBV transformed B cells, PBMC, dendritic cells and transformed eukaryotic cell lines will be performed. The antigens expressed will include GFP and tumour antigens.

The properties of the lentiviral vectors to be used are reviewed in Buchschacher and Wong-Staal, Blood 95:2499. The specific vector to be used is pHV described in Ikeda et al Nature Biotech 21:569 (2003). The vector is devoid of all accessory and potentially pathogenic genes derived from the parental virus, including vif, vpr, vpu and nef. The only remaining parental viral sequences are the long terminal repeats, the packaging signal and an internal flap incapable of multiplying and spreading to other cells unless certain complementing functions are provided in trans. The assembly events that occur in the packaging cell line results in the vector being contained in a virus containing the VSV-G protein within its envelope. The remaining lentiviral cis-acting sequences in the vector permit only a single round of vector replication in normal cells. The packaged vector can enter certain cells, either dividing or non-dividing, where it can be converted to DNA which can integrate into the host genome.

The pseudotyping of the lentiviral vector with VSV-G glycoprotein results in tropism determined by this molecule. Cellular uptake of vectors containing VSV-G is considered generally to occur by endocytosis, so that they have a very broad tropism. Such vectors have been used to transduce numerous cell types from both man and mouse. In addition, such vectors can also infect non-mammalian cells including those from insects and fish.

The vector will be used experimentally in EBV transformed B cells, PBMC, dendritic cells and transformed eukaryotic cell lines.

The gene encoding Green fluorescent protein is considered non-hazardous. The genes encoding human tumour antigens including gp100, MART-1, tyrosinase, CEA or MUC-1 are also considered non-hazardous. The gene encoding a modified form of Her2, in which the kinase domain has been removed, is also considered non-hazardous.

It is unlikely that the recombinant lentiviral vectors would be harmful to humans, animals, or plants. A potential hazard is due to integration leading to a mutagenic event. This is of low probability as the level of replicating genome within a cell will be very low as the vector is replication-incompetent. It is also relevant that there are no reported
instances of human carrying high levels of wild-type lentiviral loads showing evidence of insertional mutagensis (Buchschacher and Wong-Staal, 2000). The encoded genes have no oncogenic potential. The attenuated lentivirus vectors are expected to have very limited survival potential in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during the activity that has been in contact or potential contact with the GMM will be treated with a Virkon solution. This broad-spectrum disinfectant is effective against lentivirus at a 1% (w/v) concentration, giving terminal disinfection after 20 minutes of contact.

After treatment with the above disinfectant, the waste will then be placed into double clinical waste bags and burnt offsite.

The notification was considered by the GMSC and the panel agrees that the work should be carried out of containment level 2.

Project Ref 785/08.1

Date Ackn'd CU2 Project Title

02/03/2022
It is planned to generate vectors for the delivery of simian immunodeficiency virus (SIV) antigens to antigen presenting cells in vivo using multiply disabled herpes simplex viruses type 1 (HSV-1) vectors. The vectors will be deleted for genes involved in the avoidance of host immune responses (1CP47, vhs, UL43, ICP34.5) and/or with deletions in genes preventing replication (1CP22, 1CP34.5).

**Recipient or parental organism**

HSV-1 disabled by the deletion of a combination of the UL43, 1CP22, 1CP47, 1CP34.5 and vhs genes.

**Host/vector system**

HSV-1 as described above.

Host are: BHK cells, and cell lines expressing HSV genes that have been generated using BHK cells

Vero cells, and cell lines expressing HSV genes that have been generated using vero cells.

**Origin & function**

It is planned to generate HSV-1 vectors which express Simian Immunodeficiency Virus (SIV) mac 239 gag, gly6O (env) and a rev/tat/nef fusion protein. It is planned that the gly6O will be a membrane bound version of the protein. However, if there are problems with the level of expression of this form of the protein, the sequence encoding a secreted form may be inserted instead.

SIV sequences will be inserted into the vhs region of HSV-1 either under the control of the hCMV immediate-early promoter or the rous sarcoma virus (RSV) promoter.

**Evaluation of foreseeable effects**

The vectors will contain a combination of disabling deletions of the UL43, 1CP22, 1CP47, ICP34.5 and vhs genes. There is a small possibility of reversion of these deleted sequences to wild-type sequence if recombination of these vectors with wild-type virus were to occur. However, the vectors will contain multiple disabling deletions, Furthermore, the transgenes encoding HIV gly2O (env) and the gag-pol-nef fusion will be inserted either into the site of the deleted vhs or ICP34.5 genes. Recombination of the viral vector with wild-type HSV would therefore result in deletion of vhs from the progeny virus.
Each of the deletions in the vectors other than UL43 (ICP34.5, ICP22, vhs or ICP47) has previously been shown individually to generate viruses with significantly reduced pathogenicity (see references below. Deletion of UL43 alone probably will not significantly reduce pathogenicity, but this deletion will only be included in viruses already deleted for the other gene(s) above.

ICP47: Goldsmith K et al. (1998), J.Exp.Med., 187, 341

The SIV antigen coding sequences are not expected to alter the virulence or tropism of the vectors. All of the homologous HIV genes, as well as most SIV genes, have been added to a variety of viral vectors in the past (i.e. pox viruses, adenoviruses, vesicular stomatitis virus, herpes viruses), without producing unexpected phenotypic properties. The nef gene sequence to be used is nonfunctional as it is made as a fusion protein and the N terminus myristoylation site has been mutated. Myristoylation of the nef protein has been shown to be essential for its cellular localization in HIV (Kaminchik et al. (1991), J Virol. 65:583); nef-mediated down regulation of MHC-1 and CD4 (Harris and Neil (1994), J Mol Biol. 241:136), and nef-mediated impaired thymopoiesis by interaction with PACS-1, SH3 and PAK2 (Stove et al. (2003), Blood. 102:2925).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most of the waste (small plastic and liquid) generated during the activity that has been in contact or potential contact with the GMM will be treated with a 1% Virkon solution (a broad-spectrum disinfectant) for a minimum of 10 minutes. After treatment with the above disinfectant, the liquid waste will be flushed down the drain. All small plastic waste will then be placed into clinical waste bags and incinerated offsite using a registered company. Large plastic objects (such as roller bottles) will be placed in autoclave bags and autoclaved at 121°C using a standard waste sterilisation programme. The autoclaved plastics will then be placed into clinical waste bags and incinerated offsite using a registered company.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The notification was considered by the GMSC and the panel agrees that the work should be carried out at containment level 2 with no additional measures required.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Disposable items (plastic tips, agar plates etc) will be collected in bio-hazard bags. Glassware and other non-disposable items will be collected in a specific area beside the autoclave. All waste will be autoclaved at the end of each working day (because the laboratory and autoclave are quite small). The autoclave is an Astell Scientific Swiftlock autoclave, 5000 series, 35 litre capacity, front loading. The programme used will be 15 mins at 121 degrees C with 1-5 minutes free steam depending on load.

Each disposal run of the autoclave will be recorded and a test strip (which indicates that the correct sterilisation temperature has been obtained) will be placed in the centre of the load. The dated test strips will be kept to form a permanent disposal record. At the annual service of the autoclave, the engineer will test and record the temperature in the centre of the full autoclave.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC agreed that containment level 1 would be appropriate for the proposed work and the following points were raised in discussion:

1. Limiting scale of bacterial cultures to a maximum of 2 litres. This is for the practical reason that our incubator and autoclave are quite small, not out of consideration for the GMM.

2. Confirmation that laboratory coats and gloves would be removed before leaving the laboratory suite. This is our standard laboratory practice and will be continued.

3. Gloves will be worn when handling GMMs to avoid contamination of the products and to protect personnel from ampicillin, not the GMM.

4. In case of injury and accidental introduction of the GMM to a wound, the GMM under consideration should not pose a significant hazard and normal first aid and disinfection are appropriate.

5. Visitors, including students, may enter the laboratory whilst work is in progress but should not startle the staff.

6. Fire. Given the (non-hazardous) nature of the GMM, it is not considered necessary to inform local emergency services or prepare a specific emergency plan.

7. Advice on monitoring and testing of the autoclave; this will be undertaken by an engineer (prior to work commencing - annually thereafter). All disposal runs will be recorded.

Although assessed as a Class 1 activity, as all our microbiology laboratories are containment level 2, the work will be carried out in a containment level 2 laboratory in accordance with the appropriate level 2 procedures and controls. All experimental/contaminated material is either autoclaved in designated waste autoclaves or collected in sealed containers by a disposal company for incineration. Waste autoclaves are run at 136 degrees C for 30 minutes, there is a temperature probe in each load which gives a printout of the sterilisation cycle, also indicator strips in each load. Spore checks are carried out quarterly and servicing annually. Expected kill is 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The committee has met and discussed the risk assessment for B.Sc. and M.Sc. practical classes in gene cloning at UWIC, and agrees with the assessment as a Class 1 activity. We note that although the practical classes are a Class 1 activity they will be carried out in a containment level two laboratory with level two controls.

Please enter comments of the GM safety committee on the risk assessment:

The safety committee has approved a format for the assessment, but we are in the process of producing a better revised version.
### Project Additional Information

#### Purposes of the contained use

To elucidate the proposed function of tissue transglutaminase (tTG) in the binding to and stabilisation of the extra cellular matrix.

#### Recipient or parental organism

Mammalian cell lines including tumour cell lines of murine and human origin.

#### Host/vector system

For expression of tTG in mammalian cells vector systems will include mammalian expression vectors such as pSG5 under which the enzyme is constitutively expressed. For more controlled expression of the enzyme vectors using the tetracycline regulating promoter will be used. The expression vectors will be produced and purified using disabled E. coli eg. JM109.

#### Origin & function

Cell lines and genetic material is available at The Nottingham Trent University, other vectors will be purchased by from commercial sources. Transfected named cell lines and tumour cells will be observed for any phenotype changes especially those in the extra cellular matrix. Tumour cells are often deficient in tissue transglutaminase. Replacing this deficiency by transfection of the enzyme into the cells may have a number of affects on the malignant phenotype. Tumour cells transfected with tissue transglutaminase will be tested for any effects on tumour growth and progression in murine animal models.

#### Evaluation of foreseeable effects

The E.coli hosts to be used are well established disabled bacteria that are unable to colonise the tumour gut. Cultural transfected mammalian cells will not survive outside the tissue culture environment.

Human tumour cells and those transfected with tissue transglutaminase do have the possibility of surviving in the human body if immunologically compatible but only when injected in large quantities eg. $10^6$ (The six should be superscript) cell quantities.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Any animal studies undertaken with transfected murine cell lines eg. to observe the effects of expression of tissue transglutaminase on tumour cell growth will be undertaken under the required containment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposal of infected material will be supervised by staff specifically trained in the requisite techniques.

As Previous - Virkon and Autoclave (Copy from scripts).

For studies involving the transfection of murine cell lines including murine tumour cell lines these should be undertaken under containment level 1. For studies involving the transfection of human cell lines including tumour cell lines these should be undertaken under containment level 2.

Using these conditions the committee felt there was no risk to the environment and the risk to human health was minimal.

Project Additional Information

Purposes of the contained use
To enhance anti-tumour immunity and develop strategies for developing cancer vaccines.

Recipient or parental organism
Mammalian cell lines, of murine and human origin.

Host/vector system
Viral vectors, including disabled adeno and Herpes expression vectors.

Origin & function
The vectors have been obtained from commercial sources (either under material transfer agreements or purchased from suppliers). Genes from either antigens (including mini gene sequences encoding immunogenic peptides) and cytokine/immune response genes are incorporated into the vector. Appropriate cell infection leads to gene expression.

Evaluation of foreseeable effects
Expression of genes in appropriate cell systems. Viruses are disabled and therefore the progeny are non-infectious. An extensive literature exists on the safety of disables HSV and Adeno viruses.
Experiments are designed to evaluate the ability of gene products to activate adaptive and innate immunity to tumours.
Expression of genes in the human body is possible, but viruses have limited replicative capacity, and gene products would have a transient effect on the immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
In vivo: use of vectors will be restricted to the appropriate containment facilities (containment 2), and all experiments will conform to Home Office guidelines for the use of animals.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste material will be either inactivated with disinfectant and autoclaving, and animal waste will be prepared for incineration according to appropriate codes of conduct (approved by NTU safety services and the Home Office).

Give brief details of the genetic modification safety committee

Viragen's GMSC comprises of the Research and Clinical Directors of Viragen Europe, the BSO, the QC Manager, the Health & Safety Manager, the Regulatory Affairs/QA Manager and the Operations Manager in charge of cell handling. The BSO chairs the committee. The GMSC's role is to consider the risks associated with handling procedures, proposed and actual, for work involving GMO's. Initially the committee will meet twice yearly, or more frequently if required.

Cell suspensions will be treated by chemical means to inactivate cells, for example 1% Virkon solution. This is known to be effective for other mammalian cells and the efficiency of cell killing will be confirmed with the genetically modified cell lines. Concentrated cell masses and disposable materials that have contacted the cells will be decontaminated by autoclaving. Autoclaves are available in the Viragen facility and on the Pentlands Science Park site. Material will be incinerated following autoclaving.

Mammalian cell lines expressing transgenes.
**Project Additional Information**

**Purposes of the contained use**

The short term aim of this work is the generation of packaged lentivectors containing the sequences necessary and sufficient for transgene expression. The long term aim of this work is the generation of transgenic chickens, via lentivector transduction, that express heterologous proteins of interest in a spatio-temporally regulated manner.

**Recipient or parental organism**

This work will involve the transient co-transfection of three or four plasmids into HEK293T cells. All of these plasmids contain short, synthetic sequences derived from the Equine Infectious Anaemia virus (EIAV) genome, but at no point will the entire EIAV genome be present in the transfected cells thereby reducing the risk of any recombination events occurring. The HEK293T cell line is dependent on highly specialised growth conditions found only in the laboratory, it is not anticipated that transfection will significantly alter this characteristic. Furthermore, the cell line will only be transiently transfected and then destroyed within one week, there will be no storage for transfected cells.

**Host/vector system**

The viral vector system used during this project is based on EIAV and was developed by Oxford Biomedica to allow the highly efficient production of replication incompetent lentivectors. Numerous safety systems have been included in the system. For example, all of these sequence components required to make an infectious EIAV clone are never present, individual components are partitioned across multiple independent plasmids, codon optimisation to reduce potential homology and the elimination of accessory proteins.

**Origin & function**

The plasmids co-transfected into the HEK293T producer cells can be divided into the following groups:

1. One or two plasmids to express the essential viral proteins such as gag, pol and/or rev. These virus-related coding sequences will be synthetic, codon optimised versions and not derived directly from an infectious viral genome. Their function is to allow the efficient expression and packaging of RNAs expressed from the viral genome (Group 3 below).
2. A plasmid that expresses an envelope protein, again a synthetic copy of the gene, to allow viral pseudotyping.
3. A plasmid encoding the remainder of the minimal viral genome as well as the target gene to be expressed and associated promoter sequences. The target gene will usually be a reporter gene derived from a commercially available plasmid. The promoter will usually be a commonly used constitutive promoter derived from a commercially available plasmid. Alternatively, promoter fragments derived directly from the chicken genome may also be used.

**Evaluation of foreseeable effects**

The risks associated with the lentivector system can be broken down into the following groups.

The risk of insertional mutagenesis whereby the vector integrates into a host chromosome. This will be minimised by the use of self-inactivating vectors and the use of appropriate containment procedures. Furthermore, in the unlikely event of exposure the most likely outcome would be transient transduction or regularly replaced epithelial tissues such as skin, eye or lung lining. A related risk is that of transgene expression in transduced cells, however only commonly used reporter genes will be used, the expression of which is anticipated to have no significant impact on human health.

The potential of sensitization to lentiviral vector components and/or reagents used in the process is considered extremely unlikely.

Another theoretical risk is the generation of replication competent lentivectors (RCLs). This can occur via recombination between vector system components (minimised by reducing or abolishing any regions of shared sequence homology), or between wild type viral sequences in the producer cells (again a minimal concern as no EIAV-homologous sequences have been found in the human genome so far). Furthermore, in-process testing to allow validation of RCL negative status of both producer
cells and packaged lentivector preparations will be developed and implemented.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No applicable, work to generate transgenic chickens is not covered by this risk assessment and will be carried out by collaborators off site.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

In Part II, Schedule 8 (Table 1a) it is stated that an autoclave is required in the building for work at containment level 2. Viragen (Scotland) Limited is applying for a derogation from this requirement. VSL does operate an autoclave within our premises but it is not currently used for waste treatment. At present, all VSL GMO category 1 waste is disposed of by incineration after autoclaving, with the exception of Category 3 waste, which is disposed of by chemical inactivation. Our proposal is to dispose of Category 2 waste via the same route, and to retain an autoclave on site but to allow Category 2 waste to be disposed of by incineration instead of autoclaving. This will enable us to handle Category 2 and above waste, with no need to establish an in-house autoclave waste disposal system, and allowing it to be handled by operators who are experienced with Category 2 and above waste. Furthermore, attached data also demonstrates that the Virkon treated waste would be 100% inactivated before leaving the building. The waste will be double bagged, transferred into secure, sealable, autoclavable stainless steel containers and transported 200m to the MRI.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate contaminated liquid waste and plasticware. All waste will be soaked in 2% (w/v) Virkon, a commercially available virucidal disinfectant, for a minimum of 24 hours prior to disposal. Liquid waste will be collected in 500ml Duran bottles pre-filled with 100mls of 10% Virkon. Once full, after a minimum of 24 hour incubation, the sealed and dated bottled will be transferred for autoclaving. After autoclaving the liquid waste will be disposed of via the drains with copious dilution in accordance with the manufacturers guidelines. Virkon product information states clearly that this can be expected to have minimal environmental impact or effects on standard sewage treatment processes as Virkon will decompose into harmless by-products. Used plasticware will also be Virkon soaked for a minimum of 24 hours and then double bagged and transferred for autoclaving in secure, sealable stainless steel autoclave containers. The autoclave is located within a different building (Moredun Research Institute) on the same science park (Pentland Science Park) and is annually validated for waste disposal. Autoclaved waste is then removed for incineration off site.

All waste procedures at Viragen (Scotland) Limited are documented in the Waste Manual (VSM 005) which is available on requires.

Is an emergency plan required according to regulation 20? [Y]

### Project Additional Information

**Purposes of the contained use**

Bunyamwera virus made by a plasmid based transfection system has been obtained from collaborators at the UNIVERSITY OF Glasgow, an expert on the Bunyaviridae family of viruses. Cells will be infected by virus as a model to analyse the anti-viral activity of several cytokine products, including Multiferon™.

**Recipient or parental organism**

The system utilised for the production of transfectant Bunyamwera virus particles has been published (Bridgen, A. and Elliott, R.M. (1996) Rescue of a segmented negative-strand RNA virus entirely from cloned complementary DNAs. PNAS. 93:15400-4). HeLaT4+ cells are infected with recombinant vaccinia virus vTF7-3 to express bacteriophage T7 RNA polymerase. Cells are subsequently transfected firstly, with a mixture of three plasmids to allow for expression of all the Bunyamwera viral proteins, secondly to introduce the three plasmids containing cDNAs encoding the entisense genomes of the Bunyamwera virus. After 43 hours cell extract/virus is infected onto C6/36 mosquito cells (aedes albopictus to enrich the low yield of Bunyamwera virus particles, after 4-7 days virus in the supernatant can be plaque purified in BHK cells as is commonly performed for a number of viruses.

**Host/vector system**

The system utilised for the production of transfectant Bunyamwera virus particles has been published (Bridgen, A. and Elliott, R.M. (1996) Rescue of a segmented negative-strand RNA virus entirely from cloned complementary DNAs. PNAS. 93:15400-4). HeLaT4+ cells are infected with recombinant vaccinia virus vTF7-3 to express bacteriophage T7 RNA polymerase. Cells are subsequently transfected firstly, with a mixture of three plasmids to allow for expression of all the Bunyamwera viral proteins, secondly to introduce the three plasmids containing cDNAs encoding the entisense genomes of the Bunyamwera virus. After 43 hours cell extract/virus is infected onto C6/36 mosquito cells (aedes albopictus to enrich the low yield of Bunyamwera virus particles, after 4-7 days virus in the supernatant can be plaque purified in BHK cells as is commonly performed for a number of viruses.
Cell lines used included HeLaT4+ (a genetically modified derivative of the HeLa human carcinoma cell line), C6/36 mosquito cells, and BHK hamster kidney cells. C6/36 and BHK cells are not considered hazardous to humans. These cell lines are not used or stored at VSL. Furthermore, there are no HeLaT4+ cells present in the final Bunyamwera virus preparation used and stored at VSL as the final viral preparation has been derived from supernatant media and lysed HeLaT4+ cell extracts. This extract was then enriched for the low number of Bunyamwera virus particles present in the mosquito cell line, then plaque purified in BHK cells, in a two-step process removing any presence of host cells.

Origin & function

The nucleic acids used in these studies for the generation of Bunyamwera virus constructs (for expression of Bunyamwera viral proteins and encoding the antisense genome sequence), were derived by a combination of PCR from existing Bunyamwera virus sequences and reassembling complete sequences within plasmids. These sequences encode functional proteins and antisense genome sequences but have been subcloned into plasmid vectors with T7 promoters that require the infection of a recombinant vaccinia virus expressing T7 RNA polymerase to allow expression of these functional proteins etc. These plasmids will not be used or stored at VSL and at this point there is no proposed work involving the manipulation of these plasmids.

Resultant transfectant Bunyamwera virus produced in the GM system in all ways resembles authentic wild type Bunyamwera virus. This has been verified by comparing plaque formation (size, morphology), growth kinetics and titre, neutralisation by anti-Bunyamwera virus polyclonal antiserum, and viral protein expression profiles (by western blot).

Evaluation of foreseeable effects

Infection with Bunyamwera virus can result in febrile illness with headache, arthralgia, rash, and infrequent nervous system involvement (reviewed in Bowen et al, 2001. Virology. 291:185-90). However, infection normally occurs following arthropod transmission by mosquito bite. There is extremely little chance of this method of transmission occurring in the laboratory, as the General Virology Laboratory is at the end of a sequence of antechamber plus two laboratories specifically designed for tissue culture with double-door access between each laboratory. In the laboratory, infection of humans by the aerosol route is also considered unlikely unless very high concentrations of virus are used to generate the aerosols. The risk of human infection is low if the virus preparation is handled in an appropriate safety cabinet and not injected accidentally. VSL employs a restricted needle use policy, specifically with regards to handling virus.

Therefore, it is extremely unlikely that infection will occur upon the accidental spillage of virus during its handling, usage or storage.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable, no GM animals or plants will be generated during this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

In Part II, Schedule 8 (Table 1a) it is stated that an autoclave is required in the building for work at Containment Level 2. Viragen (Scotland) Limited has an existing derogation from this requirement for other Containment Level 2 work and would like this to be extended to cover the new Bunyaviridae waste. As stated in Section 12 of this form it is our intention to use Virkon for the chemical inactivation of all waste generated by this work. Manufacturers data demonstrates the efficacy of this product against Bunyaviridae therefore the prior inactivated waste will then be double bagged, transferred into sealable, autoclavable stainless steel containers and transported 200m to an autoclave on site (located at the Moredun Research Institute). This autoclave has been validated for waste disposal and supporting documentation is attached. Print outs of each sterilisation run (a minimum of 121 degrees Celsius for 15 minutes) are retained providing a record of time, temperature and pressure. Autoclaved waste is then removed for incineration off site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate contaminated liquid waste and plasticware. All waste will be soaked in 1% (w/v) Virkon, a commercially available virucidal disinfectant, for a minimum of 24 hours prior to disposal. Virkon usage follows manufacturers guidelines on bactericidal and virucidal activity of the product. Virkon liquid waste will be disposed of via the drains with copious dilution in accordance with the manufacturers guidelines. Virkon product information states clearly that this can be expected to have minimal environmental impact or effects on standard sewage treatment processes as Virkon will decompose into harmless by-products. Soaked plasticware such as
empty tissue culture flasks will be double bagged before being transferred for autoclaving. To avoid the risk of bag piecing, soaked pipettes will be transferred into sealable, rigid plastic containers before being transferred for autoclaving. The autoclave is located within a different building (Moredun Research Institute) on the same science park (Pentland Science Park). This autoclave has been validated for waste disposal, print out of each sterilisation cycle are retained (time, temperature and pressure). Autoclaved waste is then removed for incineration off site.

All waste procedures at Viragen (Scotland) Limited are documented in the Waste Manual which is available on request.

The GMSC raised no major concerns with the risk assessment however it was felt that a reference to Viragen (Scotland) Limited's needlestick policy in Section 3.2 should be clarified. It has now been established that needles will never be used during any handling of the virus so this reference has been removed from the text to avoid confusion.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use
The short term of this work is the generation of packaged lentiviral vectors containing the sequences necessary and sufficient for transgene expression where such transgenes are clinically relevant and potential human therapeutic proteins. The long term aim of this work is the generation of transgenic chickens, via lentiviral vector transduction, that express heterologous proteins in a spatio-temporally regulated manner.

Recipient or parental organism
This work will involve the transient co-transfection of three or four plasmids into HEK293T cells. All of these plasmids contain short, synthetic sequences based on the Equine Infectious Anaemia Virus (EIAV) genome, but at no point will the entire EIAV genome be present in the transfected cells thereby reducing the risk of any recombination events occurring. The HEK293Y cell line is dependent on highly specialised growth conditions found only in the laboratory, it is not anticipated that transfection will significantly alter this characteristic. Furthermore, the cell line will only be transiently transfected and then destroyed, within one week; there will be no storage of transfected cells.

Host/vector system
The lentiviral vector system used during this project is based on EIAV and was developed by Oxford Biomedica to allow the efficient production of replication incompetent vectors. Numerous safety features have been included in the system. For example, all of the sequence components required to make an infectious EIAV clone are never present, individual components are partitioned across multiple independent plasmids, codon optimisation to reduce potential homology and the elimination of accessory proteins.

Origin & function
The plasmids co-transfected into the HEK293T producer cells can be divided into the following groups:

1) One or two plasmids to express the essential viral proteins such as gag, pol and/or rev. These virus-based coding sequences are synthetic, codon optimised versions and not derived directly from an infectious viral genome. Their function is to allow the efficient expression and packaging of RNAs expressed from the viral genome (Group 3 below).

2) A plasmid that expresses an envelope protein, again a synthetic copy of the gene, to allow viral pseudotyping.

3) A plasmid encoding the remainder of the minimal genome as well as the target gene to be expressed and associated internal promoter sequences. The target gene will usually encode a clinically relevant, potential human therapeutic protein. The promoter will usually be one of several possible promoter fragments derived directly from endogenous chicken genes. No constitutively active internal promoter sequences will be present within the minimal viral genome.

Evaluation of foreseeable effects
The risks associated with the lentiviral vector system can be broken down into the following groups:
The risk of insertional mutagenesis whereby the vector integrates into a host chromosome. This will be minimised by the use of self-inactivating vectors and the implementation of appropriate containment procedures. Furthermore, in the unlikely event of exposure the most likely outcome would be transient transduction of regularly replaced epithelial tissues such as skin, eye or lung lining. A related risk is that of transgene expression in transduced cells, however only non-harmful, potentially therapeutic human proteins would be used the expression of which is not anticipated to have a detrimental impact on human health.

The potential of sensitization to lentiviral vector components and/or reagents used in the process is considered extremely unlikely.

Another theoretical risk is the generation of replication competent lentiviruses (RCLs). This can occur via recombination between vector system components (minimised by reducing or abolishing any regions or shared homology) or between wild type viral sequences in the producer cells (again a minimal concern as no EIAV-homologous sequences have been found in the human genome so far). Furthermore, no RCLs have ever been detected in packaged viral samples based on third generation minimal EIAV vector genomes. It is therefore extremely unlikely that any such RCLs would be present in vectors packaged at VSL. Nonetheless, at an appropriate time material will be made available for RCL testing.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable, work to generate transgenic chickens is not covered by this Risk Assessment and will be carried out by collaborators off site.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

In Part II, Schedule 8 (Table 1a) it is stated that an autoclave is required in the building for work at Containment Level 2. Viragen (Scotland) Limited has an existing derogation from this requirement for other lentiviral vector Containment Level 2 work and would like it extended to cover this closely-related work. As stated in Section 12 of this form it is our intention to use Virkon for the chemical inactivation of all waste generated by this work. Manufacturers' data demonstrates the efficacy of this product against HIV (a closely related lentivirus) therefore the chemically inactivated waste will then be double bagged, transferred into sealable, secure, autoclavable stainless steel containers and transported 200m to an autoclave on site (at Moredun Research Institute). This autoclave has been validated for waste disposal. Print outs of each sterilisation run (a minimum of 121 degrees Celsius for 15 minutes) are retained providing a record of time, temperature and pressure. Autoclave waste is then removed for incineration off site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate contaminated liquid waste and plasticware. All waste will be soaked in 2% (w/v) Virkon, a commercially available virucidal disinfectant, for a minimum of 24 hours prior to disposal. Liquid waste will be collected in 500ml Duran bottles pre-filled with 100mls of 10% Virkon. Once full, and after a minimum of 24 hour incubation, the sealed and dated bottles will be transferred for autoclaving. After autoclaving the liquid waste will be disposed of via the drains and copious dilution in accordance with the manufacturers’ guidelines. Virkon product information states clearly that this can be expected to have minimal environmental impact or effects on standard sewage treatment processes as Virkon will decompose into harmless by-products. Used plasticware will also be Virkon soaked for a minimum of 24 hours and then double bagged and transferred for autoclaving in secure, sealable stainless steel autoclave containers. The autoclave is located within a different building (Moredun Research Institute) on the same science park (Pentland Science Park) and is annually validated for waste disposal. Autoclaved waste is then removed for incineration off-site.

All waste procedures are documented in the Waste SOP (SOP/PRO/002 and VL/PRO/001)which are available on request.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMSC raised no major concerns with the risk assessment, the minor comments or recommendations that were made are listed below:

All lentiviral vector tissue culture will be done within the new Vector Laboratory. The GMSC suggested that SOP references be changed to the Vector Laboratory-specific codes (with a VL prefix) rather than general Viragen SOPs.

Minor text corrections:
The GMSC queried the origin of, and the virus tested status of foetal bovine serum (FBS) used during tissue culture and asked that this be verified prior to submission of this application. Copies of the validated gamma irradiation virus inactivation procedure for FBS have been obtained from supplier (Invitrogen).

All of the above suggestions and recommendations were incorporated into the final version of the risk assessment.

02/03/2022
The aim of the work is to assess the Interferon-modulatory effects of various viral proteins, namely VP24 and VP35 from both Ebola and Marburg viruses. Stably transfected cell lines expressing these proteins will be generated and analysed via standard antiviral bioassays.

Constructs containing the VP35 and VP24 genes in the commercial vector, pClneo (Promega) (to be constructed at off-site), will be stably transfected into African Green Monkey Kidney Epithelial Vero E6 cells and Human Epithelial Kidney 293T cells. According to the literature, expression of VP35 in 293T cells will change certain characteristics of the cells, rendering them unable to induce type I IFN. VeroE6 cells do not produce IFN, therefore the expression of VP35 is expected to leave this characteristic unchanged. It is possible but unknown whether VP35 from Marburg virus strains will have a similar effect on 293T cells. Furthermore, it is unknown whether VP35 from any strain of Ebola or Marburg to be tested will affect the cell's ability to respond to IFN treatment (applicable to both 293T and VeroE6 cells). Finally, it is unknown whether VP24 will have any effect on IFN induction or response to IFN treatment.

The virally-derived sequences will be present within the commercially available plasmid, pClneo (Promega). This plasmid is based on a pUC backbone and is non-mobilisable.

The coding sequences of both VP24 and 35 will be obtained by PCR cDNA prepared from virus-infected cells. Four types of each protein coding sequence will be analysed; from the Zaire strain of Ebola, the Ci67 strain of Marburg, the Musoke strain of Marburg and the Angola strain of Marburg. The PCR primers used have introduced suitable restriction enzyme sites to the 5' and 3' ends of the genes to facilitate cloning in the expression vector. This work will all been performed off site and not at Viragen (Scotland) Limited. These sequences will encode functional protein domains but will be subcloned into plasmid backbones that lack the control sequences necessary for expression in bacteria.

The pClneo vector contains a human Cytomegalovirus immediate/early promoter/enhancer to control expression of the virus coding sequences, note this promoter can direct heterologous gene expression in human cells. The vector also contains the neomycin resistance gene allowing selection of stably transfected cell clones.

The foreseeable risks associated with this work can be listed as:

- from base cell lines, eg. HEK293T due to either co-cultured adventitious agents or proteins within the cells such as SV40 Tag. For a series of experiments a single vial will be recovered from frozen, after the completion of that series of experiments the cultured cells will be disposed of. Long term culture of the cells will be minimised hence reducing the potential for an adventitious agent to infect the cultures. Considered extremely unlikely and measures in place to minimise contact between operator and cells.

- from plasmid DNA during transient transfection. Exposure of a human to the plasmid DNA constructs used to generate the stably transfected cell lines is considered to be unlikely but if it did occur there is a chance that human health could be harmed. Any gene introduced into cells that can inhibit cellular response to type I IFN could in theory result in that cell(s) demonstrating increased susceptibility to virus infection. This is likely to also be the case with regards to other type of infection. Considered possible but unlikely and this process constitutes a very small part of whole research programme.

- from virally derived protein expressed in the transfected cells or the introduced DNA present within them. The DNA introduced into these cells will be stably integrated at
low copy number. The transfected cells will not be manipulated using sharps so the risk of stab injuries is low. It is considered extremely unlikely that any genetic material from the cells, of which the expression plasmids only contribute a tiny proportion, will be transferred to the operator by this or related routes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

In part II, Schedule 8 (Table 1a) it is stated that an autoclave is required in the building for work at Containment Level 2. Viragen (Scotland) Limited has an existing derogation from this requirement for other lentiviral vector Containment Level 2 work and would like it extended to this work also. As stated in Section 12 of this form it is our intention to use Virkon for the chemical inactivation of all waste generated by this work. Previous submissions to the HSE have included data demonstrating efficient mammalian cell killing by 2% Virkon therefore the chemically inactivated waste will then be double bagged, transferred into sealable, secure, autoclavable stainless steel containers and transported 200m to an autoclave on site (at Moredun Research Institute). This autoclave has been validated for waste disposal. Print outs of each sterilisation run (a minimum of 121 degrees Celsius for 15 minutes) are retained providing a record of time, temperature and pressure. Autoclaved waste is then removed for incineration off-site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate contaminated liquid and plasticware. All waste will be soaked in 2% (w/v) Virkon, a commercially available virucidal disinfectant, for a minimum of 24 hours prior to disposal. Liquid waste will be collected in 500ml Duran bottles pre-filled with 100mls of Virkon. Once full, and after a minimum of 24 hours incubation, the sealed and dated bottles will be transferred for autoclaving. After autoclaving the liquid waste will be disposed of via the drains with copious dilution in accordance with manufacturers' guidelines. Virkon product information clearly states that this can be expected to have minimal environmental impact or effects on standard treatment processes as Virkon will decompose into harmless by-products. Used plasticware will also be Virkon soaked for a minimum of 24 hours and then double bagged and transferred for autoclaving in sealable, secure, stainless steel containers. The autoclave is located within a different building (Moredun Research Institute) on the same science park (Pentland Science Park) and is annually validated for waste disposal. Autoclaved waste is then removed for incineration off-site.

All waste procedures at Viragen (Scotland) Limited are documented in the Waste SOP (SOP/PRO/002) which is available on request.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
The GMSC raised no major concerns with the risk assessment, minor comments are listed below:

Request to amend reference that cell lines with a variety of expression levels will be banked (Section 2.2.2).

Suggestion that the theoretical risks from cell line exposure also include consideration of the risks specific to those cell lines, for example SV40 Tag exposure as well as general adventitious agent exposure. RA013 will be amended to this effect.

The reference to GM bacteria in section 3.4 will also be removed as at present no GM bacteria will be created at VSL during the course of this work.

Minor formatting correction in Section 3.1 to be corrected.

Also, to replace the reference in Section 3.3 to a "laminar flow hood" with "Class II Biological Safety Cabinet".

All of the above suggestions and recommendations were incorporated into the final version of the risk assessment.

**Premises Conditions**

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Y

Give brief details of the genetic modification safety committee

The committee (GMSC) comprises The CEO, The Commercial Director & one senior scientist. The GMSC shall meet quarterly. Risk assessments for new projects involving GMMs shall be fully discussed by the GMSC & no work on such projects shall commence prior to the approval of the GMSC. Approval shall only be given if the project can be safely conducted under containment levels already established & notified to the HSE. Any projects requiring additional levels of containment shall commence only following the authorisation by the HSE.

## Project Additional Information

### Purposes of the contained use

Use of transiently transfected cells for downstream processes such as panning (CIS or phage display), screening (binding assays using in-house generated binders or commercially available antibodies) and production of cell material. Possible fixation of cells prior to analysis.

### Recipient or parental organism

The recipient organism are hazard group 2 cells: HEK293 (T, S, NTR1 transformed, muCD71) and Raji cells (wt and muc1-C transformed), HeLa cells, J.RT3-T3.5 and Jurkat E6.1 cells.

### Host/vector system

Fc1.0 (in-house), pCAG (epoch), pCDNA31 (thermofisher), pCMV3-CGFPSpark (sino biological)

### Origin & function

Cells are from transformed cell culture lines of various commercial sources. The cells Use of transfected cells from part 1 for downstream processes such as panning (CIS or phage display), screening (binding assays using inhouse generated binders or commercially available antibodies) and production of cell material. Possible fixation of cells prior to analysis.

### Evaluation of foreseeable effects

Although these cells contain pathogens that may be hazardous to human health if the correct containment is used there should be no problems. In addition, there is no historical documentation of these cells nor
transformation methods either spreading disease or genetically modified material to direct users or the outside environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

we would like to apply for a derogation to use our disposal company Grundon to incinerate our waste rather than autoclave it before disposal due to having limited facilities for autoclaving waste in the lab.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste is collected in a yellow bin which is sealed before collection by an approved waste disposal contractor who is licensed to remove such waste for incineration. Small spills are absorbed onto paper soaked in disinfectant (distel (starlab) 1/10,) collected in a yellow bins for disposal as above. Liquid waste is collected for autoclaving or incineration. In both cases the waste is poured into the waste bins and disposed of via incineration. Due to the low volumes of cultures being used (no more than 100ml per flask), any spills can be absorbed onto paper soaked in disinfectant as detailed above.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum volume of waste released at any one time - All GMM waste will be treated before use however the maximum volume released after treatment would be no more than 2L per day.

Deactivation of waste - All GMM waste produced can be treated in one of two ways.
1) Solid and liquid media (including disposable plastics and glassware) will be autoclaved at 121°C for a period appropriate to the volume but for a period not less than 15min.
2) Liquid waste up to 500ml (this volume should not exceed the volume of Virkon in the pot) or pipettes can be placed in Virkon (2% w/v). This should be left for at least 1h before discarding the material down the sink. Disposable plasticware should then be rinsed with water before autoclaving.

Validation and monitoring of the deactivation method - When autoclaving GMM materials Sterilisation indicator strip are used to monitor the process. All autoclaves will also be treated every 6 months (during servicing for the larger systems) by thermocouple. The results from these will be notified to the BHO. The Virkon solution (2% w/v) is made up fresh every 2 days, however if the colour fades the solution should be discarded. The results of efficacy testing of Virkon are available from Antec International however it has been shown to produce 100% kill in a wide range of bacteria (350 strains and species including E. coli), viruses and fungi at dilutions down to 1: 200 and over a contact time of 20 min. We have also tested the efficacy of Virkon against Coliphage M13 and E. coli. Cells (10^7) or virus particles (10^6) in solution were exposed to 2% w/v Virkon (final concentration 1% w/v) for periods up to 1hour. Samples were taken and the materials washed by centrifugation to remove excess Virkon. The pelleted material was then plated out on nutrient agar or nutrient agar seeded with E. coli. By 10 min we were unable to culture either E. coli or generate plaques.

Disposal of materials:- After autoclaving material is sent for landfill.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Comments for the committee in relation to the new risk assessments

The committee had previously passed these assessments; these comments directly relate to the new regulations.
1.) Are all the bacterial vectors derived from E. coli K12?
2.) What cell lines will be used for the transient transfection system?
3.) Do we need to outline the disinfection process for the cleaning of spillages levels of kill?
Project Additional Information

Purposes of the contained use

Genes encoding for proteins involved in transport processes or chromosomal organisation and segregation, identified either by homology-based database searches or sequencing by mass spectrometry, will be cloned and manipulated in cultured insect and bloodstream forms of trypanosomes. This will allow the characterisation of gene function and contribute to our understanding of the parasites' strategies to survive in its mammalian host.

Recipient or parental organism

GMO cultured insect or bloodstream forms of the parasite. Insect forms are non-pathogenic, non transmissible. Bloodstream forms require tsetse fly transmission. These are only indigenous in Africa. No tsetse fly colonies are maintained at the University of Manchester.

Trypanosomes do not produce toxins and we expect most genetic manipulation of the parasite to reduce fitness and therefore virulence.

Host/vector system

Parental organism: Trypanosoma brucei spp, blood and insect forms.

Vector system: pGEM or pBluescript based bacterial shuttle vectors engineered to enable parasite gene expression or modulation in the parent organisms using a tetracycline regulated inducible expression system. These are non mobilisable shuttle vectors. Specific vectors are pET series, pGem, pGemT-easy, pLew100, pZJM, pBluescript II, p2T7, pHD451 and pHD430.

Origin & function

1. T.brucie spp. genes or proteins implicated in transport processes (eg chromosomal segregation) and chromatin organisation of the parasite. Their function is expected...
To address issues of gene regulation and genome stability.

2. Reporter gene expression to allow selection of transgenic parasites or detection of the expression pattern or location of those proteins described in (1). This will include genes for resistance to antibiotics used for parasite selection and green fluorescent protein gene fusions for protein localisation.

Evaluation of foreseeable effects

Depending on the specific class of proteins under investigation we are expected to see range of phenotypes. These will include defects in nuclear segregation, chromosome instability, abnormal cell morphology, or even lethality. The under investigation genes will be expressed using a tetracycline inducible expression system. Therefore, in the absence of tetracycline the genes are effectively silenced. A similar inducible system will be used for experiments using RNA interference to ablate specific proteins of the cell.

Antibiotic resistance genes used for selection of transgenic parasites are not those used for clinical treatment of the parasite and will otherwise have no foreseeable effect.

Reporter genes (*eg green fluorescent protein) are for localisation and assay of expression pattern for particular parasite genes or sequences. There is no foreseeable consequence of this.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

T.brucei spp. does not produce spores. They are rapidly killed outside of the culture vessel or blood by desiccation osmotic shock (washing with water, detergents) and cannot penetrate unbroken skin. Parasite genes are expressed or perturbed using a tetracycline inducible system and will be effectively silenced outwith the culture vessel. Tsetse flies are required for transmission and completion of the life cycle; these are indigenous only in sub Saharan Africa. Thus the parasites, whilst mammal infective as the bloodstream forms are effectively deficient in mobilisation capacity. The wild type bloodstream form parasite is mammal infective and virulent. It is highly unlikely that genetic modification will enhance this; rather gene manipulation is likely to reduce virulence and transmissibility.

We request derogation from Containment class III to containment class II for specific containment measures.

CONTAINMENT MEASURE:

1. Isolation. The laboratory is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised lab personnel. The laboratory has been designed as a fully functional level 3 facility since a previous project, now discontinued, used this facility to experiment on Mycobacterium tuberculosis.

2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation.

4. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.

5. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow. However, as stated under 1. the lab does have negative pressure that is maintained at all times.

6. Filtration of extract and input air. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms. These are opened only in a microbiological safety cabinet with HEPA filtration. We request derogation to level 2. However as stated
under 1 the lab does have filtered extract and input air.

7. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms although purification of parasites from blood is not practical in a safety cabinet. However, there is no generation of aerosols. The laboratory is self contained providing containment. We request derogation to level 2.

8. Autoclave in the laboratory suite. The laboratory is equipped with a build-in-the-wall, two-sided access autoclave which will be used to sterilise all equipment that has come into contact with parasites. Spillages are rendered non-infective by soaking in 2% Virkon. Transport within the laboratory is in sealed containers. However, we request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood:blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2. However, as stated under 1. The lab does have a built-in shower.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A laboratory scale project employing good microbiological practice and good occupational safety and hygiene.

Disinfection with 2% aqueous Virkon solution according to University Policy and Guidance document. Material that has come into contact with parasites is inactivated by soaking in hypochlorite (1:500) for 24h.

Liquid waste and solid waste (other than sharps) is sterilised in an autoclave maintained and validated by the manufacturer’s service organisation for the destruction of clinical waste prior to transfer by a licensed operator to a commercial incinerator site authorised to treat GM waste. Sharps and animal waste are transferred directly to the incinerator for destruction.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GM committee endorsed the decision of the local GM committee (dated 20/2/2004) that this project requires Containment Level 2 facilities that are available in the Microbiology Containment Laboratory in the Department. No special problems were identified that could not be contained by Good Microbiological Practice. It was noted that Group II organisms were involved and that HSE approval was required before work could start.

Please enter comments of the GM safety committee on the risk assessment

THE ORIGINAL RISK ASSESSMENT HAD GIVEN AN ACCESS FIGURE (UNDER THE BRENNER SCHEME) OF 10/1. ON FURTHER INVESTIGATION, WE FOUND THAT THE ACGM GUIDANCE NOTES (PART 2A, ANNEX II, PART III) SAY THAT BL21 CELLS MAY BE GIVEN A VALUE OF 10. THE RISK ASSESSMENT WAS ALTERED AND A CONTAINMENT LEVEL OF 2 WAS GIVEN TO THE PROJECT. IT WAS AGREED THAT ALL WORK WOULD BE CARRIED OUT IN THE GENETIC LAB AND THE PROJECT WAS SIGNED OFF.

For activities involving GMMs, describe the waste management measures which will apply to the activity

A built-in fully serviced (regularly) autoclave will be used for all heat inactivation. Monitoring tape will be used on waste vessels as a back-up indicator to ensure complete heat inactivation cycles. This autoclave is in the same building as the laboratories used, and waste will be disinfected using 30 g/l to minimise GMO growth while awaiting heat inactivation. All solid waste (plastic ware) will be autoclaved then incinerated as clinical waste. The above processes will ensure 100% kill and limit the risk of escape to the environment to effectively zero. Local rules will be displayed in all GM labs and on the Company Intranet to advise on both safe handling and disposal of GM's. All relevant staff will be trained on GMM handling as part of the Company induction process. Regular audits of GM practice will be performed by members of the GM Committee.

Project Ref 795/01.1

Date Ackn'd 30/11/2001

Date Project Ceased 12/09/2003

Class CultureVol

Class 2 1-50 litres

Consent Granted not applicable

Project notified under transitional arrangements N
The purpose of this work is to allow the pharmacological evaluation of novel chemical entities which may interact with mammalian ion channels and receptors (e.g. HERG channels are the molecular target responsible for the cardiac toxicity of many pharmaceutical agents. Evaluation of the degree of interaction of a novel chemical entity with recombinant HERG channels will therefore allow an assessment of the likely cardiac side-effects of the novel chemical entity).

HEK293 (Human embryonic kidney cells, clone 293) is a cell line with epithelial morphology which was first created in the 1970s by treating human embryonic kidney cells with sheared fragments of adenovirus type 5 (Ad5) DNA (Graham et al, J Gen. Virol., 36, 59-72). The cells contain about 22% of the viral genome, including Ad5 early region E1A. The expression of the E1A has made these cells a popular host cell line, as expression of recombinant proteins driven by an SV40 promoter are maximized (since the SV40 is activated by E1A product). Since the late 1970s, HEK-293s have been commonly used for the cultivation of adenoviruses, and the expression of recombinant mammalian (including human) membrane receptors and ion channels, and numerous other mammalian proteins. There is no evidence for the presence of infectious virus or toxic products in HEK293 cells (see ECACC [European Collection of Cell Cultures] guidelines for these cells [ECACC 85120602]). The oncogenicity of these cells has been evaluated: Injection of 10-20 million cells subcutaneously into 5-6 week-old "nude" mice. After 6-8 weeks no tumours were visible and the animals re-injected. After 15-20 weeks after the first injection tumours became apparent in a small proportion of treated animals (In contrast, Ad5 DNA transformed rat or hamster cells induced tumours in 90-100% of injected mice within 3-6 weeks).

Commercial mammalian expression vectors, such as pcDNA3, or its later derivatives, will be used. Such vectors are considered non-mobilizable.

The ion channel/receptor genes to be expressed will either be obtained commercially, or from academic institutions, or from the USA parent company of Millennium Pharmaceuticals. Genes obtained from these sources will first be sub-cloned into the mammalian expression vectors referred to above prior to any further work. The expressed protein products of the genes expressed in HEK-293 cells will be used in a variety of pharmacological assays designed to assess the interaction of small molecules with these proteins.

HEK293 cells, when injected in large numbers, have been reported to produce tumours in nude mice (see above). The live cells should therefore be considered potentially oncogenic to humans. For this reason alone it is suggested these cells should be handled at containment level 2. Such a classification is consistent with the category 2 containment level recommended by ECACC for these cells.
The expressed proteins are unlikely to alter the pathogenicity of the cloning host, except in so much as indicated below. Furthermore, HEK-293 cell lines expressing a wide variety of receptors and channels are reported to exhibit no significant alterations in growth or morphology characteristics from the parental cell line.

As a protein normally expressed on the extracellular surfaces of cells, recombinant channels and receptors might conceivably present a hazard if personnel were to develop antibodies to these proteins, and thereby develop an autoimmune reaction. However, the expression of similar membrane proteins in HEK-293 cells, and in other mammalian cell hosts, has never given rise to a single reported incidence of this type. The risk must therefore be considered minimal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The HEK-293 cells, and HEK293 cells transfected with mammalian ion channels and receptors would be grown, harvested and processed to membrane preparations using published methods. All plasticware would then be autoclaved and disposed of by incineration. Culture media supernatant will be disposed of by addition of virkon to 30g/litre, and heat inactivation by autoclave. Cells will be pelleted by centrifugation and then processed into membranes by using a tissue homogenizer. Homogenizers and related equipment will be disinfected with virkon and subsequently water. All processes will be designed to minimize exposure to the operator in the form of aerosols (all such activities, such as homogenization, will be carried out in a fume hood). All processes for disinfection and disposal will be validated prior to regular use with HEK293 cells.

In the event of spillage from the flasks either within the incubators or the laboratory, the area can be disinfected, effectively. This will be performed using virkon solution (1%) followed by 70% alcohol wipes. For laboratory operations a standard containment level 2 facility will be used. This, in combination with the use of good cell culture practice will be sufficient to limit contact with humans and the environment.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All plasticware and cells for disposal would then be autoclaved on site, then taken off-site by a licenced clinical waste disposal company and disposed of by incineration. Culture media supernatant will be disposed of by addition of virkon to a final concentration of 1% virkon, left to stand overnight, and then disposed of as aqueous waste in the normal water supply waste system.

Daily, weekly and quarterly inspection and maintenance is carried out and documented on the autoclave, according to the manufacturers instructions.

Virkon used at a final concentration of 1% is a powerful broad spectrum disinfectant, with efficacy against 61 different strains of virus falling into 19 virus families, 397 different strains of bacteria in 42 genera, 102 strains of fungi in 26 genera. Virkon also has a very favourable eco-toxicity and biodegradability profile, and is recommended for use by disposal in the normal water supply system (see www.antechh.com for further details on virkon). The use of virkon to successfully kill HEK293 cells does not appear to have been documented in the literature. For this reason, all disinfection and disposal procedures using virkon to dispose of HEK293 cells will be validated and documented prior to regular use with HEK293 cells.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
GMSC agree with the evaluation of this work, ie; that it should be considered class 2. In connection with the attached Risk Assessment, a concern was raised over documenting the training of lab personnel to work at this level of containment. It was agreed that training should be documented as a separate item on the "COSHH and safety training record" form for each individual worker.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee Members: Research Programme Manager, Research Director, Laboratory Manager, Biological Safety Officer, Administration Representative and the Consultant Biological Safety Officer.

The function of the GMSC: Provide advice on, review and approve risk assessments submitted to it for approval to start GMO activities. Review the progress of GMO activities. The GMSC will meet at least every 3 months or sooner once a risk assessment has been submitted for approval.

GM laboratory waste will be inactivated by means of autoclaving with validated autoclave cycles to ensure that the load is maintained at a minimum temperature of 121°C for a minimum of 15 minutes to effectively produce 100% kill. The temperature and time of the autoclave cycle is printed out by the autoclave chart recorder which has been calibrated for accuracy.

The autoclave will be re-validated on an annual basis using UKAS certified independent thermocouples placed in the centre of the load.

Liquid waste that has been autoclaved will be emptied to drain.

Solid waste that has been autoclaved will then be transported off site by a registered contractor for incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Give brief details of the genetic modification safety committee

Composed of Special Projects Manager, acting as Company Safety Officer, with view to overall safety issues; target development leader, acting as Biological Safety Officer, with a view to laboratory based safety issues; Science Officer who manages all science in the laboratory and the Science Director who determines the nature of the science the company undertakes. The GMSC meets to discuss all new projects and to review current company policy on safety and other GM issues. Meetings are held quarterly and additionally, as required.

Y

Give brief details of the genetic modification safety committee

The GMSC will initially consist of three members (of the current seven employees) and will expand as the company expands to incorporate representative of all involved employees. The current makeup is:
- Chairman and Biological Safety Officer
- The Chief Scientific Officer, as a representative of senior management
- Staff representative
- An external specialist advisor will be consulted on an ad hoc basis where necessary to supplement internal expertise
- As new employees are recruited, the following two additional people will be elected to the GMSC:
  - A representative of the Research Scientists (currently only Senior Research Scientists are employed)
  - A representative of the Technical Staff (as above, no technical staff are currently employed).

The Diversys GMSC will meet on a quarterly basis, or whenever necessary for company needs. Its remit is to advise on risk assessments made on new GMO activities, or proposed changes to ongoing activities, under the Genetically Modified Organisms (Contained Use) Regulations 2000.

Yes

All solid waste contaminated by GMMs and bacterial cell pellets to be disposed of by autoclaving, followed by incineration. This disposal route is considered to give essentially 100% kill of E.coli. The site autoclave is routinely tested for temperature and pressure attainment, and verification of waste inactivation.

All GMM liquid wastes to be inactivated by addition of Virkon to >0.25% final concentration, allowed to stand for 30 mins and then disposed of down sinks.

Contaminated reusable glass and plastic ware will be similarly disinfected with 0.25% Virkon prior to washing. Virkon has been shown to give >6 logs of kill of E.coli under these conditions (source: Antec International). This will be verified by streaking of a sample of the inactivated fluid onto Luria agar plates, which should show no growth if inactivation is effective.

These procedures will reduce any risk to humans or the environment to effectively zero.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

This application was considered by circulation. The work involves standard antibody repertoire expression and selection, with subsequent expression of the selected antibody. The feature where this differs from many such projects is in the expression of human cDNA libraries for use in screening. The libraries are from healthy individuals (and anonymous, so there is no ethical problem if anything unexpected is detected) and are only expressed as trace amounts of protein. Moreover, expression is in E. coli and no refolding will be undertaken, rather the cytoplasm used directly so that the protein (or fragments of it) will be denatured and highly unlikely to display any potential activity. The work falls naturally into Class 1, requiring only Containment Level 1.

**Recipient or parental organism**

E. coli JM105 (thi, rpsL(Str ), endA, sbcB15, hsdR4, supE_ (lac-proAB), f[traD36,proAB+, lacIq, LacZ_M15]), supplied by Amersham Biotech, Amersham, UK.

E.coli NovaBlue (endA1, hsdR17(rk12-,Mk12+), supE44, thi-1, recA1, gyrA96, relA1, lac[f'proA+B+,lacqZ_M15_Tn10(tet)], supplied by Novagen, Madison, USA).

E.coli XL1 blue (recA1 endA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [FcproAB lacIq ZDM15 Tn10 (Tet)] (Stratagene).

The host E coli strains NovaBlue, XL1blue and JM105 are E. coli K12 derivatives and have a long history of safe use. They are non-colonising and multiple disabled. In terms of environmental safety, the host strains are multiply disabled, and are unlikely to survive in the environment, and considered non-pathogenic to humans or animals.
The plasmids are well characterised, non-mobilisable, derivatives of commercially supplied plasmids with an established history of safe laboratory use.

**Host/vector system**

The cDNA encoding human TNF-alpha will be obtained from the Medical Research Council Laboratory of Molecular Biology, in either the native human form, or the E. coli codon optimised form. Native TNF is expressed in the human as an inactive membrane-bound 233 amino acid precursor, which becomes active upon cleavage between residues 76-77. We will clone the truncated cDNA, encoding the active portion of the molecule in-frame with the N-terminal epitope tags His6 and HA or FLAG. Induction of expression with IPTG (isopropylthiogalactoside) will result in the production of a soluble TNF-alpha fusion protein, which is likely to be biologically active. This fusion protein will be affinity purified on nickel based resin, and eluted with imidazole to produce epitope-tagged TNF-alpha, which may be further purified.

The intended function is therefore to produce active soluble TNF-alpha.

**Origin & function**

TNF-alpha is a pro-inflammatory cytokine, produced mainly by activated monocytes and macrophages, and appears to be a key mediator in the induction of cytokine cascades associated with inflammatory responses. Recombinant human TNF-alpha has been used in a number of clinical trials as an anti-cancer therapy with intravenous doses of up to 300mg being tolerated (eg F Lejeune et al (1994) Journal of Cellular Biochemistry 56:52-61).

The most likely effect of accidental ingestion or injection of recombinant TNF-alpha would be localised inflammation and pyrexia. It is extremely unlikely that a person could be exposed to TNF-alpha levels exceeding the levels used clinically through the experimental work above. Even if all native gut flora were replaced with E. coli harbouring the plasmid encoding the TNF-alpha fusion protein, in the absence of induction protein expression levels are low, and unlikely to exceed this level. There is also a small risk of anaphylaxis, although this risk is common to many proteins, and the Class 2 precautions that this work will be done under will reduce this risk to effectively zero.

The planned experiments utilise disabled host strains that are unlikely to survive in the environment. In terms of environmental safety, the host strains are multiply disabled, and are unable to survive in the environment, and considered non-pathogenic to humans or animals. The expression of a pro-inflammatory cytokine is unlikely to enhance the pathogenic potential of the final GMO, and may decrease any such potential, by inducing a more potent immune response.

**Evaluation of foreseeable effects**

TNF-alpha is a pro-inflammatory cytokine, produced mainly by activated monocytes and macrophages, and appears to be a key mediator in the induction of cytokine cascades associated with inflammatory responses. Recombinant human TNF-alpha has been used in a number of clinical trials as an anti-cancer therapy with intravenous doses of up to 300mg being tolerated (eg F Lejeune et al (1994) Journal of Cellular Biochemistry 56:52-61).

The most likely effect of accidental ingestion or injection of recombinant TNF-alpha would be localised inflammation and pyrexia. It is extremely unlikely that a person could be exposed to TNF-alpha levels exceeding the levels used clinically through the experimental work above. Even if all native gut flora were replaced with E. coli harbouring the plasmid encoding the TNF-alpha fusion protein, in the absence of induction protein expression levels are low, and unlikely to exceed this level. There is also a small risk of anaphylaxis, although this risk is common to many proteins, and the Class 2 precautions that this work will be done under will reduce this risk to effectively zero.

The planned experiments utilise disabled host strains that are unlikely to survive in the environment. In terms of environmental safety, the host strains are multiply disabled, and are unable to survive in the environment, and considered non-pathogenic to humans or animals. The expression of a pro-inflammatory cytokine is unlikely to enhance the pathogenic potential of the final GMO, and may decrease any such potential, by inducing a more potent immune response.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

*not applicable*

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

*No containment derogations are being applied for.*

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste contaminated by GMMs and bacterial cell pellets to be disposed of by autoclaving at a load temperature of 121 degrees C for 20 minutes. This disposal route is considered to give essentially 100% kill of E. coli. The site autoclave is routinely tested for temperature and pressure attainment, and verification of waste inactivation.

All GMM liquid wastes to be inactivated by addition of Virkon to >0.25% final concentration, allowed to stand for 30 min and then disposed of down sinks, with additional running water to dilute the waste.

Contaminated re-useable glass and plastic ware will be similarly disinfected with 0.25% Virkon prior to washing. Virkon has been shown to give >6 logs of kill of E. coli under these conditions (source: Antec International). This will be verified by streaking of a sample of the inactivated fluid onto Luria agar plates, which should show no growth if inactivation is effective.
These procedures will reduce any risk to humans or the environment to effectively zero.

The application was considered by the GMSC to be at class 2. The host/vector system used is of minimal hazard, but hearing in mind the potential biological activity of the cytokine produced, class 2 working was considered appropriate to contain all potential hazards.

Please enter comments on the GM safety committee on the risk assessment

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Protein L is a cell wall protein of *Peptostreptococcus magnus*. It has a multiple domain structure, consisting of an A domain, and five B domains, termed B1-B5 which are homologous IgG binding domains. The remainder of the protein anchors it to the peptostreptococcal cell wall.

Domains B1-B4 have been cloned into a E. coli expression vector, pJB, to give plasmid pAL15M, which will be transformed into E. coli RV308. On induction with toluic acid, expression of intracellular protein consisting of domains B1-4 is induced. The protein is released from the cells by freeze-thaw cycling and further purified.

The resulting protein is a high affinity capture and purification reagent for mammalian immunoglobulins and light chain antibody fragments.

**Recipient or parental organism**

RV308 ( (lac)X74 galPO-308::IS2 rpsL). Source ATCC. An E. coli K12 derivative, non-colonising.

**Host/vector system**

pAL15M. Kanamycin resistant, toluic acid inducible expression of insert protein. Mobilisable, OriV and OriT wild type from RK2 are present.

Expression is induced in this system using the specific inducer toluic acid. Expression levels in the absence of inducer are low.

**Origin & function**

Insert DNA originally from *Peptostreptococcus magnus*. Contains the B1-B4 domains of protein L, giving a high affinity IgG binding protein. This will be produced as soluble functional intracellular protein once the culture has been induced with toluic acid.

**Evaluation of foreseeable effects**

The full length protein is a bacterial superantigen. Expression of the protein in *Peptostreptococci* sp. Correlates with virulence. Expression as a cytoplasmic protein would not be predicted based on the available evidence to make the E. coli pathogenic, as the proteins role in pathogenesis correlates with cell surface expression in the wild-type organism.

The B1-B4 domain shown here will also act as a superantigen, and has been shown to stimulate B cel proliferation in a polyclonal fashion, and to cause depletion of
subsets of B-cells via apoptosis. Thus the protein may be expected to have immunological effects.

The protein has also been shown to trigger histamine and other cytokine release from mast cells and basophils via cross linking to surface IgEs. Therefore it has the potential to cause anaphylaxis on inhalation or absorption.

The protein may be a sensitiser, and thus skin contact or inhalation must be avoided.

The use of mobilisation competent vector makes transfer to related species more likely. However, expression from a mobilisation defective vector has been shown to be lower, therefore requiring larger culture volumes and increased risks (Affitech data not shown).

Various Peptostreptococci are already found in the environment, some of which express Protein L as a superantigen. Therefore, with the containment used within the lab, together with the inactivation methods used, makes the risk of any additional environmental hazards effectively zero.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Spills will be disinfected with solid Virkon powder. This has been tested by plating experiments on shake flask cultures and low cell density fermentation to give assentially 100% inactivation of organisms in split media.

Fermenters will be sterilised post fermentation at 121 degrees C for 60 minutes. This has been shown to give 100% inactivation of organisms.

Liquid waste and spent culture medium will be sterilised by autoclaving at 121 degrees C for 60 minutes. This has been shown to give 100% inactivation of viable organisms. Sterile liquid waste will then be offsite incinerated.

Centrifuge bottles and solid wastes will be sterilised by autoclaving as above. This has been shown to give 100% inactivation of viable organism. Solid waste will then be offsite incinerated with the clinical waste stream.

Re-usable lab items will be disinfected in >2% Virkon for >30 minutes. This has been demonstrated to give essentially 100% kill of viable organisms. They will then be washed.

Additional testing of inactivation will be performed, where necessary, by streaking samples onto 2xTY plus kanamycin plates.

All items to be cleaned will be kept wet to avoid the production of dry material containing Protein L with dust hazard potential and cleaned promptly.
The application of the expression of Protein L using the Affitech HCD fermentation protocol was approved at class 2 as DM38, and will be notified to the HSE.

Emphasis must be placed on the potential for sensitisation and anaphylaxis for the protein, under COSHH. All work with this system must be covered by SOPs for exposure control and cleanup. These will be drawn up and approved before work can start.

## Project Additional Information

### Purposes of the contained use

Generation of a potential therapeutic compound with extended in vivo half-life.

### Recipient or parental organism

E. coli will be transformed with an expression construct with the intention of maximising expression levels of the fused protein. It has been shown that periplasmic/soluble expression of this cytokine in E. coli results in active protein. In vivo, the protein is known to affect cell growth and development and in clinical trials has been shown to cause a range of effects, both local and systemic. The Domantis GMSC considered the possibility of deleterious effects due to this GMO warranted classification to CL2.

Likewise P. pastoris will, in all probability, secrete active protein. It is considered that the recipient organism in this instance is less liable to colonise or persist in the environment, and this work is therefore classed at CL1.

### Host/vector system

E. coli stains based upon the genetic backgrounds K12 (TOP10f', JM83, HB2151), W (Mach I) and B (BL21) will be used for cloning and expression work. Vectors used will be based upon the commercially available vectors pET21 and pET23, and the Domantis vector pDOM5. The pET vectors contain the T7 promoter under IPTG control; pDOM5 contains the lac promoter under IPTG control. None of the vectors are considered mobilizable.

### Origin & function

The cDNA for cytokine will be created synthetically under contract. The genetic material for the half-life extending moiety derives from Domantis phage libraries. In these constructs this functionality will be inactivated.

The expression constructs generated will be used to direct the production of a recombinant fusion protein, different strategies will be employed based upon refolded inclusion bodies as well as soluble secreted protein. It has been assessed that the fusion expressed in inclusion bodies results in a less hazardous GMM that can be manipulated under CL1. Soluble material will also be produced in mammalian cell culture. Due to the nature of this expression system, it is also considered to be suitable for manipulation at CL1, although for sample protection it will be handled at CL2.

### Evaluation of foreseeable effects

The cytokine is a potent growth factor, with a pleiotropic range of biological effects. Two distinct receptors exist though the specific roles of these distinct molecules has yet to be fully elucidated. The cytokine has been shown to be mitogenic for certain cancer types including breast cancer, and mutations in one of the receptors are associated with a range of adverse effects in affected individuals.

The production of a fully functional cytokine from genetically modified E. coli has the potential to, in a worst-case setting, expose workers to the effects of the cytokine, which are reportedly related to various types of pain. The formatting with a half-life extending moiety has the likely effect of extending the residence time in the circulation of anyone that may become exposed to the cytokine. This will be unlikely to occur in these compounds where the function will be inactivated; however the larger molecule may still have some minor half-life extension. Although E. coli strains being used are disabled, it is the recommendation of the GMSC that additional containment in line with CL2 regulations are applied for this work.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste contaminated by GMMs and bacterial cell pellets to be disposed of by autoclaving at a load temperature of 121°C for 20 minutes. This disposal route is considered to give essentially 100% kill of E.coli. The site autoclave is routinely tested for temperature and pressure attainment, and verification of waste inactivation. All GMM liquid wastes to be inactivated by addition of Virkon to >0.5% final concentration & allowed to stand for 30 min. Waste collected in autoclavable carboys and autoclaved prior to disposal via sink with copious amounts of water. Contaminated re-useable glass and plastic ware will be similarly disinfected with 0.5% Virkon prior to washing. Virkon has been shown to give >6 logs of kill of E.coli under these conditions (source: Antec International). This will be verified by streaking of a sample of the inactivated fluid onto Luria agar plates, which should show no growth if inactivation is effective. These procedures will reduce any risk to humans or the environment to effectively zero.

Is an emergency plan required according to regulation 20? N

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Tick to confirm that you have attached a risk assessment to this form N

Please enter comments on the GM safety committee on the risk assessment

The application was considered by the GMSC to be at class 2. The host/vector system used was considered to be of low hazard, but attention was paid to the potential biological activity of the cytokine produced and the likely extended half-life in the event of serum exposure. Therefore class 2 working was considered appropriate to contain all potential hazards.

Y

**Give brief details of the genetic modification safety committee**

The Genetic Modification Safety Committee consists of a Research Director, a Research Scientist employee (who has attended a 2-day course on genetic modification at Leeds University) and a Scientific Consultant from the Department of Genetics, University of Cambridge.

The Committee will meet as and when necessary depending on when there are any proposed changes to working conditions, equipment, level of GMO etc. The committee will review copies of all relevant documents raised within the company regarding safety aspects of genetic modification.

02/03/2022
All liquid cultures and plastics and glassware etc. contaminated with bacterial cultures will be stored in the laboratory until they are autoclaved. No more than 1 litre (in 100 ml volumes) will be allowed to accumulate in the laboratory before autoclaving. Similarly, autoclave bags will be treated as soon as they are full.

The autoclave is in a central facility provided by the Babraham Research Institute and its efficacy is monitored regularly. Autoclaved waste is then sent for incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

I confirm that the comments from all members of our GM Safety Committee are that the risk assessment and all other information given in form CU1 is acceptable and correct.
**Project Additional Information**

**Purposes of the contained use**

Contained use will allow the modification of a suitable vector to include a gene which will inhibit the growth of the ACDP hazard group 2 organism S. aureus and for this vector to be maintained in an S. aureus strain.

**Recipient or parental organism**

S. aureus strains are classified as ACDP hazard group 2 organisms, capable of colonisation and infection of humans and animals as well as survival in the general environment.

**Host/vector system**

The host comprises a strain of S. aureus and the principal vectors include non-mobilisable plasmids of both S. aureus and E. coli.

**Origin & function**

The gene to be used and the protein itself, are ubiquitous in the environment. The intended function of the protein is to inhibit growth of pathogenic bacteria. A suitable marker gene will also be included to track the presence of the proposed gene.

**Evaluation of foreseeable effects**

As an ACDP hazard group 2 biological agent, S. aureus is pathogenic to humans and animals, and capable of survival and growth in the environment. The possibility of gene transfer between S. aureus strains is possible. However, expression of the proposed gene in recipient bacterial cells will most likely lead to cell death and the propagation of any natural vector containing the gene would therefore be minimised or inhibited. Thus, whilst a risk to human health has been identified in the pathogenic nature of wild type S. aureus, none would be directly associated with the presence of the proposed gene. In fact, the gene may actually reduce the overall fitness of the GMM, and therefore the risk to both human health and the environment.

The use of the proposed marker genes would not result in the introduction of novel resistance determinants or the production of hazardous compounds in the natural S.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Appropriate disinfectant will be added to spent liquid cultures. This waste will not be stored for more than 3 days and no more than 1 litre combined volume will be allowed to accumulate before autoclaving.

Plates and other contaminated waste including plasticware will be discarded to autoclave bags and autoclaved as soon as the bags are full. The autoclave is in a central facility provided by the Babraham Institute and its efficacy is monitored regularly. Autoclaved waste is then placed into leak-proof containers and collected for incineration by a Babraham Institute appointed organisation.

Give brief details of the genetic modification safety committee

A local Genetic Modification Safety Committee (LGMSC) has been established consisting of four individuals, two from within the company (Chief Operating Officer and Principal Scientist). The University of Edinburgh staff are both involved with daily operation of the University LGMSC scheme. The Committee reviews risk assessments of proposed projects prior to their commencement and will notify HSE accordingly. Meetings are held on a quarterly basis to review the validity of any current risk assessments. The minutes of these meetings together with copies of all Risk Assessments performed and decisions taken are held by the BSO. Annual returns to the HSE will also be held by the BSE. Copies of the Regulations and The Compendium of Guidance are also held by the BSE. These are available for consultation by all company staff but must be signed out.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

In vitro generation of pure populations of cell types by genetic selection... Embryonic Stem Cells.
All such laboratory waste will be disposed of by autoclaving and/or incineration. This will be achieved using existing University of Edinburgh procedures and facilities. The efficient operation of autoclaves is ensured by regular servicing by qualified engineers.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The committee were satisfied that the risk assessment SCS001 had been undertaken satisfactorily but felt that the inclusion of the following details would make it easier to understand for the general public.
1. The Encephalo Myocarditus Virus IRES sequence to be used should be referenced
2. The calculation of risk should be explained better
3. The fact that mouse cells are manipulated in class II laminar flow hoods should be included in Section 3 stages II and IV

All of these points have been addressed in the enclosed Risk Assessment.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
### Waste Management

All waste material is routinely inactivated by sterilisation in an autoclave. This procedure will effectively result in a 100% kill of GMMs.

Validation of the sterilisation procedure is via annual testing of the autoclave using independent thermocouples.

Verification of routine inactivation is by a load probe monitored by chart recorder, and by the inclusion of test indicators.

### Project Additional Information

- Project notified under transitional arrangements N

---

**Historical Significant Changes**

- Historical Date of Additional Info
- Significant Change ID
- Date of Significant Change
### Purposes of the contained use

Creating strains of Staphylococcus aureus to be used in research into the discovery of antibiotics.

### Recipient or parental organism

Staphylococcus aureus 8325-4 and derivatives.

### Host/vector system

Vectors based on the non-mobilisable Bacillus subtilis vector pUB110.

### Origin & function

The origin of the genetic material is chromosomal DNA from various bacteria, including non-pathogenic and pathogenic (human pathogens from ACDP Class 2) bacteria. The genetic material comprises a number of housekeeping genes which are involved in normal metabolic processes in bacteria including the biosynthesis of vitamins, cofactors and amino acids. These genes are obtained by PCR amplification of DNA and sequenced prior to insertion into Staphylococcal cloning vectors such that the inserts are well-characterised. The inserted genetic material is intended to result in the over-expression of housekeeping genes.

### Evaluation of foreseeable effects

The results of the GM work will be to produce strains of Staphylococcus aureus that over-express genes coding for housekeeping proteins. These proteins are not involved in virulence mechanisms or pathogenicity and are therefore very unlikely to increase the pathogenicity of the host bacteria. Staphylococcus aureus 8325-4 is recognised to be a disabled strain and non-colonising towards humans. The possibility that over-expression of housekeeping genes could increase the pathogenicity of Staphylococcus aureus 8325-4 is negligible. Since the work will be carried out in a Level 2 containment laboratory, the level of containment applied to safeguard human health will also be sufficient to protect the environment.

Conclusions. The work is highly unlikely to have any effects on human health or the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Type and form of waste: General laboratory microbiological waste - GMMs in liquid cultures, and on agar plates, contaminated plasticware and glassware. Inactivation: All waste material is inactivated by sterilisation in an autoclave. This procedure will effectively result in a 100% kill of GMMs. Validation of the sterilisation procedure is via annual testing of the autoclave using independent thermocouples. Verification of routine inactivation is by a load probe monitored by chart recorder, and by the inclusion of test indicators.
Fate of waste: Inactivated liquid waste will be discharged into the waste water system. Inactivated solid waste will be disposed of by incineration.

The genetic modification safety committee considered that the control measures to be applied would prevent exposure to the hazard.

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee considered that the control measures to be applied would prevent exposure to the hazard.

Yes Yes Yes Yes
For activities involving GMMs, describe the waste management measures which will apply to the activity:

- **Solid waste** — Autoclaved, Essentially 100% kill, validated annually & in line temperature probe.
- **Liquid waste** — 1% Virkon; overnight exposure. Essentially 100% kill. Disposal into the drain, with liberal dilution using tapwater.

### Project Additional Information

**Purposes of the contained use**

To introduce DNA sequences of interest such as drug metabolising genes, reporter genes and inducible regulatory elements into recipient mammalian cell-lines to develop non-animal toxicological screens which facilitate drug-development.

**Recipient or parental organism**

Well characterised packaging cell-lines eg African green monkey kidney (VERO76)  
Commercially available, immortalised mammalian cell-lines such as MCF7, HepG2 and CHO. Primary cell-lines eg mouse, rat, human.

**Host/vector system**

Only well-characterised, replication deficient viral vector systems with a history of safe use will be used eg Virapower derived from the Human Immunodeficiency Virus 1 (HIV-1) genome and iBAC derived from Herpes Simplex Virus-1 (HSV-1) and Epstein-Barr Virus (EBV) genomes.

**Origin & function**

Viral genetic materials will be obtained from the licensed vector systems and used according to the manufacturer's protocols.

DNA sequences to be packaged for the generation of mammalian cell-lines shall be constructed de novo from synthetic oligonucleotides or PCR-amplified from plasmid, cDNA, BAC or genomic sources. Propagation and assembly shall be performed within disabled prokaryotic host strains.

The DNA sequences shall confer upon transduced cells the ability to report on toxicity by the following mechanisms:

1. Since metabolism by phase 1, 2 and 3 drug-metabolising enzymes are a major determinant of drug toxicity, the cell-lines shall be engineered to replicate human drug metabolism and consequent potential for toxicity through expression of these gene products.

2. Increases in the rate of expression of certain gene products eg CYP450s are indicative of toxicity. The intention is to place reporter genes under the direct control of inducible regulatory gene sequences to provide a convenient readout of potential toxicity.

**Evaluation of foreseeable effects**

The viral vectors used may infect a wide range of mammalian cells and though they will retain some of the properties of the wild-type virus, they shall be specially disabled to prevent proliferation outwith special packaging cell lines or in the presence of complimentary plasmids. Retroviral vectors, for example, will retain the ability to integrate into the host cell genome and stable express the gene of interest but shall be unable to replicate in any host. HSV-1 vectors will be maintained episomally and whilst they may replicate, their large size precludes them from being packaged into viable virus. Viral systems used contain additional safety features limiting the risk of the formation of wild-type virus via rare recombination events (1, 2).
The genes of interest are considered non-hazardous and are unlikely to pose a significant hazard to human health or the environment should exposure occur and no attempt shall be made to maximise the expression of a gene product. The inserted genetic materials are not expected to complement the disabled viral components and it is unlikely there will be any effect on the host range of tropism of wild-type virus should recombination occur.

All procedures involving viral vectors shall be performed at containment level 2 to prevent infection of staff or release into the wider environment.

Under ACDP guidelines wild-type HIV is a category 3 pathogen that can cause severe immunologic disease and whilst there is little risk of a wild-type pathogen being produced, the use of sharps will be avoided to eliminate the most likely route of transmission. Wild-type HSV-1 is a category 2 pathogen which, though common in the general population, can in rare cases cause encephalitis. The most likely route of transmission of the wild type virus is by aerosol thus all work shall be carried out in a class II biological safety cabinet.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

During the production of replication-defective viruses, all solid waste (plastics etc.) is placed in lined, biohazard, autoclavable bins. Non-sealable solid waste such as pipettes are rinsed in 1% Terminex prior to transfer to the autoclavable bin. Immediately following the completion of work the liners are loosely sealed and the lidded bin transported, on a trolley, directly to the autoclave facility for immediate autoclaving and disposal as controlled waste.

All liquid waste is collected in robust, autoclavable, sealable containers containing sufficient disinfectant (Terminex) to give a 1% final volume. After work the sealed container is transported, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving, liquid waste is disposed of to drain with copious amounts of cold water.

The autoclave is fitted with a thermocouple linked to a chart recorder to monitor the effective completion of the sterilisation cycle. SOPs stipulate that no material should be removed from the autoclave without first checking that the cycle was completed. The degree of kill for autoclaving is effectively 100%. The autoclaves are serviced and calibrated annually by a reputable service provider.

The use of sharps is avoided.

### For activities involving GMMs, describe the waste management measures which will apply to the activity

All bacterially contaminated waste will be autoclaved or soaked in Virkon prior to disposal. Autoclave programme will be as follows:
- 134°C for 20 minutes, 8 minutes freestream x 2 monitored using autoclave tape or soaking in a 1% Virkon solution for at least 4 hours.
- Once inactivated, waste will be tested by incubation in a non-selective broth or solid media.

All spent liquid media will be incubated overnight with 1% Virkon for sterilisation. Media will then be disposed of as normal liquid waste. All contaminated (disposable) solid waste ie pipettes, pipette tips, flasks and other plasticware will be double bagged in dedicated waste bins and autoclaved 20 min at 20 psi prior to disposal as solid waste. These procedures should ensure 100% kill of the recombinant bacteria. To test for killing efficacy in liquid media, samples will be removed periodically (3 monthly) for growth testing on L-agar plates.

Please enter comments of the GM safety committee on the risk assessment

The GMSC is satisfied that the cloning and small scale expression of the proteins described, which are mainly E.coli/S.aureus enzymes with no known pathogenic role, represents a minimal danger to Company personnel and to the environment; these proteins are ubiquitous in the environment (the E. coli proteins are present in the normal human gut flora) and have no known deleterious effects. The normal precautions outlined when undertaking the proposed GMO work ie restriction of laboratory access to authorised personnel and sterilisation/autoclaving of waste should minimise any unforeseen risk.

Project Additional Information

Purposes of the contained use

A non-pathogenic laboratory strain of Staphylococcus aureus RN4220 will be initially used to test the capacity of the transposon Tn917, housed in the plasmid pTn917-T7, to generate transposon mutants. Subsequently a second closely related transposon, Tn551, will also be used.

Recipient or parental organism

The recipient organism for transposogenesis, RN4220, is a non-pathogenic laboratory strain of Staphylococcus aureus. This strain is restriction minus, modification plus and possesses a capsule mutation rendering it non-pathogenic. The transposon mutations are likely to have different effects on the recipient depending on the function of the gene transposed and the position where the transposon inserts. If an essential gene is interrupted, the organism won't be viable, if non-essential it is expected that the organism will either be unaffected or may have a reduced viability. It is highly unlikely that the fitness of the organism would be enhanced significantly by any transposition event. Mutants which have taken up a transposon will be grown on erythromycin as a selectable marker.

Host/vector system

The host is the Staphylococcus strain RN4220. The vector is either:

1. The transposon Tn917, modified to incorporate a kanamycin resistance cassette, the pBR322 origin of replication and the erythromycin resistance gene or the backbone of pTn917-T7 contains a chloramphenicol resistance marker and a temperature sensitive origin of replication, allowing selection against the vector at temperatures above 43 degrees C.

2. Tn551 which is 99.8% identical to Tn917, and which will be modified in a similar way. The backbone of the Tn551 containing plasmid contains a Cadmium resistance marker and a temperature sensitive origin of replication, allowing selection against the vector at temperatures above 43 degrees C.

Origin & function

The transposon Tn917 and the closely related transposon Tn551 have been used for genetic studies on Staphylococcus aureus for more than fifteen years. The plasmid pET9d (Novagen) will be used as a source of the pBR322 replication origin and the kanamycin resistance cassette, the plasmid plD408 as a source of Tn917 and the erythromycin resistance gene. The engineered plasmid pTn917 will be electroporated into RN4220 cells using standard methods. Transformed bacteria will be selected on erythromycin plates, incubated at 30 degrees to induce transposition and integration into the S. aureus chromosome. Mutations will be investigated using an inverse PCR strategy to sequence the transposon/gene junctions and identify the targeted S. aureus gene.

Evaluation of foreseeable effects

This strain is restriction minus, modification plus and possesses a capsule mutation rendering it non-pathogenic. The transposon mutations are likely to have different
effects on the recipient depending on the function of the gene transposed and the position where the transposon inserts. If an essential gene is interrupted, the organism won't be viable, if non-essential it is expected that the organism will either be unaffected or may have a reduced viability. It is highly unlikely that the fitness of the organism would be enhanced significantly by any transposition event. Mutants which have taken up a transposon will be grown on erythromycin as a selectable marker.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Class 2 activity described will generate contaminated plasticware - flasks, pipettes, pipette tips and disposable tubes used in the growth of the microorganisms, and in the manipulation and preparation of plasmid and chromosomal DNA. There will also be spent media, both liquid broth and agar, used to grow the bacteria. Disposable plasticware will be autoclaved at 20 psi after collection in double bagged autoclave bags. Liquid media will be disinfected by incubation overnight in 2% Virkon. Following disinfection the media will be autoclaved as above before disposal via the drains. These disposal procedures should ensure 100% kill of microorganisms and destruction of residual nucleic acids.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The transposons described have a long history of use in the study of Staphylococcus aureus genetics; although the recipient organism falls into ACDP Category 2 the GMOs resulting from these experiments are not anticipated to display any enhanced pathogenicity, and the strain proposed has an additional mutation reducing its pathogenicity - the safe history of use of this system together with the proposed control measures and the fact that these experiments have been approved as Category 2 of the University of Cambridge Veterinary School satisfies the GMSC that the proposed work should proceed under the conditions described.

TO GENERATE LIBRARIES OF RANDOM GENE MUTATIONS IN SALMONELLA TYPHIMURIUM USING TWO WELL-CHARACTERISED TRANSPOSONS, TN5 AND TN10, TO INDUCE TRANSPOSITION BY CONJUGATION AND/OR ELECTROPORATION

Project Additional Information

Purposes of the contained use

A pathogenic strain of S. typhimurium will be used to test the capacity of the Tn5 and Tn10 transposons to generate random transposon mutants.

Recipient or parental organism

The recipient organism for transposogenesis is SL 1344, a pathogenic strain of S. typhimurium. The transposon mutations are likely to have different effects on the recipient depending on the function of the gene transposed and the position where the transposon inserts. If an essential gene is interrupted, the organism won't be viable, if non-essential it is expected that the organism will either be unaffected or may have a reduced viability. It is highly unlikely that the fitness of the organism would be enhanced significantly by any transposition event. Mutants which have taken up a transposon will be grown using selectable markers (kanamycin, gentamicin, tetracycline or chloramphenicol - depending on which mini Tn derivative is used successfully in the construction of random mutants).

Host/vector system

The host is Salmonella typhimurium SL 1344.

The vector is either:
1. The transposon mini Tn5 (modified to incorporate T7 and SP6 promoters, 2 rare homing endonuclease sites and a neomycin cassette), R6K ori, RP4 OriT and the ampicillin resistance gene or
2. The transposon mini Tn10 (modified to incorporate T7 and SP6 promoters, 2 rare homing endonuclease sites and either a neomycin, chloramphenicol, tetracycline or gentamicin cassette), R6L y ori, RP4 mob region and the ampicillin resistance gene.

Origin & function
Tn5 is one of the best studied transposons. Tn5, Tn10 and their mini derivatives have been extensively used for genetic studies of Gram negative bacteria. We will engineer the Mini Tn derivatives to contain SP6 and T7 promoters to facilitate mutant analysis on an oligonucleotide array. Mutants will also be investigated using an inverse PCR strategy to sequence the Tn/gene junctions and to identify the disrupted S. typhimurium gene.

**Evaluation of foreseeable effects**

The recipient organism for transposogenesis is SL 1344, a pathogenic strain of S. typhimurium. The transposon mutations are likely to have different effects on the recipient depending on the function of the gene transposed and the position where the transposon inserts. If an essential gene is interrupted, the organism won't be viable, if non-essential it is expected that the organism will either be unaffected or may have a reduced viability. It is highly unlikely that the fitness of the organism would be enhanced significantly by any transposition event. Mutants which have taken up a transposon will be grown using selectable markers (kanamycin, gentamicin, tetracycline or chloramphenicol - depending on which mini Tn derivative is used successfully in the construction of random mutants).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The Class 2 activity described will generate contaminated plasticware - flasks, pipettes, pipette tips and disposable tubes used in the growth of the microorganisms, and in the manipulation and preparation of plasmid and chromosomal DNA. There will also be spent media, both liquid broth and agar, used to grow the bacteria. Disposable plasticware will be autoclaved at 20 psi after collection in double bagged autoclave bags. Media will be disinfected by incubation overnight in 2% Virkon. Following disinfection the media will be autoclaved as above before disposal via the drains. These disposal procedures should ensure 100% kill of microorganisms and destruction of residual nucleic acids.

**Please enter comments on the GM safety committee on the risk assessment**

The proposed GM experiments using S. typhimurium would normally be done using a more attenuated strain; the reason for using SL 1344 is to ultimately give the investigators the potential to address the question of in vivo attenuation of transposition mutants. Given that mutants are likely to be either unaltered or attenuated in their virulence, doing these experiments in such a strain in Class 2 laboratories should not represent a problem providing the procedures for minimising hazard in the accompanying risk assessment are followed.

GENERATION OF GENOMIC MARINER TRANSPOSON LIBRARIES IN STAPHYLOCOCCUS AUREUS.

**Class** Class 2  
**CultureVolClass2** < 1 litre  
**CultureVolumeClass3-4**

**Non-GMM Consent Granted** not applicable  
**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To generate transposon libraries in S. aureus using a Mariner transposon derivative; the aim of this work is to obtain maximum coverage of the bacterial genome using this transposon system, which is known to have less propensity for 'hotspot' integration as occurs with other transposons such as Tn5 and Tn10 in E. coli, and Tn917/551 in S. aureus.

**Recipient or parental organism**

The GMOs will be bacterial colonies where an average one gene in the genome has been disrupted by transposon insertion; in nearly every case the insertion is expected to have either no effect or result in slower growth. There should therefore be no increased risk to the operator compared to the parental organism.

**Host/vector system**

The hosts are E. coli PIR1 cells (Invitrogen). These are recA and used for manipulation of the recombinant mini-Mariner transposon. The S. aureus strains are SH1000 (minor derivative of 8325), N315, MW2, Mu50, MSSA and RN4220. N315, MW2, Mu50 and MSSA are well-characterised strains which are used in various sequencing projects. RH4220 is a modified laboratory strain that is restriction minus/modification plus and used for propagating vectors.
Two vectors will be used:
TS1 has a S. aureus ts origin and chloramphenicol resistance marker, and carries a recombinant mini-Mariner transposon which will be exchanged with a second variant. The latter contains a y-ori R6K (to permit replication in E. coli expressing PIR1), a kan resistance marker (to allow vector selection in E. coli and an erythromycin resistance marker (for vector/mutant selection in S. aureus).
pFA is compatible for replication with recombinant TS1 and contains a tetracycline resistance marker and the Mariner transposon gene.

Origin & function
The mariner transposon system is used for transposition into a variety of organisms, the transposon originating from the horn fly. Transposition systems in S. aureus are limited and the mariner system offers a way of generating a random library. The intended function of the libraries thus generated is to provide templates for RNA runoffs to identify the disrupted gene in a similar strategy as in the previous notified S. aureus activity GM 804/01.1

Evaluation of foreseeable effects
The effects of transposition of mariner or any other transposon depend on the gene into which the transposon insets and also the position it inserts within the gene. If the gene is non-essential the organism is likely to be either unaffected or have reduced viability-if essential it won't grow. It is highly unlikely that any significant enhancement of viability would result from a transposition.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The Class 2 activities described will generate contaminated plasticware - pipettes, pipette tips, flasks and disposable tubes used in the growth of the microorganisms, and in the manipulation and preparation of plasmid and chromosomal DNA. Spent liquid and solid (agar) media used to grow the bacteria will also be produced. Disposable plasticware will be autoclaved at 20 psi after collection in double bagged autoclave bags. Autoclaving is validated by printouts from every run, weekly use of indicator strips and monthly by measuring the kill of Bacillus stearothermophilus spores. Liquid media will be disinfected by incubation overnight in 2% Virkon. The disinfection efficacy is periodically validated by plating out Virkon treated and untreated bacterial cultures. The disposal procedures have been demonstrated to give 100% kill of microorganisms and destruction of residual nucleic acids.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
During discussion of this proposal the possibility of enhanced virulence of a microbe if a transposon inserts randomly was raised. The consensus view was that while this is a formal possibility eg insertion resulting in enhanced promoter activity it has never been reported and reduction rather than enhancement of virulence is more likely (and is mentioned in Part 2, p2 of Arrow's Risk Assessment form for this project).

The use of erythromycin as a selective marker was also queried; this antibiotic is used in some cases of human infection. However the strains to be used are all confirmed as being MSSA ie sensitive to penicillin and derivatives; thus there is no danger of non-treatability in the highly unlikely scenario of infection with an erythromycin-resistant Staphylococcus aureus strain. The approach proposed is complementary to the original S. aureus transposon work. In addition, resistance will disappear following plasmid cure at 44 degrees. The GMSC had no further comments and approved the proposal.

Purposes of the contained use

To study the antiviral activity and mode of action of small molecule compounds against HCV.

Recipient or parental organism

The parental organism is the JFH1 strain of hepatitis C virus, an ACDP class 3 pathogen, derived from a Japanese patient with a fulminant hepatitis C infection. The virus has been shown to replicate in human hepatoma cell lines following transfection with HCV RNA transcribed in vitro. Propagation of virus therefore occurs only under defined culture conditions.

Host/vector system

Viral cDNA is propagated as a recombinant DNA plasmid in a pUC-derived vector, and the plasmid is non-mobilisable. The plasmid is maintained in E.coli strains which do not encode T7 polymerase, the enzyme required for transcription of HCV RNA from the T7 promoter.

Origin & function

The original JFH1 HCV sequence was isolated from a fulminant HCV viral infection in a Japanese patient and is a consensus sequence obtained from sequencining multiple overlapping clones derived from PCR analysis of the HCV cDNA. The virus is genotype 2a. RNA transcribed from the cloned JFH1 sequence was shown to be infectious for the human hepatoma cell line Huh-7 and to produce HCV viral particles (Wakita, T et al., (2005). 'Production of infectious hepatitis C virus in tissue culture from a cloned viral genome' Nat. Med. 11, 791-796; Pietschmann, T et al. (2006). A series of intra and intergenotypic HCV chimeras has also been described based on the JFH1 and J6CF-derived sequences (both genotype 2a). 'Construction and characterization of infectious intragenotypic and intergenotypic hepatitis C virus chimeras' Proc. Natl. Acad. Sci. USA 103, 7408-7413).

A firefly luciferase reporter gene fused to the 5'untranslated region and part of the core gene comprises the first cistron; the second cistron comprisin the HCV RNA is expressed through the encephalomyocarditis virus internal ribosome entry site (IRES) and translated into a polyprotein which is then proteolytically cleaved to produce the individual viral proteins listed below:

- C - virus capsid protein.
- E1, E2 - viral envelope glycoproteins.
- P7 - ion channel.
- NS2 - autoprotease.
- NS3 - protease/helicase.
- NS4A - protease co-factor.
- NS4B - pleiotropic functions including mediation of membranous web formation.
- NS5A - also pleiotropic functions, control of viral replication, cellular interactions/signalling.
- NS5B - RNA polymerase.

Evaluation of foreseeable effects

Transfection of cultured human liver cells with in vitro transcribed HCV RNA will lead to viral protein expression and the assembly of HCV particles. These particles are able to propagate in liver-derived cells and can be assumed to be infectious to man by the percutaneous route, the main route for normal infection. In the context of experimental data from chimpanzees, it is not foreseen that there will be an increase in the pathogenicity of the GMO's generated: productive replication in chimpanzees. Proc. Natl. Acad. Sci. USA 99, 14416-14421.

Engineering variant HCV genomes, where changes are introduced into the parental genome by construction of intra or intergenotypic chimeras or by site-directed mutagenesis, could lead to a change in the replication properties of the virus. HCV replication of any variant sequences will be monitored and recorded.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste generated within the CL3 laboratory will be handled only by trained personnel until decontaminated. Solid waste eg paper gowns, gloves, plastic pipettes, eppendorf tubes, pipette tips, will be disposed in double bagged autocleavable bags in a biohazard waste bin. The bags will be sealed prior to removal to the CL3 lobby room where they will be autoclaved in a cycle held at 134ºC for 15 mins. After autoclaving the bags will be disposed of as clinical waste by an external contractor. All solid waste will be autoclaved at the end of the working day or session. Each autoclave cycle is monitored electronically and validated. A printed record is kept of each cycle. The autoclave will be tested every six months under a maintenance contract. Biological validation of autoclave efficacy will be verified on a regular basis using ampoules of a bacterial spore suspension (Geobacillus stearothermophilus, Raven Laboratories) with the autoclave waste, which give a colorimetric readout of successful killing. This method has been used routinely in the company over the last 8 years to provide a biological validation for our main autoclave in Biology. All liquid waste will be treated with Trigene at a final concentration of 5% for at least 12 hours (in practice overnight). Trigene has been shown to inactivate enveloped viruses, and is widely used as an effective virucidal agent.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment  

The GMSC felt that the risk assessment and containment classification address the key safety issues for handling and propagation in vitro of the HCV infectious particle.

02/03/2022
All solid waste exposed to viable GMMs will be collected in a double autoclavable biohazard bag left open to allow steam penetration, and autoclaved for 20 minutes at 121 degrees C. The autoclaved waste will subsequently be disposed of by incineration. A correct autoclave procedure is considered to reach 100% kill. The efficiency of the autoclave is validated using sterilization indicator strips placed in the middle of the load and the autoclave itself is serviced and calibrated every 6 months.

All liquid containing viable GMMs, will be inactivated by incubating the sample in at least 1% (w/v) Virkon for a minimum of 12 hours. After this inactivation step, the waste will be disposed of down the sink with copious quantities of water. This chemical inactivation procedure is considered to typically result in virtually 100% kill, as shown in independent testing performed by the Virkon manufacturer (Antec International) on all retroviruses and E.Coli strains tested.

Drug Discovery (expression and purification of recombinant proteins)

For activities involving GMMs, describe the waste management measures which will apply to the activity

All members of the Safety Committee have reviewed the risk assessment and consider it adequate for the type of work proposed.

Project Ref 805/01.1

EXPRESSION OF MURINE ECOTROPIC RECEPTOR IN HUMAN CELL LINES USING AN MULV REPLICATION-DEFECTIVE RETROVIRAL VECTOR.

Class 2 Consent Granted

Consent Granted

Project notified under transitional arrangements

Class 2 non-GMM

< 1 litre
**Project Additional Information**

**Purposes of the contained use**

Drug discovery.

**Recipient or parental organism**

The introduction of the murine ecotropic receptor into human cell lines will not alter the pathogenicity of the recipient cell. They will become infectable with ecotropic retroviruses that cannot normally infect human cells, and are therefore safer to use.

**Host/vector system**

The amphotropic replication-defective retrovirus used can infect human cells but, being replication-defective, cannot propagate. Moreover, the amphotropic retrovirus cannot survive outside laboratory conditions.

**Origin & function**

The ecotropic receptor is a basic amino acid transporter expressed by murine cells and is not inherently harmful. It is also exploited by the MuLV ecotropic retrovirus for entering the target cell. Since it is not expressed by human cells, ecotropic MuLV cannot infect human cells, unless they have been modified to express the ecotropic receptor. This would allow the use of MuLV ecotropic retroviral vectors on human cells that have been modified, reducing the risk to the operator. Indeed, MuLV ecotropic retrovirus-defective work is considered to be a Class 1 activity.

**Evaluation of foreseeable effects**

The risks associated with the modified retroviral vector we intend to use are mainly related to its ability to infect human cells. This means that potentially this virus could infect the operator and for this reason only we propose a containment level of 2. In the unlikely event of such an infection occurring, the infection will not spread to other cells as the virus we intend to use is replication-defective. Therefore, the risks to human health associated with this work are very low.

The risk associated to the environment are very low too, as the MuLV retrovirus we intend to use is unlikely to survive outside laboratory conditions. In addition, as mentioned before, the virus cannot self propagate and therefore cannot proliferate in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste exposed to the GMM will be collected in a double autoclavable biohazard bag left open to allow steam penetration, and immediately autoclaved for 20 minutes at 121 degrees C. The autoclaved waste will subsequently be disposed of by incineration. A correct autoclave procedure is considered to reach 100% kill. The efficiency of the autoclave is validated using sterilization indicator strips placed in the middle of the load and the autoclave itself is services and calibrated every 6 months. In addition, the TC dishes exposed to the virus will be left to soak in 1% w/v Virkon for at least 12 hours and subsequently autoclaved.

All liquid containing viable GMMs, will be inactivated by incubating the sample in at least 1% w/v Virkon for a minimum of 12 hours. After this inactivation step, the waste will be disposed of down the sink with copious quantities of water. This chemical inactivation procedure is considered to typically result in virtually 100% kill, as shown in independent testing performed by the Virkon manufacturer (Antec International) on all retroviruses and E.Coli strains tested.

The risk assessment was reviewed by all the members of the safety committee and was considered adequate for the type of work proposed.

**Project Ref 805/17.1**

- **Date Ackn'd**: 24/02/2017
- **CU2 Project Title**: Use of Hela GFP-LC3 stable cells to screen for modulators of LC3 lipidation
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Non-GMM Consent Granted**: Consent Granted

**Project notified under transitional arrangements**: N
**Project Additional Information**

**Purposes of the contained use**

*Drug Discovery: Identification of novel compounds, which modulate LC3 lipidation*

The HeLa GFP-LC3 stable cells will be supplied by an external client. This cell line will be employed in a screening assay to identify novel compounds, which modulate LC3 lipidation.

**Recipient or parental organism**

The HeLa GFP-LC3 stable cell line was generated by transfecting HeLa cells (ATCC® CCL-2™) with a pEGFPLC3 plasmid and selecting with geneticin (G418).

**Host/vector system**

The pEGFP-LC3 plasmid used to generate the HeLa GFP-LC3 stable cell line was generated according to the reference: EMBO J. 2000 Nov 1;19(21):5720-8. Briefly, cDNA encoding rat LC3 was obtained by RT-PCR from rat brain total cDNA, which was subcloned into the EcoRI site of the eukaryotic expression vector pCL-neo (Promega, Madison, WI). The pEGFP-LC3 plasmid was generated by inserting the rat LC3 cDNA into the BglII and EcoRI sites of the pEGFP-C1, a GFP fusion protein expression vector (Clontech Laboratories). This plasmid was then employed to generate the HeLa GFP-LC3 stable cell line as described previously.

**Origin & function**

*The parental HeLa cell line contains sequences of the human papilloma virus genome (HPV18), and is therefore Biosafety Level 2, according to the ATCC. The Hela GFP-LC3 cells are therefore GMO Class 2, as they are a Biosafety Level 2 cell line, transfected with the pEGFP-LC3 plasmid. Therefore, all culture and use of the cell line must be carried out in a Class II Containment Laboratory.*

Several specific practices beyond standard aseptic technique are required for handling the Hela LC3-GFP cell line (GMO class 2). The following practices will be adhered to:

- **Signage** will be displayed outside the tissue culture lab, notifying other employees of the usage of the GMO cell line.
- **Materials should always be manipulated within a Class II safety cabinet.** A beaker of 1% Virkon should be placed in the safety cabinet and pipette tips should be decontaminated in this, prior to disposal into bin for autoclaving and incineration.
Pipettes should similarly be immersed immediately in a cylinder of 1% Virkon, prior to autoclaving and incineration.

Cell culture flasks should have the lid closed prior to disposal into biohazard bags for autoclaving.

Generation of aerosols should be minimised by careful pipetting.

Passage of GMO cell lines, should be separated in the safety cabinet from other cell lines, such that flasks of other lines are not present in the cabinet at the same time. This is to prevent any possible cross contamination between cell lines.

Use a dedicated 37°C incubator for the Hela LC3 GFP cells, to prevent cross contamination between cell lines.

Cells must also be inactivated in this laboratory in a Class II safety cabinet (e.g. by addition of detergent to generate a lysate or fixation) prior to transfer to other laboratories for analysis.

Cells should always be centrifuged in sealed buckets.

Safety cabinets must be cleaned with 1% Virkon and 70% IMS before and after use.

Public Register

Health and Safety

Executive

CU 2 2015 (rev 11/15) Page 4 of 10

All solid tissue culture waste will be collected in double autoclavable biohazard bag and autoclaved for 20 minutes at 121°C. The autoclaved waste will subsequently be disposed of by incineration by licenced contractor.

All liquid containing viable GMOs, will be inactivated, by incubating the sample in at least 1% (w/v) Virkon for a minimum of 1 hour. After this inactivation step, the waste will be disposed to drain.

Due to the containment procedures and the waste management systems described above, the risks to laboratory personal and the environment are very low. Good microbiological containment practices will be adhered to and all waste will be either be autoclaved and incinerated OR treated with disinfectant.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid tissue culture waste will be double bagged in autoclavable biohazard bags, and transported to an autoclave via a communal corridor using a leak proof trolley with a lid, which provides secondary containment. The double-bagged waste will then be autoclaved for 20 minutes at 121°C (100% kill). This procedure will be carried out at the end of each day. NB: Autoclaves are serviced twice a year and have a 12-Pen Validation test for Plastic discard waste (121°C for 15 minutes) performed annually to UKAS Quality Procedure UQP.

Following autoclaving, the bagged sterile waste will be placed into a yellow class 6.2 marked sack and placed in UN approved 7701 yellow 'wheelie bins' marked with the appropriate biohazard diamond. Grundons Waste Ltd are certified to handle and dispose Level 2 waste from the Harlow site.

All liquid containing viable GMOs, will be inactivated, by incubating the sample in at least 1% (w/v) Virkon for a minimum of 1 hour (100% kill). After this inactivation step, the waste will be disposed to drain.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Yes

Give brief details of the genetic modification safety committee

The OSI Genetic Modification Safety Committee (GMSC) will be a sub-committee of experienced biologists drawn from the Biological Safety Committee (BSC). The BSC will report to the Main Safety Committee (MSC). The MSC will represent all of the company's major functions and include senior management representation. The GMSC will review all GMO risk assessments. It will be empowered to categorise level 1 and II activities, to approve level 1 activities and to recommend BSC approval of level II; level II activities will be notified to the HSE in parallel with BSC review. The GMSC will comprise the Biological Safety Officer (BSO) (PhD scientist with >15 years GMO experience), a deputy BSO (23 years experience in molecular biology plus experience of the role in a former employment) and at least one other experienced biologist with GMO experience. The BSC will contain additional representation from within the Biology Department. Should the company appoint a Health and Safety Manager, she/he will also sit on the BSC.

Individual scientists will present their written risk assessments to the members of the GMSC prior to review to allow time for due consideration. Review will be conducted on an ad hoc basis in the form of open discussion with the involvement of all interested parties. The BSC will meet bimonthly or more frequently if required.

Tick if confidential
Contaminated solid waste and glassware will be treated by autoclaving (140min/134 degrees C/3.2bar absolute). The autoclaves are maintained and tested annually. A hard copy output detailing the temperatures/pressures achieved is generated for each run.

Culture medium/liquid waste will be decontaminated by treatment with Trigene prior to disposal via the drain (2% (v/v) final; >1h under high organic load eg blood). Trigene (MediChem International Ltd, PO Box 237, Sevenoaks, Kent, TN15 OZJ) is a non-toxic, non-hazardous, biodegradable agent with broad spectrum activity (bactericidal, fungicidal, virucidal, mycobactericidal and sporidical) which is suitable for use under conditions of high soilage. See http://www.medichem.co.uk/medical_products.html for laboratory test data on this product.

Contaminated, small glass articles eg vials, microscope slides etc will be discarded into sharps containers (Cinbins) destined for incineration by Grundon at their Colnbrook site (Slough, SL3 OEG).

Routine surface disinfection will use 1% Trigene. Any substantial bio-spills will be treated with the Body Fluid Response Kit supplied by the same manufacturer.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

The work in question involves the expression of a human serine protease in CHO-K1 cells for subsequent biochemical studies. The GMSC has examined the potential impact of this GMM in terms of hazard to human health and damage to the environment. The protease in question is expressed as an inactive zymogen and, particularly at the level of protein expression anticipated, it is unlikely to offer any hazard to human health or the environment.

All E.Coli manipulations will be performed in K12 (DH5a) or K12/B hybrid (DB3.1) strains of ADCP hazard group 1. Furthermore, since the parental CHO-K1 cell line is a commonly used line of hamster origin with a proven track record in safe utility and the introduction of a serine protease is unlikely to alter this fact, the GMSC has recommended this work be carried out under containment level 1 conditions.

Give brief details of the genetic modification safety committee

The Hammersmith Hospitals Trust Gene Therapy/Genetic Modification Safety Committee (GT/GMSC) is a sub-committee of the Hammersmith Hospitals Trust Health and Safety Committee.

The GT/GMSC includes representatives from the following:

* Management of the Gene Therapy Centre
* Infection Control
* Facilities - waste disposal, portering and domestic services
* Staff representatives (Chair of Joint Staff Committee)
* GMSC chairs and other representatives of the HHT’s ‘Partner’ organisations - Imperial College (IC) and The Clinical Sciences Centre (CSC?MRC)
* Occupational Health
* Research heads in the Imperial Cancer Research Fund (ICRF)
* The Ethics Committee
* Pharmacy
* The Safety Office
* Department of Infectious Diseases
* Director of Service’s Office

The Committee members experience of genetic modification work varies from nil to many years. Each member is very experienced in their own area of work.

The Committee meets as and when projects are received for approval - but will meet at least quarterly.

The Committee will advise on, and approve risk assessments for genetic modification work (it's statutory role). It will also undertake other roles as described in the ACGM compendium of guidance such as advise on good practice, training, inspections and review accidents/incidents.

The majority of Committee members have managerial responsibility across both campuses of the Trust. Therefore the Trust will have one Committee that approves risk assessments for both Hammersmith and Charing Cross Hospitals.

The GT/GMSC includes representatives from the following:

<td>25/10/2001</td>
<td>ANGIOPGENIC GENE THERAPY TRIAL FOR CORONARY ARTERY DISEASE.</td>
<td>Class 2</td>
<td>&lt; 1 litre</td>
<td></td>
<td>non-applicable</td>
<td></td>
</tr>
</tbody>
</table>
In the proposed clinical trial programme, an angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for
the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD).

Generation of new blood supply in the diseased heart by intracoronary administration of the angiogenic gene therapy product represents a potential new therapeutic
approach to relieve this condition.

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map unit 1.3 to 8.7 of
wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

The FGF-4 gene was originally isolated from a CDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells.

The intended function is angiogenesis, the formation of new blood vessels.

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to noneexistent.

Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or
noneexistent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of
infectious particles.

Hazards associated with the adenoviral vector are believed to have a low potential of adverse environmental consequences in humans or animals. The theoretical
consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (eg
promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being
administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.
The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

* All waste will be transferred to the autoclave in Hammersmith Hospital to be autoclaved by Microbiology staff. It will be transported in sealed leakproof autoclavable containers. Inactivation of Ad5FGF-4 is by autoclaving at 134 degrees C for 15 minutes (This is the standard cycle used in the Microbiology Department - it is not changed for GM waste collections). This results in 100% kill of the vector, the material is then transported off site and incinerated. The chemical disinfectant is now Actichlor (10,000 ppm chlorine)

* Service contracts are in place for the autoclaves.

* Formal inspections will be conducted quarterly with the safety officer.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

On original submission the committee asked for more information about the potential transmissibility and survival of the vector based on other previous use in USA.

The Committee also requested a description of the patient pathway.

The Committee was satisfied with the detailed information provided and agreed that the project could be safely conducted as described.

Project Containment
### Project Additional Information

**Purposes of the contained use**

The study has been set up to assess the safety, biodistribution and biological activity of OncoVex GM-CSF. The study involves intratumoural injection into cutaneous or subcutaneous nodules.

**Recipient or parental organism**

The oncovex human GM-CSF vector (Oncovex hGM-CSF) is a replication competent herpes simplex type-1 virus which will be tested in a phase 1 clinical trial for its safety, biodistribution and efficacy in a variety of solid tumours. The strain of HSV which OncoVEX is based on is JS-1 (ECACC no. 85011433). The oncovex GM-CSF vector is deleted for the neurovirulence factor, ICP34.5 which is essential for pathogenicity. This deletion allows the vector to selectively replicate in dividing cells. The vector is also deleted for ICP47, which blocks antigen presentation to MHC class 1 and II molecules by blocking the transporter associated with antigen processing (TAP 1 and TAP 2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HC MV IE). This is an infectious gene therapy product that can only replicate in rapidly dividing eukaryotic cells.
Reference:

Host/vector system
HSV strain JS1/34.5-/47-/CMVGM-CSF (OncoVEX GM-CSF)

Origin & function
The hGM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF is a potent cytokine responsible for the differentiation and proliferation of dendritic cell precursors and therefore is a potent immune stimulator. Thus if the vectors were to enter a human it would be anticipated to give an improved immune response against HSV.

Evaluation of foreseeable effects
GM-CSF should enhance the immune response towards tumour cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste will be placed in a sharps bin or bag. These will then be placed in an external container in order to prevent external spillages and will be identified as potentially containing genetically modified organisms according to Hammersmith Hospital Trust standard operating procedures. They will then be transferred to the pathology department for autoclaving. The degree of kill is effectively 100%. The autoclaves are validated on an ongoing basis. Autoclaves are validated at least once a year and for each cycle autoclave tape and the integral autoclave printer readout will be used to confirm that waste has been autoclaved. After autoclaving, the waste then enters the Trust Clinical Waste route. The waste is then placed into yellow eurocarts which are locked and transported offsite for incineration or microwaving elsewhere. The chemical disinfectant has been changed to Actichlor (10,000 ppm chlorine) and the autoclave cycle is 134C for 30 minutes.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Committee requested:
- more information to support the statement regarding the non pathogenic nature of the organism
- more detail on the time and protocols for screening samples
- Occupational Health information be included
- the timing and management of specimens to be taken be added to the patient pathway.

The Committee was satisfied with the detailed information provided and agreed that the project could be safely conducted as described.

**Project Ref 807/06.1**

- **Date Ackn’d**: 01/11/2006
- **CU2 Project Title**: A Phase 2, Randomised, Double-blind, Placebo-controlled, Parallel-group, Multicentre, Dose-selection Study of Adenovirus type2/Hypoxia Inducible Factor (HIF)-1a/VP16 in Patients with Intermittent Claudication.
- **Class**: Class 2
- **Consent Granted**: Not Applicable

**Historical Significant Changes**

- **Historical Date of Additional Info**
- **Significant Change ID**
- **Date of Significant Change**
Purposes of the contained use

The purpose of this study is to assess the effect of Ad2/HIF-1a/VP16 as a gene therapy agent to induce angiogenesis and thus improve the clinical function of patients with lower limb ischaemia.

Recipient or parental organism

The agent studied contains Adenovirus type2. However, the Adenovirus used in this study should not be able to reproduce in the body (and even accidental inoculation is unlikely to cause symptoms) due to the deletion of E1 genes and all but one of the E4 genes.

Host/vector system

The hypoxia inducible factor / VP 16 hybrid is comprised of amino acids 1-390 of (HIF)-1a fused to amino acids 413-490 of Herpes simplex virus VP16. This is then recombined with Adenovirus type2 to transport the transcription factor.

Origin & function

HIF-1a (hypoxia inducible factor - 1a) is an inducible transcriptional regulatory factor that, in combination with its constitutively expressed dimerisation partner, HIF-1a, plays a principal role in the cellular response to changes in oxygen tension. Experiments in animals have established that HIF-1a is essential for regulating gene expression in response to changes in oxygen tension both during development and in response to hypoxia in postnatal life. The HIF-1a/VP16 hybrid transcription factor is part of the amino acid chain of HIF-1a fused to that of Herpes Simplex Virus. It is hoped that the administration of the modified HIF-1a/VP16 transcription factor via gene therapy will allow new blood vessels to grow in the ischaemic tissues. In patients suffering from lower limb ischaemia and whose walking is limited by pain, this effect should improve their circulation and in turn their symptoms and allow them to walk further.

Evaluation of foreseeable effects

There is a very minimal risk that the virus could be passed from an individual accidentally exposed to Ad2/HIF-1a/VP16, or the blood/serum of a patient having been treated with Ad2/HIF-1a/VP16 within the previous 7 days, to another person. Replication of Ad2/HIF-1a/VP16 in the patient is extremely unlikely. Deletion of E1 genes and all but one of the E4 genes have rendered the Ad2/HIF-1a/VP16 viral construct defective for autonomous replication. Shedding of the virus from the individual exposed to Ad2/HIF-1a/VP16, or the blood/serum of a patient having been treated with Ad2/HIF-1a/VP16 within the previous 7 days, to someone else is also extremely unlikely. Fertile men and women should follow an approved method of contraception for 60 days after an exposure to Ad2/HIF-1a/VP16 or in the event the exposure is to the blood/serum of a patient having been treated with Ad2/HIF-1a/VP16.In the extremely unlikely event that environmental release was to occur, the most likely virus involved would be wild-type adenovirus that had overgrown Ad2/HIF-1a/VP16 or a recombinant with no biological activity other than that associated with a generalised infection of the wild-type virus. This includes mild cold-like symptoms and more severe respiratory infections like bronchitis, croup and pneumonia.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste is disposed of in labelled autoclave bags or sharps bins, transported in sealed, leak proof containers to the autoclave suite in the Microbiology Department. Waste is autoclaved then placed in solid yellow (UN approved) bins, sealed, tagged and removed for incineration or microwaving off site. The standard autoclave cycle used is 134. C for 30 minutes. The autoclaves are tested weekly, quarterly and annually. A chart recorder is used. Autoclave tape is used to indicate that autoclaving has taken place. Twelve-point thermocouple testing is carried out.
The Hammersmith Hospitals NHS Trust Gene Therapy and Genetic Modification Committee were satisfied with the risk assessment for this project. The committee was assured that all potential risks were identified at storage, preparation, transport, administration and disposal stages of the study. They were also satisfied that all necessary controls have been put in place to ensure minimum risk of exposure for staff, public and the environment.

Please enter comments on the GM safety committee on the risk assessment

Pexas-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed contained use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexas-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexas-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX94-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. In the control arm, the 300 patients will not receive Pexas-Vec. After study completion, all patients will be followed up for survival. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexas-Vec by IT injections.

Pexas-Vec is a replicative oncolytic recombinant vaccinia virus (VV) derived from the commonly used vaccine Wyeth strain, DryvaxTM.

VV is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of VV exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988).

VV has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As VV contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. VV may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination against smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexas-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes replication in normal cells more difficult than the smallpox vaccine. Rare complications included eczema vaccinatum (patients with eczema), disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) (Fields B.N., 1996). Recent studies of smallpox vaccines have identified cardiac injury including pericarditis and myocarditis as a potential risk (Halsell J.S. et al., 2003).

VV replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host genome (Moss B., 2007).

In terms of classification of hazard, VV is considered as a Group 2 biological agent as per Directive (2000/54/EC). VV is also classified as a Biosafety Level 2 (BSL-2) infectious substance by the US Centers for Disease Control and Prevention (CDC) (CDC, 2009) and as a risk group 2 organism by the US NIH Guidelines (NIH).

Pexas-Vec was generated by co-transfection of CV-1 cells (Monkey kidney cells) with VV (Wyeth strain obtained from the Center for Disease Control, Atlanta, Georgia) and the plasmid pSC65/hGM-CSF. The vector pSC65/hGM-CSF contains DNA sequences coding for the hGM-CSF and β-galactosidase proteins and for their respective promoters. In addition, the transgene sequences are flanked by two VV genomic regions (TKL and TKR) that allow homologous recombination between the transfer plasmid and VV. The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland (Chakrabarti 1997).
The plasmid pSC65/hGM-CSF is inserted into VV. The insertion of pSC65/hGM-CSF into VV can be detected by using colorimetric identification of plaques containing recombinants expressing β-galactosidase. The pSC65 vector when provided by Dr. B. Moss contains the LacZ gene. The LacZ gene is a reporter gene, under control of the VV p7.5 early/late promoter. The additional donor gene (i.e. gene coding for hGM-CSF) is inserted in pSC65 as follows. The plasmid pCSF-1 (No. 39754) was obtained from American Type Culture Collection and comprises the full-length cDNA for hGM-CSF (Wong 1985). The hGM-CSF gene was cloned first into the EcoR1 site of pBLUESCRIPTII SK (Stratagene, La Jolla, California), generating plasmid pBLUE/hGM-CSF, and providing restriction enzyme sites to allow cloning of the hGM-CSF gene into the Sal I and Bgl II sites of pSC65. This positioned the hGM-CSF gene downstream of a synthetic promoter (PsE/L) designed by Dr Moss' laboratory to give maximal levels of transcription during both the early and late phases of vaccinia infection (Chakrabarti 1997).

Origin & function

Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF) gene and 3) insertion of the LacZ gene.

Due to the insertion of the transgenes, the TK gene is inactivated. This decreases VV virulence (Buller R. et al., 1985) by restricting viral replication to proliferating cells. This also targets dissemination of the virus to tumors (Puhlmann M. et al., 2000).

The plasmid pCSF-1 (No. 39754, American Type Tissue Culture Collection, Rockville, Maryland) contains the full–length cDNA for hGM-CSF (Wong G.G. et al., 1985). The cDNA for the hGM-CSF gene was inserted into the TK gene to help elicit an immune response to tumor cells both at the site of viral replication and in distant metastases. The cytokine hGM-CSF was chosen because it was the most potent stimulator of systemic anti-tumor immunity among many tested (Dranoff G. et al., 1993), probably due to its unique ability to promote differentiation of hematopoietic precursors into dendritic cells (Pardoll D.M., 1995). Dendritic cells are professional antigen presenting cells that may take up and present released tumor antigens as the tumor cells are killed by the VV.

The LacZ gene is contained in the pSC65 plasmid which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland. The LacZ gene encodes for β-galactosidase which is a hydrolase enzyme that catalyzes the hydrolysis of β-galactosides into monosaccharides.

Evaluation of foreseeable effects

Pexa-Vec is non-integrative, and replicative and propagative characteristics of VV have been attenuated in Pexa-Vec, which makes the virus replication dependent on actively dividing cells such as cancer cells. Therapy with a replicating virus can theoretically lead to shedding of the virus into the environment, and potentially to the public, although controls are used in this trial to minimize this occurrence. The clinical information available to date suggests that Pexa-Vec is safe at the clinical dose of 1 x 10^9 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 35 will likely have been previously immunized with vaccinia. In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. Therefore, public health risks with this virus are extremely low and in fact should be lower than with standard vaccination procedures. To date, no reports of transmission to health care personnel from vaccinia recipients have been published. Routine barriers nursing approaches should be used per institutional guidelines for infectious organisms (e.g. such as for M. tuberculosis, Pseudomonas). The information regarding the risk to patient contacts and guidelines for reducing the risk of viral transmission is contained within the Participant Information Sheet and Consent Form (PISCF) and the Pexastimogene Devacirepvec (Pexa-Vec) Guidelines (provided in Appendix B of Pexa-Vec Investigator’s Brochure). The PISCF will be reviewed with the patients, and their written consent will be obtained, before they undergo any study-specific procedures. A signed copy of the PISCF will be given to the patients so that they can come back to the guidelines at any time. Pexastimogene Devacirepvec (Pexa-Vec) Guidelines will be given to investigators, pharmacists, and all personnel involved in the handling of the product.

The genetic modification of the virus is not expected to result in any post-release shift in biological interactions or host range or in any known or predictable effects on.
non-target organisms in the environment. It is also not expected that the release of the recombinant virus would result in any increase in pathogenicity as compared to the parental virus strain and/or in any increase in the capacity to recombine with other related viruses. Therefore, under the conditions for use in the proposed clinical trial, Pexa-Vec is not considered to represent a risk for the environment and for the public health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste, including any dressings returned by patients, will be disposed via hospital waste stream which is treated according to Trust procedures for infectious waste. (The Orange waste stream which is for waste items that are infectious waste, clinical waste contaminated with blood or bodily fluid from patients with transmissible infectious diseases and large volumes of blood, pus and wound exudates). Infectious waste is collected and incinerated/destroyed by a contractor approved by the Trust.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The Trust Committee is the Joint Clinical Research Committee of Imperial Healthcare NHS Trust and Imperial College London. The committee incorporates the role of GMSC for the Trust.

The committee queried whether this study required Class I or Class II since all the work with GMOs on site is low risk. Agreed to proceed with Class II in line with other centres involved in this study.

The committee requested clarification of the infectious waste stream and Q12 has been amended accordingly.

Pharmacy noted procedures on preparation of the IMP to ensure purity of the production for injection not due to excessive risk of the IMP for workers.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to manufacture CD19-targeting CART cells for potential immunotherapeutic use. The Lentiviral Vector developed for the ex vivo transduction of T cells in order to confer expression of an anti-CD19 chimeric antigen receptor (CAR).

**Recipient or parental organism**

Lentivirus-modified recipient T-cells

**Host/vector system**

This Lentiviral system is designed for the ex vivo transfer of genes to target cells which can be expanded and delivered back to patients. The vector is pseudotyped containing a heterologous envelope protein, the vesicular stomatitis virus G envelope protein (VSV-G), to confer broad tropism for transduction of a wide variety of mammalian cell types. The particular replication deficient construct is a modified HIV-1 backbone based on the pNL-A-3 molecular clone which possesses the following features:

- A deletion in the enhancer of the U3 region of the 3'LTR to ensure self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of target cells
- Multiple deletions of accessory genes to remove as much of the HIV backbone as possible and still maintain efficient production of lentiviral particles
- The vector and helper constructs contain no significant areas of homology, minimizing possibility for recombination
- Separation of the gag-pol open reading frame (ORF) from the VSV-G ORF on two plasmids, with the transducing...
vector carried on a third plasmid.

**Origin & function**

The intended use is expression of an anti-CD19 chimeric antigen receptor (CAR).

**Evaluation of foreseeable effects**

This construct is replication-defective, therefore poses no risk to humans or animals. Lentiviral vectors can however integrate into host chromatin, and thus pose some risk on insertional mutagenesis. In the the finished CAR-T cell product, free lentiviral particles are significantly diluted and washed during the manufacturing process. The transduction efficacy of these lentiviral particles will be considered inefficient by the end of the manufacturing process and therefore we consider the product to be safe for therapeutic application.

Operators undertaking the manufacturing process will be fully trained and apply use of personal protective equipment.

There is added assurance that the process is designed as a 'closed system' and the lentivirus will be introduced to culture by connecting to kit using a sterile tubing welder.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No autoclave in building and therefore require the services of an established third party provider for waste disposal.

Packaging: Will be as recommended by waste management service provider, with dedicated collection. Waste will be destined for autoclave / high temperature Incineration.

Storage & Collection: Dedicated storage area will be denoted in the laboratory until the waste management company collects for disposal.

Transportation & Disposal: Dedicated collection will be arranged with waste will be destined for autoclave / high temperature Incineration.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste, spills: Allow aerosols to settle; contain spill and decontaminate with 10% chlorine bleach; allow sufficient contact time (30 min) before clean up. Surface is then cleaned with 70% ethanol for residual removal of cleaning agent.

Sharps & other solid waste: Packaged as recommended by waste management service provider with dedicated collection. Waste will be destined for autoclave / high temperature Incineration.

**Is an emergency plan required according to regulation 20?**

Give brief details of the genetic modification safety committee

Discerna GMSC will meet a minimum of once per year to review existing risk assessments and arrange for an audit of the laboratories. Meetings to approve new risk assessments will be held as required. The Discerna GMSC activities are reported to the Discerna Health & Safety Committee and the GMSC of the Babraham institute who oversees site GM safety.

Discerna GMSC is made up of:
- Chairman and Management Representative
- Biological Safety Officer
- Technical Staff Representative

Inactivation of GMMs in contaminated material will be as follows:

**Liquid Discharge:** Waste to be treated with 1:1 Trigene (Halogenated tertiary amine compound) to a final concentration of 1% v/v or with 1% Virkon S. Trigene and Virkon are MAFF approved and conform with British and European Standards (CE93/42/EEC) with a 99.999% degree of kill.

**Solid Waste:** Solid waste will be sealed, retained in Biohazard waste sacks and autoclaved. Clinical waste will be removed for incineration off-site by a nominated commercial 'clinical waste' carrier in accordance with all relevant legislation and guidelines. Degree of inactivation is 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

The GMSC has reviewed the company's GM procedures and the risk assessments performed. The GMSC confirmed the work to be carried out is Class 1 and were satisfied with the assessment of risks to both human health and the environment. The control and containment measures in place are appropriate for Class 1 activities.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Y

Give brief details of the genetic modification safety committee

The genetic modifications committee is a sub-committee of the University Health and Safety Committee and has been constituted according to the guidelines in ACGM/HSE and comprises of: Chairperson, School of Applied Sciences Safety Co-ordinator, Biological Safety Officer, University Safety Officer. The GM committee will meet biannually to oversee the running of GM operations at the University of Huddersfield.

Bacteriology  Yes  Parasitology  Transgenic Birds  Microbiology Research
All GMMs will be disposed of by autoclaving at 121 degrees C for 15 minutes. This method of killing is 100% effective. Validation of effective killing of GMOs will be based on the annual testing of the autoclave using independent monitors placed at the centre of the load so that it is confirmed that the correct temperature and pressure have been reached for the required time.

As a precautionary measure any bulk liquid left to stand around untreated for any length of time prior to autoclaving will be treated with the appropriate disinfectant.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GM safety committee are all concordant with the risk assessment and are happy that the work outlined in the risk assessment should proceed.
### Project Additional Information

**Purposes of the contained use**

Generation of human skin cells by reprogramming of human fibroblasts and keratinocytes to induced pluripotent stem (iPS) cells and differentiation: The project aims at molecular characterisation of monogenic skin diseases and the development of advanced in vitro disease models suitable for drug testing and screening and therapeutic approaches. Primary fibroblasts and keratinocytes are obtained from skin samples and cultivated using standard procedures. Fibroblasts are reprogrammed using 'Yamanaka factors', Oct4, Sox2, Klf4, and cMyc.

In vitro models to study cancer development and cellular responses to pro-apoptotic signals: The aims of the work are to determine how specific molecular/genetic events contribute to the initiation and progression of cancer in human epithelial tissues as well as how they modify the apoptotic susceptibility of epithelial cells to the immune system and its products. ATCC derived cell lines are transduced using viral vectors to express fluorescent protein reporters and small hairpin RNAs (shRNAs) to study pro-apoptotic (cell death) signals.

Development of an iPS cell model system, which can be differentiated into a neuronal model for drug and biomarker development. Fibroblasts are reprogrammed using the "Yamanaka factors", Oct4, Sox2, Klf4, and cMyc. Their genes are contained in a polycistronic plasmid, pHAGE2-EF1aFull-Oct4-F2A-Klf4-IRES-Sox2-E2A-cMyc-LoxP. The genes are transferred into fibroblasts and expressed using a non-integrative sendai virus transduction. Generated iPS cells are thoroughly characterised using morphological and molecular characteristics. iPS cells are cultivated, manually passaged, and differentiated into target cells with selected media. Target cells are further characterised and used to generate in vitro models.

**Recipient or parental organism**

Mammalian cell line commercially available from ATCC, HEK293, is hazard group 1 and not known to cause harm to human health.

PT67 (Clonetech) mouse fibroblast packaging cell line (contains env, gag and pol genes integrated separately) used for retroviral production is Biosafety group 2.

Primary fibroblasts and keratinocytes are not serotyped, however, are non-permissive for HIV, HBV and HCV and therefore not supposed to cause harm to human health.

**Host/vector system**
Viral vectors: pLXSN or pSIREN-RetroQ-based vectors (both Clontech) are replication deficient and do not contain the structural genes (gag, pol, and env) necessary for particle formation and thus pose negligible risk to human health. The structural genes (gag, pol, env) are stably integrated into PT67 packaging mouse derived cell line and subsequent introduction of pLXSN, and the gene of interest produces replication-incompetent infectious virus inside the PT67 cells. Lentiviral vectors used (pHAGE2, pLenti and pLKO) are 2nd/3rd generation and are replication deficient. pHAGE2 is used in combination with pHDM and pRC/CMV-Rev1 b, pLenti (Thermo) with pLP1 , pLP2, pLPIVSVG and pLKO (SigmaAldrich) with pMISSIONgagpol and pMISSIONvsvg helper plasmids for viral packaging. Helper plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. Helper plasmids are nonmobilisable and not known to cause harm to human health. Co-transfection of mammalian (HEK293T) cells with the pHAGE2/pLenti/pLKO plasmid and helper plasmids results in the packaging of replication deficient lentiviral vectors. Mammalian cells are destroyed by the virus, which is harvested from the media and further used for transduction of target cells (human fibroblasts). The virus is not capable of producing further virus particles in the target cells. The Sendai virus contains a polycistronic vector that has a backbone containing new temperature sensitivity mutations to the polymerase-related genes, and this helps to clear the virus faster after reprogramming and causes less cytotoxicity to the cells. Sendai virus is ACDP hazard group 1.

Origin & function

1) Human genes for Oct4, Sox2, Klf4, cMyc. These genes are known for their role in cell differentiation rather than driving cell proliferation and malignancy. 2) Inserts also include sequences designed to knock-down endogenous mRNAs (siRNAs, shRNAs) encoding for mammalian proteins, and thus reduce encoded protein products. Inserts of mammalian origin used in combination with viral vectors include genes (or parts of) known to promote cell death/apoptosis or attenuate cell proliferation. The inserts have no foreseeable risk to human health or to the environment. 3) Regulatory sequences upstream (EF1a promoter) or downstream (3' regulatory element: woodchuck hepatitis virus post-transcriptional regulatory element) of coding sequence. 4) HIV gag, pol, tat, rev1 b, VSV-G (in helper phage; used only for HEK 293T). 5) Green fluorescent protein from Aequorea victoria or luciferase from firefly.

Evaluation of foreseeable effects

Transduction of the mouse PT67 cell line, which contains stably integrated structural genes (gag, pol, env), with replication-deficient retroviral vectors results in replication and packaging of novel virus particles resulting in breakdown of the parental PT76 cells. Co-transduction of replication deficient pHAGE2/pLenti/pLKO and helper plasmids into HEK293 cells similarly results in replication and packaging of the virus and death of the parental cells. The resulting virus particles are collected into containers with sealed caps whilst working within laminar flow class II safety cabinet. Personal protective equipment (lab coats, gloves and safety goggles) are used and all virus particles are handled in a dedicated laboratory space and in class II safety cabinets with laminar flow using safe operating protocols. No sharps are to be used in the viral work. The viral vectors are replication-deficient and do not contain sequences that would allow the gene of interest to recombine and insert into the parental cell genome. Lentivirus is unstable and non-transferrable by air. The risks to human health or to the environment are thus negligible to effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMMs will be disposed of by autoclaving at 126 degrees Centigrade for 60 minutes. This method of killing is 100% effective. The effectiveness of the autoclave at reaching the correct temperature and pressure is continuously monitored by an electronic monitor that prints out the temperatures and pressure reached at the end of each run. Validation of effective killing of GMMs is monitored by annual testing of the autoclave using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time.

As a precautionary measure any bulk liquid left to stand around for any length of time prior to autoclaving will be treated with Distel (formerly Trigene; 10%; by Tristel) or 2-4% Virkon (DuPont) according to the manufacturers recommendations. To minimise the generation of aerosols, safe removal of supernatants from cultured mammalian cells (handled in class II laminar flow cabinets) is performed by aspiration using a vacuum ('trap') system, where liquids are treated in 10% Virkon. All types of culture medium and plastic ware used in mammalian cell culture are treated with 2% Virkon (final concentration) overnight, followed by autoclaving at 126 degrees for 60 minutes for all plastic ware before disposal. All virus-containing culture medium is decontaminated in 10% Virkon, which effectively kills enveloped and non-enveloped viruses.

Any laboratory ware that has been in contact with GMMs will be treated with Distel or 0.5 - 2 % Virkon for a minimum of four hours prior to dish washing. Disposable plastic ware that has been in contact with GMM will be autoclaved at 126 degrees Centigrade for 60 minutes prior to disposal. Random samples of waste will be checked for living GMMs once every two weeks. All discard going out from the School is recorded.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

GM safety committee has been consulted and has found the risk assessment as appropriate.

Give brief details of the genetic modification safety committee

The genetic modification committee is composed of the following four members:

- Biological Safety Officer
- Associate Medical Director
- Clinical Pharmacy Manager
- Radiation Protection Supervisor

In addition, there are four co-opted members from Schering affiliated companies in the USA and Germany. They provide, when necessary, additional advice on biotechnology, medical, pre-clinical and toxicological matters respectively.

The committee generally meets on a quarterly basis, although it can convene in the interim should the need arise.

Give brief details of the genetic modification safety committee

The GMSC is a sub-committee of the Cellzome UK Health & Safety Committee. It is comprised of the following:- Chairman; Biological Safety Officer; Secretary and research scientist involved in the GMM work. The committee meets at least every 2 months or more frequently if required during the initial start-up phase. Each meeting has an agenda, recorded minutes and actions. As the company expands, the membership broadens to ensure a fuller representation of scientific expertise.

A risk assessment must be completed and submitted to the GMSC prior to the work commencing. The GMSC must review and approve the risk assessment and assign a final activity class. The approved risk assessments are available electronically to all workers on a shared computer area. Local codes of practice are available for work involving GMMs at both containment levels 1 and 2. The GMSC also ensures good laboratory practice and ensures full discussion with all those concerned, on safety, training and laboratory discipline.

A number of different routes will be used for category 1 waste disposal.

**SOLID WASTE DISPOSAL:**

1. All waste will be placed in EU designated yellow bags in solid bins. When the bags are 2/3rds full the bags are sealed and placed in a wheelie bin belonging to accredited waste management company, White Rose Environmental. These bins are lockable and are collected by White Rose for incineration.

2. All category 1 biological waste will be placed in autoclave bags inside solid autoclavable bins with lids. These bins will be placed directly into the autoclave which is available in the building. The waste will be autoclaved at 121C for 20 minutes. The autoclave bags will then be placed in yellow bags and placed in the wheelie bins for incineration by White Rose. Laboratory staff are responsible for the waste they produce.

In the event of autoclave malfunction, Category 1 biological waste may be disposed of in hermetically sealed containers provided by White Rose. These containers are then disposed of in the aforementioned wheelie bins for incineration.

The autoclaves are fully compliant with BS 2646:1993 - autoclaves for sterilisation in laboratories. They are commissioned and validated by the manufacturer and independently certified to PD 5500:2000 Cat 3. They are also compliant with European pressure equipment directive 97/23EC. They are regularly serviced by an independent qualified engineer.

**LIQUID WASTE DISPOSAL:**

**SHARPS:**

All sharps must be placed in specially provided sharps bins and discarded in White Rose wheelie bins.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid waste will be autoclaved (121 C for 30 minutes) and in each autoclave run, monitors will be included to ensure effective temperature and pressure. The degree of kill will be 100%. The autoclave is tested annually (12 point test) and is serviced twice a year. After autoclaving, solid waste is disposed as clinical waste (for incineration).

Liquid waste will be treated with a laboratory disinfectant such as Virkon following the manufacturers guidelines to achieve 100% kill. After treatment, liquid waste is disposed down the drain.

All workers will be trained to follow local rules.

All liquid and solid waste contaminated with GMMs will be autoclaved prior to disposal by incineration. Autoclaves used in this process will be validated, by qualified persons, on a yearly basis.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Activities involving this low risk GMM require containment at level I. However, process requirements dictate that the activity will be undertaken at a level similar to containment level II.

Give brief details of the genetic modification safety committee

The local genetic modification safety committee has been established as a subgroup of the Trust's Risk Management Group and includes representatives from various backgrounds within the hospital. It is chaired by the Director of Nursing and Quality. It includes both clinical and non-clinical staff. The committee has reviewed both the risk assessment and the standard operating procedures for the trial and will meet periodically throughout the project to review safety issues. The first review is envisaged when 3-5 patients have been treated but will be sooner if felt appropriate by the risk or biological safety officers.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Having reviewed the risk assessments, the Genetic Modifications Safety Committee (GMSC) were satisfied that the arrangements for containment and disposal of the drug containing the GMM, and any associated clinical or patient wastes, are adequate and that suitable facilities are available for segregation of the patients who are included in the trial. The GMSC require that all staff associated with the treatment or care of patients to whom GMM drug therapy is given will receive suitable training and information about the procedures, the safety measures and the nature of the hazards the drug presents.

Project Ref 816/02.1

Date Ackn'd 21/01/2002

CU2 Project Title PART OF A MULTI-CENTRE TRIAL TO LOOK AT THE CLINICAL EFFICACY OF AN ANGIGENIC GENE THERAPY PRODUCT IN THE TREATMENT OF REFRACTORY ANGINA IN PATIENTS WHO ARE UNSUITABLE FOR OR FOR WHOM THERE IS NO ...

Class 2

CultureVol

Class 2

CultureVolumeClass 2

< 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

The purpose of this trial is to assess whether the use of angiogenetic growth factors such as FGF-4 will improve symptoms of angina and enhance the quality of life for patients with chronic refractory angina. Previous studies suggest that there is likely to be a positive benefit, however this has not been assessed systematically. This is the first European trial to attempt to do this.

#### Recipient or parental organism

The transgene is a human fibroblast growth factor 4 gene driven by a CMV promoter. The recipients of the GMO will be patients in whom there is no conventional (ie angioplasty or bypass surgery) option. The transgene will be delivered by cardiac catheterisation directly into the coronary circulation.

#### Host/vector system

The vector is based on a serotype 5 adenovirus. Adenovirus type 5 is typically a respiratory pathogen, with 50% of the adult population having antibodies to the wild-type virus. The vector is replication incompetent (the E1 area of the viral genome has been deleted.) It is expected to have the same tissue tropism as the wild type virus.

#### Origin & function

The E1 area of the viral genome is replaced by the FGF-4 transgene. This is a 1.2Kb cDNA for the human FGF-4 gene driven by a Cytomegalovirus promoter. The gene therapy product will be delivered by a single injection at cardiac catheterisation. Induction of angiogenesis is potentially a new therapeutic option. The effect is based on the growth of collateral vessels to ischaemic areas of heart muscle. This effect has been demonstrated in animal models and in small numbers of patients but has not been evaluated in a systematic way.

#### Evaluation of foreseeable effects

Infection of immunocompetent adults with wild type adenovirus would be expected to produce a mild upper respiratory tract infection. The normal method of spread is as an aerosolised droplet infection spread person to person. Measures are to be undertaken to minimise staff contact and to reduce the risk of aerosolisation of the virus. Conjunctivitis and gastroenteritis are also described. Insertion of the FGF-4 or CMV promoter is not expected to alter the tissue topiism or infectivity of the virus. Accidental injection of the study product would be expected to cause local inflammation.

Adenovirus type 5 has not been shown to have any tumorigenicity in vivo. There is a theoretical risk of abnormal angiogenesis and oncogenesis from the transgene. The risk of this is likely to be low for the following reasons;

To become oncogenic the, transgene would have to be incorporated into cellular DNA. Combination with cellular DNA is described in only 0.1 to 0.001% of transfected cells. Transfection efficiency is itself low (circa 25%) and is concentration dependent. Following intracoronary administration, the amount reaching the systemic circulation is 10,000 fold lower than that given locally and is cleared from the bloodstream in minutes.

b) Long term gene expression is necessary for oncogenesis. Following aerosolised administration of an adenovirus type 5 to normal individuals, it was found that vector DNA peaked at day 7 and reached less than 10% of baseline levels by 2 weeks. This effect was again concentration dependent. In animal studies, with an adenovirus-FGF product the longest adenovirus DNA could be detected was 3 months - at this stage no transgene could be detected.

There is not expected to any environmental impact from this project.

---

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No autoclave in building: The method of waste disposal for material used during the preparation and delivery of the gene therapy product will be by autoclaving. The autoclave facility to be used is located in the building used to prepare the product (when concentrations of adenoviral product will be highest). The actual delivery of the product will be in the cardiac catheterisation laboratories which are in a separate building. At the end of the procedure all equipment which has been in contact with the adenoviral product will be placed in sealed autoclave bins for transport to the autoclave - which is approximately 200m away. All waste will be double bagged prior to transportation. The metal boxes are leak proof and are tested for compatibility with the autoclave prior to use.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste containing the adenovirus material will be disposed of as biohazardous. All contaminated material will be put into sealable, leakproof autoclavable containers. Inactivation of the adenovirus product is by autoclaving at 121 degrees C for 15 minutes giving 100% kill. The autoclave cycle will be validated prior to commencement of this project and will be validated on a yearly basis. For each cycle, autoclave indicator tape and the integral autoclave printout will be used to confirm that the waste has been autoclaved. All autoclaved waste will then be incinerated.

Autoclave boxes will be kept at each location that biohazard waste will be generated, namely at product reconstitution and at cardiac catheterisation.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee felt that the risks represented by this project were likely to be small and that with the proper conduct of the trial, and adherence to the safety procedures that these risks could be minimised further. It was noted that Papworth Hospital has been involved in randomised controlled trials amongst similar patient groups previously and that these trials had been well conducted and received. However, this is a new technique at Papworth so they were keen that the project is appropriately supervised and managed and that staff will appropriately trained and familiarised with the project. They noted that any member of staff who had the potential (through family disease history or current infection) to be affected by the GMO would not be expected to work with patients receiving the therapy.

Virology

02/03/2022
All biological waste is processed in the following ways:

1. Autoclaved on an automatic waste cycle of a pre-programmed MDH Labclave (122C/2 bar for 40 minutes). Each run has a chart recorder recording the load temperature measured by a wandering probe placed in the load. This generates a trace record of each run to verify that the load has reached the specific temperature for the prescribed time. This is augument by visual checks. The autoclave is serviced on a six monthly basis and calibrated to a NAMAS specified standard.

2. Additional sanitation on equipment that cannot be autoclaved e.g. filtration units is by re-circulation of 1.0M Sodium Hydroxide for 1 hour as described in the standard operating procedure for the unit.

3. Fermentation Equipment is sterilised with steam in situ with the vessel being held at 121C for 40 minutes after each use. Sterility of the vessel is tested by refilling with fresh sterile media and running at 37C for 24 hours. No growth should be observed after this period.

4. Centrifuge tubes and test tubes used in the down stream processing are autoclaved (121C/40 minutes) and then acid washed in a commercial glass washing machine.

5. General work surfaces are frequently decontaminated using either 70% methanol or 2% virkon leaving the area in question to be in contact with the disinfectant for 20 minutes.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The first of 2 standard systems used is:

The standard host vector system used is E coli JM109 host which is a K12 derivative and therefore none colonising with pUC18 which is recognised as a non-mobilisable vector.

This has been assessed as having an overall risk factor of 10- and therefore category 1 is appropriate.

The second typical system used for protein expression.

The host strain is Ecoli Novablue (DE3) which is an E.coli B strain and is recognised as a disabled or non-colonising. The vector generally used is pET 30, which is a mobilisation defective vector. The typical gene product is a DNA modifying enzyme. The expression is inducible from a strong T7 promoter using IPTG and is optimised for the production of the protein. Damage is extremely unlikely that the over expression could occur except in vitro and should the product enter the environment it is unlikely to cause any damage as it is unstable outside of the cell at ambient temperatures and unlikely to survive. The toxicology of the product is unrecorded as it will be naturally present in the environment. The Overall risk for this system is 10-5 . Therefore containment level 1 is appropriate.

Yes

Give brief details of the genetic modification safety committee

Head of Biology (Management representative), Senior Research Scientist Biology, Research Scientist Biology & Biological Safety Officer.

A combination of formal and informal evaluation and approval procedures will be implemented.

Researchers will circulate risk assessments (available on line via local network) to the members of the committee. Individual members of the committee may advise researchers on an informal basis.

A three monthly meeting will be called for formal review of all applications and current issues relating to genetic modification.

Yes
Only small scale liquid waste will be generated (< 5 litres at any one time). Liquid waste will be collected and inactivated using chlorine releasing tablets prior to sink disposal. Solid waste will be collected in buckets lined with autoclave bags. Waste will be autoclaved in a cycle of 121°C for 15 minutes. A fully calibrated autoclave will be used for inactivation. Calibration will take place yearly. Waste will be collected as clinical waste by an external contractor (Grundon). Sharp solid waste will be collected separately in sharpsafe bins and autoclaved as above. Chlorination and autoclaving are accepted procedures which will result in complete killing.

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Project Additional Information

#### Purposes of the contained use

To immortalise human and rat cells, for potential therapeutic use in the treatment of various cytodegenerative disorders.

#### Recipient or parental organism

The recipient cells will be human and rat cells derived from various body tissues.

#### Host/vector system

The retroviral shuttle vector to be used is essentially that reported by Cepko et al (Cell 37 [1984] 1053). The vector is based on the moloney murine leukemia virus (M-MULV) and comprises the following M-MULV sequences: Long terminal repeats (LTRs) necessary for the initiation of viral transcription, the polyadenylation of viral transcripts as well as for genomic integration; sequences necessary for the reverse transcription of the viral genome; sequences for the encapsulation of viral RNA; 5' and 3' splicing signals involved in the generation of genomic viral env RNA. In place of the M-MULV sequences encoding the gag-pol and env polypeptides, BamH I and XhoI restriction sites have been inserted. Within the BamH I restriction site, a temperature-sensitive mutant of the simian virus 40 large tumour antigen (ts)A58SV40T has been placed, allowing expression of the large T mutant A58. In addition, sequences derived from the transposon 6 encoding the geneticin resistance (G418) selection marker, have also been included. The pBR322-derived SV40-derived origins of the replication have been introduced into the XhoI site allowing the construct to act as a shuttle vector, (for review see Noble et al (Brain Pathology 2 (1992) 39).

The aforementioned retroviral vector construct in plasmid form was used to transfect an amphotropic packaging cell line (Dance and Mulligan, PNAS 85 [1988] 6460). The packaging cell line has been designed so the helper functions are encoded by two separate segments of DNA, ensuring the safe generation of recombinant retroviruses. There is no possibility of transduced cells producing infectious virus particles (Stamps et al Eur J Cancer 28A [1982] 1495).

#### Origin & function

The temperature-sensitive form of the simian virus derived large T-antigen binds endogenous p53 at 33 degrees C to inhibit cellular apoptosis.

#### Evaluation of foreseeable effects

The process has been widely practiced in many laboratories throughout Europe and the USA. No untoward effects have been reported.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment of all consumables and liquid waste that have, or may have been in contact with virus with Chloros, Virkon or Microsol 3, followed by double-bagging. Alternatively where use of virocides is not practicable double-bagging will be used. Double-bagged waste will then be autoclaed prior to being sent for incineration to give 100% kill. Mammalian cells are destroyed outside growth medium, however, swabs of work surfaces will be performed and cells screened by bioassay to check for cross-over reactivity.
The Safety Committee believes that the procedures put in place meet the relevant criteria and is seeking advice from the HSE that all appropriate procedures are in place.

Please enter comments on the GM safety committee on the risk assessment

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The Safety Committee advise on risk assessments of contained use activities and check that waste received are from registered centres, and are properly packaged for transport/handling.

Committee comprises:
DGSA & Maintenance Manager - Chairman
Prof of Infectious Diseases & Hon. Consultant Physician
Engineering Services Manager
Co-ordinator Waste Management

Committee meets annually

The registration is specifically for an incinerator facility, receiving GM waste from other registered users.

The waste will be collected or delivered in double packed UN approved leak-proof containers and tipped into a hopper from where it is automatically conveyed into the incinerator.

Incineration achieved 100% destruction of any biological material and therefore will achieve complete inactivation of all GMOs.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste will be treated with hypochlorite (concentration 10,000ppm available chlorine) once the waste is deactivated it will be run to drains. All plasticware will be treated with hypochlorite (10,000ppm) before being bagged up and autoclaved at 121 degrees C 15 mins, this achieves 100% kill.

All sterile plasticware is then sent for incineration by authorised contractors.

The autoclaves are tested annually for validation purposes.
The aim of the project is to express ion transport systems (as the Na+ -Ca 2+ exchanger, the plasma membrane Ca 2+ pump), the calcium indicator protein aequorin and the green fluorescence protein (GFP) in primary neuronal cultures and neuronal cell lines. We will use a new replication-defective hybrid lentiviral vector originally derived from HIV.

Origin & function

Evaluation of foreseeable effects
The lentivirus vectors have been developed as tools for gene therapy in conditions when known viral vector systems proved ineffective. In addition to their capacity to integrate into the genome in absence of the original viral genes and the lack of typical immunological effects of the parental (HIV) vector, lentiviral vectors possess an enormous capacity to infect non dividing cells. The viral vector particles are replication defective and consist of the core and enzyme of a lentivirus and the envelope of the Vesicular stomatitis virus (VSV). To assemble the lentiviral vector, a third-generation packaging system is used:
> Three plasmids (packaging constructs) for respectively
  * the gag and pol genes,
  * the envelope,
  * the gene for Rev protein

> One transfer construct containing the transgene and sequences for all cis functions allowing efficient encapsidation, reverse transcription, nuclear transport and integration of the vector into the target cells.

Transient cotransfection in 293T cells (with calcium phosphate-DNA precipitation) of these four separate plasmids reduce remarkably the likelihood of replication-competent virus (RCR).

To improve the biosafety of this vector and to reduce the likelihood of recombination between the constructs used to make vectorm, the following measures have been
adopted:
- Elimination all viral genes, that are not essential for gene transfer (vif, vpr, vpu, nef) from the packaging constructs.
- Elimination of tat gene (transcriptional activator, that plays a pivotal role in the exceedingly high replication rates that characterise HIV-imdicted disease).
- Elimination of the gene for Rev protein (implicated in the cytoplasmic export of unspliced and singly-spliced viral transcripts expressing the late viral proteins) from the core packaging construct.
- Deletion of the U3 region of the LTR from the transfer construct (transcriptional inactivation of the LTR > self inactivating transfer vectors > diminished risk of vector mobilisation).

We have chosen this vector system because of the particular ability of HIV-based viral vectors to deliver genes in vivo not only into proliferating cells of cell lines but into non-dividing cells, like primary neurons.

The production of the viral particles is the major hazard in our work, where we have concentrated all our attention to achieve the biosafety...
In the neuronal cultures the viral-derived particles inactivate very quickly. The probability of spontaneous recombination events is extremely low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

<table>
<thead>
<tr>
<th>Waste disposal:</th>
<th></th>

<tr>
<td>* All waste material containing viable GMM (spent culture fluid and other media) are inactivated by the addition of sodium hypochlorite 10% in robust leak proof container.</td>
<td></td>
</tr>
<tr>
<td>* Pipettes contaminated by the virus will be immersed in sodium hypochlorite, drained and collected in the cabinet where they will be double bagged ready for autoclaving. All contaminated plastic waste is immersed in sodium hypochlorite (10000 ppm active chlorine) for at least 8 hours, drained, double bagged, then autoclaved 121 degrees C 20 minutes. All sterile waste then goes for incineration.</td>
<td></td>
</tr>
</tbody>
</table>

**Proposed testing/monitoring measures:**
- The cells culture infected with the virus are tested, after the change of the medium, with p24 ELISA test and with RT-PCR to see the presence of the replication competent recombinants (RCR).
- Culture are set-up by adding aliquots of the medium to C8166 (or other mammalian cells) to see eventual RCR.
- The cells infected with Lentiviral particles are fixed, washed or lysed in level 2 containment room (513b).

This project transfers to GM Centre 14 on 15/10/2009

---

**Project Additional Information**

**Purposes of the contained use**

To study the effect of overexpression or down regulation of PML and DAXX on apoptosis and the regulation of the response to irradiation. The c-Jun and June-N-terminal kinase 1/2 pathway regulates apoptosis induced by UV radiation. We wish to test the effect of the siRNA-based downregulation or functional inactivation of various components of this pathway on the response to UV.

**Recipient or parental organism**

02/03/2022

Page 11482 of 15326
Mouse and human primary keratinocytes, mouse embryo fibroblasts, mouse bone marrow cells, mouse foetal liver cells, 293 cells (epithelial cell line), primary mouse cerebellum granule cells, neuroblastoma cell lines and adrenal chromaffine cells.

Host/vector system

Retroviral vectors such as MoMLV, MSCV and HIV-derived lentiviral vectors will be used. All the vectors are replication defective. All the trans acting genes (structural, regulatory and accessory proteins) are excluded from the transfer vectors, which encode the genes of interest. The transacting plasmids are provided by the packaging plasmids. The biosafety of these vectors is further advanced by deleting unnecessary genes and the two regulatory genes (tata and rev).

Origin & function

PML and DAXX cDNAs are from human and mouse origin. siRNA oligos for PML, DAXX, c-JUN and JNK1/2 will be designed based on mouse and human sequences. All the genes we intend to study are involved in the regulation of apoptosis.

Evaluation of foreseeable effects

There is a potential risk of infection at the stage of packaging and infection while using the lentiviral vectors, however the inserts we plan to transduce are not a hazard to human health. The host cells and plasmids generated by the parental virus are not harmful. The virus can infect the cells with which it comes into contact but cannot replicate, therefore the hazards to human health are low and containment level 2 is appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Solid waste will be treated with hypochlorite (10,000ppm) before being autoclaved prior to disposal (100% kill). The sterile waste is then sent for incineration by authorised contractors.

Liquid waste:
Liquid waste will be treated with hypochlorite (concentration 10,000ppm available chlorine) overnight and autoclaved before disposal. Any spillages will be cleaned with chlorine disinfectant and the waste paper autoclaved and incinerated.

Autoclave cycle - 121 degrees C for 15 minutes. The autoclaves are validated annually in the MRC Toxicology Unit.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
It has been agreed by the Genetic Modification Safety Committee that a designation of class 2 is appropriate for this work and that the risk assessment is sound and should be carried out at Containment level 2.

**Date Ackn'd**
28/01/2004

**CU2 Project Title**
EXPRESSION BY LENTIVIRAL INFECTION OF THE FOLLOWING CLONED GENES - GFP, CEBP FAMILY, BCL11A AND B, MLT, PRDM6 - IN B CELLS.

**Date Project Ceased**
17/01/2014

**Consent Granted**
not applicable

**Project notified under transitional arrangements**
N

**Historical Significant Changes**
Transferred to GM11 on 17/01/2014

**Project Additional Information**

**Purposes of the contained use**
To clone and express genes that have been identified as having a possible involvement in haematological malignancies, in primary B cells and B cell lines of human origin. The aim in the first instance is to assess whether the genes of interest have an effect on cell growth and/or apoptosis. Primary B cells cannot easily be made to express cloned genes by any other transfection method.

**Recipient or parental organism**
Primary normal human B cells and B cell lines of human origin.

Host/vector system

Pseudolentiviral particle based on HIV is used to infect the primary B cells (Naldini et al., Science. 1996 Apr 12;272 (5259):263-7). The lentiviral transfer vector pRRLsin.PPT.hCMV.pre will contain the gene of interest under the CMV promoter and between the 5' and 3' LTRs of HIV for integration into the cellular genome. It is transfected into 293T cells together with 3 core packaging plasmids and hybrid viral particles are made with the core proteins and enzymes of a lentivirus and the envelope of vesicular stomatitis virus. All structural, regulatory and accessory genes of HIV are excluded from the lentiviral vector and from the packaging plasmids. Virus particles are made which are replication-defective. The procedure involves transient transfection ie a short time for production of particles. The particles are collected from the culture supernatant, concentrated by centrifugation and can be stored frozen before being used to infect the target cells.

Origin & function

GFP - green fluorescent protein. Non-harmful.
Bcl11A and B - zinc finger genes, possible transcription factors. Human genes.
MLT - a paracaspase and may be involved in apoptotic pathways. Human gene.
PRDM6 - SET domain, may be involved in chromatin remodelling. Human gene.
It is likely that we will use mutated versions of all these genes also.
GFOP is only used as a test control gene. All the other genes are possible oncogenes.

Evaluation of foreseeable effects

At the packaging stage the viral particles could infect human cells. Therefore, the production of the virus and infection of host cells with the virus is carried out in containment level 2. Cells infected by the lentiviral particles are not hazardous as the virus cannot replicate. However, they could be overexpressing the gene inserted. The inserted genes are of unknown function and could be oncogenes but it is unlikely they will function on their own without other cellular changes. There is a low possibility of infecting individual cells in vivo. The virus particles cannot replicate and infection would remain localised to the site of entry.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### Project Additional Information

#### Purposes of the contained use

Spinocerebellar ataxia type 1 (SCA1) is an autosomal-dominant neurological disorder. We wish to understand the role of the calcium extrusion system and its deregulation in this disorder. The aim of this project is to express ataxin-1 wild type and ataxin-1 containing a 92-polyglutamine expansion in primary neuronal cultures.

#### Recipient or parental organism

<table>
<thead>
<tr>
<th>293T cells (epithelial cell line)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary cultures of cerebellum granule cells.</td>
</tr>
</tbody>
</table>

#### Host/vector system

The proposed lentiviral vectors are replication-defective so only the early steps of the life cycle are maintained. The vector to be used is a pseudotype HIV-derived lentiviral vector using a third generation packaging system (pRRLsin.PPT.hCMV.Wpre). The transfer plasmid contains the human cytomegalovirus promoter. It is defective for the expression of the viral proteins required in trans but retains all the cis-acting sequences crucial for packaging, reverse transcription and integration of the transcript derived from the transfer vector. An almost complete deletion in the U3 region of the LTR region has been made thus enabling the generation of self-inactivating virus particles and increasing the biosafety of the system.

#### Origin & function

The Ataxin genes are of human origin. These will be cloned into the Self-inactivating (sin) transfer vector plasmid pRRLsin.PPT.hCMV.Wpre and viral particles prepared by co-transfection of 293T cells with a 3rd generation packaging system (three packaging plasmids). The transducing viral particles obtained by this method will then be added directly to target primary cultures of cerebellum granule cells thus allowing an assessment of the role of Ataxin-1 in neuronal cells.

#### Evaluation of foreseeable effects

There is a potential risk of infection at the stage of packaging and infection while using the lentiviral vectors, however, the vectors are replication defective and the likelihood of recombinant events is low. The hazards to human health are low and containment level 2 is appropriate.

02/03/2022
Calcium signals govern a wide range of vital cell functions, necessary for cell survival. However, a prolonged perturbation of intracellular calcium homeostasis can trigger cell death. Our aim is to investigate the mechanism whereby changes in calcium are toxic to cells using a variety of probes to assess the role of calcium in primary cells. The aim of this project is to express calpastatin, calpastatin (AA 1-251) conjugated with Yellow Fluorescent Protein (YFP), caspase-3- and calpain-sensitive fluorescent probes (C-devd-Y and C-u calpain site-Y, respectively), cameleon and Ratio-Pericam (2mtRP) in primary cell cultures.

Recipient or parental organism

293 cells (epithelial cell line).
Primary cultures of cerebellum granule cells, cardiac myocytes and skeletal muscle cells.

Host/vector system

The proposed lentiviral vectors are replication-defective so only the early steps of the life cycle are maintained. The vector to be used is a pseudotype HIV-derived lentiviral vector using a third generation packaging system (pRRLsin.PPT.hCMV.Wpre). The transfer plasmid contains the human cytomegalovirus promoter. The biosafety is further advanced by deleting unnecessary genes and the two regulatory genes (tata and rev), so any replication-competent virus that could be generated during vector manufacture will lack the genes necessary for replication. Furthermore, the generation of self-inactivating lentivirus has been obtained by almost complete deletion in the U3 region of the HIV 3’LTR.

Origin & function

The calpastatin genes are of human origin. The caspase-3 and calpain probes and cameleon and Ratio-Pericam are engineered chimeric DNA sequences. These DNA sequences will be cloned into the Self-inactivating (sin) transfer vector plasmid pRRLsin.PPT.hCMV.Wpre and viral particles prepared by co-transfection of 293T cells with a 3rd generation packaging system (using three packaging plasmids). The transducing viral particles obtained by this method will then be added directly to target primary cultures of cerebellum granule cells, cardiac myocytes and skeletal muscle cells thus allowing one to assess the role of calcium signalling in primary cells.

Evaluation of foreseeable effects

There is a potential risk of infection at the stage of packaging and infection while using the lentiviral vectors, however the vectors are replication defective and the likelihood of recombinant events is low. The hazards to human health are low and containment level 2 is appropriate.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Ref 821/04.5
To clone and express genes that may be involved in the pathogenesis of B cell lymphoma in primary B cells and B cell lines of human origin. The aim of the project is to assess whether the genes of interest have an effect on the proliferation and/or apoptosis of primary B cells.

Recipient or parental organism

Primary B cells.
B cell lines of human origin.

Host/vector system

The transfer vector is pBabe puro and consists of portions of the MMLV provirus. The genes of interest will be cloned downstream of the SV40 promotor and between the 3’ and the 5’ LTRs of MMLV (RU5) which are necessary for integration into the cellular genome. The 3’ U3 of the enhancer region of the LTR has a deletion which results in a transcriptionally inactive vector that cannot be converted into full length RNA. The only transcription comes from the SV40 promotor through the gene of interest. Therefore the virus and resulting virus particles are self inactivating.

The final retroviral particle is created by transient transfection of the transfer vector into Phoenix 293T cells. These cells are an amphoteric cell line that contains integrated gag, pol and env genes under separate antibiotic selection markers. The transfection plasmid contains the sequence for part of the gag gene and a puromycin resistance marker. Hybrid virus particles are made with the core proteins and enzymes of a retrovirus and the envelope of a vesicular stomatis virus.

Origin & function

GFP-Green fluorescent protein. Non harmful.
Bc111A and B-zinc finger genes, possibly transcription factors. Human genes.
MLT-a paracaspase and may be involved in apoptotic pathways. Human gene.
PRDM6-SET domain gene. May be involved in chromatin remodelling. Human gene.
BCNP1 - may be involved in cell signalling. Human gene.
SNX25 - could be involved in signal transduction and cell cycle control. Human gene.

Mutated forms of these genes may also be involved.

GFP is a test control gene. Other genes are possible oncogenes.

**Evaluation of foreseeable effects**

The retroviral particles made at the packaging stage can infect human cells but are replication defective.

Cells infected with the retroviral particles are not hazardous as the virus cannot replicate however they could be overexpressing the gene inserted. The inserted genes are of unknown function and could be oncogenes however it is unlikely they will function on their own without other cellular changes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Solid waste**

Solid waste will be treated with hypochlorite (10,000 ppm) before being autoclaved prior to disposal (100% kill). The sterile waste is then sent for incineration by authorised contractors.

**Liquid waste**

Liquid waste will be treated with hypochlorite overnight (10,000ppm available chlorine) and autoclaved before disposal. Any spillages will be cleaned with chlorine disinfectant and the waste paper autoclaved and incinerated.

Autoclave cycle: 121 degrees C for 15 minutes. The autoclaves are validated annually in the MRC Toxicology Unit.

**Is an emergency plan required according to regulation 20?**  
N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form  
Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  
N

**Please enter comments on the GM safety committee on the risk assessment**

It has been agreed by the Genetic Modification Safety Committee that a designation of Class 2 is appropriate for this work and that the risk assessment is sound and should be carried out at Containment Level 2.
Project Additional Information

Purposes of the contained use

The m3-muscarinic receptor is expressed in neurones, salivary cells and smooth muscle. The purpose of this proposal is to investigate the signalling role of this receptor and the processes that regulate the receptor.

Recipient or parental organism

Top 10 E. coli
HEK 293 cells.
Rat and mouse cerebellar, salivary and smooth muscle preparations.
**CHO cells.**

**Host/vector system**

Inserts will be cloned into the pRRLsin transfer vector. This HIV-derived vector lacks the structural, regulatory and accessory proteins required for making replication competent retrovirus. This vector will be co-transfected into HEK293 cells alongside the pMDLg/pRRE, pRSV-Rev and pMD2.VSVG vectors in order to create replication defective lentiviral particles.

**Origin & function**

GFP - Green fluorescent protein. Non harmful. To be used as a test control gene.

M3 - muscarinic receptor
M3 - muscarinic receptors containing point mutations in the phospho-acceptor sites.

The receptors are of mouse origin and are involved in cell signalling.

**Evaluation of foreseeable effects**

At the packaging stage the virus particles could infect human cells. The virus is, however, replication deficient. Transacting structural genes are excluded from the transfer vector, which only encodes the gene of interest. The essential regulatory genes gag and pol are encoded in a separate plasmid, as is rev gene. These constructs have been altered to contain non-overlapping sequences hence minimising the possibility of recombination. In addition non-essential genes have been eliminated, hence any replication-competent virus generated would lack essential factors for replication and virulence in vivo.

The inserts are extremely unlikely to be hazardous. There is no experimental evidence that wild type or mutant receptor proteins act as oncogenes, drive cell growth or induce apoptosis. It cannot, however, be ruled out that the insert in an environment as yet untested may have a deleterious effect on host cells. For this reason the insert is considered here as 'potentially harmful'.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

### Purposes of the contained use

To reduce NTE expression in primary cultured cells using lentiviral mediated RNAi technology.

### Recipient or parental organism

Primary cultures of mouse cells including neurons and glia  
293T cell line  
Hela cell line

### Host/vector system

A pLV-THM lentiviral vector will be used. The vector will be co-transfected into 293 T cells alongside pMDLg/pRRE, pRSV-Rev and pMD2G vectors to create replication defective lentiviral particles. Trans-acting element genes are excluded from the transfer vector, which contain only the genes of interest. The essential regulatory genes gag and pol are encoded in a separate plasmid, as are Rev and envelope genes. These vectors have been engineered to contain non-overlapping sequences, thereby minimizing the possibility of recombination. Non-essential genes have also been eliminated so any replication-competent virus generated would lack essential factors for replication and virulence in vivo.

### Origin & function

Short hairpin RNA will be expressed that is homologous to human and mouse NTE genes with the aim of lowering their expression by means of RNAi. The 30 bp insert comprises of a 19bp sense sequence of DNA homologous to NTE cDNAs, a 9bp look and an intensense sequence of the same 19bp DNA to form a hairpin structure when expressed in infected cells. This hairpin RNA will mediate specific degradation of NTE mRNA through RNA interference mechanisms.

### Evaluation of foreseeable effects

At the packaging stage the virus particles could infect human cells. Therefore the production of the virus and the infection of host cells with the virus is carried out at containment level 2.

Cells infected by the virus particles are not hazardous as the virus cannot replicate, however they could lower NTE expression in local infected cells, it is very unlikely that inhibition of NTE expression at the local cell level will be hazardous.

### Project Additional Information

#### Purposes of the contained use

To immortalize rodent cells. SV40 Large T is a transforming oncogene inhibiting both p53 and Rb tumour suppressors.

#### Recipient or parental organism

- Bosc 23 ecotropic packaging cell line
- Ecotropic Phoenix packaging cells
- 293 epithelial cells
- Primary rodent cells

#### Host/vector system

The vectors used will be the retroviral vectors pBabe, pRetrosuper and pSuperior. These vectors are replication defective so only the life cycle of the vectors are maintained. All trans acting genes (structural, regulatory and accessory proteins) are excluded from the transfer vectors which encode the genes of interest. The biosafety of these vectors is further advanced by deleting unnecessary genes and the two regulatory genes tata and rev. The vectors can be transferred to eukaryotic cells but are self inactivating once inserted into the genome.

#### Origin & function

SV-40 Large T of simian virus origin. The function is to immortalize primary rodent cell lines.

#### Evaluation of foreseeable effects

The retroviral vectors to be used can be transferred to eukaryotic cells but are self inactivating once inserted into the genome, however if retroviral viruses are produced in ecotropic packaging cells they can only infect cells from rodents. The transduced molecules are a known hazard to human health. Neither the host rodent cells nor the plasmids generated by the parental virus are harmful. In cell cultures the virus can inactivate very quickly. The possibility of spontaneous recombination events is low. There is a low possibility of infecting individual cells in vivo, however the viral particles inactivate rapidly and the infection remains localised to the site of entry. Care is required in handling this GMM to avoid skin contact.

It has been agreed by the Genetic Modification Safety Committee that a designation of Class 2 is appropriate for this work and that the risk assessment is sound and should be carried out at Containment level 2.
Purposes of the contained use

To clone and express genes encoding proteins involved in cellular processes such as apoptosis, the cell cycle, cell signalling and neuronal pathology. Genes will be expressed in cell lines of human and rodent origin.

Recipient or parental organism

Human cells including cell lines of human origin and primary cells. Amphotropic packaging cells (for example Phoenix 293 cells) will be used to express the core packaging plasmids, therefore the virus produced could infect human cells. However, the packaged virus cannot replicate so infected target cells would not be hazardous, although they would be overexpressing the gene inserted. To minimise risk sharps will not be used and primary human cells will only be obtained from donors outside the building.

Rodent cells will also be used, both primary and cell lines. In this case ecotropic packaging cells will be used to ensure the viruses produced cannot infect human cells.

Host/vector system

The vectors used will be retroviral vectors pPINCO puro and pXy.puro consisting of portions of the MMLV provirus. The genes of interest will be cloned downstream of the SV40 promoter and between the 3' and the 5' LTRs of MMLV necessary for integration into the genome. The 3' U3 of the enhancer region of the LTR has a deletion which ensures the vector is transcriptionally inactive and cannot be converted into full length RNA. The only transcription comes from the SV40 promoter through the gene of interest. Therefore the vector and resulting viral particles are self-inactivating.

Origin & function

The genetic material to be expressed will include genes encoding proteins known to regulate cellular processes. This will include genes involved in apoptosis, the cell cycle, cell signalling and neuronal pathology. Examples will include ALAS1, CREB, HIF, cJun, CEBP family, BCPN1, MLT, Bcl, m3-muscarinic receptor, PML, DAXX, calpastatin genes and Green fluorescent protein.

Genes will be expressed that are well characterised as well as potential oncogenes or tumour suppressors and also mutated forms of these genes (including the CEBP family, BCNP1, PRDM6, MLT, Bcl11, SNX25 and C2TA). However, it is unlikely these genes would function as potential oncogenes or tumour suppressors on their own in the absence of other additional cellular changes.

Evaluation of foreseeable effects

Amphotropic retroviral particles made at the packaging stage could infect human cells, however the vector and resulting viral particles are self-inactivating (sin). The vector contains the psi-signal for packaging but the envelope gene (dENV) has been deleted. The vector also contains the gag gene necessary for transcribing the helper genes. Cells infected with the retroviral particles would not be hazardous as the virus is replication defective, however the cells could be overexpressing the genes of interest. Some inserted genes would be of unknown function and could be oncogenes; however it is unlikely these inserts could function on their own without other cellular changes occurring.

Project Ref  821/15.1
Investigation of the signalling properties of protein kinases in Plasmodium falciparum

Plasmodium falciparum is one of the parasites responsible for human malaria. The aim of this study is to establish the role of protein phosphorylation in maintaining the blood stage of the parasite and the essential processes involved in progressing the parasite through the blood stage. For this we will be generating and importing mutant parasite strains where certain protein kinase genes have been mutated as well as other genes involved in invasion and gametogenesis.

General overview of the project:
It is estimated that 300-500 million people world wide suffer from malaria with over 2 million deaths per year, mostly in children under the age of 5 (Breman, 2001). The most severe cases of malaria are caused by the parasite Plasmodium. falciparum. This parasite is transmitted to humans in the saliva of an infected mosquito. Once in the blood stream the parasite makes its way to the liver where it invades liver cells. Inside liver cells the parasite divides and changes into a form that is able to infect red blood cells. The infected liver cells eventually release parasites into the blood stream where they quickly invade red blood cells. Once inside the red blood cells the parasite once again divides filling the red blood cells with new parasites which are released when the cell membrane eventually ruptures. These released parasites invade other red blood cells and the cycle is repeated.

Many studies aimed at developing novel treatments for malaria focus on the blood stage form of P.falciparum (Pleass and Holder, 2005). Hence a detailed understanding of this stage in the life cycle will provide robust targets for further drug discovery.

We will study the biochemical processes of invasion of P.falciparum into human red blood cells, progression of the parasite through the red blood cell cycle and gametogenesis with particular focus on the role of protein phosphorylation. The following will be undertaken:
1. Investigation of novel potential drug targets including protein kinases and signalling molecules involved in parasite development and gametogenesis. Gene knockout experiments have demonstrated that certain proteins are essential for viability of malaria parasites. Among these genes are those that encode for protein kinases. Therefore, replacement of wild-type alleles of protein kinases with alleles carrying a mutation conferring hypersensitivity to inhibitors will allow validation of these proteins as potential drug targets.

2. Localisation and purification of tagged proteins/parasites: Subcellular localisation of Plasmodium proteins is important for determining how they may be pharmacologically targeted. Localisation of potential drug targets to different parts of the cells will be achieved through GFP or epitope-tag gene constructs. The addition of tags (such as 6-His, HA) to proteins such as kinases, cyclins and metabolic enzymes will allow direct purification of these proteins complexed with their natural protein partners, which can then be analysed further. Such purified proteins can also be used to directly screen against potential drug compounds in luminescent assays.

3. Investigation of erythrocyte invasion by malaria parasites. Gene knock-out of Plasmodium genes of the EBA family presumed to be involved in invasion will determine the role of individual proteins in this process.

4. Determination of the phospho-proteome of plasmodium falciparum using wild-type and genetically-modified parasites in comparative studies.

We will be looking at mutants of various protein kinases and signalling proteins including PfCPDK1, PfCLK1, PfCLK3, PfGSK3, PfPK6 and the gatekeeper mutant of PfPKG and NEK family (PfNEK1-4) kinase mutants as well as mutants in invasion related proteins (such as the EBAs) and regulatory proteins including K13-propeller and PfRh protein.

Recipient or parental organism

Plasmodium falciparum -307 and NF54

Host/vector system

DNA vector to be used will be pH1
This vector will confer ampicillin resistance

Origin & function

The genetic material used has its origin in a cDNA library obtained from the reverse transcription of mRNA derived from the schizont stage of P. falciparum.

The specific genetic material is discussed below:

Dominant negative mutants of:
PfGSK3 (+GTP/HA/His tagged versions)
PfPK6 (+GTP/HA/His tagged versions)

We will inhibit the action of specific protein kinases by overexpression of dominant negative mutants. These will include dominant negative mutants to GSK3 and PK6.

PfGSK3 is a protein kinase. The normal function of this kinase in malaria is unknown other than it is an essential kinase to maintain the blood stage of the parasite.

PfPK6 is a protein kinase. This kinase is homologous to the cyclin-dependent kinase and therefore likely to be involved in the cell cycle.

Gatekeeper mutant of:
PfPKG (+GTP/HAIHis tagged versions)

Mutants of the essential protein kinase PKG that render the parasite insensitive to inhibitors of PKG will be used to dissect the role of this kinase in the survival of the parasite.
PIPKG is a protein kinase. It is an essential kinase for parasite survival and is involved in parasite development in the red blood cell, egress and invasion into red blood cells. This kinase is also involved in formation of gametocytes. Protein kinases:

- CDPK1 (HA-tagged)
- NEK 'kinase family (NEK1 -4)(HA and GFP tagged)
- CLK1 and CLK3 (+GTP/HA/His tagged versions)

Wild type and mutants of a number of protein kinases that are essential for the progression of the parasite through the erythrocytic cycle will be investigated to establish the role played by these kinases in maintaining the viability of the parasite. The mutations to be introduced either involve epitope tags or removal of regulatory phosphorylation sites or introducing mutations that change sensitivity to protein kinase inhibitors.

PfCLK1/3 are protein kinases. They are involved in RNA processing in the parasite.

Invasion proteins

- EBA family (e.g. EBA-175)

Wilde type and mutants of key proteins involved in invasion (such as EBA-family) will reveal the role played by these proteins and the mechanisms of regulation such as protein phosphorylation.

EBA family. These are cell surface antigens involved in binding parasites to the surface of red blood cells.

Regulatory proteins

- K13-propeller. This is a transcriptional regulator of unknown function.
- PfRh family (+GTP/HA/His lagged versions)

Drug resistance is a major problem in malaria. It is becoming clear that a number of proteins including K13-propeller proteins are mutated in drug resistant parasites. We will use mutants of these proteins to establish what mechanisms are in play during drug resistance.

The PfRH-family are a group of rhoptry proteins which are released from the parasite during invasion and are essential for the invasion process.

**Evaluation of foreseeable effects**

*P. falciparum* is a serious human pathogen but the parasite is unable to infect any vertebrate species apart from man and certain primates, and can only infect certain species of Anopheles mosquitoes. Natural infection of humans occurs through the bite of an infected mosquito vector of the genus Anopheles. The research programmes that will be implemented in the Cat3 facilities do not involve mosquito vectors, so the risk of insect-borne inoculation is very low. The only way that the GM could enter the environment and survive is if a mosquito able to transmit malaria was to enter the lab, feed on the culture and pick up from the culture gametocytes. This is almost impossible for the following reasons:

Firstly there are only a few species of mosquito in the UK able to act as the vector for *P. falciparum*, of those that do exist they are in very low numbers in Leicestershire.

• The mosquito would then have to enter the closed environment of the malaria lab and gain access to the class 2 hood, or the incubator, which is extremely unlikely.

The mosquito would have to feed on the culture (which it is unlikely since it is only 10% human blood)

In the meal the mosquito would need to pick up gametocytes which are in extremely low numbers in Pf in vitro cultures (less the 0.5% of the infected red blood cells)

After all this it is almost impossible for a single infected mosquito to successful propagate malaria. For this to happen a large number of mosquitoes would have to go through the above process.

In the laboratory environment, infection of humans may take place by direct inoculation of infected blood (cultured material) into the bloodstream of the laboratory worker, e.g. through contaminated hypodermic needle. This risk is minimal since no needles or any glass are used in the dedicated culture room.

Since the parasite may enter through a cut in the skin then any skin abrasions should be cover in a plaster and the
operator where gloves and appropriate PPE. This should reduce any risk of infection to close to zero.
The only parasite lines which will be used in this programme (307, NF54) are all susceptible to chloroquine and,
importantly, the effectiveness of commonly used antimalarial drugs, e.g. chloroquine, is unaffected by the genetic
modification.
The function of the inserted parasite gene product will frequently be unknown, or can only be implied through
homology with other organisms. Knockouts of potential drug targets (e.g. protein kinases) are aimed at reducing the
fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic
replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with
increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of
these experiments. The GMM is very unlikely to be more harmful to humans than the parental organism.
Pathogenicity in Plasmodium does not depend on any known toxin or clonable agent. Malaria parasites are extremely
host-specific and there have been no reports of malaria parasites crossing species barriers, with the exception of
some non-human primate malarias that are able to establish very mild infection in humans, and experimental infection
of certain non-human primates with human malarias. It is not possible for the human malarias to establish infection in
any other vertebrates.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

<table>
<thead>
<tr>
<th>Not applicable</th>
</tr>
</thead>
</table>

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

P. falciparum is a parasite responsible for human malaria. As such this organism is categorised by ACOP as a Hazard
group 3 parasite but handling without negative pressure/HEPA filler is permitted (appendix 3.2 Biological agents
managing the risks in laboratories and healthcare premise). This is justified on the following grounds:

- The only way to contract malaria from an in vitro erythrocytic culture of P. falciparum is through a puncture wound
  of the skin. It is not possible, for example, to gain infection via spillage on the skin, touching contaminated cloths or
  by touching or rubbing eyes with contaminated hands or tissues.
- It is not possible to be infected by inhalation of parasites contained in aerosols, for example caused by
  centrifugation or by pipetting, or from evaporation from culture media.
- It is not possible to be infected by contaminated clothing.
- It is not possible to become infected by spillages unless some how the spillage was able to enter the body through
  punctured skin.

Since the parasite may enter through a cut in the skin then any skin abrasions should be cover in a plaster and
the operator where gloves and appropriate PPE. This should reduce any risk of infection to close to zero.
For these reasons it is not necessary to implement full cal 3 containment. Specifically the following key elements of
cat 3 contained are not required for P. falciparum in vitro culturing for the following reasons:

- The laboratory is sealable for fumigation:
  This is not necessary as there is no inherent risk of infection from P. falciparum through inhalation. Hence fumigation
does not present any inherent risk of parasite infection. Thus, it is not necessary to conduct fumigation in a sealed
  room. It would seem that this would in fact seriously increase the risk associated with the fumigation procedure with
  no benefit in decreasing the risk of parasite infection.
- There is an autoclave available within the laboratory suite:
  Health and Safety Executive

Il is not possible to become infected by the parasite culture other than through a puncture wound. Thus, the solid
waste is currently double bagged and autoclaved in the building autoclave facility because it is not possible to contract
an infection through accidental contact of any residual waste culture material with the skin, by inhalation or ingestion.
There is no justification therefore for autoclaving in the malaria lab. In fact having an additional autoclave would increase risk of injury through autoclaving.

Note that all liquid waste is decontaminated in the malaria lab and disposed of in the malaria lab therefore is not autoclaved.

Entry to the lab is via an airlock
This is unnecessary since it is not possible to be infected by the malaria parasite from inhalation or from aerosols or vapour or any airborne source. Hence an airlock is not necessary.

The lab is at negative pressure relative to the pressure of the immediate surroundings
This is not necessary for the same reasons as described above for the airlock.

Extract and input air from the laboratory must be HEPA filtered
This is not necessary for the same reasons as described above for the airlock/negative pressure.

Controls to mitigate risk of infection from in vitro P. falciparum cultures.
To mitigate the risk of infection from a puncture wound the following standard operating procedure for P. falciparum in vitro culture has been in operation for some time in line with the recommendations from the University and MRC safety office and as approved by the HSE.

a) Only the culture of P.falciparum is permitted in this laboratory.
b) Each culture batch will be up to 30ml
c) Only staff that have gone through the appropriate safety training and that have been approved by the University and MRC safety officers will be allowed to work in lab 201.
d) Access to lab 201 will be limited to personnel who have received training and approval by the supervisor/group leader.
e) Only trained personnel will be given the access code to enter the lab that will be locked at all times with a swipe card entry lock.
f) All the equipment required for the culture of P.falciparum will be contained in lab 201. This includes the class 2 microbiological cabinet, incubator, centrifuge and microscope.
g) Liquid tissue culture medium is stored in lab 202/209.
h) The use of sharps is strictly forbidden. This includes in particular glass pipettes and glass bollies. Glass slides will, however, be permitted for the staining of parasites in culture.
i) Liquid waste will be inactivated with presept (1,000ppm equivalent to 4 x 2.5g tablet per 50ml) and disposed of down the designated sink.
j) All solid waste will be double bagged and autoclaved.
k) Gloves will be worn at all times.
l) Safety glasses to be worn at all times.
m) Dedicated blue lab coats will be worn at all times.
n) Buckets in the centrifuge must be capped when spinning tubes containing the parasite cultures.
o) In the event of spillage, liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in solid waste and autoclaved. Area will then be washed with presept (10,000ppm equivalent to 4 x 2.5g tablet per 50ml) for disinfecting.
p) In the event of centrifuge disruption or if a spill is suspected then the following procedure must be adhered to:
   1. Leave 20 minutes before opening
   2. If the integrity of the buckets is not comprised, these (with caps) will be moved into the class II microbiological cabinet and opened.
3. Liquid will be disposed of in liquid waste container, treated with presept (1,000ppm equivalent to 4 x 2.5g tablet per 500ml) and disposed of in the designated sink. Solid waste will be disposed of in the solid waste disposal bin and autoclaved.

4. If the integrity of the buckets is comprised, then liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in solid waste and autoclaved.

5. The centrifuge should then be thoroughly cleaned with presept (10,000ppm equivalent to 4 x 2.59 tablet per 500ml) and all waste disposed of as solid waste and autoclaved.

Q) Transport of potentially infected material from laboratory 201 (e.g. cell lines, frozen ampoules, serum etc.) will be done in an approved sealed vessel clearly labeled and a trolley will be used.

r) All solid waste is autoclaved.

s) Eating, chewing, drinking, smoking, taking medication, storing food and applying cosmetics is forbidden in the laboratory.

t) Mouth pipetting is forbidden.

u) In case of a spillage of P. falciparum on broken skin or a puncture wound (from for example a contaminated slide) the wound should be washed thoroughly under running water and Occupational Health consulted.

v) When leaving the malaria lab (room 201) with malaria samples gloves and lab coats need to be changed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be inactivated by addition of Presept (Johnson & Johnson Medical) - 4x2.5g tablet per 500ml (equivalent to 10,000ppm) overnight and disposed of down the designated sink.

In the event of a large spillage, liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in solid waste and autoclaved. Area will then be washed with Presept (10000ppm equivalent to 2.59 tablet in 500ml). In the event of small spillages or splashes, the surface should be cleaned with 70% IMS.

All solid waste will be placed in an appropriate autoclave bag, taped closed and autoclaved at 133°C for 12 mins. All pipettes will be placed in a sealed orange topped 7L sharps bin and autoclaved at 133°C for 12 mins.

All waste will then be incinerated by an approved contractor.

*Note:- Presept data - a solution of presept was made up in water where the presept concentration was 10,000ppm. 1ml of this solution was added per 10ml 307 or NF54 P. falciparum culture for 24 hours (final concentration was 1,000ppm). In the control culture parasitemia was 1% and in the presept treated culture, no live parasites were observed. Therefore a final concentration of 10,000ppm is deemed far higher than necessary to kill the parasites.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The genetic modification safety committee have agreed the following:

i. That a designation of Class 2 is appropriate
ii. That the risk assessment is sound and that work should be carried out at Containment Level 3 but can be handled without negative pressure/HEPA filter
iii. That the project will be notified to the HSE,
and, further, they have noted:
iv. That the proposer will contact HSE to notify the work as a new project.

Purposes of the contained use

To clone and express genes encoding proteins involved in cellular processes such as apoptosis, the cell cycle, cell signalling, neuronal pathology and the process of haematopoietic lineage commitment and megakaryopoiesis. This project aims to characterise such genes by over-expression and knockout in primary cells or cell lines of human and rodent origin.

Recipient or parental organism

Human cells including cell lines of human origin and primary cells will be used. The unmodified cell lines are nonharmful, unable to colonise or cause disease (hazard group 1). Primary cells are derived from screened healthy donors, however as there is a possibility that material may contain adventitious infectious agents, it will be handled at Containment level 2.

Amphotropic packaging cells will be used to express the core packaging plasmids therefore the virus produced could infect human cells, however the packaged virus cannot replicate so infected target cells would not be hazardous, although they would be overexpressing the gene inserted. To minimise risk sharps will not be used and primary human cells will only be obtained from donors outside the building.

Rodent cells will also be used, both primary and cell lines, including stem cells. In this case ecotropic packaging cells will be used to ensure the viruses produced cannot infect human cells.

Host/vector system

Vectors are defective lentiviruses (i.e. replication incompetent, e.g. second or third generation derivatives of HIV-1) in which the structural and accessory genes necessary to produce lentiviral particles are located on separate blocks of DNA (i.e. separate plasmids). This means that three (for second generation) or four (for third generation) recombination events would have to occur simultaneously to generate replication competent lentivirus. Wildtype virulence and replication genes are deleted, therefore the HIV vectors lack the structural, regulatory and accessory proteins required for making replication competent retroviruses. Such vectors may infect human cells and integrate into the cellular DNA but when unmodified are considered Class 1 GMMs. The SACGM guidance on 'pseudotyped' vectors suggests they should be considered as Class 2 GMMs. When modified with genes of interest they will be treated as Class 2.

Origin & function

The genetic material to be expressed will include genes encoding proteins known to regulate cellular processes. This will include genes involved in apoptosis, the cell cycle, cell signalling, neuronal pathology and haematopoiesis. This will include known human leukaemia genes, including MEIS1 as well as factors involved in transcriptional regulation. Examples will also include ALAS1, CREB, HIF, cJun, CEBP family, BCNP1, MLT, Bcl family, m3-muscarinic receptor, PML, DAXX, calpstatin genes and Green Fluorescent Protein.

Genes will be expressed that are well characterised as well as potential oncogenes or tumour suppressors and also mutated forms of these genes, however it is unlikely these genes would function as potential oncogenes or tumour suppressors on their own in the absence of other additional cell changes.

In addition to ectopically express genes short hairpin RNAs and the genetic editing system CRISPR/CAS9 will be used to knock down/out target genes and modulate their expression. CRISPR/CAS9 will be also used to perform genetic screens.

Evaluation of foreseeable effects

In addition to ectopically express genes, short hairpin RNAs and the genetic editing system CRISPR/CAS9 will be
used to knock down/out target genes and modulate their expression. CRISPR/CAS9 will be also used to perform genetic screens. At the packaging stage the virus particles could infect human cells. The virus is, however, replication deficient. Trans-acting structural genes are excluded from the transfer vector, which only codes the gene of interest. The components required for viral production are present on separate vectors, transfected into the packaging cell line so that newly formed viral particles contain only the transgene and the minimal viral genes required for its genome integration and expression. They do not contain all the factors necessary for replication of the virus. In addition virulence genes have been completely removed from the system. The constructs have been altered to contain non-overlapping sequences, minimising the possibility of recombination. The possibility of sequential recombination events in the packaging cell line giving rise to replication-competent virus is extremely unlikely. Viral stocks will be stored in lockable freezers in areas of restricted access thus the vectors do not present a risk to the wider human population or the environment. The viruses will be VSV-G pseudotyped. This coat protein confers a wider tissue tropism than for the natural virus. The vectors may be transmitted by contact/aerosol as well as the natural percutaneous route. Lentiviruses are able to infect non-dividing cells unlike other retroviruses; the range of cells and modes of transmission are thus significant. Such chimaeric particles exhibit physical stability but are more sensitive to the complement system. Considered class 2. On infection, these viruses insert their DNA into the cellular DNA and so are capable of expression for the life of the cell. Insertion itself could lead to a deleterious mutagenic event but this is of low probability. Some inserted genes would be of unknown function and could be oncogenes, however it is unlikely they could function on their own without other cellular changes occurring and a single expression event is unlikely to result in any clinical manifestation. It cannot however be ruled out that an insert in an environment as yet untested may have a deleterious effect on host cells. For this reason these inserts are considered as potentially harmful. The overall risk may be considered as Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be treated with hypochlorite (10,000ppm for at least 16 hours) before being autoclaved prior to disposal or another suitable, validated disinfectant. The Sterile waste is then sent for incineration via authorised waste contractors. (100% kill).
Liquid waste will be treated with hypochlorite (10,000ppm for at least 16 hours before disposal via the sink or another suitable, validated disinfectant. (100% kill).
Any spillages will be cleaned with a chlorine disinfectant or other suitable, validated and any waste tissues autoclaved and sent for incineration.
Autoclave cycle: 121°C for 15 minutes. The autoclaves are validated annually within the MRC Toxicology Unit.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The committee comprises two representatives of ExpressOn BioSystems Ltd. The Technical Director who is ultimately responsible for ExpressOn's GMO operations and represents the management, and the company biological safety officer who additionally represents ExpressOn's employees. Also on the committee are the health and safety officer from the Roslin Institute and an educated lay person with a background in insurance and no vested interest in either ExpressOn or the Roslin Institute. This person represents the wider community. The company is small enough that the committee meets as and when necessary at the start of any new project and to review risk assessments if any new information comes to light.

ExpressOn BioSystems Ltd is a sub-tenant of the Roslin BioCentre and as such is expected to comply with waste management systems in place at Roslin.

Solid disposable (plastics, solid media) waste contaminated or potentially contaminated with biological material, whether GMO or not, will be collected in clearly marked HMHD autoclave bags and autoclaved for 15 min at 121°C. The autoclave is within ExpressOn's laboratory and will be tested monthly using TST strips included with a waste load. A test log will be kept. Once made safe autoclaved waste will be disposed of in black bags to general waste.

Liquid waste will have virkon powder added to 1% and will be stored overnight before disposal to drains. This process results in complete kill of micro-organisms of the type in use. Because of the low risk associated with the GMOs in use, degree of kill is not usually verified. If higher risk experiments were to be carried out then degree of kill will be assessed by culturing a sample of liquid waste on appropriate plates prior to disposal.

Non-disposable lab-ware contaminated with biological material will be soaked overnight in a solution of 1% virkon before washing as normal.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The two risk assessments enclosed are derived from projects that were assessed at the University of Edinburgh prior to ExpressOn moving to Roslin and setting up its own GMO committee. The project risk assessments have been re-written as part of this application and have been circulated to ExpressOn's GMO committee. Because the constructs used in the present projects are not designed to express in the host organism and because the cloned sequences are not known to be associated with any pathological condition it was considered that class 1 containing is adequate.

The TSE-related small RNA project is considered low risk but careful monitoring of the literature is necessary. If any nucleic acid component is ever thought to be associated with the TSE agent then this project will be stopped immediately and reassessed. A weekly literature alert will be set up with ExpressOn's information service, NERAC, to draw our attention to any emerging research that we might otherwise miss. A level of containment is afforded by the fact that sequences of interest are maintained and propagated as CDNAs whereas any activity would be associated with the RNA version. The cDNAs are derived from hamster brain RNA. Purified nucleic acid fractions from TSE infected animals are not infections and pose no greater risk than nucleic acids purified from non-infected animals.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee consists of a group of senior scientists including the Scientific Director, all members are at PhD level and have several years laboratory experience. Meetings are held at the start of new projects to ensure all aspects of risk assessment are considered. Projects are reviewed periodically to ensure that no deviation from the original classification has occurred.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All contaminated waste will be inactivated prior to disposal. Liquid waste (cultures) will be treated with 1% Virkon for a minimum of 30 minutes (according to manufacturer's instructions) to reduce viability to $<10^{-5}$. Solid waste will be autoclaved prior to disposal for incineration using a licensed waste management company. The autoclave will be serviced and include an annual UKAS calibration. Period test swabs from autoclaved waste will be used to ensure that the levels of survival are below detectable levels.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The PLMS project in the Risk Assessment summary represents an acceptably low risk and as such can be classified as Hazard Group I.

Y

Give brief details of the genetic modification safety committee

The GMO committee comprises of a Chairman (Chief Operating Officer), a senior management representative (Chief Executive Officer) the laboratory Manager (also designated Health and Safety and ISO/Quality Manager) and a laboratory representative. Where deemed necessary, an independent external advisor from an appropriate scientific background will be invited to attend. Due to the small size of the Company, the role of Biological Safety Officer will be shared between the COO and CEO who are both suitably qualified for this position. In addition to renewing risk assessments for new procedures involving GMOs the Committee will advise on preparation of facilities, training and the development of SOPs to ensure the safety of exposed workers and the environment. Meetings will be called on an ad hoc basis but not less than every six months where a complete review of current practices will be held.

All used liquid growth media will be sterilised by the addition of 10% (v/v) of 10g/1 Virkon for 60 minutes. The treated waste will then be discarded down a designated sink, accompanied by copious quantities of water, in the containment level 1 laboratory where the work has taken place. All other waste will be sterilised by autoclaving and then incinerated.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

With reference to the analysis outlined in the attached summary, the GMSC recommended that GLP will adhered to, that GMM works should only be conducted in laboratories which are of containment level 1 status within the School, that waste management should be conducted as set out in Section 6, and investigators are especially aware of local procedures for the treatment of inevitable minor biological accidents, such as bacterial culture spills (these will require immediate treatment with a powdered disinfectant - Virkon).

Date of Significant Change

Project Additional Information

Purposes of the contained use

The work to be carried out will address the fundamental biology of bacterial pathogens with respect to their:

1. nutritional adaption to colonisation and infection, 2. biosynthesis and construction of envelope layers, 3. trafficking of materials across envelope layers, 4. development of resistance to envelope-targeted antimicrobials and 5. their responses to challenge by the innate immune system.

Recipient or parental organism

Respiratory pathogens, particularly Rhodococcus equi and Streptococcus equi will be the focus of much of the work.

Other ACDP Hazard Group 2 nocardioform actinomycetes maybe used for comparison to Rhodococcus equi, for example Mycobacterium smegmatis.

Some gastrointestinal pathogens may be used for comparison, for example Salmonella enterica. The extent of the modification here will be limited to using reporter constructs to facilitate detection of bacterial growth or gene expression in model infection systems.

Host/vector system

For Nocardioform actinomycetes:

Only vectors that are either non-mobilisable or mobilisation-defective in bacteria as defined in the Compendium of Guidance will be used. These will include the broad host range pNV18 and 19 series (the low copy number variants are most appropriate) and the low copy mycobacterial vectors pMV261 and pMIND, and the integrating pMV306.

For mutagenesis, the anticipated systems are the pSELACT system, which has been developed for constructing unmarked in-frame deletion mutants in rhodococci.

Inducible merodiploid strains may be constructed using the integrating pMV306 vector or similar, if necessary, to explore conditional genetic essentiality in targeted genes.

Streptococcus equi:

Mutagenesis will be carried out in S. equi using homologous recombination using the thermosensitive shuttle vector pG+host9. Complementation analyses will be carried out using non-mobilisable vectors such as pCD123.

Random insertional mutagenesis will use the EZ-Tn5<KAN-2>Tnp Transposome system, which relies on a pre-formed complex of a simple T5 transposon and transposase components to introduce a Kanamycin resistance cassette stably into the bacterial chromosome.

RNA interference: The 'knockdown' of essential genes by RNA interference in nocardioform actinomycetes will be attempted using the tetracycline-inducible mycobacterial shuttle vector pMIND.

It is anticipated that newer systems based around CRISPR-Cas9 will be explored as these are developed. These are often stably incorporated into the bacterial chromosome and would not be transferable to other organisms.

Origin & function

Inserted DNA will be derived from genomic DNA extracts of bacterial pathogens of the respiratory tract, particularly nocardioform actinomycetes and Streptococcus equi.

Where ACDP Hazard group 3 pathogens are used, such as Mycobacterium tuberculosis, sterile DNA extracts will be obtained from other laboratories.
The genetic manipulation involved will include:

(i) the mutagenesis of bacterial pathogens (ACDP hazard groups 1 and 2) in targeted genes relating to the 5 categories described above in section 6. Mutagenesis will be carried out using homologous recombination on a ‘suicide’ plasmid such as pSELACT or a thermosensitive plasmid such as pG+host9 to form unmarked in-frame deletions or by random insertional inactivation using transposons.

(ii) the complementation of such mutants with related sequences of bacterial origin (or synthetic derivatives thereof) to validate gene function.

(iii) RNA interference to transiently silence essential genes

(iv) the generation of harmless reporter functions (e.g. GFP/luciferase/β-galactosidase) to probe bacterial viability and/or gene expression and its regulation.

For activities i-iii, the bacteria used principally will be respiratory tract pathogens of humans and mammals, and their close relatives. These will be limited to:

(a) the nocardioform actinomycetes principally Rhodococcus equi, however, other rhodococci, and selected bacteria from other closely-related genera including Nocardia, Corynebacterium, Gordonia, Segniliparus and Mycobacterium will be used periodically for comparison. Where possible and experimentally valid, ACDP hazard group 1 species will be used. Periodically, genes encoding transporter proteins or enzymes of ACDP hazard group 3 pathogens Mycobacterium tuberculosis and/or Mycobacterium leprae will be used in activity ii.

(b) Streptococcus equi.

The range of pathogens used in activity (iv) will be more diverse to include ACDP hazard group 2 species in general. Our principal interest is in respiratory pathogens, likely subjects will be Haemophilus influenzae and Pseudomonas aeruginosa. Sometimes gastrointestinal tract pathogens such as Salmonella enterica will be used for comparison.

Our interest lies in the characterisation of gene products that are related to the fundamental biological systems of these bacterial pathogens rather than ‘aggressive’ virulence factors such as toxins or super-antigens. Cloning of such sequences is excluded from this proposal. Predominantly, we will focus our investigations on genes that (i) direct the biosynthesis of the bacterial cell envelope (ii) enable the trafficking of proteins across the envelope, (iii) enable the import and exploitation of nutrients or the biosynthesis / export of components of dedicated acquisition systems (e.g. siderophores), (iv) allow the bacterium to adapt to environmental changes such as acidification. (v) In studies of the regulation of these genes or of the persistence of the organism in in vitro infection models, various well-described reporter genes will be used (e.g. β-galactosidase, fluorescent proteins, luciferase).

Our aims will require authentic physiological expression levels to validate gene function. Genes assessed in complementation studies will be expressed from native promoters or well-characterised constitutive or regulated promoters.

**Evaluation of foreseeable effects**

**Potential Hazards:**

(i) Genes that direct the biosynthesis of the bacterial cell envelope.

Genes that will be targeted will include glycolysyltransferases, components of fatty acyl synthases, fatty acid modifying enzymes, and associated genes that provide substrates via reactions such as epimerisation. Principally, these genes will be deleted individually but in some cases in low numbers. Complementation experiments will involve the low level expression of single genes or operons to establish gene function. In almost all situations, modifications will likely merely replace deleted functions that should severely limit the fitness of the microorganism and will generate no greater hazard than the original host. The modification of the biosynthesis of cell wall lipoarabinomannan, a likely immune suppressor, might induce a more aggressive response to the bacterium by macrophage but this would be expected to lead to early clearance by the innate immune system rather than an amplified inflammatory response.

(ii) Genes that enable the trafficking of proteins across the envelope.

Genes that will be targeted will include genes that have been identified by a functional genomic / bioinformatic approach. By definition, these sequences will not be limited to pathogenic species so risks associated with cloning uncharacterised sequences are adequately controlled.

(iii) Genes that enable the import and exploitation of nutrients or biosynthesis / export of components of dedicated acquisition systems.

Genes will be manipulated in isolation or in small numbers. Deletion will be expected to limit the ability of the bacterium to establish an infection through loss of fitness. The
mutation of genes encoding iron-responsive regulatory proteins might de-regulate virulence-associated factors like adhesins and siderophores. These genes would be at least partly deregulated as part of the normal colonisation process; the outcome is likely to be inefficient biosynthesis reducing bacterial fitness. The mutation of such regulatory genes will be only attempted in Rhodococcus equi as the organism produces no known toxins that might be subject to transcriptional control by iron availability and thus overexpressed as a consequence of this manipulation.

(iv) Genes that allow the bacteria to adapt to environmental changes such as acidification. Deletion of such genes is expected to severely limit the fitness of the organism and lead to rapid clearance by the innate immune system. Complementation studies will not seek to over express such systems and thus significantly enhance the tolerance of the bacterium to the killing mechanism applied by the innate immune system. Low gene doses will be maintained throughout to ensure physiological relevance of the observed phenotype and avoid the generation of exceptionally tolerant strains.

(v) Reporter constructs. The purpose of the reporter constructs is to indicate organism viability or differential gene expression. The reporters are all well characterised and accepted as harmless research tools.

</tr>
</thead>
<tbody>
<tr>
<td>The work will generate various wastes that may contain live GMMs, often at low densities. These will include bacterial pastes, bacterial lysates and spent medium. All will be sterilised by autoclaving before disposal as solid or aqueous waste, as appropriate. Additionally, there will be some generation of contaminated plasticware and glassware. Predominantly, these will be sterilised by autoclaving. If the material is to be reused and heat treatment is not compatible with such reuse, the items will be disinfected by treatment with 1% Rely+On Virkon for at least one hour. To avoid corrosive damage, the metal probes used in our ultrasonication equipment will be cleaned after each use by thorough wiping with 70% ethanol. This is a precautionary measure as the ultrasonication in itself will kill the overwhelming majority of the bacteria in the sample. With reference to manufacturers’ data, Hernández et al. 2000 (J Hosp Infection 46: 203–209) and in our own experience, these treatments are adequate to disinfect surfaces contaminated with these vegetative bacteria. Autoclave performance is regularly monitored by technical staff. Spills will be contained by adsorption on tissues or 3M Powersorb spill management kits (SK5), choice will be based on size of the spill. The spill management kits can contain 5L spillages. The contaminated adsorbant will be bagged and sterilised by autoclaving. The area affected by the spill will be mopped/swabbed using 1% virkon which will be allowed to stand for at least one hour. If the surface is metal, Virkon will be applied for 10 minutes and followed up with 70% Ethanol, to avoid corrosive damage. The efficacy of the clean up procedure for spills of &gt;10 ml high density cultures and &gt;100ml of spent media will be monitored by attempting to culture bacteria from the spill site.</td>

### Purposes of the contained use

This project is an investigation into the molecular basis for Bordetella infection and immunity. It attempts to elucidate the processes by which these bacteria colonise the host tissues, multiply within these tissues, cause pathology, transmit to other hosts and how the host immune response reacts to the bacteria. In particular, it studies the genetic and cellular basis for these processes. Data arising from this project will obviously expand understanding of the infection biology of these bacteria. However the
Bordetella are models for numerous processes that are of general interest to the infection and immunity field, including control of gene expression, interactions with ciliated respiratory epithelia, mucosal immunity in the respiratory tract, host-adaptation and the evolution of virulence. This project involves studies at the cellular level using whole bacteria and at the molecular level using purified bacterial components (proteins, nucleic acids, carbohydrates, lipids and glycolipids).

Recipient or parental organism

B.pertussis, B. parapertussis, and B. holmesii are pathogens of the human respiratory tract and the causative agents of whooping cough. Infants who have yet to receive the full schedule of pertussis vaccinations are susceptible to whooping cough. Adolescents and adults for whom vaccine or infection-induced immunity has waned are susceptible to chronic cough and are sources of infection of susceptible infants. Pertussis is naturally endemic in the human population. Little is known about the contribution of B. parapertussis and B. holmesii to the burden of whooping cough disease. The pertussis vaccines do not fully protect against B. parapertussis or B. holmesii but may lessen the severity of parapertussis and holmesii disease. Thus, laboratory workers are at risk from infection but the morbidity from such infection is very low. Appropriate control measures to prevent exposure should be used. B. bronchiseptica infects a very wide range of mammals but is described as a pathogen of just a few (cats, dogs, pigs), causing a relatively mild respiratory tract infection. Human infections are rare and almost always associated with immuno-compromised people or close contact with infected animals. It is not considered a risk to healthy humans.

The other Bordetellae cause sporadic disease in humans including respiratory disease and septicaemia. Risk factors for infection by these organisms are unknown, as is their true pathogenic potential. Although infections by these bacteria are rare, appropriate control measures are sensible. Workers may spread the bacteria, particularly B. bronchiseptica, to other susceptible animals if they are carried out of the lab on clothing or person. All workers will be made explicitly aware of the need to maintain rigorous standards of occupational hygiene to minimize the risk of this. All workers will be required to sign that they understand this risk and the control measures required to prevent it on personal safety training/risk assessment records.

Importantly, Bordetella that are pathogenic to humans, and capable of aerosol transmission, will be handled in a Class II Biological Safety cabinet to minimise the chance of exposure of humans to these bacteria.

Host/vector system

Bordetella DNA will be cloned, maintained and manipulated in lab strains of E. coli. The main purpose for this is to introduce defined mutations into the DNA and then to move the mutated loci back into Bordetella to generate allelic replacement mutants. Mostly, mutations will be constructed by inserting an antibiotic resistance cassette into the Bordetella locus.

Origin & function

The creation of defined bacterial mutants via allelic exchange mutagenesis is a powerful technique for elucidating gene function, is a standard technique in my laboratory and forms the majority of genetic manipulation in this project. The phenotype of the wild-type parental strain is compared to that of the isogenic mutants. Changes in phenotype are correlated to the genotype. This approach is a powerful technique for ascribing gene function, for elucidating the role of that gene in the biology of the host organism and is used widely in studies of bacterial pathogenicity.

Some Bordetella mutants will be used to infect mice to test their phenotypes in an in vivo model of infection and immunity. The mouse model of Bordetella infection is well characterised and has been instrumental in understanding the infection biology of these bacteria, this will be conducted outside of Northumbria University.

In other cases, Bordetella genes will be cloned to express them from the recombinant plasmids and is also used to study gene function. Complementation of mutations is used to confirm that a mutant phenotype is due to the experimentally constructed mutation and not a secondary effect or artifact. Expression of genes in heterologous hosts is used to identify possible functions of the gene by analysing the phenotypes of the recombinant strain. Finally, heterologous gene expression in appropriate E. coli host strains is widely used to generate high levels of recombinant, purifiable protein for in vitro studies of protein function.
Evaluation of foreseeable effects

It is considered very unlikely that using lab strains of E. coli in this way will result in a pathogenic phenotype. A vast majority of DNA constructs used will not encode functional proteins. Bordetella promoters are not well recognised in E. coli. In the very rare instances where a Bordetella encoded protein is expressed in these E. coli hosts, it is highly unlikely to convert them to an infectious phenotype.

Deleterious effects from mutating Bordetella are unlikely. Most mutants are of lower virulence/fitness than the parental wild-type strains (for example see: Pilione, M. R., Pishko, E. J., Preston, A., Maskell, D. J. and Harvill, E. T. 2004. PagP is required for resistance to antibody-mediated complement lysis during Bordetella bronchiseptica respiratory infection. Infect. Immun. 72: 2837-42; Burns, V. C., Pishko, E. J., Preston, A., Maskell, D. J. and Harvill, E. T. 2003. The role of Bordetella O-antigen in respiratory tract infection. Infect. Immun. 71: 86-94; Harvill, E. T., Preston, A., Cotter, P. A., Allen, A. G., Maskell, D. J. and Miller, J. F. 2000. Multiple roles for Bordetella lipopolysaccharide molecules during respiratory tract infection. Infect. Immun. 68:6720-8). To my knowledge, there is no report of a Bordetella mutant showing increased infectivity or causing greater pathology compared to its wild type. There is clear scientific evidence that the host ranges of these bacteria is determined by multiple factors (multiple different adhesins are used, multiple toxins interact with different components of the host immune system, defective metabolic pathways (e.g. glycolysis, cysteine synthesis) contain multiple genetic deficiencies and thus would not be activated by gain of a single gene.

There are no foreseeable adverse effects from performing in vivo work with Bordetella mutants. The bacteria will be handled in containment level two facilities and infected animals housed in isolator facilities (outside of Northumbria University) that will not permit release of bacteria in to the environment or to other animals. Transport of the GMOs will be in accordance with .

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None made

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste-autoclave. Autoclave at 134°C for 10 minutes (+10 minutes free steaming), validated by temperature probe. Liquid cultures- autoclave. Autoclave at 134°C for 10 minutes (+10 minutes free steaming), validated by temperature probe.

Liquid spills will be mopped up by paper towels and these will be autoclaved as above (hazardous cultures will be handled in a safety cabinet which will aid containment of spills).

Autoclave performance is regularly monitored by technical staff.

Contaminated materials and surfaces will be disinfected using 70% ethanol which achieves a 100% kill of Bordetella. This was validated in house by the PI. Suspensions of bacteria were deposited on bench surface, bio-safety cabinet surface and floor. 1x10^3, 1x10^5, 1x10^7, 1 x10^9 and 1x10^10 colony-forming units were deposited in PBS in a 100μl volume and allowed to dry for 1 hour. Each spot was then sprayed with a saturating volume of 70% ethanol (no fixed volume) and allowed to stand for 1 minute. The ethanol was then removed by wiping dry with a paper towel. PBS was then pipetted onto the spot where bacteria were deposited and agitated with a sterile swab. The PBS was then collected by aspiration and plated onto Bordet-Gengou agar supplemented with 15% defibrinated sheep blood (standard Bordetella growth medium) and incubated at 37°C for the appropriate length of time to allow growth. No colonies were recovered from any surface. The experiment was repeated twice with the same result.

Is an emergency plan required according to regulation 20?

N

If yes, tick to confirm that it is attached to this form

N
We have considered the proposed project under the management of Dr Iain MacArthur and are satisfied that the risk assessments made and countermeasures proposed are appropriate. New workers will be directed towards our generic in-house training which will be supplemented with project specific training provided by Dr MacArthur or a trusted delegate. The site intended for in vivo testing currently is at University of Louisiana, USA and we have discussed appropriate packaging for the transfer.

**The GMSC approved the GM RA as a Class 2 activity.**
In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map until 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to non existent. Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or none existent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (eg promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

Class Non-GMM Consent Granted
Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed contained use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexa-Vec by IT injections. This is being submitted as a Connected Programme Notification to facilitate the possibility of conducting other, future clinical trials of the same product, e.g. in patients with other cancers or in combination with other treatments.

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (VV) derived from the commonly used vaccine Wyeth strain, DryvaxTM. W is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of W exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988). W has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As W contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. W may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccinia nation to smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexa-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes replication in normal cells more difficult than the smallpox vaccine. Rare complications included eczema vaccinatum (patients with eczema), disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and...
encephalitis (1-2 per million vaccinated) (Fields B.N., 1996). Recent studies of smallpox vaccines have identified
cardiac injury including pericarditis and myocarditis as a potential risk (Halsell J.S. et al. , 2003).
W replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host
genome (Moss B. , 2007).

In terms of classification of hazard, W is considered as a Group 2 biological agent as per Directive (2000/54/EC). W is
also classified as a Biosafety Level 2 (BSL-2) infectious substance by the US Centers for Disease Control and
Prevention (CDC) (CDC, 2009) and as a risk group 2 organism by the US NIH Guidelines (NIH).

Host/vector system

Pexa-Vec was generated by co-transfection of CV-1 cells (Monkey kidney cells) with W (Wyeth strain obtained from
the Center for Disease Control, Atlanta, Georgia) and the plasmid pSC65/hGM-CSF. The vector pSC65/hGM-CSF
contains DNA sequences coding for the hGM-CSF and ~galactosidase proteins and for their respective promoters. In
addition, the transgene sequences are flanked by two W genomic regions (TKL and TKR) that allow homologous
recombination between the transfer plasmid and W.
The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National
Institute of Allergy and Infectious Diseases, Bethesda, Maryland (Chakrabarti 1997).
The plasmid pSC65/hGM-CSF is inserted into VV. The insertion of pSC65/hGM-CSF into VV can be detected by
using colorimetric identification of plaques containing recombinants expressing ~galactosidase.
The pSC65 vector when provided by Dr. B. Moss contains the LacZ gene. The LacZ gene is a reporter gene, under
control of the W p7.5 early/late promoter. The additional donor gene (i.e. gene coding for hGM-CSF) is inserted in
pSC65 as follows.
The plasmid pCSF-1 (No. 39754) was obtained from American Type Tissue Culture Collection and comprises the full-length
cDNA for hGM-CSF (Wong 1985). The hGM-CSF gene was cloned first into the EcoR1 site of pBLUESCRIPTII SK
(Siratagene, La Jolla, California), generating plasmid pBLUEhGM-CSF, and providing restriction enzyme sites to
allow cloning of the hGM-CSF gene into the Sal I and 8g1 II sites of pSC65. This positioned the hGM-CSF gene
downstream of a synthetic promoter (PsE/L) designed by Dr Moss’ laboratory to give maximal levels of transcript when
during both the early and late phases of vaccinia infection (Chakrabarti 1997).

Origin & function

P!/xa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral
thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGMCSF)
gene and 3) insertion of the LacZ gene.

Due to the insertion of the transgenes, the TK gene is inactivated. This decreases W virulence (Buller R. et al., 1985)
by restricting viral replication to proliferating cells. This also targets dissemination of the virus to tumors (Puhlmann M.
01 al., 2000).
The plasmid pCSF-1 (No. 39754, American Type Tissue Culture Collection, Rockville, Maryland) contains the full-length
cDNA for hGM-CSF (Wong G.G. et al., 1985). The cDNA for the hGM-CSF gene was inserted into the TK gene
to help elicit an immune response to tumor cells both at the site of viral replication and in distant metastases.
The cytokine hGM-CSF was chosen because it was the most potent stimulator of systemic anti-tumor immunity
among many tested (Dra noff G. et al., 1993), probably due to its unique ability to promote differentiation of
hematopoietic precursors into dendritic cells (Pardoll D.M., 1995). Dendritic cells are professional antigen presenting
cells that may take up and present released tumor antigens as the tumor cells are killed by the W.
The LacZ gene is contained in the pSC65 plasmid which was provided by Dr. B. Moss, National Institute of Allergy
and Infectious Diseases, Bethesda, Maryland.
The LacZ gene encodes for ~galactosidase which is a hydrolase enzyme that catalyzes the hydrolysis of 13-
galactosides into monosaccharides. Of note, following recombination between the Wand pSC65/hGM-CSF, the antibiotic resistance gene contained in pSC65 is not part of the insert. The final GMO does thus not contain any genes conferring resistance to antibiotics.

**Evaluation of foreseeable effects**

Pexa-Vec is non-integrative, and replicative and propagative characteristics of W have been attenuated in Pexa-Vec, which makes the virus replication dependent on actively dividing cells such as cancer cells. Therapy with a replicating virus can theoretically lead to shedding of the virus into the environment, and potentially to the public, although controls are used in this trial to minimize this occurrence. The clinical information available to date suggests that Pexa-Vec is safe at the clinical dose of 1 x 10^9 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 35 will likely have been previously immunized with vaccinia. In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. Therefore, public health risks with this virus are extremely low and in fact should be lower than with standard vaccination procedures. To date, no reports of transmission to health care personnel from vaccinia recipients have been published. Routine barriers nursing approaches should be used per institutional guidelines for infectious organisms (e.g. such as for M. tuberculosis, Pseudomonas).

The information regarding the risk to patient contacts and guidelines for reducing the risk of viral transmission is contained within the Participant Information Sheet and Consent Form (PISCF) and the Pexastimogene Devacirepvec (Pexa-Vec) Guidelines (provided in Appendix B of Pexa-Vec Investigator's Brochure). The PISCF will be reviewed with the patients, and their written consent will be obtained, before they undergo any study-specific procedures. A signed copy of the PISCF will be given to the patients so that they can come back to the guidelines at any time. Pexastimogene Devacirepvec (Pexa-Vec) Guidelines will be given to investigators, pharmacists, and all personnel involved in the handling of the product.

The genetic modification of the virus is not expected to result in any post-release shift in biological interactions or host range or in any known or predictable effects on non-target organisms in the environment. It is also not expected that the release of the recombinant virus would result in any increase in pathogenicity as compared to the parental virus strain and/or in any increase in the capacity to recombine with other related viruses. Therefore, under the conditions for use in the proposed clinical trial, Pexa-Vec is not considered to represent a risk for the environment and for the public health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Not applicable.**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Used vials, needles, syringes and gauze will be discarded into a designated autoclavable sharps bin. This will be closed (but not locked, so as to permit steam penetration), and placed into an autoclave bag. Disposable gowns, gloves and other personal protective equipment will be discarded directly into an autoclave bag. These are labelled to indicate GM waste, and placed in a rigid, lockable container for temporary storage and transportation. The research nurses will follow King's College Hospital's Yellow Waste Stream Standard Operating Procedure and...
will arrange for the designated waste porter to transport the waste to a suitably licensed incineration facility. Any sharps will be safely disposed of according to local institutional policies. All contaminated material, including sharps, should be disposed of in a clearly-marked biomedical waste container and discarded according to regular institution procedure for infectious waste i.e.: autoclaving, incineration, or treatment with sodium hypochlorite solution. Textiles and fabrics can be decontaminated by laundering using routine protocols for healthcare facilities (e.g., hot water washing with detergent and hot air drying).

Please enter comments on the GM safety committee on the risk assessment
The Kings Health Partners Biosafety Committee discussed the risk assessment at a meeting held on the 22 July 2016, with further information discussed on the 1st September 2016. The committee noted that Pexa-Vec is a GM H2 recombinant product which will be given by direct injection into the tumour. It is a vaccinia virus modified by the insertion of two external genes into the viral thymidine kinase gene. Although it retains reproductive potential, PexaVec is active only in tumour cells and not normal cells. The virus remains active for 2 weeks post administration. Approximately 300 people have received Pexa-Vec, with systemic side effects reported with intravenous administration. This study aims to assess the efficacy of intratumoral injection.

The committee identified the following potential risks:
- shedding of the virus from skin lesions (a small proportion of previously treated patients developed up to 5 pustular lesions typical of the vaccinia)
- shedding of the virus from the oral cavity if mouth lesions develop
- accidental inoculation of the IMP (this has previously occurred in 2 members of staff, which one developing a pustule at the site of the injection).

The committee acknowledged that although the risk from intralesional injection would be smaller than IV administration; they cannot be totally negated.

The IMP will be reconstituted at the Guy’s Hospital GM facility and transported by specialist courier to the KCH site. The courier has experience of in the transportation of GM materials.

The committee commented on the suitability of facilities to accommodate these patients and further information was provided as follows:

The IMP will be administered in the angiotherapy room in the Radiology Department; and the patient will be isolated immediately after the procedure for 4 hours before transfer into a single room on the private patients suite. Although there has been no evidence of transmission via urine, patients will use disposable bedpans and urinals which will be appropriately disposed off. There will be no interaction with other patients.

All staff involved will receive appropriate training and education by the biological safety officer to enable provision of safe care, and ensure that universal infection control precautions are maintained. Standard operating procedures have been written to cover training and waste disposal and will be disseminated to all persons involved with the study. The committee has indicated that all staff (nursing, ancillary, catering and housekeeping) who are either pregnant, immunocompromised or have chronic skin conditions, should not be exposed to the IMP.

The committee also raised the issue of the unavailability of immunoglobins within the UK (stored in Singapore); and was satisfied with Sillajen’s response that the response noted in the case of exposure was of a mild nature (flu-like symptoms) and self-limiting. However, should the IG be needed, Sillajen could ensure it was made available within 24-48 hours. Sillajen also has robust plans in place to follow up each case of exposure until resolution.

The biological safety committee was satisfied that all potential risks had been identified and suitable resolutions were in place.

### Purposes of the contained use

In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

### Recipient or parental organism

See box below

### Host/vector system

The AD5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map unit 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

### Origin & function

The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi’s sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

### Evaluation of foreseeable effects

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to none existent.

Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or none existent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (e.g., promotion of existing malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being...
administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low. The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

02/03/2022
Project Additional Information

Purposes of the contained use

This notification and risk assessment relates to a planned phase 1 clinical trial of "T4 immunotherapy", involving patients with squamous cell carcinoma of head and neck. T4 immunotherapy refers to a combined gene/ cell therapy, as described below. The trial will be conducted in patients with terminal malignancy, for whom alternative therapeutic options do not exist.

Squamous cell carcinoma of the head and neck (SCCHN) is the sixth most common cancer worldwide, with 600,000 cases diagnosed annually. Despite state of the art multimodal and multidisciplinary therapy incorporating surgery, radiotherapy, chemotherapy and targeted agents, five-year survival remains at only 50%. Indeed there has been little improvement in patient survival over the past 30 years. In patients with recurrent or metastatic disease the median survival time is a mere six months.

In designing this clinical trial, we have identified two key areas of unmet need. The first of these is loco-regional recurrent disease, which accounts for the majority of deaths in patients with SCCHN. Second, about 10% of patients who present to GSTFT have locally advanced tumours that are not amenable to any form of active therapy.

This study aims to investigate intra-tumoral administration of a novel cellular immunotherapy in patients with at least one measurable and accessible site of loco-regional progressive/ advanced disease, with or without concurrent distant metastases.

We will harvest peripheral blood from recruited patients in order to generate an autologous therapeutic cell product. Specifically, peripheral blood T-cells will be genetically engineered using the SFG retroviral vector to co-express two new proteins, named T1E28z and 4 alpha beta respectively. Consequently, this experimental therapeutic approach is referred to as T4 immunotherapy.

(i) T1E28z is an example of a chimeric antigen receptor (CAR). These are bespoke fusion molecules that direct T-cell
activation upon engagement of a chosen target found on tumour cells. In the case of T1E28z, tumour cell recognition is mediated by the ability of this CAR to bind several ErbB heterodimers. ErbB receptors (notably ErbB1) are highly upregulated in SCCHN. T-cell activation ensues because T1E28z contains a fused CD3 zeta + CD28 endodomain. (ii) 4 alpha beta is a chimeric cytokine receptor that allows the selective proliferation and enrichment of gene-modified T-cells using IL-4. This makes the ex-vivo expansion of therapeutic cell products more efficient since gene-modified cells have a selective advantage (compared to non-transduced T-cells) in the presence of IL-4.

Recipient or parental organism

Therapeutic genes will be delivered to activated T-cells for re-infusion into patients from whom they were originally isolated

Host/vector system

Origin & function

Two insert genes will be used, which encode for:
(i) T1E28z is a second-generation chimeric antigen receptor (CAR). Second generation CARs are fusion molecules in which a targeting moiety specific for a tumour-associated molecule is coupled via a hinge and transmembrane segment to a modular signalling domain in which the CD28 endodomain is placed upstream of CD3 zeta. In T1E28z, the targeting moiety is chimeric peptide named T1E which is a promiscuous ligand for the ErbB family of receptor tyrosine kinases. As a result T1E28z can bind to several ErbB receptor dimer species that are expressed at high levels by head and neck cancer cells. Following this binding process, an activating signal is delivered to the T-cell by CD28 (“signal 2”) and CD3 zeta (“signal 1”). This combined signal elicits T-cell activation and tumour cell attack. (Ref: Davies et al. Manuscript in preparation).

Evaluation of foreseeable effects

Potential toxicities related to T4 immunotherapy are classified into five categories:

- Related to the 4 alpha beta transgene
- Related to the T1E28z transgene
- Related to infusion of transduced T-cells
- Delayed inflammatory reactions
- Related to retroviral gene-modification of human cells

1. T-cell proliferation related to the 4 alpha beta transgene:

Use of the 4 alpha beta chimeric cytokine receptor may permit in-vivo exploitation of the elevated level of endogenous IL-4 found in serum and at the invasive tumour margin in patients with SCCHN. At best however, this effect is likely to be operate only in the tumour microenvironment, where small numbers of IL-4-producing leukocytes have been identified. Serum IL-4 is elevated in patients with some cancers (including SCCHN), in addition to atopic subjects. However, circulating concentrations found in these pathological states are uniformly in the low picogram range. Such
levels are 10,000-fold below the saturating concentration of IL-4 required for optimum support of the expansion of 4 alpha beta-expressing T-cells in-vitro. Thus, IL-4 in patients is highly unlikely to promote the uncontrolled proliferation of these cells.

2. ErbB targeting related to the T1E28z transgene:
Members of the ErbB family have been safely targeted using several pharmaco- and immunotherapy approaches to treat diverse solid tumours, including SCCHN. Importantly, toxicity attributed to these approaches has been acceptable, despite the prevalent expression of targeted ErbB receptors at low levels in many normal tissues (eg skin toxicity with ErbB1 targeting). Of concern however, Rosenberg and colleagues have recently treated a patient with widely metastatic ErbB2+ colorectal cancer with autologous T-cells genetically re-targeted with an ErbB2-specific chimeric antigen receptor. The patient succumbed to a fatal serious adverse event which was clearly attributable to the infused T-cells (Morgan et al (2010) Mol Ther. 18: 843-51). The cause of death has variously been ascribed to immune recognition of target antigen (ErbB2) either within the pulmonary parenchyma or microvasculature. This event has important implications for the safe development of T-cell immunotherapy targeted against the ErbB family and requires detailed analysis. We have identified five attributes of the experimental therapy used in that study that we believe are highly relevant to the fatal outcome reported, none of which will apply in our clinical trial.

(i) The patient underwent preparatory lymphodepletion with cyclophosphamide and fludarabine prior to receiving the infused T-cells. Lymphodepletion has also been used in one other patient who died following CAR-based immunotherapy (although the connection with the T-cells was less clear in that case). Furthermore, lymphodepletion was used in a third clinical trial that has recently been terminated owing to pulmonary and other toxicities. By contrast, no comparable toxic event(s) have been reported in any CAR-based clinical study where lymphodepletion was not used. This may reflect the fact that lymphodepletion eliminates buffering cell populations such as regulatory T-cells and some suppressive myeloid cell populations that would be expected to counter the development of cytokine storm. Lymphodepletion will not be used in this study.

(ii) The infused dose in the Rosenberg study was 10,000,000,000 gene modified T-cells of which 79% expressed the CAR transgene. By contrast, in our study it is planned to commence with a T-cell dose that is 1000-fold lower. A group of three patients will be enrolled at this low initial dose. Dose escalation will only proceed in the absence of dose limiting toxicity. Should dose limiting toxicity not occur, the maximum T-cell dose will be 1,000,000,000 cells which is 10-fold less that used by Rosenberg. Taken with the lack of lymphodepletion and cautious dosing regimen, we anticipate that the risk of cytokine storm is rendered remote under these circumstances.

(iii) A rapid ex-vivo T-cell expansion process was used in the Rosenberg study. Gene-modified T-cells were cultured for 14 days using ultra-high dose IL-2 (6,000 IU/ml) with 50ng/ml anti-CD3 mAb OKT3 and 100-fold excess of irradiated allogeneic peripheral blood lymphocytes. The latter served as “feeder cells” and would also have potentiated the action of the OKT3 antibody through Fc receptor immobilisation. This T-cell expansion process generates a highly activated cell product, which in turn would favour delayed transit through the pulmonary circulation. By contrast, we will expand T-cells ex-vivo using cytokine alone (IL-4, used to deliver an IL-2 type signal).

(iv) T-cells were administered by rapid IV infusion. Activated T-cells traverse the pulmonary circulation with a greatly reduced intravascular velocity, compared to non-activated or naïve counterparts. This is T-cells. By contrast, a regional (intratumoral) T-cell delivery system will be used in this clinical trial.

(v) Finally, the endodomain used by Rosenberg et al. consisted of an in-series fusion of CD28, 4-1BB and CD3 zeta. Incorporation of the 4-1BB co-stimulatory domain lowers the threshold for T-cell activation. In fact, some studies have demonstrated that 4-1BB-based CARs may provide constitutive signalling in
activated T-cells the absence of ligand binding. We will not employ a 4-1BB-based CAR in this study.

3. Infusion-related reactions:
Allergic reactions including rash, fever, rigors and bronchospasm are possible after infusion of transduced T-cells, but this is considered unlikely.

4. Delayed inflammatory reactions:
Localised T-cell activation within the tumour microenvironment would be expected to incite a local inflammatory response, particularly as ErbB+ tumour cells are engaged. Efforts to control local inflammation in principle might also reduce therapeutic efficacy. Consequently, we would not routinely propose to treat patients with anti-inflammatory agents unless local reactions were symptomatic. Patients to be enrolled in this study will only be selected if the lesion for injection is not situated near an airway or major artery. Furthermore, a tracheostomy will already be in place in some enrolled patients, thereby mitigating risks further. Nonetheless, it should be appreciated that inflammatory reactions within the oral cavity can track to involve the upper airway. Consequently, patients considered at high risk of airway occlusion will be cared for on an ENT ward on the night after immunotherapy is administered.

5. Related to retroviral gene-modification of human cells:
The ability of retroviruses to integrate into the host cell chromosome raises the possibility of insertional mutagenesis and oncogene activation. This event has been observed in clinical studies involving the use of retrovirus-transduced haemopoietic stem cells to treat primary immunodeficiency disorders. By contrast, this event has never been reported in human studies where T-cells have been genetically modified with similar vectors. Such clinical experience encompasses over 120 patients treated with suicide gene-engineered T-cells and extends back over 20 years to the first clinical study in which T-cells were genetically modified. Consequently, we envision that the likelihood of insertional mutagenesis is very low in this study.

Based upon these considerations, patients will be admitted for the 24 hour period following the administration of T4 immunotherapy. Extensive monitoring tests will be performed to screen for toxicity over the following 6 weeks. These are summarised in the risk assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have been in contact with genetically modified material will be chemically disinfected with Virkon (10g/l overnight). All waste is double bagged and labelled with purple GM waste labels. This material is transported to the autoclave room (Room 5E) on the 15th floor of Guy's tower, nearby to the GMP facility, where it is autoclaved at 134 degrees Centigrade for 20 minutes. This results in effectively 100% kill, a finding that is validated using biological indicators prior to waste disposal. Validation of the autoclave used to HTM 2010 is performed every 3 months. Once waste has been autoclaved, it is bagged into yellow incineration plastic bags and transported to the waste store and placed into the yellow waste stream.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N
Several comments were provided. Details in response to these comments have been added to the amended risk assessment. Other responses are provided in capital text.
- Clarify that full disclosure to public register will occur - YES
- Complete details in response to Q2 - ENTERED WITH DATA PROVIDED BY COMMITTEE
- Clarify waste control. What data supports virucidal activity of virkon (NOW PROVIDED); how will waste control measures be validated (DETAILS NOW PROVIDED).
- Clarify control of PPE (DETAILS NOW PROVIDED).
- Provide names of safety personnel (NOW PROVIDED)
- Outline how blood and tissue will be transported in the hospital (NOW PROVIDED)
- Outline risk associated with use of a therapeutic blood product and how this is mitigated by screening of patients for relevant chronic infective agents (NOW PROVIDED).
- Explain what EUFETS is and provide relevant contact details (NOW PROVIDED).
- Explain dosing regimen in greater clarity (DETAIL NOW PROVIDED IN BACKGROUND SECTION)
- Greek characters not visible in CU2 (FONT ALTERATIONS NOT PERMITTED IN CU2 FORM SO GREEK LETTERS HAVE BEEN SPELT OUT)
- Remove reference to work not to be performed in the GMP facility (MODIFIED WHERE POSSIBLE)
- Outline where patients will physically be during treatment (PATIENT JOURNEY DESCRIPTION ADDED)

Thymidine Kinase-Deactivated Virus) Followed by Sorafenib Versus Sorafenib in Patients with Advanced Hepatocellular Carcinoma (HCC) Without Prior Systemic Therapy

Purposes of the contained use

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, Dryvax(TM). Pexa-Vec contains three genetic modifications compared to the wild-type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by; 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF) gene and; 3) insertion of the LacZ gene. Pexa-Vec is designed to replicate selectively in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response immune response through the expression of its transgene, hGM-CSF, in the context of tumour lysis. Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoural (IT) injections to patients as part of an international, multicentre clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile. Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexa-Vec by IT injections. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival.

Recipient or parental organism

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, Dryvax(TM).

Host/vector system

The transfer plasmid pSC65/hGM-CSF is used to generate Pexa-Vec. The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65, which was provided by Dr B. Moss, National Institute of Allergy and Infectious Diseases,
Pexa-Vec is manufactured by Transgene (France) and labelled, OP released and shipped to investigational sites from PCIIBiotec (UK). At the investigation site, PexaOVec will exclusively be used for administration to patients as apart of clinical study JX594-HEP024. Thus, only the GMO (Pexa-Vect), but not the wild-type host organism or the vector used to generate the GMO, will be used at the investigational site.

Pexa-Vect contains three modifications compared to the wild-type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by; 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGM-CSF) gene and; 3) insertion of the LacZ gene. Pexa-Vect is designed to replicate selectively in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response through the expression of its transgene, hGM-CSF, in the context of tumour lysis.

Origin & function

The GMO, Pexa-Vect, is a non-integrative (cytoplasmic localisation), preferentially replicative in actively dividing cells (i.e. tumour cells), oncolytic (lysis of infected tumour cells) and propagative (able to spread locally to adjacent cancer cells and systemically by release into the blood stream and lymphatic system of infectious particles (Smith G.L. et al., 2002).

Over 300 adult and paediatric patients with advanced treatment refractory cancers have received more than 1,200 doses of up to approximately 1 billion infectious units (1 x 10^9) of Pexa-Vect via IV and/or IT administration (as of January 2014). Treatment with Pexa-Vect doses of approximately 1 billion pfu (approximately 10,000-fold more than the dose of standardised [non-attenuated] vaccinia delivered with vaccinia vaccine), has been generally well-tolerated with transient (<24 hours) flu-like symptoms (fever, chills, fatigue), nausea, hypotension and injection site pain as the most common adverse events (AEs). The overall risk of the wild-type (parental) Wyeth (USA smallpox vaccination) strain indicates that out of 14 million vaccinations, there were 572 hospitalisations, 9 deaths and many less severe complications. The rate of severe adverse reactions for the wild-type parental strain is approximately 1 in 50,000 vaccinations. Pexa-Vect has been attenuated when compared to the smallpox vaccine, and therefore the safety is improved.

Secondary spread could occur by direct contact (with a pustule, with bandages or other wastes contaminated by pustules, with expelled droplets from wound sites or liquid preparations) and indirect contact via medical devices contaminated through contact with a pustule. W is not spread through the air (US Department of Health & Human Services, www.smallpox.gov/QuestionsAnswers.html). Transmission of the virus by inhalation can be assessed as negligible. The clinical information available to date suggests that Pexa-Vect is safe at the clinical dose of 1 billion pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 43 will likely have been previously immunized with vaccinia (UK smallpox vaccination ceased in 1974). In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. To date, no reports of transmission to health care personnel from vaccinia recipients have been published; however, at least nine reports of infection of laboratory workers exist from the last 25 years (see safety data sheet www.phacaspc.gc.ca/lab-bio/res/psds-ftss/vaccinia-virus-eng.php). Infection control/Containment level 2 standards and procedures and related healthcare approaches are to be implemented for worker safety.

Viral shedding data collected in a clinical study with Pexa-Vect administered by the IT route (i.e. JX-594-IT-HEP001 trial) demonstrated that the virus is not shed to the environment via urination. The virus could also not be detected in
throat-swab samples. There are no known or predicted environmental conditions which may increase survival, multiplication and dissemination of the Pexa-Vec. It is commonly thought that W is not naturally found in the environment; however, human to cattle (and vice versa) transmission has been reported via broken skin. Recombination events of the wild-type W with the GMO are not thought likely, as current genetic stability studies on Pexa-Vec have not detected spontaneous revertants of Pexa-Vec.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

I would not like to request derogation from full containment measures

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid contaminated waste will be bagged and inactivated by autoclave (135°C for 20 min) prior to being placed into clinical waste streams for incineration. Sharps waste will be placed in sharps containers after use and prior to autoclaving and incineration. All open processing of Pexa-Vec will be undertaken in isolators. Any spillage of contaminated liquids in isolators will be inactivated with Klercide biocides and hydrogen peroxide vapour decontamination.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Please enter comments on the GM safety committee on the risk assessment

Guy's and St Thomas' Biological Safety Committee reviewed the risk assessment on 24JAN2018 and agreed with the classification of GM class 2. Approval for this study was given by the Committee on the condition the following additional information be added to the risk assessment:
- state the autoclave temperature and hold time
- justify the use of sharps
- state who has responsibility for the product during transportation
These updates were completed on 25JAN2018 and approved on 06FEB2018.

**Project Additional Information**

**Purposes of the contained use**

To assess the ability of ovine adenovirus vectors expressing foreign antigen genes to induce a potent immune response to that foreign antigen.

**Recipient or parental organism**

The parental organism is wild-type ovine adenovirus, strain OAdV7. Ovine adenoviruses are members of the adenoviridae family. As such, the Advisory Committee on Dangerous Pathogens classifies them as Hazard Group 2 pathogens. (Categorisation of biological agents according to hazard and categories of containment, Fourth Edition, 1995. HSE Books).

OAdV7 is known to infect a wide range of human cell types. However, the virus will replicate efficiently only in ovine foetal lung (CSL503) and skin (HVO 156) cell lines, (GW Both 2004 Immunol. Cell Biol. 82: 189-195).

**Host/vector system**

No prokaryote work associated with this project will be performed by or at Oxxon Therapeutics Ltd.

**Origin & function**

The foreign gene to be delivered by the recombinant ovine adenovirus encodes:

1. A marker gene, (either Escherichia coli beta-galactosidase, firefly luciferase, or Aequorea victoria green fluorescent protein), derived from commercially available plasmids.

2. Human immunodeficiency virus type 1 (HIV1) antigens which have been extensively mutated to destroy the activities of the encoded proteins. These mutations allow the proteins to function only as antigens in the recombinant vaccine.

Both marker genes and the HIV1 antigens will be expressed from either the human cytomegalovirus immediate-early promoter or the rous sarcoma promoter.

**Evaluation of foreseeable effects**

Strain OAdV7 was isolated from a sheep in Western Australia. Challenge experiments with this strain in adult sheep have failed to produce noticeable symptoms. However, although the US strain of ovine adenovirus was isolated from three dead lambs, it still remains to be demonstrated whether ovine adenovirus can be harmful in lambs, (GW Both 2004 Immunol. Cell Biol. 82: 189-195).
Ovine adenovirus strain OAdV7 is known to infect a wide range of human cell types. However, the virus will replicate efficiently only in ovine foetal lung (CSL503) and skin (HVO156) cell lines. OAdV7, produces abortive infections in all human cell lines tested; the block in replication occurring at the early or late transcription stages, or during assembly, depending on the cell type, (D. Kumin et al 2002 J. Virol. 76(21): 10882-10893).

OAdV7, like human adenovirus strains, maintains an episomal (non-integrated) state after infection; this precludes insertion event-dependent mutagenesis or activation, such as can occur with retrovirus vectors.

OAdV7 shares little sequence homology with human adenovirus: There is no apparent homologue of the E1a protein and the putative E1b homologue, LH3, has a three amino acid insertion in the p52 oncogene-binding region, (GW Both 2004 Immunol. Cell Biol. 82: 189-195).

The ACGM Compendium of Guidance, Part 2B, Annex III states that genes encoding marker genes, such as beta-galactosidase, luciferase, or green fluorescent protein, do not increase the hazards associated with adenovirus vectors. Expression of either of these marker genes from an ovine adenovirus vector is not expected to increase the risk of harm to human health or the environment.

The synthetic polypeptide encoding disabled HIV 1 antigens will function only as an immunogen and is not expected to increase the risk of harm to human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be deactivated in Lifeguard disinfectant used at 5% (v/v) for 30 minutes or Virkon solution at 1% for 10 minutes before disposal down the drain. Plastic waste will be chemically deactivated with Lifeguard used at 5% (v/v) for 30 minutes or Virkon solution used at 1% (w/v) for 10 minutes before being double-bagged, autoclaved and/or incinerated. All contaminated surfaces will be wiped down using Lifeguard and then sprayed with Microzid, which is left to evaporate.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N

The safety Committee agreed that recombinant ovine adenoviruses based on strain OAdV7 expressing commonly used marker genes, or inactivated HIV1 antigen genes, pose no risk to either human health or adult sheep, but that there is possible risk to young lambs. Consequently, the recombinant ovine adenoviruses must be stored and handled under Containment Level 2 conditions.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

Onyx has an established health and safety committee which meets regularly on a monthly basis. The committee consists of senior directors within the company (CEO and Finance director), the laboratory manager, the radiation protection supervisor (RPS) and the biological safety officer (BSO). The committee reviews all operational health and safety matters along with new items, which require its consideration.

All on-going projects involving GMMs and risk assessments are reviewed regularly. An agenda of items for discussion is drawn up prior to the health and safety meetings and the minutes of the meeting are open to all staff members for reading, once approved by the committee. The committee has the power to approve, adopt and change company policies and procedure (within the current legislation framework). These changes are then disseminated through the company by an approved route from the safety officers through to the laboratory group leaders to the scientists working in the laboratories/project concerned.

02/03/2022
Yes All trained operatives will be properly attired in white laboratory coat and surgical gloves. Such attire is only to be used in the level 2 designated area. All surfaces exposed to potential contamination by retrovirus will be sprayed with 70% Ethanol before and after use.

All solid waste (serological pipettes, tissue flasks, used gloves, etc) is first autoclaved and placed in yellow bags and finally incinerated.

All liquid waste is disposed of by inactivation with a 1% Virkon for 12 hrs followed by sink disposal. This product has been tested and proven effective against major pathogens including viruses (HIV, hepatitis B and C, herpes and enteroviruses), bacteria (staphlococcus aureus) and fungi. A 1% solution of ‘Virkon’ has a good safety profile. Precautions for its use: wash splashes from eyes and skin immediately, keep concentrate of skin. Do not mix with other chemicals and keep out of direct sunlight. We have a copy of the validation tests for this product.

Specimens (supernatants and cell lines) testing positive for replication-competent viral particles will be destroyed by disinfection and autoclaving as soon as possible.

Records of destroyed specimens should be kept up to date. All work areas and equipment will be decontaminated with virkon and/or autoclaving.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Following review by the local GMSC, the risk assessment was modified and now has been approved.
In order to provide permanent cell lines, from surgical discarded material, for the development of whole cell vaccines, cells have to be immortal. This can be achieved spontaneously or by the introduction of an immortalising gene. Such genes are the cloned E6 and E7 genes isolated from the wild type human papillomavirus 16.

We propose to use retroviral vectors to immortalise human cells in vitro. The first retroviral construct will contain the cloned subgenomic HPV 16-E6 and -E7 genes in combination in the same construct, pLXSN. This construct has been modified to remove all origins of replication to minimise potential recombination events. The pLXSN vector is a commercially available retroviral vector provided by Clontech Laboratories Inc. Palo Alto, CA. The second construct will contain the HPV16-E6 gene alone in pLXSN. The HPV16-E7 and -E7 genes code for nuclear oncoproteins that have the ability to initiate the transformation of primary human cells to an immortalised state. In doing so they have transformed the recipient human cells into a condition that renders them susceptible to further genetic insults resulting in the full transformation to a malignant state.

Our required use of the constructs is to develop immortalised cell lines, not to fully transform the recipient cells. Due to the small possibility of a recombination event occurring and wild type, replication competent virus being produced and the presence of oncogenic sequences, all cells (producer cell lines and recipient human cells) will need to be cultured under Level 2 containment in accordance with the ACGM Compendium guidelines. Further, Level 2 containment will be required for all cultures whether proven to be free of replication competent virus or not. If replication competent virus is found the stock and recipient cultures will be destroyed.

Recipient or parental organism

The first recipient organism will be the packaging cell line used to generate the retroviral supernatant. This cell line will either be PA317 (a second-generation packaging cell line) or preferably, a third generation packaging cell line (if available). These types of cell lines contain the gag, pol, and env genes necessary for viral production. However due to deletion, they lack the ps1 and 3'LTR sequences, so that two recombination events are necessary to generate a wild-type virus. Third-generation packaging cell lines contain the packaging genes as to separate components, thereby significantly reducing the frequency of recombination between the vector and packaging sequences further.
The second recipient organism(s) will comprise of actively dividing human cells in culture (epithelial, fibroblastic or endothelial). When these human cells are transduced with these oncoproteins they will be transformed into a condition that renders them susceptible to further genetic insults resulting in the full transformation to a malignant state.

A close association between cervical cancer and the HPV's has been established (zur Hausen 1996). The high-risk HPV types are HPV 16 and 18. HPV16 DNA can be found in >50% of cervical cancers. Functional studies of the early region of these high-risk genomes have demonstrated that the two early genes, E7 and E7, are both necessary and sufficient for the efficient immortalisation of primary human keratinocytes in vitro, (Hudson JB 1990). The major mechanism by which E7 and E7 contribute to immortalisation is by targeting two distinct cellular tumour suppressor proteins for inactivation or degradation. E7 binds and inactivates the reinoblastoma tumour suppressor protein (pRB) and two closely related proteins, p107 and p130, leading to the activation of E2F responsive genes and the loss of a G1 checkpoint (Jones and Munger 1996). E6 forms a ternary complex with p53 and the E6AP ubiquitin protein ligase resulting in the ubiquitination and degradation of p53 (Scheffner et al 1990). Loss of p53 results in deregulated cellular growth and genomic instability, both of which are characteristics of immortalised cells (Hartwell 1992).

These recipient human cells are derived from surgical material obtained following informed consent at SGHMS. Normally these cells would be classified as Class 1 material. However, it is possible that these primary cultures may contain adventitious viruses. As these cells are going to be infected with retrovirus and will have not been prescreened for adventitious viruses at this point in the immortalisation process we will treat them as potentially suspect material and use them under Level 2 containment and work with them using Level 2 procedures.

References

Host/vector system
The vector construct into which the HPV16 sub-genomic sequences will be cloned will be pLXSN and the packaging cell line PT67 will be supplied by Clonetics, Palo Alto California, USA.
A more detailed description of this construct is given on the manufacturer's website, www.clontech.com

Origin & function
The HPV E6 and E7 genes were originally cloned as sub-genomic fragments from the wild type HPV 16 virus provided by H zur Hausen at Deutsches Krebsforschungszentrum, Heidelberg, Germany

The supplier of the HPV16 E6 and E7 retroviral producer cell lines will be the Department of Biology, University of York, UK. The provenance of the retrovirus and its producer line will be provided by the supplier. Further, viral titering results and data from helper virus testing of producer clones will also be provided by supplier. These recipient human cells are derived from surgical material obtained following informed consent at SGHMS and grown in our own facilities at SGHMS.

Evaluation of foreseeable effects
The recipient cells or tissues, in culture, will be immortalised and will provide a source of permanent, non-mortal, cell lines. Cell lines in this partially transformed state are rendered susceptible to further modification by either the introduction of additional genes or by mutagenesis with chemical carcinogens resulting in the potential development of fully transformed cells capable of forming tumours in immuno-compromised mice.

Given that these HPV-E6 and E7 sequences can partially transform human cells operatives will at no time introduce the E6 or E7 genes into human cells derived from a member of the research team. Further, all operatives will not use sharps in the containment lab and will be free of sores or open cuts. Also appropriate attire (gowns,
gloves hats and masks) will be worn at all times thereby minimising risk.

Further, operatives will be disqualified from working in the Level 2 containment facility if they have any pre-existing condition that may render them susceptible to cancer-incidence following exposure to the retrovirus containing the E7 and E7 genes. All retroviral work is performed in a designated Class 2 bio-safety cabinet and cultures are grown in an assigned incubator. Both are located in a separate room(s) set aside for human and retroviral work under Level 2 containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The retrovirus(s) will be capable of infecting and transforming human cells. As such all retrovirus supernatants and infected recipient cells will be manipulated under Level 2 containment and conditions.

Operatives will at no time introduce the E6 or E7 genes into human cells derived from a member of the research team. Further, all operatives will not use sharps in the containment lab and will be free of sores or open cuts. Also appropriate attire (gowns, gloves hats and masks) will be worn at all times thereby minimising risk.

Further, operatives will be disqualified from working in the Level 2 containment facility if they have any pre-existing condition that may render them susceptible to cancer-incidence following exposure to the retrovirus containing the E7 and E7 genes. All retroviral work is performed in a designated Class 2 bio-safety cabinet and cultures are grown in an assigned incubator. Both are located in a separate room(s) set aside for human and retroviral work under Level 2 containment.

All cultures exposed to and producing wild type virus will be disinfected and disposed of in accordance with ACGM guidelines (Section IV). All aqueous material will be treated with Virkon (1% solution, Manufacturer's recommendation). After 24 hours the disinfected aqueous material will be put down the sink with an excess of running water. All tissue culture plastic will be disinfected, bagged, autoclaved and incinerated.

The hoods in the Level 2 containment facility will then be decontaminated by fumigation prior to and following any program of retroviral work. The level 2 containment facility will be sited separately from any clinical or animal facility so the risk of human or animal infection is minimised.

The hazard in the use of these constructs is the potential for recombination of the HPV E6 and E7 genes with any contaminating wild type retrovirus resulting in the development of a new oncogenic retrovirus which would be infectious. We will test for infectious virus and reverse transcriptase activity on every batch of retrovirus that is produced.

In addition, the same tests will be employed when the virus is used to immortalise the human cells. Once an immortalised cell line has been produced the same test will be used prior to cryo-preservation and storage. We will also regularly test, once a month, our human cell cultures for mycoplasma and bacterial contamination. So the transfer of virus to other organisms is minimised.

As the retroviruses will be supplied by an outside laboratory European and International regulations govern the packaging and shipment of such biological materials. The supplier will be responsible for the shipment and will strictly follow the principle of triple packaging systems. This is absolutely necessary in the case of infectious and non-infectious biological substances. It is the obligation of the supplier to comply with the regulations relating to the biological material which is to be transported.

**Basic triple packaging system**

The system consists of three layers as follows:

1. **Primary receptacle.** A labelled primary watertight, leak-proof receptacle will be used to contain the retrovirus packaging cell lines. The receptacle will be wrapped in enough absorbent material to absorb all fluid in case of breakage.
2. **Secondary receptacle.** A second durable, watertight, leak-proof receptacle to enclose and protect the primary receptacle(s) will be used. Several wrapped primary receptacles may be placed in one secondary receptacle. Sufficient additional absorbent material will be used to cushion multiple primary receptacles.
3. **Outer shipping package.** The second receptacle will be placed in an outer shipping package which will protect it and its contents from outside influences such as physical damage and water while in transit.
Specimen data forms, letters and other types of information that identify or describe the specimen and also identify the shipper and receiver will be taped to the outside. Accurate and informative signage on the outer shipping package will be used.

Receiving broken or damaged specimen packages. If packages are received from the shipper and the contents are not intact, then the package and contents will be destroyed by autoclaving. The shipper (and) courier will be notified and if necessary amendments made to the packaging. Records of destroyed specimens will be kept.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation from full containment under Containment Level 2 will be required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All trained operatives will be properly attired in white laboratory coat and surgical gloves. Such attire is only to be used in the level 2 designated area. All surfaces exposed to potential contamination by retrovirus will be sprayed with 70% Ethanol before and after use.

All solid waste (serological pipettes, tissue flasks, used gloves, etc) is first autoclaved and placed in yellow bags and finally incinerated.

All liquid waste is disposed of by inactivation with a 1% Virkon for 12 hrs followed by sink disposal. This product has been tested and proven effective against major pathogens including viruses (HIV, hepatitis B and C, herpes and enteroviruses), bacteria (staphylococcus aureus) and fungi. A 1% solution of ‘Virkon’ has a good safety profile. Precautions for its use: wash splashes from eyes and skin immediately, keep concentrate of skin. Do not mix with other chemicals and keep out of direct sunlight. We have a copy of the validation tests for this product.

Specimens (supernatants and cell lines) testing positive for replication-competent viral particles will be destroyed by disinfection and autoclaving as soon as possible.

Records of destroyed specimens should be kept up to date. All work areas and equipment will be decontaminated with virkon and/or autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Following review by the local GMSC, the risk assessment was modified and now has been approved.

Y

Give brief details of the genetic modification safety committee

The standing committee is composed of four staff members:-
1. The Chief Scientific Officer.
2. Company safety officer.

The committee meets as the situation dictates, eg this application process and the examination and adoption of Standard Operating Procedure (SOP's) appropriate to the facility. Staff safety representatives are invited to attend GMSC meetings.

Minutes are kept as emails between standing committee members and copies are posted onto company shared files space.

Yes

Please see attached waste operating procedures document. All laboratory waste will be segregated into chemical and GMO contaminated waste streams, and also segregated by the nature of the hazard ie contaminated sharps, liquids and solids. GMO contaminated materials are autoclaved using a validated autoclave following SOP’s designed to achieve a 100% kill. The inactivated materials are then contracted out for incineration.

The disinfectant Virkon will be used, as the manufacturer direct, for the inactivation of any accidental spills of GMOs. An active solution of Virkon will be present in the laboratory at strategic locations at all times.

Validation of autoclave. This is a new instrument, which is the subject of a yearly service contract and validation testing. The autoclave has a process printer attached for clear automated record keeping producing a hardcopy print out put of each run using a load temperature probe.

The expected degree of kill by all procedures is to below detectable levels.

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

The GMSC of Angel Biotechnology Ltd. will be composed of representatives from the departments and groups within the company that might be expected to come into contact with GMO’s, as well as a senior manager. All assessments done under the regulations will be distributed to the members for comment, the full committee will meet if there are any concerns or problems. Otherwise, there will be an annual review meeting to ensure that all assessments and legislation are discussed. The senior manager will be the chair and primary contact for the HSE and will distribute information and call meetings when necessary. Any member of the committee will be able to call a meeting at any time.

#### Level 1 (GMMs)

</tbody>
</table>
Laboratory waste (agar, small volumes of liquid, disposable plasticware that has come into contact with GMMs etc) will be autoclaved at 121°C for 20 minutes. This has been validated by looking for surviving organisms. Checks will be made at regular intervals that the inactivation is complete. Separate, labelled, handling facilities (bins etc) are in place to manage the waste prior to sterilisation. Pilot fermentation waste broth is inactivated by heating to 80°C for 30 minutes. This is enough to kill the organism in use beyond detectable levels, even in its spore stage. This has been validated by growth tests. Checks will be made at regular intervals to ensure the validity of these results. Spills and non-autoclavable equipment will be cleaned using standard laboratory disinfectants (e.g. 70% ethanol, cetrimide soaked wipes, etc). These then go to be autoclaved via the standard laboratory waste route. Swabs or contact plates will be used to validate the disinfection. Glassware will be autoclaved before cleaning, or exposed to disinfectants if autoclaving is not possible. In all cases at least 99.999% kill will be looked for, although the preferred situation is that there will be no detectable viable organisms in any waste sent for disposal.

TO MODIFY A STRAIN OF STAPHYLOCOCCUS AUREUS BY TARGETED GENE MODIFICATION AND DELETION FOR ENHANCED PRODUCTIVITY OF A TARGET GENE

Class 2 1-50 litres

Non-GMM Consent Granted: not applicable

Project notified under transitional arrangements: N

Historical Significant Changes

Tick if notifying a connected programme of work: Y

Withdrawn: N

Project Additional Information

Purposes of the contained use

i) To reduce the levels of secretory toxin.
ii) To enhance the levels of target protein secretion.

Recipient or parental organism

A target protein secreting strain of Staphylococcus aureus, A676.

Host/vector system

A common cloning vector for Bacillus Subtilis and Staphylococcus aureus will be used.

Origin & function

A DNA is amplified by PCR from a wild type strain of Staphylococcus aureus.

Evaluation of foreseeable effects

1. The strains produced will exhibit negligible/zero levels of a specific enterotoxin, which may make them less pathogenic than the equivalent wild type strain.
2. The amount of target protein secreted will be increased (by up to 10x) This may increase the infectivity of the organism but the nature of work is such, that the possibility
of infection is low and all work will be contained.
3. The micro-organism will be unlikely to survive outside of the culture vessel due to the growth requirements.
4. No vector DNA will be present in the final GMO as the plasmid is temperature sensitive and can be cured from a bacterial population.
5. No mobilisable elements will be introduced into the micro-organism.
6. No mobilisable elements will be introduced into the micro-organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

* Solid waste eg LB agar plates, contaminated disposable falcon tubes; All waste will be autoclaved at 126 degrees C for 30 minutes, then incinerated before disposal.
* Liquid waste eg waste media, culture; All liquid waste will be autoclaved as above and then pH treated [pH taken to 10.5, then reduced to neutral] before disposal.
* Drain waste; All drain waste will be pH treated as above.
* Sharps; All contaminated sharps will be placed in designated sharps bins and will be autoclaved as above and then incinerated.

Testing: The conditions for all waste management systems will be checked to ensure that they are appropriate for the organism at regular intervals. Samples will be taken at regular intervals (1 month) for plate testing post-autoclaving and waste treating. At regular intervals waste will be tested for viable organisms. We expect no viable GMOs to remain after sterilisation.

### Project Additional Information

**Purposes of the contained use**

To maximise expression of the fusion gene in *E. coli*

**Recipient or parental organism**

*E. coli* K12 and B strain derivatives

**Host/vector system**

- Disabled *E. coli* K12 derivatives JM109(DE3), AD494(DE3), HMS174(DE3), Origami(DE3), E104, TG1, BL21(DE3)
- Disabled *E. coli* B strain (BL21) derivatives BL21(DE3), BL21trx(DE3)
- Disabled *E. coli* B strain (Tuner) derivatives NovaBlue(DE3), Rosetta(DE3), Tuner(DE3)
- Mobilisation defective pBR322 derivative
- Mobilisation defective pET21A derivative

**Origin & function**

The gene encoding the fusion protein is derived from human, synthetic and plant sequences.

**Evaluation of foreseeable effects**

If expressed within the human body the fusion protein has the potential to be toxic to human cells. In the worst case scenario, cells expressing the protein would colonise the human gut and produce toxin at a toxic level. The following factors reduce the possibility of this eventuality:
1) The E. coli strains to be used are disabled strains unlikely to survive outside the culture vessel. It should be noted, however, that the work will involve a number of BL21-derived strains. Though recent research indicates that these strains can now be considered disabled for risk assessment purposes (Chart et al, 2000)), these strains may present a higher colonisation potential (ACGM Newsletter 30).

2) The expression plasmids involved are mobilisation defective and unlikely to transfer to a colonising E. coli strain.

3) The fusion gene will be under the control of tightly regulated promoters:
   * The araB promoter requires arabinose and the product of the araC gene to initiate expression.
   * The T7 promoter requires T7 RNA polymerase to initiate expression, the polymerase being encoded on a lysogenised DE3 phage sequence. The T7 polymerase gene is in turn under the control of the lacUV5 promoter inducible by lactose or IPTG and would be unlikely to express in the gut. Also, in the event of transfer to a colonising E. coli strain, the mechanism for expression would not be present.

4) The plasmid vectors to be used confer resistance to ampicillin and tetracycline. Alternative prophylactic antibiotics are readily available for treatment.

Non-GMM Consent Granted

Project notified under transitional arrangements

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to develop intermediate-scale methods for the culture and cell banking of human stem cell lines. No GMMs will be constructed by Angel Biotechnology during this project. Instead, the project will involve the culture of GM human stem cell lines that have been produced by a collaborating company in Guildford.

**Recipient or parental organism**
The GM stem cell lines were derived by ReNeuron from a variety of human tissues including brain, pancreas and liver.

**Host/vector system**

The derivation process involved immortalising the cells by infecting them with replication-defective murine leukaemia virus (MLV)-based retrovirus vectors carrying a recombinant 'conditional' oncogene, c-mycER. The retrovirus vectors were pLNC-cmycER and pBABEpuro-cmycER, derived from pLNCX (Clontech) and pBABEpuro respectively.

**Origin & function**

The C-mycER gene is a genetically engineered oncogene, composed of sequences from the human c-myc proto-oncogene and the mouse oestrogen receptor gene. (An oncogene is a gene whose function is to trigger cell growth). The encoded protein is only functional in the presence of the synthetic steroid 4-hydroxy tamoxifen (4-HT).

Stem cells are usually difficult to grow culture and it is usually necessary to add 'feeder cells' to them to support their growth. However, stem cells that carry the c-mycER gene can be stimulated to grow without feeder cells by adding 4-HT to the cell culture medium. As their growth is totally dependent on the continual presence of 4-HT in the medium, these stem cell lines are described as being 'conditionally immortal'.

**Evaluation of foreseeable effects**

The MLV retrovirus vectors that were used to introduce the c-mycER gene into the stem cells are replication-defective because they don't carry any retroviral structural protein genes. However, they do possess retroviral LTR and packaging sequences, so it is possible that they could be mobilised as replication-defective virus particles if the GM stem cells were to become infected with a replication-competent retrovirus that had 'helper' properties. The production of a replication-competent virus carrying c-mycER gene to a full set of retrovirus structural genes would not favour efficient packaging of a recombinant genome. Even if such a recombinant virus were to be created, its pathogenic properties should not be enhanced because of the requirement for 4-HT for c-mycER function. If a breach in containment took place and the GM stem cells were released into the environment they would not survive long enough for infection with potential helper viruses to take place. Retrovirus particles themselves do not survive well in the environment and require close contact between hosts for transmission to occur. Consequently, if a containment breach happened after the stem cells had been accidently infected with a helper virus, it is unlikely that any 'mobilized' c-mycER virus particles would survive long enough or in sufficiently high titres to be transmitted to new hosts in the environment.

Although considered to pose no risk to the environment because of their extreme sensitivity to adverse culture conditions, the GM stem cells may pose a risk to human health because they were derived from primary human tissue, so the possibility exists that the cells carry on as-yet-undiscovered infectious agent. For this reason the work will be carried out at Containment level 2 using a class 2 safety cabinet when necessary.

With regards to risks arising from the genetic modification of the stem cells, the 'conditional' oncogenic property of the c-mycER gene is dependent on 4-HT being added to the cell culture medium. 4-HT is not a natural compound and it is not found in vivo unless it is being deliberately administered for therapeutic reasons. Therefore under normal circumstances (ie in normal, healthy individuals) the c-mycER gene will not make the cells more invasive in vivo than their non-GM equivalents. The stem cells will be unable to colonize laboratory workers who have normal, non-suppressed immune systems because the cells will be recognised as foreign, and rejected.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Disposal.**

All cell culture-contaminated solid waste, and most liquid waste will be autoclaved at 121 degrees C (15lb) for 30 minutes prior to disposal. Some culture supernatants may be mixed with hyperchlorite to a final concentration of 5% and left for a minimum of 1 hour at room temperature before disposal via the waste water drain. Any spillages will...
be treated either with hyperchlorite solution or Virkon. Liquid disposed of via the waste water drain is collected in a kill tank and pH treated prior to release into external drains.

Plastic graduated and Pasteur pipettes, and pipette tips will be soaked in hyperchlorite solution before removal from the class 2 safety cabinet, then autoclaved as above prior to disposal.

Testing
Two internal probes are used to record the chamber temperature and load temperature of the autoclave. Post-sterilisation samples will be taken at three monthly intervals to check for viable organisms. We expect no viable organisms to remain after sterilisation.

The attached risk assessment was discussed at a meeting of the Angel Biotechnology GMSC on 30th June 2005. The GMSC agrees with the proposed containment level and with the precautions to be taken to safeguard human health.

### Project Additional Information

**Purposes of the contained use**

The aim of the project is to develop large scale culture processes for a human recombinant T cell line, and to establish bioassays using a recombinant cancer cell line to measure T cell function. No GMOs will be constructed by Angel Biotechnology during this work. Instead, the project will involve the culture of GM cell lines that have been obtained either from a client company, a research institute, or from a national cell culture collection.

**Recipient or parental organism**

- The parental T cell line originated from a biopsy taken from a patient suffering from cutaneous T cell lymphoma.
- The parental cancer cell line originated from a patient suffering a non-lymphoid malignant disease.

**Host/vector system**

- The process of generating the recombinant T cell line involved transducing the parental T cell line with a replication-defective Moloney murine leukemia virus (MMLV) retroviral vector (MMLV phi+packaging signal, mobilisation defective).
- The recombinant cancer cell line was produced by transfecting the parental cancer cell line with the plasmid pcDNA3.

**Origin & function**

- **MMLV vector**
  
  Instead of MMLV structural protein genes, this vector carries a gene for a human T cell receptor (TCR) alpha-chain, and a gene for a human TCR beta-chain. Each gene is under the control of a separate constitutive promoter element to drive gene expression. When expressed in the T cells, the alpha and beta chains associated to form functional TCR proteins on the cell surface. The vector also carries a neomycin resistance gene that gives the transduced cells resistance to the antibiotic G418.

- **pcDNA3 vector**
  
  This vector is a commercially available plasmids expression vector into which MHC class I molecule gene has been cloned. The MHC gene is under the control of a constitutive promoter element derived from human cytomegalovirus (CMV). Cancer cells transfected with this vector express the MHC molecule on their surface. As in MMLV vector above, pcDNA3 also carries a neomycin resistance gene that gives transfected cells resistance to the antibiotic G418.

**Evaluation of foreseeable effects**

The recombinant T cells are CD8+ and have cytotoxic properties. The TCR protein they express (via the MMLV vector) on their surface gives them the ability to recognise...
and kill the recombinant cancer cells which express the human MHC molecule.

The MMLV retrovirus vector that was used to introduce the TCR genes into the T cells is replication-defective because it does not carry any retroviral structural protein genes. However, it does possess retroviral LTR and packaging sequences, so it is possible that it could be mobilized as replication-defective virus particles if the recombinant T cells were to become infected with a replication-competent retrovirus that had ‘helper’ properties. The production of a replication-competent virus carrying the TCR genes in this situation is unlikely because the increase in virus genome size that would be caused by linkage of the TCR genes to a full set of retrovirus structural genes would not favour efficient packaging of a recombinant genome. Even if such a recombinant virus were to be created, its pathogenic properties should not be enhanced because TCR proteins are not toxic per se. They are naturally occurring proteins that all humans possess on their T cells. If a breach in containment took place and the recombinant T cells were released into the environment they would not survive long enough for infection with potential helper viruses (e.g., from mice) to take place. Retrovirus particles themselves do not survive well in the environment and require close contact between hosts for transmission to occur. Consequently, if a containment breach happened after the T cells had been accidentally infected with a helper virus, it is unlikely that any ‘mobilized’ TCR-positive virus particles would survive long enough or in sufficiently high titres to be transmitted to new hosts in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work involving these cell lines will be performed in a class II biological safety cabinet and any manipulations (centrifugation etc.) will be sealed containers, sterile-vented tissue culture flasks or sterile-vented bioreactors* (8T-cells only). No sharps will be used and all pipettes will be plastic, single-use disposables. The laboratory suite is Class II and HEPA-filtered, all workers will don laboratory coats, latex gloves, overshoes and mob caps that are to be removed on leaving the room. All intended workers are vaccinated against Hepatitis B and persons with open wounds will not be allowed access to the facility. We have in place SOPs for use and rotation of disinfectants, regular cleaning of the Class II suite and spillage procedures. All waste will be autoclaved on site. Please refer to Angle Biotechnology GM risk assessment 0065 for specifics.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Small volumes of liquid waste (e.g. spent culture medium) and disposable pipettes and pipette tips will be added to a bleach solution so that the final concentration does not fall below 5% v/v. After a 24 hour incubation period the liquid waste will be disposed of via the laboratory sinks and the plastic disposables transferred to an autoclave bag and autoclaved on site.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee shall consist of the Principal Scientist and a Director of the Company. It shall meet on a Quarterly basis, or at such times as are necessary to monitor and update internal processes concerning genetic manipulation with reference to health, safety and environmental impact. It shall be responsible for ensuring that the Company and its Personnel comply with all national and local rules, regulations and statutory requirements. It shall ensure that it also liaises with and complies with all rules and regulations established by the Genetic Modification Safety Committee of the University of Wales College of Medicine. The Committee shall be responsible for the assessment of the genetic modification of GMMs requested by its Clients and to maintain all such information in strict confidence, due to commercial sensitivity and issues relating to the intellectual Property Rights of both the Company and its Clients.

The idENTIGEN Genetic Modification sub-committee agree to the risk assessment proposed for the programme of work entitled: Construction of eukaryotic expression vectors containing inserted cDNAs encoding intracellular, membrane-bound and extracellular proteins. The recommendations of the Genetic Modifications sub-Committee are in agreement with the proposal for the classification of the work as Group 1, containment level 1, whereby it is noted that all manipulations undertaken with vector/eukaryotic host are performed in a containment level 2 environment.

- [Y]

Give brief details of the genetic modification safety committee

The F2G Ltd GMSC is a sub-committee of the main H&S committee which reports to the F2G board directly.

1. Composition:- Company Director, BSO, H&S Coordinator (chairperson), H&S Officer (liaises between GMSC and main H&S committee), Office Representative, Technical Representative, Post Doctoral Representative, Fire Officer, First Aid Officer, External Representative (University of Manchester BSO).
2. Operating Procedures:- (a) advise on risk assessments relating to activities involving GMO’s (Regulation 6 - Contained Use Regulations 2000); (b) advise on risk assessments relating to the environment (required under the EPA); (c) review safety, training and lab discipline; (d) review accidents and incidents; (e) all members views to be heard so that advice given is genuinely that of a committee and not a single individual (f) meeting minutes, progress and achievements to be monitored, published and reviewed regularly by senior management at board meetings.
3. Frequency of Meetings:- Meetings to be held every 6 months.

Please enter comments of the GM safety committee on the risk assessment

The F2G Limited GMSC, at a meeting held on 19/2/2002, endorsed the decision that this project requires Containment Level 2 facilities that are available in laboratories 2N09 and 2N07 (second floor, Manchester Incubator Building). No special problems were identified that could not be adequately controlled by level 2 containment methods and by the application of good microbiological practice and good occupational health and hygiene practices. It was noted that Group II organisms were involved and that HSE approval was required before work could start. The forms CU1 2000, CU2 2000 and the attached risk assessment were examined in detail and it was agreed by all members that the application process was to proceed.

Project Ref 836/02.1

Date Ackn'd 17/06/2002

Date Project Ceased

CU2 Project Title INSERTIONAL MUTAGENESIS OF ASPERGILLUS SPECIES (INCLUDING ASPERGILLUS FUMIGATUS)

Class 2

Consent Granted not applicable

Project notified under transitional arrangements N
Aspergillus fumigatus is an opportunistic pathogen of humans. Immunocompromised individuals such as premature babies, cancer sufferers, transplant patients and AIDS sufferers are at risk from invasive aspergillosis which is often fatal. This project aims to aid the drug screening process used to develop novel anti-fungal compounds. A fumigatus will be transformed using an insertional mutagenesis approach to identify essential genes and genes critical for growth and virulence. The genes knocked out of these strains will be identified using the inserted sequence as a tag to identify the flanking gene sequence.

Recipient or parental organism

The parental organism of the host strains to be used in these experiments is the A. fumigatus wild-type clinical isolate AF293 (available to the public from the NCPF repository (Bristol, UK) and the CBS repository (Belgium)) used in the A. fumigatus genome sequencing project at TIGR (see http://www.tigr.org/tdb/e2k1/afu1). This wild-type parental strain will not be used directly in any experiment, only multiple auxotrophic mutants will be used.

Host/vector system

We will use an engineered plasmid pMB3 based on the cloning vector pCR2.1 which contains the A. fumigatus pyrG gene as a selective marker, bacterial antibiotic resistance genes and a bacterial origin of replication. This plasmid will be linearised and used to transform (in a random integration manner) an A. fumigatus AF293 diploid (niaD+/niaD-/cnx+/cnx-/pyrG-/pyrG-/pabaA-/pabaA-) Insertion of this linearised plasmid DNA into the host genome can be screened for by a change in the phenotype from pyrG- to pyrG+. The host gene or non-coding region of DNA which has been disrupted, can then be identified by plasmid rescue and a relationship established between gene and phenotype.

Evaluation of foreseeable effects

Insertion of the foreign DNA into the diploid host genome will allow the diploid transformant to overcome its pyrG auxotrophy. This does not restore full wild-type activity due to a gene dosage effect (only one copy of the functional pyrG gene is active instead of two) and in this case the resultant transformant would be less pathogenic than the parental wild -type clinical isolate. Due to the cripling PABA mutation these diploid transformants would only grow on media supplemented with PABA.

These insertions/modifications are expected to have an adverse effect on the fungus, reducing its fitness. Insertion of a large piece of transforming DNA (in this case 5.8 kb) into an active gene will in most cases lead to the disruption of that gene's function (by halting transcription and therefore stopping expression of the gene product) and
would in turn reduce its survivability/function in the body or the environment. However, as the studies are aimed at elucidating the function of genes, we cannot be absolutely certain that all modification will lead to a less harmful fungus (Smith et al., 1996) although the fitness of these mutants in the environment will be severely reduced by their absolute requirement for PABA in the growth medium.

A. fumigatus is readily isolated from most environmental locations (air, soil and leaf litter) and does not have an adverse effect on the environment. Indeed it has an important role to play in the degradation of environmental wastes ie leaf litter, decaying organic matter etc. Although wild-type A. fumigatus has no adverse effects on plants in the environment it is sometimes found as an opportunistic pathogen of mammals (ie dogs) and birds (ie parrots in captivity and falcons) and causes similar symptoms to those found in humans, affecting ly immunocompromised animals.

In the event of a breach of containment, a transformed diploid GMM would not be viable in the environment or indeed in the human body in the absence of PABA supplementation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable - no transgenics involved.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

This application covers a laboratory scale project where F2G Ltd applies the principles of good microbiological practice and good occupational health and hygiene practices.

Disinfection with % aqueous Virkon solution is used for spillages, contaminated plasticware and laboratory surface decontamination. Degree of kill (should always be 100%) is measured by plating out samples from known concentrations of fungal inoculum after being subjected to a standard method of Virkon decontamination. This decontaminated plasticware is then autoclaved as detailed in the following section as a double safeguard measure. The ultimate form of this type of waste is decontaminated plasticware which is placed in clinical waste bags, the contents are tagged and recorded in a log book and the bags are then sent to be incinerated by a registered clinical waste disposal service. Full written records regarding autoclave settings, degree of kill and clinical waste disposal via incineration are kept.

Liquid GM waste (culture supernatants containing GM fungi) and solid GM waste (agar plates containing GM fungi) is sterilised in an on-site (same floor of building) autoclave maintained and validated for GM waste sterilisation by a specialist autoclave validation company Lab3 (http://www.lab3.co.uk). The Lab3 Preventive Maintenance Contract allows us to fulfil our legal obligations and includes full servicing, validation and calibration services. All certification is available for viewing. Storage of non-inactivated waste is restricted to within the generating laboratory. The material may not be stored longer than 24 hours prior to inactivation. Degree of kill (should always be 100%) is measured by plating out samples from known concentrations of fungal inoculum after being subjected to a validated GM sterilisation autoclave cycle in different parts of the same autoclave. The ultimate form of this type of waste is decontaminated liquid waste which is cooled to allow solidification and then placed in clinical waste bags to be incinerated by a registered clinical waste disposal service. Full written records regarding autoclave settings, degree of kill and clinical waste disposal via incineration are kept.

All current and new employees who handle GM waste are trained regarding the proper handling of this type of waste.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Purposes of the contained use

The disruption or deletion of bacterial genes to determine the effect of knocking out specific genes on growth and virulence. Thus, identifying potential gene targets for antibiotic drug development.

Recipient or parental organism

Escherichia coli, Acinetobacter baumannii and Pseudomonas aeruginosa

Host/vector system

Cloning steps will involve laboratory strains of E. coli, such as DH5α and NEB 10β. Genes will be targeted in Escherichia coli ATCC 11775 (NCTC 9001); Acinetobacter baumannii ATCC® 19606, Pseudomonas aeruginosa ATCC® 10145 or similar strains. Vectors will be pGEMTeasy, pACD4K-C (from TargeTron KO system, Sigma), pRED-ET (Red/ET Recombination, GeneBridges), 707-FLPe (Red/ET Recombination, GeneBridges). It is likely that the final construct for transformation will be a linear piece of double stranded DNA containing sequences homologous to the gene to be targeted and an antibiotic -resistant selection marker.

Origin & function

Genes will be cloned from the target organisms: Escherichia coli, Acinetobacter baumannii and Pseudomonas aeruginosa. The genes will be disrupted and used to engineer bacteria with specific genes knocked out. The knockout strains will be tested for changes in growth and virulence.

Evaluation of foreseeable effects

The intention is to create GMMs that will likely be less fit than the parental strain as we are attempting to knockout putative antibiotic target genes. The only situation where the GMMs created could have a selective advantage over the parent organisms would be if the gene targeted was not important for growth and virulence, and at the same time the GMMs are challenged with the antibiotic used as a selection marker (ampicillin, kanamycin, zeocin) which is highly unlikely. As the parent organisms are ACDP hazard group 2 organisms capable of causing human disease the worst case scenario is that they infect a lab worker. This is highly unlikely as good microbiological procedures, personal protective equipment and disinfection, decontamination and disposal protocols are in place. A class II microbiological cabinet will be used for processes involving the possibility of aerosol creation and for large culture volumes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plasticware contaminated with GMO’s will be decontaminated by soaking in 1% Virkon for a minimum of 24h followed by collection in Wiva bins and disposed via incineration by an approved healthcare waste specialist (currently SRCL Ltd.). Liquid waste will be decontaminated by soaking in 1% (w/v) Virkon for a minimum of 24h, prior to autoclaving or disposal in sealed containers in Wiva bins that are incinerated as above. Glassware contaminated by Class 2 GMMs will be soaked with 1% Virkon for 24h, then autoclaved before washing and re-use. 1% Virkon has been shown to leave no viable cfu after a 5 min exposure of 1-3 x 10^6 of E. coli and P. aeruginosa, a greater than 5-log reduction in cfu (Hernandez et al, J Hosp Infect. 2000, 46: 203-209). This rate of disinfection will be tested in house for these organisms together with A. baumannii. Autoclaving and/or incineration will ensure complete sterilisation. Thus degree of kill will be 100%.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The F2G Ltd Genetic modification safety committee met on 11th February 2016. The project covered in this application (GM risk assessment F2G016) was discussed. The committee endorsed the content of the risk assessment, agreeing to the classification as a Class 2 activity. The safety measures and associated processes (waste disposal etc) were discussed and approved during the meeting. Drafts of the RA have been distributed to the committee at various stages for comment and they approved the final version.

Give brief details of the genetic modification safety committee

The genetic modification safety committee is a joint committee between ML Laboratories and Cobra BioManufacturing and also acts as the biological safety committee. This committee is known as the GMBSC (Genetic Modification and Biological Safety Committee). The committee meets approximately every six weeks and consists of the following posts.

Chairman, Biological Safety Officer, Assistant Biological Safety Officer, Safety Advisor, M L Management representative, Cobra management representative, ML staff representative, Virologist, Pharmacologist.

02/03/2022
All waste generated from this work will be handled according to the in-house protocols for handling of containment level 2 waste. Liquid waste will chemically inactivated using Virkon, or other appropriate inactivating agent, as recommended by the manufacturer to achieve most effective killing (usually 1% solution). Virkon treatment has been validated by the manufacturer to inactivate all known 18 families of human and animal viruses (including Mastadenoviruses).

Solid waste is collected in a plastic 'Weaver' bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Park). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all disposals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological Safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer.

In the case of an accidental puncture of the skin by a contaminated sharp, the procedure is to wipe the wound with 70% ethanol and report immediately to the Medical Centre.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Genetic Modification and Biological Safety Committee (GMBSC) have received and considered this proposal and are in agreement with the classification suggested. Two example immunostimulatory genes have been described in the risk assessment but the GMBSC will require to review any other genes on a case-by-case basis and notify HSE if there is any resulting alteration to the classification.
The aim of this project is to evaluate the immune-therapeutic benefit of expressing immune-stimulating proteins in murine tumour cells killed in vivo by enzyme/prodrug combinations, namely NTR/CB1954 or Cyp1A2/acetaminophen. Immune-therapeutic effects will be studied using the mouse 4T1 breast cancer cell line in the host BALB/c mice in the first instance. The mouse TRAMP spontaneous prostate tumour model will subsequently be used.

The parental organism is a replication-defective, human Adenovirus (Ad) type 5. Human Ad are found worldwide, and over 40 different serotypes have been isolated. Ad5 is associated with mild upper respiratory tract infections in young children. Immunity to Ad infection is thought to be life-long following primary infection. Although some serotypes are closely related they nevertheless remain distinct entities suggesting that the potential for recombination in vivo is not high. Human serotypes do not naturally infect other animal species and there are relatively few reports of virus replication following inoculation of Ad into experimental animals. There is no evidence that human Ad cross species and so a replication defective virus could not be maintained in non-human hosts. The replication-defective vector is not expected to be harmful. The potential hazard to the environment, from inadvertent release of the quantities of virus expected to be handled, is extremely low.

The recipient cell line sued to produce the virus is the human PER.C6 cell line (Fallaux et al., Human Gene Therapy, 1998,9: 1910-1917). This E1-containing cell line is engineered to avoid recombination between the vector genome and the viral sequences present in the genome of the producer cells and thereby RCAs (Replication-Component Adenoviruses) should not be generated at significant levels.

The final constructs will express the immune stimulatory molecules along or in combination with either bacterial NTR or rodent/human Cyp1A2. For additional safety reasons, the immunostimulatory gene will be cloned into the E1 region. In a case of recombination in vivo (to generate a replication competent virus) this will result in the...
The NTR or Cyp1A2 cDNA can be inserted into E1 or E3. In case of recombination in vivo, to generate a replication competent virus, by a virus containing NTR or Cyp1A2 in the E3 region the recombinant virus would still contain the NTR cDNA or the Cyp1A2 cDNA but there is no obvious reason that these viruses could be more dangerous than an E1-recombined virus that does not contain one of these two cDNAs in E3. This is a justified assumption because the gene products NTR and Cyp1A2 are not toxic by themselves to the human cells. There are no native substrates so far described in the human organism for NTR. Moreover, Drabek et al. (Gene Therapy, 1997, 4:93-100) showed that transgenic mice expressing NTR in T cells are completely healthy and give no changed phenotype.

Cyp1A2 is constitutively expressed in human liver and is induced to higher levels if exposed to exogenous compounds like aromatic hydrocarbons and halogenated hydrocarbons. Endogenous substrates include steroids, fatty acids, prostaglandins and vitamins (Quattrochi et al., 1994, JBC 269:6949-6954). Therefore if a replication-competent virus expressing Cyp1A2 should infect cells, the Cyp1A2 would only convert its natural occurring substrates which are anyway converted by Cyp1A2 already present in the cell or by redundant CytochromeP450-dependent enzymes.

Finally, as all the prepared viruses are deleted for the E3 proteins all generated viruses are considered to be much more immunogenic as E3 proteins help to escape the host immune response against the infected cell (eg MHC class 1 down regulation, inhibition of TNFalpha-mediated effects). In agreement with this, the likelihood that these viruses will persist in the human population should be much lower, again because they are much more immunogenic and therefore the effective production of viral progeny should be significantly decreased.

**Host/vector system**

The vector system is a replication-defective human adenovirus type 5 (E1 and E3 deleted). The host cell line is PER.C6 (Fallaux et al., Human Gene Therapy, 1998, 9:1910-1917).

**Origin & function**

Murine immune stimulatory genes will be generated by PT-PCR from mouse splenocytes or from commercially available sources with immune modulating activity in humans.

**Evaluation of foreseeable effects**

Ad expressing xenogeneic proteins such as a bacterial nitroreductase or a mouse cytokine that is inactive in humans may be immunogenic. It is possible that the Ads expressing a mouse cytokine that is active in man (ie that can bind the equivalent human cytokine receptor) could give additional immunogenicity, eg a local inflammatory response. However, this would be very limited and cleared rapidly in most humans, since the great majority of people have antibodies to Ad coat proteins through exposure to the virus in early childhood. Human cytokines have been evaluated in clinical studies and only show toxicity with systemic administration of high levels.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Ref 838/02.2

Date Ackn’d CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
# Rescue and Propagation of Recombinant Ovine Adenovirus

## Project Additional Information

### Purposes of the contained use
To rescue recombinant ovine adenovirus (OAV) from a plasmid in an ovine cell line, and its use to transduce human dendritic cells to achieve transgene expression in vitro for immunological assay only.

### Recipient or parental organism
The recombinant OAV will bear transgenes for either the fluorescent reporter protein, eGFP, or for the human melanoma-associated proteins, MART1 and gp100. In all cases, expression will be governed by the IECMV promoter. OAVs are capable of infecting human cells but have been shown to be unable to complete their full cycle of replication (Khatri, A et al [1997]: Virology 239 p.226-237), resulting in an abortive infection. Infection is still abortive in the presence of co-infected human adenovirus suggesting minimal risk to the worker when propagating this virus. It is expected however that there will be an immune response in humans on exposure to this virus.

### Host/vector system
A plasmid that contains the whole OAV viral genome, and is therefore a GMM once modified, though of similar or lower risk to the parental virus. The host cells and viral vector are both ovine and the virus is incapable of effective replication in humans.

### Origin & function
Virus and cell line are ovine. The cell line is to allow efficient propagation of the recombinant ovine virus. The virus encodes the genes for either a fluorescent reporter protein (eGFP), or a human gene derived from melanocytes, immunity to which is associated with protection from melanoma. It is intended to deliver the transgene via the OAV transduction vector to human dendritic cells, which is an infective but non-replicative action. Dendritic cells so infected will then be evaluated for transgene expression, and for the presentation of the melanoma-associated antigens to T-cells derived from either healthy volunteers, or patients suffering from melanoma.

### Evaluation of foreseeable effects
OAV is capable of infecting human cells, but it has been shown to be unable to complete its full replication cycle (Khatri, A et al [1997]: Virology 239 p.226-237), resulting in an abortive infection. OAV has also been shown to replicate abortively in human cells, which are co-infected with human adenoviruses. The abortive replication cycle of these viruses suggests that there is minimal risk to the worker when propagating these viruses. However, due to the lack of pre-existing immunity of the worker to OAV, there will be limited immunity on first exposure to the virus. Subsequent exposure would result in a strong immune response to the virus.
The plasmid DNA containing the full OAV genome will be used to rescue the virus under segregated conditions. As the plasmid contains the same genetic material as the intact virus, it is highly unlikely that the plasmid would be of greater risk to the worker than the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The virus will only be handled in class II microbiological safety cabinets that will be swabbed with a viricide (eg Virkon or Klearcide) after use. All contaminated materials will be treated by chemical means (eg 1% Virkon solution, which is proven to destroy both Mastadenoviruses and Aviadenoviruses). Solid waste is collected in a plastic 'Weaver' bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Park). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all dispossals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological Safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1%Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer.

In the case of an accidental puncture of the skin by a contaminated sharp, the procedure is to wipe the wound with 70% ethanol and report immediately to the Medical Centre.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agree that class 1 would normally have been appropriate for the protection of human health, but as this virus can cause mild infection in sheep it becomes a class 2 activity to ensure protection of sheep in the environment.

Project Containment

| Laboratory Activities | Glass Houses | Growth Rooms |

02/03/2022
Project Additional Information

**Purposes of the contained use**

To produce replication incompetent amphotropic murine leukaemia virus using packaging cell lines which express heterologous envelope proteins that will extend the tropism of the virus to human cells and to a broad range of mammalian cells.

**Recipient or parental organism**

The recombinant virus will be produced using the "Ampho Pack-293" or "Retro Pack PT67" packaging cell lines (www.clontech.com) which express heterologous envelope proteins ("4070A" or "10A1") that will extend the tropism of the virus to human cells. Since MuLV is an integrating virus there is the potential for insertional mutagenesis. The virus will be replication incompetent. There is however a theoretical risk of contamination with low levels of replication competent retrovirus (RCR), generated during the packaging process. The recombinant virus will have a wide tropism and thus presents the same hazards as above to other mammals.

**Host/vector system**

The Retro Pack PT67 packaging cell line is a mouse fibroblast (NIH-3T3-derived line. Ampho Pack-293 is a human embryonic kidney (HEK 293) - derived cell line. The vector is cloned into a non-mobilisable plasmid backbone. Viral components in the plasmid are all under eukaryotic promoters and therefore will not be expressed in...
bacteria. The gag/pol and env genes are not present in the vector and therefore there is no possibility of viral production by transfection of cells with the plasmid alone. The virus produced is murine but will express a heterologous envelope protein that will extend the tropism to a broad range of mammalian cells.

Origin & function

The packaging cell lines will be of mouse or human origin. The cell lines contain stably integrated copies of gag, pol and env genes necessary for particle formation and replication. The lines were created by sequential stable transfection resulting in the integration of gag/pol and env genes at different locations thus minimising the chance of producing replication competent virus.

The vector is cloned into a non-mobilisable plasmid backbone. The vector contains the packaging signal +, transcription and processing elements required for virus production. These components are erived from murine leukaemia virus.

The final GMM will express a reporter gene (β-galactosidase, EGFP or luciferase) from the ubiquitous CMV promoter/enhancer downstream of a DNA fragment encompassing portions of the bidivergently transcribed RNP1A2 and HP1HY genes (“UCOE”). No additional hazard would be predicted due to the expression of these transgenes since they encode innocous proteins that have been widely used to measure promoter activity in both cultured cells and in vivo (expression in all tissues throughout the life of transgenic animals has no detectable pathological effect).

Evaluation of foreseeable effects

Infection of humans could potentially result in an insertional inactivation event:

The vector will be of the self-inactivating variety (“SIN”) preventing activation of genes adjacent to the integration site by the viral LTRs. However, there will be the potential for activation of adjacent genes by the UCOE element. This may occur over a large distance (extent is currently unknown).

Thus the detrimental consequences of provirus insertion would be a contribution to tumorigenesis through either the inactivation of a tumour suppressor gene, such as p53, or the activation of a dominant oncogene by the UCOE element.

However, tumour suppressor gene inactivation would leave one allele intact, except for the minority of individuals carrying a defective allele.

Furthermore, integration will only occur in cycling cells further reducing the chance that exposure will result in an

Finally, infected cells will express a reporter gene encoding a foreign protein and would be expected to be eliminated by the immune system in the majority of cases.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated from this work will be handled according to the in-house protocols for handling of containment level 2 waste.

Liquid waste will chemically inactivated using Virkon, or other appropriate inactivating agent, as recommended by the manufacturer to achieve most effective killing (usually 1% solution). Virkon treatment has been validated by the manufacturer to inactivate all known 18 families of human and animal viruses (including Mastadenoviruses). Solid waste is collected in a plastic ‘Weaver’ bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the plant manager.
of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Pak). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all disposals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological Safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer.

In the case of an accidental puncture of the skin by a contaminated sharp, the procedure is to wipe the wound with 70% ethanol and report immediately to the Medical Centre.

According to the ACGM compendium of Guidance amphotropic replication defective retrovirus' containing a non-harmful insert should not need additional containment over containment level 1 (Part 2B - Annex III paragraph 30). Thus this risk assessment could be considered to be containment level 1. However, due to the presence of the UCOE and a lack of certain knowledge of the distance at which it may act (although anecdotal data suggests this is not great) the possibility of ongogene activation by insertional mutagenesis MAY be increased). Thus, as a precautionary measure the committee feels containment level 2 is appropriate for this activity.

Class 2
Culture Vol Class 2 < 1 litre

02/03/2022
The aim of this project is to evaluate the therapeutic benefit of expressing a parasite derived immune-stimulating protein in murine tumour cells to enhance anti-tumour immunity, resulting in the in vivo death of the tumour. Immune-therapeutic effects will be studied using the mouse 4T1 breast cancer cell line in the BALB/c mouse in the first instance.

The parental organism is a replication-defective, human adenovirus (Ad) type 5. Human Ad are found worldwide, and over 40 different serotypes have been isolated. Ad5 is associated with mild upper respiratory tract infections in young children. Immunity to Ad infection is thought to be life-long following primary infection. Although some serotypes are closely related they nevertheless remain distinct entities suggesting that the potential for recombination in vivo is not high. Human serotypes do not naturally infect other animal species and there are relatively few reports of virus replication following inoculation of Ad into experimental animals. There is no evidence that human Ad cross species and so a replication defective virus could not be maintained in non-human hosts. The replication-defective vector is not expected to be harmful. The potential hazard to the environment, from inadvertent release of the quantities of virus expected to be handled, is extremely low. The recipient cell line used to produce the virus is the human PER.C6 cell line (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917). This E1-containing cell line is engineered to avoid recombination between the vector genome and the viral sequences present in the genome of the producer cells and thereby RCAs (Replication-Component Adenoviruses) should not be generated at significant levels.

The final constructs will express the immune stimulatory molecule from the E1 locus. In a case of recombination in vivo (to generate a replication competent virus) this will result in the deletion of the immunostimulatory gene cassett in E1. finally, as all the prepared viruses are deleted for the E3 proteins, all generated viruses are considered to be much more immunogenic as E3 proteins help to escape the host immune response against the infected cell (e.g. MHC class I down regulation, inhibition of TNFalpha-mediated effects). In agreement with this, the likelihood that these viruses will persist in the human population should be much lower, again because they are much more immunogenic and therefore the effective production of viral progeny should be significantly decreased.

The vector system is a replication-defective human adenovirus type 5 (E1 and E3 deleted). The host cell line is PEr.C6 (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917).
Total parasite mRNA will be sourced via an academic collaboration. A cDNA encoding the open reading frame for the immunostimulatory factor will be generated by standard RT-PCR techniques. A cDNA for a protein associated with the induction of apoptosis will be generated by RT-PCR from mouse splenocytes. All expression cassettes will be inserted into the E1 locus of Ad5.

**Evaluation of foreseeable effects**

It cannot be excluded that accidental incorporation of even very small amount of Ad vector expressing immune-modulating proteins could result in a local inflammatory response that is enhanced compared to exposure with an empty virus, or a virus expressing a non-hazardous foreign protein. Local and immediate inflammatory responses should be cleared relatively fast as most humans have been exposed to Ad5 infection in early childhood, and have low-to-high serum antibody levels against Ad5 hexon and fibre protein. The immunostimulating factor is a foreign protein that will invoke a neutralising antibody response, which is capable of inhibiting its pro-inflammatory activity, thus limiting any longterm effect on the host. A fusion construct incorporating elements of a molecule associated with the induction of apoptosis will not contain the native extra-cellular domains associated with the ligation of the protein by its native ligand. Therefore, all biological effects will be dependent upon the behaviour of the parasite derived moiety, and hence the fusion protein does not represent any greater risk than the soluble native parasite material.

As with other replication-defective Ad constructs, any inadvertent generation of replication-competent virus, or helper virus, in the viral stocks would be readily apparent from the appearance of typical cytopathic effects in culture. The effects on the operator of accidental ingestion, absorption or inoculation are, however, difficult to estimate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste generated from this work will be handled according to the in-house protocols for handling of containment level 2 waste.

Liquid waste will chemically inactivated using Virkon, or other appropriate inactivating agent, as recommended by the manufacturer to achieve most effective killing (usually 1% solution). Virkon treatment has been validated by the manufacturer to inactivate all known 18 families of human and animal viruses (including Mastadenoviruses). Solid waste is collected in a plastic 'Weaver' bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Park). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all disposals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological Safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer.

In the case of an accident puncture of the skin by a contaminated sharp, the procedure is to wipe the wound with 70% ethanol and report immediately to the Medical Centre.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The parasite-derived immunostimulating molecule has been used in vivo as a vaccine candidate without any adverse reactions, however, as its activity is not well characterised and could have unknown functions it is recommended that the work is carried out at containment level 2. Thus the Genetic Modification and Biological Safety Committee (GMBSC) is in agreement with the classification suggested by the risk assessment.

### Purposes of the contained use

The aim of this project is to evaluate the immunogenicity of an oncoprotein in vivo. The ability of the resulting anti-oncogene immune responses to have anti-rumour effects in in vivo models will also be evaluated.

### Recipient or parental organism

The parental organism is a replication-defective, human Adenovirus (Ad) type 5. Human Ad are found worldwide, and over 40 different serotypes have been isolated. Ad5 is associated with mild upper respiratory tract infections in young children. Immunity to Ad infection is thought to be life-long following primary infection. Although some serotypes are closely related they nevertheless remain distinct entities suggested that the potential for recombination in vivo is not high. Human serotypes do not naturally infect other animal species and there are relatively few reports of virus replication following inoculation of Ad into experimental animals. There is no evidence that human Ad cross species and so a replication defective virus could not be maintained in non-human hosts. The replication-defective vector is not expected to be harmful. The potential hazard to the environment, from inadvertent release of the quantities of virus expected to be handled, is extremely low.

Any virus produced in-house will be produced in PerC6 cells (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917), an E1-containing cell line designed to avoid recombination between the vector and the viral sequence present in the genome of the producer cells, and thereby replication-competent adenovirus (RCA) vectors should not be generated at significant levels. Some virus will be obtained from collaborators and this will be produced in 293 cells and thus will have a higher risk of RCA contamination. As with other replication-defective Ad constructs, any inadvertent generation of replication-competent virus, or helper virus, in the viral stocks would be readily apparent from the appearance of typical cytopathic effects in culture.

The oncogene will be inserted at the E1 locus. In a case of recombination in vivo (to generate a RCA), this will result in the deletion of the oncogene cassette in E1. Finally, as all the prepared viruses will be deleted for the E3 proteins, all generated viruses will be considered as much more immunogenic than non E3-deleted Ad5. Indeed, E3 proteins help to escape the host immune response against the infected cell (eg MHC class I down regulation, inhibition of TNFalpha-mediated effects). In agreement with this, the likelihood that these viruses will persist in the human population should be much lower, again because they are much more immunogenic and therefore the effective production of viral progeny should be significantly decreased, due to clearance of infected cells by the immune system.

### Host/vector system

The vector system is a replication-defective human adenovirus type 5 (E1 and E3 deleted). The host cell lines are PER.C6 (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917) for in house viruses, and 293 for viruses obtained from collaborators.

### Origin & function

E1/E3-deleted, replication-deficient Ad-5 vector expressing the oncogene will be sourced via academic collaboration. This construct should temporarily express the oncoprotein within infected cells in vivo. This oncoprotein is intended to raise a tumour-protective, specific immune response in mice.

### Evaluation of foreseeable effects

Oncogene overexpression has been shown to immortalise cells. Thus the major risk to human health is stable insertion of oncogene into an individuals cells resulting in the development of a tumour. For this risk of tumour induction to be realised the following events must take place i) the adenovirus must be accidentally administered to an individual, ii) the administered adenovirus must transduce susceptible cells (avoiding the anti-adenovirus immune response which would already be present in the majority of immunocompetent individuals), iii) a transduced cell must stably express the oncogene, iv) transient expression and stable integration is a rare event, ie the oncogene expressing cell must not be lysed by anti-oncogene or anti-adenovirus immune responses (adenoviral proteins are highly likely to be co-expressed with the oncogene), v) the oncogene must not be silenced, vi) the oncogene expressing cell must have other gene disregulation events such that the cell can become tumourogenic. Thus although there is a risk of tumour formation if there was an inadvertent administration of the virus to an individual, this risk is deemed to be low. The risk assessment also puts in place control measures to minimise the risk of administration of the virus to an individual.

The risk of the virus to the environment is deemed to be negligible since the virus is replication defective (any RCAs are unlikely to carry the oncogene), the virus will be more immunogenic than wild-type virus due to the deletion of E3 and most importantly control measures are in place to ensure that the virus is not released into the environment.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated from this work will be handled according to the in-house protocols for handling of containment level 2 waste.

Liquid waste will be chemically inactivated using Virkon, or other appropriate inactivating agent, as recommended by the manufacturer to achieve most effective killing (usually 1% solution). Virkon treatment has been validated by the manufacturer to inactivate all known 18 families of human and animal viruses (including Mastadenoviruses).

Solid waste is collected in a plastic 'Weaver' bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Park). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all disposals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment will be carried out using 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer. No sharp or glassware will be allowed during cell culture involving the construct.

In the case of an accidental puncture of the skin by a contaminated needle during animal injection, the procedure is to apply pressure around the wound to encourage bleeding, resulting in physical expulsion of the accidentally injected product, and report immediately to medical centre.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMBSC felt that the risk assessment clearly identified the hazards and risks and put suitable measures in place to control the risks. It also examined whether any of the containment measures that would be required for an increase to containment level 3 would reduce the risk to the workers or the environment and took the view that this would not be the case. Thus, after much discussion, the GMBSC agreed with the assignment of containment level 2 for this work. As this is the first risk assessment dealing with an oncogene (and especially since the oncogene will be placed in a viral vector) the GMBSC would appreciate some feedback from the HSE on this risk assessment.

Growth Rooms

02/03/2022
The aim of this project is to evaluate a particular DNA element termed "UCOE" (ubiquitous chromatin opening domain) to prevent the silencing of a eukaryotic promoter-driven marker gene(s) in cells transduced in vitro using an amphotropic (VSV-G pseudotyped) lentiviral vector based on HIV-1.

The recombinant virus is 3rd generation SIN (self inactivating) replication-incompetent lentivirus based on HIV-1 (Human Immunodeficiency Virus-1). The virus is amphotropic and expresses the VSV-G envelope protein which gives the virus a wide tropism including human cells. This type of vector has been used safely and successfully in various laboratories worldwide. Since lentiviruses are integrating vectors there is the potential risk for insertional mutagenesis. The recombinant virus will have a wide tropism and thus presents the same hazards as above to other mammals.

The recombinant virus will be used to transduce category 1 cell lines such as N1H3T3, HT1080, HeLa, CHO and Category II primary cells such as human mesenchymal stem cells (MSCs) and human haematopoietic stem cells (HSCs). These transductions will result in stable integration of the recombinant lentivirus. The final GMM (stably transduced cell line) will express a marker protein (either GFP, luciferase or B-galactosidase) and a gene for antibiotic resistance.
The vector system is a replication-defective 3rd generation SIN lentivirus produced using 293FT cells (obtained from Invitrogen). The vector is cloned into non-mobilisable plasmid backbones based on the on Puc series (obtained from Invitrogen). A total of 4 plasmids is used to transiently transfect the 293FT cells. Viral components in the plasmids are all under eukaryotic promoters and therefore will not be expressed in bacteria in which they are prepared. 3 plasmids contain the packaging and viral genes (gag/pol on one, env on another and rev on the third). These plasmids contain the genes required for production of the lentiviral particles in trans and do not contain a packaging signal, so the final vector is devoid of these viral genes. In addition they do not contain viral LTRs and are designed to have minimal regions of viral homology therefore minimising homologous recombination events. The expression plasmid will encode one of the marker genes under the control of a eukaryotic promoter along with the bidivergently transcribed UCOE under test and an antibiotic resistance gene. This plasmid will encode the RNA transcript that is packaged into the lentiviral vector. The recombinant virus is replication incompetent. However there is the theoretical risk of contamination with very low levels of replication competent virus. However only three of the HIV-1 genes present in wild type virus remain in this vector and upon integration the vector self-inactivates due to a deletion in the U3 region of the 3’LTR and cannot undergo further rounds of replication. The recombinant virus will contain a reporter gene (either LacZ, EGFP or Luc) driven by a eukaryotic promoter downstream of a DNA fragment encompassing the test UCOE. It may also contain mammalian antibiotic resistant genes pac or BSD.

Origin & function

The recombinant virus will be used to transduce and to stably integrate genes into mammalian cells in culture (as detailed above). EGFP is derived from the jellyfish Aequoria Victoria, the Luc from the firefly Photinus Pyralis and LacZ from the bacterium E. coli. Test UCOE elements and a number of eukaryotic promoters may be used. Pac is derived from Streptomyces alboniger and BSD from Aspergillus terreus. EGFP is a fluorescent protein that can be easily detected by fluorescence activated cell scanning (FACS) and acts as a marker protein for detection of gene expression in the final GMM. Similarly Luc encodes for luciferase and LacZ encodes for B-galactosidase, which are enzymes that can be detected by enzyme assay or histochemistry. A eukaryotic promoter is required to drive expression of the marker genes, as the promoter in the integrated LTR is self-inactivated in this vector system. The UCOE is the functional element that will be under test to evaluate its potential to prevent the silencing of the marker gene(s). Pac encodes for N-acetyl-transferase an enzyme that confers resistance to the antibiotic puromycin and similarly BSD encodes for blasticidin-S deaminase that confers resistance to the blasticidin S. Conferring antibiotic resistance allows for in vitro selection of cells containing integrated transgenes. No additional hazards would be predicted due to the expression of these transgenes since they encode proteins that have been widely used to measure promoter activity in both cultured cells and in vivo (expression in all tissues throughout the life of transgenic animals has no detectable pathological effect) or have been widely used for the selection of stable integrants.

Evaluation of foreseeable effects

There is a theoretical possibility of generating RCV either in the packaging cell line or in the final transduced GMM. However this is minimised by design of the vector system and by use of cells or cell lines that do not have known lentiviral sequences. Infection of humans could potentially result in an insertional inactivation event. However the vector will be of the self-inactivating variety ("SIN") preventing activation of genes adjacent to the integration site by the viral LTRs. There may be the potential for activation of adjacent genes by the UCOE element. This may occur over a large distance (extent is currently unknown). Thus the detrimental consequences of provirus insertion would be a contribution to tumorigenesis through either the inactivation of a tumour suppressor gene, such as p53, or the activation of a dominant oncogene by the UCOE element. However, tumour suppressor gene inactivation would leave one allele intact, except for the minority of individuals carrying a defective allele. Any infected cells will express a reporter gene encoding a foreign protein and would be expected to be eliminated by the immune system in the majority of cases.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated from this work will be handled according to the in-house protocols for handling of containment level 2 waste. Liquid waste will chemically inactivated using Virkon, or other appropriate inactivating agent, as recommended by the manufacturer to achieve most effective killing (usually 1% solution). Virkon treatment has been validated by the manufacturer to inactivate all known 18 families of human and animal viruses (including Mastadenoviruses).
Solid waste is collected in a plastic 'Weaver' bin (50L) lined with a plastic bag. When full the bag is tied and the lid secured to seal the box. The box is externally disinfected and then transferred to a designated 820L wheeled waste unit. The wheeled waste unit is collected by White Rose Environmental and handled and incinerated according to their procedures for Class 2 waste. Prior to collection a completed consignment note (detailing the type of waste and the precautions taken) is faxed to the Plant Manager of the receiving incinerator. A copy of the consignment note travels with the waste and the original is kept by the Facilities Manager at Stephenson Building (Keele University Science Park). When disposal of the waste is complete the disposers section of the consignment note is completed by the Plant Manager and faxed to the Facilities Manager. Thus a record of all disposals and confirmation of disposals is kept by us. White Rose's documentation has been audited by our Biological Safety Officer.

Local decontamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer. No sharps or glassware will be allowed during cell culture involving the construct.

The committee felt that all the risks associated with this program of work had been addressed in the risk assessment and agreed with the containment measures and level proposed.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

Level 1 (GMMs)

Level 2 (GMMs)

Level 3 (GMMs)
Waste materials that have contained or otherwise contacted the virus dose will be collected in appropriate rigid container, transported to Microbiology Department by the Urology Research Nurses and autoclaved prior to disposal and incineration as per GMO SOP. Disposal of this decontaminated waste, and all other waste produced within the patient's room, will be in accordance with the Trust Waste Management Policy and GMO SOP. Waste unlikely to be contaminated with the GMO would be processed via the Trust's routine 'infectious waste' stream ie by incineration.

Processing in the autoclave (SAL MC type) would be expected to completely inactivate the adenovirus. The process is monitored by automatic parametric testing and recording and a regular schedule of validation and autoclave testing in accordance with HTM2010.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Waste materials that have contained or otherwise contacted the virus dose will be collected in appropriate rigid container, transported to Microbiology Department by the Urology Research Nurses and autoclaved prior to disposal and incinerated as per GMO SOP. Purposes of the contained use

The realization that the infectious agent responsible for variant Creutzfeldt-Jakob disease (vCJD) can be transmitted by blood transfusion and that effected individuals are infectious during a protected preclinical phase has raised concerns that a pool of potentially infectious asymptomatic individuals could exist in the UK blood donor population. Assays capable of detecting infectivity in blood/plasma could help to prevent further cases of secondary disease transmission. Prion diseases, including cCJD, are closely associated with the conversion of the normal host cellular prion protein (+PrPC) to a misfolded, disease-associated form (PrPSc), which is considered by some to be the major (if not the sole) component of the infectious agent and is the only unambiguous disease marker identified to date. Hence the assays for the detection of vCJD infectivity in blood/plasma have focused on the detection of PrPSc. However, such a screening assay would have to specifically detect minute amounts of PrPSc in a large excess of PrPC.

One such potential plasma screening assay has been developed SNBTS. The assay is based on the amplification of minute amounts of PrPSc to readily detectable levels using a technique called protein misfolding cyclic amplification (PMCA) and its subsequent detection by conformation dependent immunoassay (CDI). In the assay's original format, plasma samples are first treated with NaCl to both precipitate any PrPSc present in the sample and remove the factor/factors found in plasma which inhibit PrPSc amplification, following centrifugation the resulting pellets are resuspended in the PMCA substrate (10% (w/v) human platelet lysate in PMCA conversion buffer) and subjected to 4 rounds of serial PMCA (sPMCA), finally the 4th round sPMCA products are screened for the presence of PrPSc by CDI. In this format the assay could reproducibly detect PrPSc in plasma spiked with a 10-8 dilution of a 10% (w/v) vCJD brain homogenate and no false positive results were detected in the limited number of normal US plasma samples tested. Whilst these initial results were encouraging, in all probability in order to detect the amounts of PrPSc the assay would need to be improved. A 100-fold increase in PrPSc detection sensitivity, resulting in the reproducible detection of PrPSc in plasma spiked with a 10-10 dilution of a 10% (w/v) vCJD brain homogenate, was achieved using a PMCA substrate supplied by Japan Blood Products Organisation (JBPO). This substrate was prepared form a transfected embryonic kidney cell line (293-F) that over-express normal human PrPC of the PRNP methionine codon, 129 genotype. In order to further evaluate and validate the use of this substrate in the assay developed at the transfected 293-F cell line from Japan Blood Products Organisation to SNBTS so that the transfected cell line can be cultured, harvested and used to prepare the PMCA substrate in-house at SNBTS.

Summary of the project

- Import of the transfected 293-F cell line and the expression vector used to transfect the cells from Japan Blood Products to SNBTS.
- The transfected 293-F cell line will initially be grown in suspension cultures and frozen stocks will be laid down.
- For routine preparation of PMCA substrate, suspension cultures will be seeded from the frozen stocks and the cells harvested by centrifugation.
- The resulting cell pellets will be lysed in PMCA conversion buffer to a prepare a 20% (w/v) cell lysate which will be stored, in suitable sized aliquots at -80°C ready for use in subsequent PMCA reactions.

Note that the aims of this project only cover the culture, harvesting and subsequent use of the transfected cells to prepare PMCA substrate. All PMCA reactions using this substrate will be carried out in the dedicated derogated containment level 2 C D Research Laboratory.

Recipient or parental organism

293-F human embryonic kidney cells

The 293 cell line is a commercially available, well characterised cell line established from primary embryonic human kidney cells transformed with sheared human adenovirus type 5 DNA. The EIA adenovirus gene is expressed in these cells and participates in transactivation of some viral promotors, allowing these cells to produce very high levels of protein expression.

The 293-F cell line is a variant of the 293 cell line that has been adapted to grow in suspension culture.

Host/vector system

pIERESneo3 is a mammalian expression vector that contains the internal ribosome entry site (URES) of the encephalomyocarditis virus (ECMV), which permits the translation of two opening reading frames from one messenger RNA, in this case the gene of interest (gene encoding normal human cellular prion proteins) and the gene conferring resistance to neomycin (neomycin phosphotransferase NPT 11 gene). Thus after selection in neomycin nearly all surviving colonies will stably express the gene of interest.

For propagation, selection and expression in mammalian cells the expression cassette of pIRESneo3 contain the human cytomegalovirus (CMV) major immediate early promoter/enhancer followed my a multiple cloning site (MCS) that precedes stop codons in all three reading frames, a synthetic intron known to enhance the stability of the mRNA the EVMNV IRES followed by the neomycin phosphotransferase (NPT II) gene (which confers resistance to neomycin), and the polyadenylation signal from sv40. Ribosomes can enter the bicistronic mRNA at the 5’ end to translate the antibiotic (neomycin) resistance marker. When using the pIRESneo3 vector, the antibiotic exerts selective pressure on the entire expression cassette; thus a high dose of antibiotic will select cells expressing a high level of the gene of interest. This selective pressure also ensures that the expression of the gene of interest will be stable over time in culture.

The vector also contains an ampicillin resistance (b-lactamase) Gene and a ColE1 origin of replication for selection in E. coli, and an f1 origin for single-stranded DNA production.

Origin & function

The gene sequence inserted into the pIRESneo3 expression vector is a chimeric mouse/human DNA sequence which encodes the N-terminal signal sequence from the mouse prion protein gene and the full length human prion protein amino acid sequence with methionine at codon 129. Thus the transfected 293-F cell line will over-express normal cellular prion protein (PrPC) which is homoyzogus for methionin at codon 129 of the human PRNP gene. The normal form of human PrPC is expressed in most cell and tissue types with the highest expression levels found in the brain. The exact role of PrPC is not known, however, it is believed to be involved in signal transduction and cell adhesion

Evaluation of foreseeable effects

The 293-F cell line is a well characterised, commercially available cell line, which should be of no risk to human health and would be incapable of surviving within an accidentally inoculated immunocompetent host. However, the supplier (Invitrogen) recommends that 293-F cells should be handled as potentially biohazardous material under at least Containment Level 2 conditions.
The pIRESnneo3 expression vector is commercially available and has no known associated hazards.

At normal physiological levels human PrPC is not considered a risk to human health. However, Section 34, Page 45 of Part 2 of the SACGM Compendium of Guidance states that GMMs over-expressing normal prion proteins should be handled at Containment Level 2 as they may be pathogenic. It is conceivable that in culture the human PrPC gene sequence could undergo mutation leading to the production of pathogenic forms of human PrPC such as those associated with genetic/familial forms of human prion disease. This potential risk is highlighted even though there is no evidence to suggest that these forms of human prion disease can be transmitted from person-to-person. It has also been reported that cell cultures expressing PrPC can support the propagation of the agents causing a variety of animal and human prion disease. Thus it is conceivable, but highly unlikely, that a cell line over-expressing human PrPC could propagate the infectious agent responsible for variant Creutzfeldt-Jakob disease (vCJD) should it be exposed to the infectious agent responsible for bovine spongiform encephalopathy (BSE) through the use of contaminated bovine-derived products in tissue culture supernatants. This could lead to a potential exposure to the infectious agent that causes cCJD in humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Culture of the transfected 293-F cell line will be carried out at Containment Level 2 and the following additional control measures will be adopted:-

- Cell culture supernatants to be centrifuged in sealed containers which will only be opened in a Biological Safety cabinet.
- All work where aerosols might be generated will be carried out in a Biological Safety Cabinet.
- The use of sharps and glassware will be avoided.
- Transfected 293-F cell to be cultured in serum free medium and bovine-derived tissue culture supplements will not be used.
- All waste generated from the culture of the transfected 293-F cell line to be treated as potentially infectious and will be decontaminated and disposed of as described in SOP LIB 049 CJD RESEARCH LABORATORY: WASTE DISPOSAL.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations are requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste products generated from the culture of the transfected cell line will be treated as potentially infectious for human prions will be decontaminated and disposed as described below:-

- All liquid waste (spent culture medium) will be decontaminated using NaOH at a final 2M concentration for a minimum of 1 hour (ideally overnight) in sealable buckets, sawdust will then be added to absorb the liquid waste, the buckets will be sealed, double bagged in yellow clinical waste bags and disposed of by incineration.
- Used pipette tips will be disposed of into sharpsafes, when the sharpsafes are full they will be sealed, sprayed with 2M NaOH, left for a minimum of 1 hour (ideally overnight), rinsed with tap water and disposed of by incineration.
- All other waste which has not been exposed to potentially infectious agents will be double bagged in yellow clinical waste bags and disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Th attached risk assessment was discussed and approved at the SNBTS Biological safety & GMO Committee meeting held on the 11th July 2014

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

Committee members: Chief Scientific Officer UK, Regulome Corporation; Regulome Corporation staff representative; Biological Safety Officer, John Innes Centre; Resources Manager, Norwich Bio-Incubator; external member from John Innes Centre Biological Safety Committee.

The committee will meet annually to review all risk assessments and HSE notifications. Additional meetings will be held to consider new risk assessments and notification requirements as required. All assessments and notifications will be circulated by email and comments from the committee taken into account prior to any new procedures being adopted. Any assessments which fall outside the expertise of more than three of the committee will be sent to external advisors drawn from experienced scientists working in the relevant area on the Norwich Research Park.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid biological waste will be placed in unsealed bags placed in lidded but unsealed plastic boxes and removed from the laboratory to the John Innes Centre central autoclave service where it will be sterilized. The autoclave cycle will include heating the material to at least 120 degrees C for 15 minutes to ensure 100% kill for all material.

Liquid waste and contaminated glassware will be treated with hycolin disinfectant, diluted according to the manufactures instructions, overnight at room temperature. An initial check will be carried out the first time the process is carried out to check that no culturable cells remain before disposal. This check will be repeated periodically depending on classification of risk and whenever waste from different cell types or quantities of culture are produced to ensure that the procedure results in 100% kill.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All members of the genetic modifications safety committee have read the attached risk assessment and have agreed with its conclusions.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Heat inactivation**
All solid GMM material will be disposed in autoclavable bags placed in clearly labelled 'biological hazard' bins. When half-full bags will be autoclaved (30 min at 130 degrees C) and placed in special bins for incineration. All liquid GMM material will be autoclaved (30 min at 130 degrees C) and subsequently disposed with wastewater.

Degree of kill
Degree of kill with this autoclaving procedure is 100%

Monitoring measures:
A Brown T.S.T Control test strip (Albert Browne Ltd) is included with every run of the autoclave as a control for proper heat-exposure.

Please enter comments of the GM safety committee on the risk assessment

* A comment was made on the lack of specification of a species under 9i)(b) par.2, with regards to the cloning of anonymous cDNAs. The BSO explained that no other species has been targeted yet, but that a new risk assessment will be performed as soon as this happens.
* Addition of text under (i)(b) par.2: 'for in vitro RNA production'.
* The Standard Operating Procedure (SOP) for cloning of cDNA, of which a draft version is in place, will be merged with a SOP for use of micro-organisms.
* Advise to include an additional reference (HSE compendium).
* Advise to include author, site and date in the footer of the document.
* Some minor editing comments were made.

Give brief details of the genetic modification safety committee

GMSC consists of the Technical Director of DRI, the Quality Management Systems Manager, a Senior Research and Development Scientist, the COSHH Safety Officer and the Biological Safety Officer (BSO). The committee meets monthly to discuss and review GM and Health and Safety issues within the company. All GM work is approved by the BSO/GMSC and a risk assessment carried out to determine the class of activity before commencement.

All GMM waste will be collected in an autoclave bag, separate from standard laboratory/clinical waste. GMM waste will then be inactivated by autoclaving at 121 degrees C for 20 mins in an autoclave within the same building before being incinerated with other laboratory/clinical waste by a laboratory/clinical waste disposal company (at present the contractor is PHS Allclear Limited).

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Tick to confirm that you are attaching a summary of the risk assessment  
Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

Good microbiological practice should ensure that the GMM is contained and will not cause harm to people or the environment.

The GMSC has agreed that the GM activity in the risk assessment is low risk and agrees that the activity should be categorised as a Class 1 activity.

The waste disposal measures for GMM waste are suitable for treatment of Class 2 waste even though this is not required for Class 1 activities, but this is standard practice for the inactivation of GM waste within DRI Limited.

Yes

Give brief details of the genetic modification safety committee

The Oxford BioBusiness centre has an established Genetic modification safety committee comprising of suitably qualified members from some of the companies based there and an outside expert from the University of Oxford. Our risk assessment has been studied and approved by the committee.

Solid virus-containing waste is bagged and placed in a designated metal container which is removed to the autoclave. Liquid virus waste is discarded to bottles which are placed in a designated metal container for autoclaving. All liquid waste is treated by autoclaving at 130 degrees C for 60 mins, before disposal to drains.

Disposable solid waste, which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees C for 30 mins, before removal as "clinical waste" by specialist contractors, with final disposal by incineration.

The exceptions to the above are:
Sharps and pipets are steeped in 1% Virkon for a minimum of 30 minutes before disposal in an approved sharps box. The Virkon is discarded down the sink.
Glassware is soaked overnight in 1% Virkon before removal for normal tissue culture wash up processing.
Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.
The autoclave on site is regularly tested and services.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMMs.
The manufacturer's information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and we have demonstrated that 15 minutes exposure to 1% Virkon achieves >4 log (10) kill for adenovirus-infected cell pellets, and >6 log (10) kill of adenovirus seed stocks.
It was suggested that we test our adenovirus preparations for recombinant adenovirus (RCA). A recombination event would generate a wild-type Ad5. Bulk preparation of virus will not be performed at Littlemore Park, but will be provided by colleagues working in the Department of Clinical Pharmacology at Oxford University. We have arranged for all virus preps to be tested for RCA by performing plaque assays on A549 cells, which support the growth of wild type virus but not replication deficient viruses.

**Project Additional Information**

**Purposes of the contained use**

Development of polymer-coated retargeted viral vectors.

**Recipient or parental organism**

The vectors are attenuated and are less pathogenic than their corresponding wild type virus. They have also been engineered to be more active in tumour cells than normal tissues. The inserts encode reporter genes, prodrug activating enzyme genes or anti-angiogenic genes which will not increase the pathogenicity of the viruses. The inserted gene products are expressed at very low levels, however it is possible that they may cause an immune response in healthy subjects. Immunocompromised individuals may be less likely than normal healthy individuals to mount an immune response to incoming viruses, but as the modified viruses are replication defective, this should not lead to replicative spread of the virus. With respect to the environment, the viruses require a host to replicate; it is very unlikely that the GM strains will be able to form a successful infection.

**Host/vector system**
Commercially available human tumour cell lines, 293 and 911 cells, BHK21 fibroblasts, BSC-1 (African green monkey kidney) cells. Attenuated Vaccinia virus, attenuated HSV1, conditionally replicating adenoviral vectors.

**Origin & function**

The viral vectors and inserts will be obtained from collaborators. All the vectors are attenuated and are less pathogenic than the corresponding wild type virus. The inserts encode products which will not increase the pathogenicity of the viruses. We plan to non-genetically modify the viruses using polymer coating and attachment of targeting ligands for use in cancer gene therapy.

**Evaluation of foreseeable effects**

The vectors are conditionally replicating, and the inserts code for innocuous products that will be expressed at very low levels. The recombinant viruses are less pathogenic than their parental wild types. There is little risk to human health or the environment as it is very unlikely that the GM viruses could find a host in which to successfully replicate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Non

Describe the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon is used for soaking pipettes, TC plates and flasks, Virkon powder is added to liquid waste to give a final concentration of 1%.

Virkon is used in accordance with the manufacturer's instructions (ie 1% solution). It has been validated as being effective within 10 minutes at this concentration. See www.antechh.com/virkonapps.html. We routinely decontaminate for at least 1 hour.

Virkon stocks are routinely tested. Viruses are exposed to 1% Virkon for 15 minutes, dialysed and diluted in culture media. This is then put on to cells and transgene expression, which indicates viability of the virus, is assayed after 24 hours.

Decontaminated waste is allowed to dry before being put into clinical waste bags, these are then transferred into large clinical waste bins located approximately 20 metres from the laboratory. The yellow bags are labelled with the date and time of decontamination and a written record is kept. Bags are removed from the site by a commercial company for incineration.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment
We should emphasise that we are not genetically modifying any vaccinia, or HSV ourselves, just using GM strains that are commercially available or available through collaborations. That polymer coating and retargeting would further limit the tropism of all viruses and therefore the survival of the GMM in the environment is likely to be less than for wild-type.

### Project Additional Information

**Purposes of the contained use**

Development of conditionally replicating adenovirus vectors expressing therapeutic transgenes for cancer therapy

**Recipient or parental organism**

02/03/2022
ColoAd1 is an Ad11p/Ad3 chimeric group B adenovirus virus that demonstrates selective replication in tumour cells. ColoAd1 is attenuated and is less pathogenic than the corresponding wild type virus. The inserts will encode for tumour associated antigens, cytokines, mammalian receptors and ligands, enzymes, siRNA's and full length antibodies or antibody domains which will not increase the pathogenicity of the viruses. The inserted gene products will be expressed under a range of different promoters including tumour specific promoters and endogenous viral promoters.

It is possible that the gene products may cause an immune response in healthy subjects. Immunocompromised individuals may be less likely than normal healthy individuals to mount an immune response to incoming viruses. However, normal human cells are non-permissive for ColoAd1 replication, which will not lead to replicative spread of the virus.

With respect to the environment, the viruses require a host to replicate and do not replicate in non-human cells, so it is very unlikely that the GM strains will be able to form a successful infection.

### Host/vector system

Commercially available human tumour cell lines, 293 and 911 cells conditionally replicating adenoviral vectors.

### Origin & function

Vectors will be generated in house and will be based on conditionally replicating adenoviruses. All the vectors are attenuated and are less pathogenic than the corresponding wild type virus. The inserts encode mammalian protein products which will not increase the pathogenicity of the viruses, to evaluate their potential function for treatment of cancer when delivered in this form.

### Evaluation of foreseeable effects

The vectors are conditionally replicating, and the inserts code for products that will be expressed at low levels. The recombinant viruses are less pathogenic than their parental wild types. There is little risk to human health or the environment as it is very unlikely that the GM viruses could find a host in which to successfully replicate.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

The GMSC has been established as a sub-committee of the Trust R&D Committee with the R&D Director as Chair. The Committee comprises

* Chair of Trust Control of Infection Committee
* Trust Head of Health and Safety
* Assistant Director of Nursing with responsibility for clinical risk
* Academic member of Edinburgh University medical School GM Safety Committee
* Academic representative on GTAG
* R&D Director
* Nominated Biological Safety Advisor
* Staff representative
* Project co-ordinator (study specific)

Level 1 (GMMs)  
Level 2 (GMMs)  
Yes
Level 3 (GMMs)  
Level 4 (GMMs)  
Non-microbial
For activities involving GMMs, describe the waste management measures which will apply to the activity

N/A

Please enter comments of the GM safety committee on the risk assessment

GMSC assessed this project and the risk assessment provided. The Committee felt this was a thorough assessment and approved the activity with the following requirements:

* An SOP or equivalent should be readily available in the event of a needlestick injury
* A return visit by the Chair of Control of Infection Committee must be organised by the principal investigator when the Class II cabinet has been commissioned. Operational procedures will be reviewed at that stage. No patient should be recruited
* Occupational Health should know of the procedures so they can give advice in the unlikely event of an incident
* There should be a record of all staff who handle the product
* It is the responsibility of the principal investigator to ensure all staff working in the Unit are aware of the study and reassured about containment procedures
* A copy of any report submitted must be forwarded to the Chair of Trust GMSC
Project Additional Information

**Purposes of the contained use**

In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

**Recipient or parental organism**

See box below

**Host/vector system**

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map unit 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

**Origin & function**

The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

**Evaluation of foreseeable effects**

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to nonexistent.

Risks resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or nonexistent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical
consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (eg promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as negligible. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation by autoclaving and effectively 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Trust has set up a Genetically Modified Safety Committee as a sub-committee of its R&D Committee. GMSC assessed this project and approved the activity with the following requirements:-

* An SOP or equivalent should be readily available in the event of a needlestick injury
* A return visit by the Chair of Control of Infection Committee must be organised by the principal investigator when the Class II cabinet has been commissioned. Operational procedures will be reviewed at that stage. No patient should be recruited
* Occupational Health should know of the procedures so they can give advice in the unlikely event of an incident
* There should be a record of all staff who handle the product
* It is the responsibility of the principal investigator to ensure all staff working in the Unit are aware of the study and reassured about containment procedures
* A copy of any report submitted must be forwarded to the Chair of Trust GMSC

---

**Please enter comments of the GM safety committee on the risk assessment**

Risk assessment E1 was approved by the committee, subject to registration of the lab with the HSE. The committee noted that the biological materials to be used were well within the containment level 1 category, and requested that the risk assessment should include reference to good laboratory practice with respect to the use of lab books to record all experimental activities, and a log book to record the sterilisation and disposal of waste. Appropriate COSHH forms and Safe systems of work should be completed before work commences.

No mouth pipetting, manipulate potentially infectious materials carefully to avoid spills and minimise production of aerosols. Restrict the use of needles and syringes to those procedures for which there are no alternatives. Use protective lab coats and gloves. Wash hands following all laboratory activities following the removal of gloves and immediately following contact with infectious materials. Decontaminate work surfaces with chloros or virkon before and after use and immediately after spills. The use of sharps in operations involving GMOs (hyperdermic needles, scalpels) should be avoided whenever possible. Where possible the use of glassware for containing GMOs should be minimised in favour of disposable plasticware. Cultures of GMOs in glass flasks should be transported between labs by way of communal throughfares must be carried in a suitable leak-proof container capable of containing any spillage and made from a material permitting subsequent disinfection. Operations involving the potential generation of aerosols (eg tissue homogenisation, sonication of genetically modified organism) must be performed in a Class 1 microbiological safety cabinet. Where the samples have been lysed (ie all cells dead) beforehand by the addition of detergent or strong alkaline denaturant then the operations may be performed in a fume cupboard. Dispose of contaminated GMO waste in biohazard waste bins for incineration by an external waste disposal company. Decontaminate liquid cultures with chloros or 1% virkon for at least 20 minutes before pouring down the sink into the drains.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All experiments involving GMOs must be risk assessed in accordance with procedures laid down by the GMO safety committee. All work must be approved by the biosafety committee before experimental work is begun. A risk assessment system will be stored on the company shared drive electronically, and also a filed paper copy.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee will consist of the Head of Research, the Laboratory Manager, the Site Safety Manager and an expert Molecular Biologist. The committee will meet as necessary to discuss new work as requested whether it falls within the current containment level or if an increase in containment level is required. The committee will also meet quarterly to review the progress of GMO studies, whether new work has been requested or not.

Bacteriology Yes  Parasitology  Transgenic Birds  Microbiology Research Yes
All work will be conducted with commercially available attenuated strains. All material resulting from studies with GMMs will be autoclaved or treated with a suitable antibacterial detergent (e.g., Triagene) and then transported for incineration by a registered waste carrier and disposer or disposed of to the sewage system respectively. GMM material undergoing inactivation procedures will be periodically tested for viability using standard plate counting methods.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The genetic modification safety committee (GMSC) considers that the work outlined in the risk assessment will be confined to specific laboratories and falls well within the existing safety protocols. As a result the work poses minimal risk to individuals working with the genetically modified micro-organisms. As the work involves commercial attenuated strains there will be minimal risk to the environment following accidental release. Equally, as this work is confined to the laboratory and will be used as a laboratory tool it poses minimal risk to the associates and animals housed on site. Therefore, the GMSC considers that this work requires level 1 containment.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Pseudomas aeruginosa strain uu3OR2::CM is a non-EPS producing mutant that will be used as a negative control in screening studies for an oral health research programme.

**Recipient or parental organism**

P. aeruginosa strain 883OR2::CM is a gift from Institute of Infections and Immunity and Inflammation, University of Nottingham. P aeruginosa strain 8830R2::CM is a mutant of P. aerugompsa straom 8830, which is a mucoid cystic fibrosis isolate (Darzins & Chakrabarty, 1994, J. Bact., 159:9-18).

**Host/vector system**

N/A

**Origin & function**

The mutation of P. aeruginosa strain 8830R2::CM is in the algR2 gene, which is a regulator of alginate production. Alginate is a virulence factor in P. aeruginosa pathogenesis. P. aeruginosa strain 8830R2::CM will be used as a negative control in EPS producing oral isolate screening and as such will not be further modified.

**Evaluation of foreseeable effects**

P. aeruginosa is an opportunistic pathogen of humans and animals and is a class 2 pathogen. Although rarely, if ever, infectin healthy tissues, infections in immunocompromised individuals and cystic fibrosis patients may be fatal. The mutation in the algR2 locus of P. aeruginosa strain 8830R2::CM results in a lack of alginate (EPS) production. Key to the pathogenicity of P. aeruginosa, is its ability to form biofilms and hence resist antibiotic therapy. EPS (alginate in P. aeruginosa) is vital for biofilm formation and as such is an important virulence compared to the wild type strain 8830. In accordance with safe microbiological practice the GMO would still be treated as a class 2 pathogen and would be handled under containment level 2 conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All broths, agar plates, biological waste and laboratory consumables which have been used in experiments with the GMM will be autoclaved. All experimental materials, except glassware, will be disposed of by incineration by Whiterose Environmental. Following autoclaving any glassware will be washed in a suitable detergent and reused as appropriate. A record will be kept of all GMO waste disposals.

The genetic modification safety committee (GMSC) considers that the work outlined in the risk assessments will be confined to specified laboratories and falls well within the existing safety protocols. As a result the work poses minimal risk to individuals working with the genetically modified micro-organisms. As this work is confined to the laboratory and will be used as a laboratory tool it poses minimal risk to the associates and animals housed on site. Equally, by following the Waltham Centre Laboratory standard operating procedures, utilising the appropriate safety equipment (eg class 2 safety cabinets) and undertaking the waste disposal methods outlined previously in this application, there will be minimal risk to the environment as a result of work with this organism. The GMM is derived from a class 2 pathogen, therefore, the GMSC considers that this work requires level 2 containment.

</table>
Expressed recombinant proteins will be used to measure antibody cross reactivity and/or tested for bioactivity in order to produce functional assays for the proteins.

The African green monkey cell line, COS1, was derived from the parental CV1 cell line by transformation using a plasmid containing the SV40 virus sequence containing a deletion in the viral origin of replication (Gluzman et. Al.). The cell line is permissive for growth of SV40 but no free viral DNA was detected in this cell line. As SV40 infection causes a cytopathic effect in COS1 cells and this is not seen during normal culture of these cells it can be assumed that no viable virus is produced by the cells.

cDNAs will be inserted into the commercially available plasmid vector pCDNA3.1. This will be introduced and amplified in E. Coli K12.

Origin & function
DNA encoding a number of canine and/or feline genes will be amplified by polymerase chain reaction and inserted into the plasmid vector. These plasmids will be introduced into the COS1 cell line. Driven by the SV40 origin in the plasmid vector this will amplify to a high number episomally and result in a high level of expression of the protein encoded in the cDNA.

None of the recombinant proteins being expressed will have the same sequence as the orthologous human protein nor will any proteins suggested to be oncogenic be expressed. The COS1 cell line is incapable of producing viable SV40 virus by itself. There is a very slim possibility that the inserted SV40 DNA could recombine with the SV40 origin of the replication contained in the pCDNA3.1 plasmid vector to produce a viable SV40 virus. SV40 virus has not been proven to be pathogenic in humans but viral DNA has been isolated from a number of human tumours. Because of this, this work will be carried out under level II restrictions.

None of the recombinant proteins being expressed will have the same sequence as the orthologous human protein nor will any proteins suggested to be oncogenic be expressed.

SV40 virus has not been proven to be pathogenic in humans but viral DNA has been isolated from a number of human tumours. Because of this, this work will be carried out under level II restrictions.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Transfected COS 1 cells will be killed by a variety of methods including treatment with 100% metanol, 1% paraformaldehyde and/or heating to 95C with 2% SDS, 1% beta-mercaptoethanol. These methods should result in 100% cell death and this will be confirmed via microscopic examination. All supernatant will be treated with a 1:50 dilution of the viricidal disinfectant trigene. Following confirmation that all GMO's have been killed, all products will be transferred offsite for incineration.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

It was recommended that the size and sequence of the insert once cloned was determined (using any of the universal primers spanning the cloning sites - from each direction) prior to commencing transfection experiments in the COS 1 cells. This would ensure the correct insert had in fact been inserted before any protein was produced.

The GMSC were satisfied with the list of genes initially identified for this study. Any intentions to clone and express any additional genes in future would have to be formally reviewed and recorded by the GMSC prior to work commencing.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All disposable material will be autoclaved at 121°C for 20 minutes. Following this process the material will be sent off-site for incineration. The autoclave is a new LTE Osprey 150 which will be maintained to the manufacturers recommendations and validated at least once a year. Autoclave indicator tape will also be used to ensure this process is effective.

Glassware and hard surfaces which have come into contact with any GMM will be cleaned with a 1% solution of Virkon (as per manufacturer’s recommendations) for at least 10 minutes. 1% solution of virkon are stable for 7 days so fresh solution will be made on a weekly basis or sooner if required.

Spillages of solutions containing a GMM will be treated by covering with Virkon powder until the liquid is absorbed. The powder will then be scrapped into a suitable container for disposal.

Laboratory clothing coming into contact with a GMM will be soaked in a 1% solution of Virkon for 10 minutes.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

As both the adenovirus and HSV to be used have been genetically modified to make them safe to use in a class 1 environment and therefore they pose no risk to humans, animals or the environment the GMSC will allow this project to begin subject to the approval of the HSE for the premises notification form CU1 2000 (Notification of intention to use premises for contained use activities).

**Premises Conditions**

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  Y

Give brief details of the genetic modification safety committee

The genetic modification safety committee representative of ASM Scientific Ltd will be the Director of Research. This representative will meet at least twice annually with an on-site safety committee at the BBT (Babraham Bioscience Technologies), within which the company is located. This committee serves to uphold and enforce on-site standards in accordance with a policy and code of practice drawn up for the BBT site. Each on-site company has a representative on this committee.
Class 1 activities at ASM Scientific Ltd will comprise the propagation of recombinant plasmid vectors in standard laboratory strains of E. coli ie strain K12 and its derivatives. Waste management of bacterial cultures, and contaminated materials such as handling gloves and plastic ware will be as follows:

1. Liquid cultures and infected media will be sterilised prior to disposal by treatment with chloros or Virkon. Following complete sterilisation solutions will be disposed of by foul sewer.

2. Contaminated clothing, plasticware, culture dishes and other items will be placed into dedicated autoclave bags and subsequently autoclaved. Disposal of sterile autoclaved rubbish will then occur through on-site laboratory waste disposal service.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment
The company is based on a research campus, Babraham Bioincubator, which has its own safety committee and infrastructure to which we must conform. (see letter of file dated 10.12.02)

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

Committee Members:
From Novacta: Research Director (Company Safety Officer), Fermentation Group Leader (Biological Safety Officer), Molecular Biology 1 Group Leader, Molecular Biology 2 Group Leader and a Molecular Biologist.
From Norwich Bioincubator: The Resources Manager.

The Committee will meet annually to review all risk assessments and HSE notifications. Additional meetings will be held to consider new risk assessments and notification requirements as required. All assessments and notifications will be circulated by email and comments from the committee taken into account prior to any new procedures being adopted. Any assessments which fall outside the expertise of more than three of the committee will be sent to external advisors drawn from experienced scientists working in the relevant area on the Norwich Research Park.

- Level 3 (GMMs)

- Level 4 (GMMs)

- Non-microbial

---

02/03/2022

Page 11683 of 15326
Solid biological waste will be placed in unsealed bags placed in lidded but unsealed plastic boxes and removed from the laboratory to the John Innes Centre central autoclave service where it will be sterilized. The autoclave cycle will include heating the material to at least 120 degrees C for 15 minutes to ensure 100% kill for all material.

Liquid waste and contaminated glassware will be treated in one of two ways:
1) Autoclaving: The autoclave cycle will include heating the material to at least 120 degrees C for 15 minutes to ensure 100% kill for all material.
2) Hycolin disinfectant: Hycolin disinfectant, diluted according to the manufactureres instructions, overnight at room temperature.

In either case an initial check will be carried out the first time the process is carried out to check that no culturable cells remain before disposal. This check will be repeated periodically depending on classification of risk and whenever waste from different cell types or quantities of culture are produced to ensure that the procedure results in a 100% kill.

Members of the Genetic Modification Safety Committee have read the attached risk assessment and have agreed with its conclusions.
To produce a long-chain polyunsaturated fatty acid for application as a dietary supplement

The host strain Pythium irregulare is regarded as a plant pathogen. Pythium strains are generally less damaging than Phytophthora, but can cause damping-off of seedlings, attacking the roots and stems of a variety of plants including ornamentals. P. irregulare is widespread globally and is indigenous to the UK. Long-chain polyunsaturated fatty acids do not represent a component of plant pathogenicity or virulence, and the likelihood that increased production of these or any other genetic manipulation involved in fatty acid biosynthesis would increase the virulence of this strain is considered highly unlikely.
The host is Pythium irregularare, an oomycete regarded as a plant pathogen. The vectors to be used will be standard oomycete, fungal or yeast vectors, eg pTOR, widely used for oomycete genetic manipulation. pTOR is selectable with the G418 antibiotic.

Origin & function

Much of the work will involve upregulation or deletion of host genes, but some heterologous genes will be used. These will be derived from fungal, plant or bacterial sources, and be well-characterized genes involved in fatty acid biosynthesis.

Evaluation of foreseeable effects

P. irregularare is classified as ACDP1, having no known pathogenicity to man. The E.coli hosts to be used as intermediates for cloning are non-pathogenic laboratory strains (K12 or BL21) and do not represent a human health problem. In the case of E.coli strains, multiple mutations and nutritional requirements ensure that prolonged survival and propagation in the environment is unlikely. Therefore the overall risk to human health and to the environment of these disabled E.coli strains is low. The use of nonmobilisable vectors minimises the risk of transfer to other microorganisms. Any heterologous genes to be used will represent well-characterised genes for enzymes of known function or homologous to genes of known function, and are highly unlikely to influence the pathogenicity or survival and propagation of the host strains. In the very unlikely event of a construct escaping into the environment and surviving, it is difficult to conceive of any hazards arising that would be greater than those represented by naturally-occurring environmental microorganisms including native Pythium irregularare strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated materials will be autoclaved (124°C/30min) or treated with disinfectants (0.5% Presept, minimum 10 minutes contact time) as appropriate. These procedures have been shown to give 100% kill. In the event of accidental breakage of a culture vessel, escape of the organism will be contained, either by the incubator or secondary containment (i.e. tray, carrying basket). Spillages will be treated with antimicrobial agents (eg 0.5% Presept) as appropriate. Personal contamination (skin & clothes) is the most likely accident to result from such cultures. The use of suitable and appropriate protective clothing (lab coats, gloves etc) should enable effective decontamination. Contaminated lab coats or other clothing must be autoclaved. Gloves and all other disposable items must be double-bagged and autoclaved before disposal. Escapes should be negligible.
Classification Class 2 considered appropriate as the organism is a plant pathogen, and DEFRA require such strains to be handled under category 2 conditions. The genetic modifications planned should not increase pathogenicity or virulence of the strain or represent any threat to human health or the environment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste produced falls into either group A, B, or C as defined by the Health Services Advisory Committee.

Liquid waste (maximum culture volumes of 500 ml) will be chemically treated with Virkon powder to a final concentration of 1% solution for at least 30 minutes (the manufacturers specified conditions for inactivation), before disposing of via the drainage system with copious amounts of water.

Solid waste will be chemically treated with a 1% solution of Virkon for 30 minutes (the manufacturers specified conditions for inactivation), then placed into autoclavable waste bags and autoclaved at 123 degrees C for 15 minutes to inactivate. Sharps waste will be placed in containers conforming to BS7320 and will be autoclaved at 123 degrees C for 15 minutes to inactivate. The load temperature of the autoclave will be monitored by means of a UKAS/NAMAS certified internal temperature probe. Additionally the autoclave will be tested and calibrated four times per year.

Carcasses and soiled bedding from transgenic animals will be autoclaved at 123 degrees C for 15 minutes to inactivate. Inactivated waste will then be placed into sealed, yellow, printed pathology waste bins meeting BS381C. Individually numbered ties will be attached.

Sealed bins and bags will be stored in locked clinical waste bins before collection by designated staff for transportation to a registered off site facility for incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The risk assessment was approved as a Class 1 activity at the local GM committee meeting on 18 December 2001. Minor modifications were made to comply with current policy on GM waste disposal.

Liquid waste is disinfected with Virkon solution (Antec International Ltd. USA) the appropriate concentration and time of immersion will be used according to manufacturer's instructions. Treated waste is then disposed of as part of normal laboratory waste. Disposable plasticware and glassware is disinfected with Virkon as above and then held in a closed container pending sterilisation by steam (121°C for 20 min). This waste is then collected by contracted waste disposal services and incinerated. The autoclave used for this purpose is validated routinely by Oxfordshire BiotechNet.

We would expect the level of kill to be high using these procedures with surviving GMOs to be negligible and to be 'below detectable level'.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

GM Committee was happy with the risk assessment made and consequently made no recommendations.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

COMPOSITION
Vice President Biology (Chair)
Biology Safety Rep
Facilities and Laboratory Manager
Senior Biologist

ROLES
The Chairman makes the final decisions
The Biology Safety Representative deals with the safety aspects of the operation
The Facilities and Laboratory Manager deals with the practical aspects of the safety concerns (air flows, safety cabinet servicing, waste disposal etc)
The Senior Biologist deals with the organisms that need to be discussed and brought in to the company.

OPERATION
The GMS committee meets quarterly (or more often if required)
The results of the meetings are reported at the Company Health, Safety and Environment Committee meetings. The minutes of these meetings are reported to the Board.
The GMS committee decides the risk category of the work involved, and the necessary safety precautions to be carried out.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

All waste material will be autoclaved before being disposed of in clinical waste bins which are then collected by an authorised company (at present White Rose Environmental) for incineration.

**Tick to confirm that you are attaching a summary of the risk assessment** Y

**Tick if you are claiming exemption from disclosure for sections of the risk assessment** Y

**Please enter comments of the GM safety committee on the risk assessment**

All the organisms to be used in this initial screen are hazard class 1.

All work with these organisms will be carried out by trained staff, in a specified tissue culture laboratory equipped with a double hepa filtered class II biological safety cabinet. All work with exposed cells will be carried out in the cabinet. At all other times cells will be stored in a closed container.

All waste will be treated with the appropriate disinfectant if necessary, autoclaved, and then placed in a clinical waste bin in a clinical waste bag. The bins are collected regularly by an approved waste management company (currently White Rose Environmental) and taken for incineration.

It was concluded that there is no safety risk to either the staff, public or the environment if these precautions are followed at all times.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The waste generated from the production of the recombinant antibodies will be subjected to initial sterilisation with Virkon to prevent both viral and bacterial survival. Subsequently the waste will be autoclaved, this will result in 100% kill of any GMOs and result in destruction of all genetic material. All processes involving GMOs will be logged by Supervisors and the Biological Safety Officer and will include the monitoring of waste disposal. The autoclave used is serviced and certified in good working order every 6 months.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC has reviewed the Risk Assessment submitted to them for the production of recombinant antibodies. They have concluded that the process and resultant GMO pose no danger to human health or the environment.

I have enclosed a copy of the minutes of the first meeting of the GMSC where the Risk Assessment for recombinant antibodies was discussed.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The GMSC consists of 8 permanent members.

- 2 users of the proposed GMO laboratory (both of whom have previous molecular biology/practical GMO experience)
- The site safety officer
- The local R&D safety advisor
- A representative from the current microbiology team
- A representative user from the current class 2 laboratory
- Two senior managers (including the head of R&D)

In addition to the above we have enlisted the aid of a third party (an external academic with experience of working with GMOs/GMO safety issues) to give general advice to the committee on an ad hoc basis. During this initial set up phase for the laboratory the GMSC will be meeting at least once a month (or more frequently if required) to identify any issues that arise during the course of the notification and risk assessment process. It is anticipated that once appropriate procedures and practices are in place, the group will meet every 2-3 months to review current practices and any new risk assessments that have been submitted. Minutes will be taken at each meeting and specific comments and recommendations from the committee will be recorded therein.

<td>not applicable</td>
<td></td>
</tr>
</tbody>
</table>
Purposes of the contained use

The proposed work programme seeks to generate and express single-chain antibody fragments in Escherichia coli (TG1) from a protein expression cDNA library. This will be performed using a phagemid/helper phage expression system. These fusion proteins (consisting of antibody fragments joined to purification tags or standard reporter enzymes) will then be used in proof of principle experiments to examine the binding properties of these fragments in in vitro assay formats. The contained use risk assessments cover the steps required to produce such proteins in solution in sufficient quantities for use in such experiments (i.e., 0.1-10 mgs of protein). Whilst we will seek to maintain the fragments inherent biological activity (i.e., their ability to bind target antigens) the proteins are not intended for use in vivo. A variety of target binding partners are under consideration (said targets are confidential due to commercial sensitivity/IP consideration).

Recipient or parental organism

The recipient/host organism (TG1 strain of E. coli) is generally recognised to be a non-colonising and disabled micro-organism that is unlikely to survive outside of a laboratory environment. It is not considered to be pathogenic to humans, animals or plants. As such it is considered to be equivalent to ACDP hazard group 1. The original genetic material (i.e., coding DNA that is to be expressed in the host via a phagemid/helper phage system) was obtained from a (non-human) mammalian source via a third party organisation. The parental/donor mammals are bred commercially and the genetic material obtained via ethically approved means (by the above-mentioned third party).

Host/vector system

As stated above, the chosen host organism (TG1 strain of E. coli) is a well-characterised laboratory strain commonly used in GMM work. The target genetic material will be expressed in a non-pathogenic phagemid plasmid (derived from pHEN1, containing an antibiotic (ampicillin) resistance gene) and helper phage M13K07 (an M13 variant with a kanamycin resistance gene) will be used to facilitate transfer of the phagemid to the host organism. Whilst the phagemid in itself is considered mobilisation-defective, the presence of the helper phage does increase its potential mobility to the host and other micro-organisms.

Origin & function

The inserted genetic material is derived from a (non-human) mammalian source and expressed a fragment of the antigen-binding site of an antibody. The coding regions, when expressed as fusion-proteins are for in vitro assay use only and are not thought to be toxic or represent a hazard to humans at the anticipated levels produced here (0.1-10 mgs of protein) or through reasonably foreseeable routes of accidental exposure. Further information is given in the confidential section of this document. The exact nature of the antibody fragments (including the original parental animal from which the original mRNA/cDNA was extracted) is being withheld for reasons of commercial sensitivity.

Evaluation of foreseeable effects

The antibody fragments will be expressed as fusion proteins to standard purification tags/reporter enzymes (e.g., hexa-his tags). The fragments are intended for laboratory
scale proof of principle studies in in vitro assay formats. They are not destined for in vivo use nor are the fragments considered to be inherently toxic to humans, animals, insects or plants. As such the hazards associated with the proposed GMM (E. coli TG1/antibody fragment coded by the phagemid) is deemed to be low. However, accidental transfer of the phagemid via the helper phage to other micro-organisms may represent a slightly higher risk to human health (primarily by conferring antibiotic resistance to the new host rather than inherent dangers associated with the expressed fusion protein). As such it is important that phagemid/helper phage be segregated from other procedures within the lab (ie where both the helper phage and the phagemid are present at high titres eg during transformation/infection of the TG1 etc.) The use of microbiological safety cabinet (Class 2) will help limit the inherent risk to an acceptable level.

In terms of environmental impact, the hazards associated with the proposed GMM (ie TG1/fragment insert) are deemed to be low due as (1) the host strain a well characterised/disabled laboratory strain that is unlikely to survive in the environment; (2) the host is non-pathogenic to humans, animals, insects and plants and (3) the expressed antibody fragments are thought to be both non-toxic and non-oncogenic. However there is a potential hazard associated with the accidental transfer of antibiotic resistance genes to other micro-organisms due to the use of the phagemid/helper phage system. The use of Class 2 containment measures (including isolation of the phage work to a dedicated class 2 microbiological safety cabinet, the combined Virkon S treatment/autoclave based inactivation regime that are to be implemented in the waste disposal measures should reduce any environmental risks to acceptable levels.

Based on the above information (given in sections 5-7) the level of hazard associated with this work predominantly falls within the Class 1 activity area. However, additional class 2 measures are being applied to limit hazards associated with the phagemid/helper phage system. These include the use of a microbiological safety cabinet (Class 2) for handling of all solutions that contain high titres of phagemid and/or helper phage enriched cultures. In addition, all work will take place in a suite of rooms that are self-contained, hepa-filtered and under negative pressure. Waste disposal measures entails chemical inactivation of phage followed by autoclaving. We propose that these measures (class 1 with some class 2 measures) classify the overall work programme as Class 2 and we intend to comply with Class 2 requirements throughout.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations from full containment are being sought for this work.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM contaminated waste will be dealt with in the following way;

* Cultures/glassware/disposal plastic-ware and consumables that have been exposed to non-transformed micro-organisms and phagemid carrying micro-organisms in the absence of helper phage (ie where the phagemid has limited mobility) will be autoclaved (at 134 degrees C for 30 minutes) within a reasonable time period (ie within 24 hours of the work being completed). The self-contained molecular biology laboratory has autoclave facilities en-suite. Autoclaving efficiency can be monitored by chart-based time and temperature readings. In the event of autoclave failure, additional autoclaves are available outside the molecular biology suite.
* Cultures/glassware used to grow cultures that have been in contact with high titre cultures of phagemid/helper phage will be treated with solutions of Virkon S (a commonly used, well established virucidal agent) and allowed to stand overnight prior to autoclaving as above.
* Disposable plastic-ware/consumables that have been in contact with high titre culture of phagemid/helper phage (including micro-organism cultures that have been infected with phagemid/helper phage combinations) will be discarded into waste containers containing 1% solutions of Virkon S and allowed to stand overnight prior to autoclaving as above.
* After autoclaving, all disposal solid waste (eg disposable plastic ware and consumables) will then be transferred off site. Autoclaved liquid waste will be disposed of via the main drainage system.
* Work areas potentially exposed to high titre phagemid/phage will be cleaned/wiped with 1% Virkon S solutions immediately before and after use.
* Large volume spills of liquids containing high titre cultures of phagemid/helper phage will be treated with undiluted Virkon S powder (to absorb the liquid). This waste will then be treated as above and the area cleaned/wiped with 1% Virkon S solutions immediately following the spill.
The above measures are based upon validated, well-established regimes for handling E. coli based GMMs and bacteriophage based work. As such, full implementation of the above procedures should result in a 100% kill of GMMs and helper phage. As such these measures have been deemed to be sufficient for class 2 work.

Is an emergency plan required according to regulation 20?

Y

Please enter comments on the GM safety committee on the risk assessment

Having reviewed the risk assessments, the committee (aided by external advice from a consultant academic with experience in the field) was satisfied that considerable effort had been made to identify potential hazards and minimise the likelihood of them occurring. It was noted that the greatest risk appeared to be associated with accidental infection of bacterial cultures (via the phagemid/phage transformation system) rather than being inherent to the planned experimental output (ie the recombinant antibody fragments). They agreed that extra emphasis should be placed upon the safe handling and disposal of phage-based cultures (eg the use of a dedicated class 2 cabinet microbiology cabinet and Virkon S disinfection/autoclaving). It was also agreed that the proposed waste disposal measures represent well-established procedures that should be more than sufficient to inactivate both the GMMs and the phage.

It was pointed out that in the future, other microbiology based studies may occur within the molecular biology suite of rooms (ie work which is unrelated to the GMM studies but that required access to similar equipment eg culture hoods). Providing that the phage work was limited to a dedicated hood (and other users were prohibited from using it for other purposes), it was deemed that accidental infection was unlikely to occur (and thus the level of risk to human health and the environment was low).

As such the GMSC agree with the final classification of Class 1 plus some class 2 measures (equating to class 2 overall). This classification is deemed cautious but warranted under the circumstances (particularly as the proposed experiments are to be the first GMM work to be performed in the refurbished laboratory suite).

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMMs that are currently made by Paradigm are completely destroyed by standard autoclaving. All laboratory waste (for example gloves, used plasticware, pipettes, and anything else contaminated) will be subject to autoclaving before leaving the premises. In the case of liquids, a strong disinfectant (for example Chloros) will be used to treat samples and regular testing will take place to gauge the level of killing. For minor spillages it is anticipated that a solution of 70% Ethanol or 60% Isopropanol will be used to decontaminate - any solid waste from the decontamination process will be autoclaved before leaving the building. The laboratory is designed so that it can be easily cleaned. Carpets and rugs in laboratories are deemed inappropriate. Laboratory furniture is capable of supporting anticipated loading and uses. Spaces between benches, cabinets, and equipment are accessible for cleaning. In accordance with Good Laboratory Practice, Protective laboratory coats, gowns, smocks, or uniforms designated for lab use are worn while in the laboratory. This protective clothing is removed and left in the laboratory before leaving for non-laboratory areas (e.g., cafeteria, library, administrative offices). All protective clothing is either disposed of in the laboratory or laundered by the institution; it should never be taken home by personnel. Gloves are worn when hands may contact potentially infectious materials, contaminated surfaces or equipment. Wearing two pairs of gloves may be appropriate. Gloves are disposed of when overtly contaminated, and removed when work with infectious materials is completed or when the integrity of the glove is compromised. Disposable gloves are not washed, reused, or used for touching "clean" surfaces (keyboards, telephones, etc.), and they should not be worn outside the lab. Hands are washed following removal of gloves.

Paradigm has been working under licence #GM 253 (to JH Rogers of the Physiological Laboratories, University of Cambridge) with the GMMs outlined in Appendix 1. In accordance with this, the GMSC has recommended that Paradigm continue to work only with fully verified commercial sources of Host strains and vectors to maintain all work at Hazard Level 1 and Containment Level 1.

**Historical Significant Changes**

- Project transferred to GM3043 on merger with Paradigm Therapeutics

**Historical Date of Additional Info**

**Significant Date of Change**

**Historical Date of Additional Info**

**Date of Significant Change**

### Project Additional Information

#### Purposes of the contained use

1. Measure the concentration of specific materials in samples.
2. Use extracted RNA for cDNA synthesis for expression profiling of human genes.
3. To transiently generate proteins incorporating an antibody detectable tag to confirm protein expression.

####Recipient or parental organism

- Adenovirus - recipient - mammalian cells grown in culture.

####Host/vector system

- Adenovirus
  - attenuated (non-replicative) adenovirus particles supplied as a suspension
  - no production of virus to be carried out

####Origin & function

- Adenovirus
  - Originator: Invitrogen Corporation
  - the virus suspension is supplied frozen by the above company
  - an aliquot of supernatant is added to cultured mammalian cells and allowed to infect them
  - the virus encodes a mutated tRNA that permits read through of the TAG stop codon in the gene sequence
  - mRNA encoding a TAG stop codon is read through and the subsequent nucleotide sequence used to add additional amino acids to the protein being synthesised
  - in recombinant cells the cDNA encoding the gene of interest contains a TAG stop codon followed by gene sequence encoding a number of amino acids that when synthesised generate an epitope that can be recognised by an antibody
  - the addition of the epitope will allow confirmation of protein expression of the gene of interest in the recombinant cell line
Evaluation of foreseeable effects

The adenovirus particles can infect human cells. In the unlikely event of a user being infected the following effects are likely to happen:

1. Viral particles will infect cells
2. The tRNA will be expressed
3. There will be read through of any mRNA which has a TAG stop codon
4. It is estimated that this will be about 33% of all transcribed genes in each cell infected
5. The adenovirus does not replicate in the human cells so any effect will be transient, a maximum of 8 days
6. The resultant change in the proteins is most likely to be toxic to the cells
7. This may result in cell death of those cells infected
8. As a result of cell death in the local area of administration and an inflammatory immune response will be elicited
9. It is not anticipated that there will be any long term effects due to the attenuated nature of the adenovirus

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

ELISA and human tissue
- human sample material and plastics contaminated with material to be treated with strong disinfectant
- human samples processed for RNA will be effectively neutralised in the extraction process
- all disinfected material will then be incinerated
- for spills, solid materials will be collected and put in a container with disinfectant, liquid spills will be treated with disinfectant and then absorbed with paper towels, the area will then be further cleaned with 1% virkon solution. All collected materials will be incinerated.

Adenovirus
- all contaminated materials and plastics to be treated with strong disinfectant
- all disinfected material will then be incinerated
- for spills, solid materials will be collected and put in a container with disinfectant, liquid spills will be treated with disinfectant and then absorbed with paper towels, the area will then be further cleaned with 1% virkon solution. All collected materials will be incinerated.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Paradigm Therapeutics Ltd has been working under license GM 860 with fully verified commercial sources of host strains and vectors at hazard level 1 and containment 1. Due to foreseen expansion of experimentation, the GMSC has identified that Paradigm Therapeutics Ltd applies that the license be modified to include hazard level 2 and containment 1. All ELISA materials will be sourced commercially and have undergone routine screenings for infectious agents. The adenovirus materials will be sourced commercially from a reputable company and human tissue samples if used will be stored in appropriate containers at low temperature prior to extraction in chaotrophic salts and then phenol/chloroform, which will effectively neutralise any biological hazard. The GMSC feels that these measures detailed above reduce the risk significantly.

Give brief details of the genetic modification safety committee

The CEFAS Lowestoft Laboratory Safety Panel functions as the GM Safety Committee for GM operations at the Laboratory.
The panel comprises:
Chairman
Secretary
CEFAS Health Safety and Quality Team Co-ordinator
Managers/representatives of CEFAS Lowestoft Science Areas and Support units
Biological Safety Officer
CEFAS employee representatives
Representative of SMIT, Research Vessel management on behalf of CEFAS
Representatives of Caxton Contractors (CEFAS Facilities managers)
The Panel meets routinely every 6 months to discuss, review and advises on safe conduct of health and safety of operations and procedures including GM activities, undertaken at the laboratory. Special meetings are convened as and when needed. The Panel have access to medical advice and support via CEFAS Occupational Health Provider.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All equipment used in GM procedures including glassware for re-use, and waste materials are autoclaved on site at 121 degrees C for at least 15 minutes, with full steam penetration. The procedure ensures 100% kill and inactivation of the GMO and sterilisation of equipment.

Validation of autoclave conditions is undertaken yearly. Between checks confirmation of correct functioning is carried out with each load using an appropriate indicator autoclaved with the load. In event of unsatisfactory operation the load is retained pending suitable repair of the autoclave.

After autoclaving waste material is disposed to landfill with consignments of general waste arising from the laboratory.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The proposal and risk assessment were discussed at a meeting of the Committee on 10th October 2002 and again on 13th February 2003. The committee were content with the assessment and endorsed Notification of intention to use premises for contained use activities.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The Evotec OAI Genetic Modification Safety Committee (GMSC) exists as a sub-committee of experienced scientists within the Biological Safety Committee (BSC), which reports to the main Safety Committee. The latter has board level representation. The GMSC reviews GMO and Hazard I & II pathogen risk assessments. The GMSC is empowered to categorise containment level I & II activities, to provisionally approve containment level I activities, subject to review by the BSC and to recommend approval for containment level II activities by the BSC. Once approved by the GMSC, level II activities will be notified to the Competent Authority and in parallel will be reviewed by the BSC. The GMSC is chaired by the company Health and Safety Officer (MIOSHG, Dip2.OSH), and also comprises the Biological Safety Office, who has >13 years post-doctoral experience in microbial genetics in Gram-ve and Gram+ve bacteria and molecular biology in yeast and mammalian cells, and experienced scientists representing each laboratory area using GMOs. The BSC comprises these individuals with additional scientists representing each laboratory are using biological materials. The GMSC and BSC invite scientists requesting approval for risk assessments for discussion at meetings and runs with an open structure including all interested parties. Approximately 40% of the Company’s biological scientists are invited to ad hoc BSC meetings.
Contaminated solid waste and glassware is treated by autoclaving at 121 degrees C. The autoclaves are maintained and tested annually. Culture medium and liquid waste is decontaminated by chemical disinfection prior to disposal via the drains. TEGO 2000 is used for the disinfection of E. coli cultures. This is an amphoteric sanitiser recommended for use with these organisms. Waste is treated according to the manufacturer's instructions to give a final concentration of 0.5% (1:200) and left in contact for a minimum of 30 minutes. Under these conditions viability is reduced to below detectable limits.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Over-expression of the gene (def) encoding the various PDFs (Polypeptide Deformylase) is dependent on the addition of IPTG to the culture. def has the function across the range of bacterial species. It should not effect the pathogenicity of the organism, nor should it confer any extra beneficial properties to the E. coli.
Project Additional Information

**Purposes of the contained use**

To establish cell lines expressing human voltage-gated potassium ion channels. The aim is to develop cell-based assays for high-throughput screening of potential inhibitors of the ion channels.

**Recipient or parental organism**

The final recipient organism is a Chinese Hamster cell line; either lung (CHL) or ovarian (CHO) cells. These are well characterised non-human/ primate cells presenting no hazard to laboratory workers or to the environment. The intermediate hosts for production of recombinant viral particles are either BHK-21 cells (a hamster kidney cell line) or HEK293 cells (human embryonal kidney cells). These are both well characterised cell lines with a history of safe use in the laboratory and present no hazard to laboratory workers or to the environment.

**Host/vector system**

The vector systems to be used are both viral-based systems. One expression system to be used is a Moloney Murine Leukaemia Virus (MMLV)-based retroviral expression system. With this system, the production of recombinant viral particles is based on the cotransfection of HEK293 cells with three independent plasmids. The first contains the viral packaging signal and the potassium ion channel under investigation. The other two contains the other elements required for packaging; one contains the gag and pol genes, whilst the third contains the env gene encoding the envelope protein. Replication-deficient virus-containing supernatant from the cells cotransfected with the three plasmids is then used to infect target cells (Chinese Hamster Lung or Ovarian cells (CHL/CHO) for expression of the potassium ion channel. The host range of the recombinant virion is dependent on the specificity of the envelope protein encoded in the particular env-containing plasmid used. The safest vector produces an ecotropic virion capable of infecting only murine or rat cells. Other vectors to be used have a broader host range and will produce replication-deficient virus capable of infecting human cells. Work with these vectors will require handling at containment level II during the viral production stage of the process.
The second system to be used is a Semliki Forest Virus (SFV)-based expression system. Here the production of recombinant viral particles is based on the cotransfection of BHK-21 cells with three independent RNAs. The first contains the replicase gene and the potassium ion channel under investigation. The other two are helper RNAs, containing the genes for the structural capsid and envelope proteins respectively. Only the replicase-containing RNA is packaged, as the packaging signal is absent from the helper plasmids. Again, replication-deficient virus-containing supernatant is used to infect target cells (Chinese Hamster Lung or Ovarian cells (CHL/CHO)) for expression of the potassium ion channel.

Origin & function

The insert DNAs to be expressed are human voltage-gated potassium ion channel genes obtained as cDNAs and cloned into plasmid vectors. The cDNAs are then inserted into the viral expression vectors. The genes, upon expression in a host cell, enable the cells to express the potassium channels within their cell membranes and allow monitoring/screening of drug interactions with the ion channel.

Evaluation of foreseeable effects

With both systems, the production of recombinant viral particles is dependent on the cotransfection of three independent plasmids or RNAs, with the packaging components split between them. The use of these systems is recommended in the AGCM Compendium of Guidance (Part 2B, Annex 111) as it significantly reduces the frequency of recombination between the sequences, eliminating the generation of replication-competent wild-type virus. With the two systems, only the RNA for the potassium ion-channel is packaged and when the recombinant virus particles are used to infect the host cells, only the ion channel gene is expressed. The expression cassette is then unable to proceed through any further rounds of virus production, limiting the expression of the ion channel to within the initial cells infected.

With the two systems, replication-deficient virus is produced that is capable of infecting human cells. Work with these vectors will require handling at containment level II during the viral production stage of the process.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Spent cells/waste media and contaminated plasticware/solid waste will be decontaminated by autoclaving at 121 degrees C for 15 minutes. The autoclave will be maintained and tested annually.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
The vector systems to be used enable production of replication-deficient virions capable of infecting human cells. Handling of cells/viral supernatant at this intermediate stage must be carried out within a Class II MSC. Production of aerosols should be minimised and the use of sharps is prohibited.

The final modified CHL or CHO cell lines are no more hazardous than the parental cells. Incorporation of the potassium ion channel gene in these cells is non-hazardous. It enables the cells to express these potassium channels within their cell membranes and allows monitoring of drug interactions with the ion channel.

All GMMs and material in contact with recombinant DNA will be autoclaved on site under class 2 guidelines (i.e., in excess of required containment). Liquid waste will be disposed of into the waste water system after autoclaving and appropriate treatment. In agreement with the Laboratory of the Government Chemist (LGC) solid waste will be bagged separately in clinical waste disposal bags and included in the LGC clinical waste disposal route (incineration in compliance with clinical waste disposal regulations).

Explanatory note: LGC and NPL are co-located on site.
### Project Additional Information

#### Purposes of the contained use

Production of recombinant proteins using yeast and bacterial expression systems.

#### Recipient or parental organism

Escherichia coli, Pichia pastoris

#### Host/vector system

Escherichia coli (predominantly Novagen and Qiagen T7 expression systems) using K-12 and B strains (BL21), Pichia pastoralis (Invitrogen expression system).

#### Origin & function

The genetic material will be cDNAs originating from human, mouse, yeast and bacterial cDNA collections that are maintained by the academic community (eg the I.M.A.G.E. consortium) and also donations of non-publicly available from cDNAs from academic groups or companies. The cDNAs are anticipated to encode enzymes, soluble proteins and membrane proteins that are considered to be "druggable targets" ie proteins of commercial interest due to their involvement in disease states. The cDNAs will be cloned into non-mobilisable vectors. No clinical material will be used or cDNA for virulence factors or cDNAs derived from pathogens.

#### Evaluation of foreseeable effects

Under class 1 containment, there are no foreseeable adverse effects. The proteins expressed will be used to underpin pure research and to provide "proof-of-concept" data for technology and intellectual property development. E coli BL21 is a laboratory derivative of an E coli B strain; though B strains are category 2 pathogens the strain in question is laboratory attenuated and is effectively category 1.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMMs and material in contact with recombinant DNA will be autoclaved on site under class 2 guidelines (ie in excess of required containment). Liquid waste will be disposed of into the waste water system after autoclaving and appropriate treatment. In agreement with the Laboratory of the Government Chemist (LGC) solid waste will be bagged separately in clinical waste disposal bags and included in the LGC clinical waste disposal route (incineration in compliance with clinical waste disposal regulations).
Explanatory note: LGC and NPL are co-located on iste.

## Project Additional Information

### Purposes of the contained use

Study to evaluate treatment of patients with angina pectoris.

### Recipient or parental organism

Schering AG (subsidiary of Schering Health Care Ltd) hold the IPR rights.

### Host/vector system

Human adenovirus.

### Origin & function

Human gene for the fibroblast growth factor 4 (FGF-4) referred to as Ad5FGF-4. Intended function to stimulate new blood vessel formation.

### Evaluation of foreseeable effects

Improvement in morbidity and mortality in patients with severe coronary artery disease, who are unable to undergo surgery.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GMMs to be used.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Wastes containing this material should be properly contained, labelled, stored and disposed of as biohazardous waste. Local and country regulations for the disposal of biohazardous wastes will be met. All contaminated waste products will be placed in a box and autoclaved before disposal. Labels will be used on the container with the wording "WARNING - HAZARDOUS WASTE-CONTAGIOUS". Inactivation of Ad5FGF-4 is by autoclaving at 121 degrees C for 15 minutes, giving effectively 100% kill. Using a higher temperature, or a longer time, is permissible. To comply with UK and Irish regulations, the autoclave is in the same building. The autoclaves are validated on at least an annual basis (including the placing of independent thermocouples at the centre of the load. For each cycle of Ad5FGF-4 waste, autoclave indicator tape and the integral autoclave printer readout will be used to confirm that the waste has been autoclaved.

Puncturing - cutting waste should be put in a special box marked externally with labels: "WARNING - HAZARDOUS WASTE - PUNCTURING, CUTTING, CONTAGIOUS". Other waste products should be handled as conventional waste.

### Give brief details of the genetic modification safety committee

The Nottingham City Hospital Genetically Modified Organism Safety Committee has met on five occasions to discuss this project. It is proposed that further meetings will take place to review progress, to offer advice and to review accidents/incidents as the need arises.

The majority of committee members have managerial responsibilities within the Trust and are very experienced.

The Committee included the following members:-

- Consultant Microbiologist, Nottingham City Hospital.
- Chief Technician, Cardiology Department, Nottingham City Hospital
- Ward Manager, Nightingale Ward, Nottingham City Hospital.
- Consultant Clinical Scientist, Centre for Medical Genetics, Nottingham City Hospital
- Infection Control Specialist Nurse, Nottingham City Hospital
- Manager CSSD, Nottingham City Hospital
- Manager of Clinical Sciences Building
- Senior Technician, Pharmacy Department, Nottingham City Hospital
- Clinical Nurse Manager, Cardiothoracics, Nottingham City Hospital
- Senior Nurse, Cardiology, Nottingham City Hospital.
- Manager, Health and Safety Department, Nottingham City Hospital
- Senior Pharmacist, Nottingham City Hospital.
- Consultant Microbiologist, Nottingham City Hospital.
- Representative from the Health and Safety Department, University of Nottingham
- Radiographer, Nottingham City Hospital.
- Consultant Physician (with special interest in Virology), Nottingham City Hospital.

**Project Ref** 866/03.1
ANGIOGENIC GENE THERAPY PRODUCTS FOR CORONARY ARTERY DISEASE: A RANDOMISED CLINICAL TRIAL.

In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

Recipient or parental organism
See box below.

Host/vector system
The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map unit 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

Origin & function
The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells.

Evaluation of foreseeable effects
The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to nonexistent.

Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or nonexistent for the following reason: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.
Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (e.g., promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste that may have been directly exposed to the study product will be placed in double autoclave bags and transferred by Cardiac Catheter Laboratory staff to an autoclave in the Clinical Sciences building to be autoclaved. Inactivation of Ad5FGF-4 is by autoclaving at 121 degrees C for 15 minutes, resulting in 100% kill of the vector. The material is then incinerated on site. Service contracts are in place for the autoclave.

Waste from managing the patient on the ward will be sealed in yellow clinical waste bags and then be taken for incineration.

All procedures will be tested in a dry run.

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

The specific aims of this project are to:
1) assess the efficacy of EIAV-based lentiviral vectors expressing the human bcl-2 gene to protect cells in models of apoptotic death;
2) assess the efficacy of HIV-based lentiviral vectors expressing marker genes to transduce rodent organotypic brain slices, rodent primary neurons, neuronal cell lines and other mammalian cell lines in vitro.

**Recipient or parental organism**

Viral production will use immortalised mammalian cell lines, such as HEK293Ts.

**Host/vector system**

All manipulations of plasmid DNA will make use of E. coli K-12 derived strains, such as DH5a, which are non-colonising and disabled. The genome plasmids, into which foreign genes are cloned, of both vector systems are derived from pUC18, and are therefore considered to be non-mobilisable.

Viral vector production will use immortalised mammalian cell lines, such as HEK293Ts.

Vectors will be used to transduce rodent organotypic brain slices, rodent primary neurons, neuronal cell lines and other mammalian cell lines in vitro.

**Origin & function**

All manipulations of plasmid DNA will make use of E. coli K-12 derived strains, such as DH5a, which are non-colonising and disabled. The genome plasmids, into which foreign genes are cloned, of both vector systems are derived from pUC18, and are therefore considered to be non-mobilisable.

Viral production will use immortalised mammalian cell lines, such as HEK293Ts.

Vectors will be used to transduce rodent organotypic brain slices, rodent primary neurons, neuronal cell lines and other mammalian cell lines in vitro.

**Evaluation of foreseeable effects**

The risk to humans is due to the possibility of transduction of cells by minimal EIAV-based or HIV-based lentiviral vectors which will be pseudotyped with either VSV-G.
(vesicular stomatitis virus G) or rabies-G envelopes. These envelopes allow vector particles to enter a wide range of mammalian cells; however they have been shown to have a far more restricted range in vivo than in cultured cell lines. Since the vectors are replication defective, the extent of spread would be limited to the cells initially transduced. Furthermore, the vector systems both have a long (>5 years) history of safe use at Oxford BioMedica plc (EIAV) and Cell Genesys Inc (HIV), from whom Invitrogen have licensed the technology.

Bci-2 has been shown to be anti-apoptotic. Although it is potentially tumourigenic, the formation of a cancer requires the activation of oncogens and the activation of tumour suppressor genes. The introduction of one change into a small number of cells is unlikely to cause cancer.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

This is a notification of premises only as recommended by the paper relating to Newsletter 30, 'Inactivation of Waste Through Off-site Incineration'. The Shanks Risk Assessment attached refers to local arrangements for loss of containment as the only activity with the GMO Class 1 waste will be destruction of customer-packaged material. General procedures exist for handling, storage and processing of hazardous wastes on the Shanks' site. Avecia, Billingham, have previously submitted information to the HSE on their GMS Committee's comments.

Project Ref 868/05.1

Date Ackn'd 23/12/2005

Date Project Ceased

CU2 Project Title

The incineration of waste arising from the Production of Human Influenza Pandemic Vaccines undertaken at Chiron Vaccines, Liverpool (GM 781)

Class

CultureVolClass2

CultureVolumeClass3-4

Class 2 > 500 Litres

Non-GMM Consent Granted Not Applicable
Project Additional Information

Purposes of the contained use
To remove liquid waste from IBC containers and incinerate. All remaining solids and the containers will be shredded immediately prior to incineration.

Recipient or parental organism
A/Puerto Rico/8/1934 (PR8) & A/Vietnam/1203/2004 (H5N1). A/Puerto Rico/8/1934 (PR8) Flu virus strain has been routinely used as a basis of flu vaccines with an extensive history of use. This has been combined with A/Vietnam/1203/2004 (H5N1) to produce the reverse genetics virus: rg A/Vietnam/1203/2004 X A/PR/8/34 6:2 which will be used in the manufacturing activities at Chiron.

The only foreseeable risk arises from dual "infection" of humans or animals with the reverse genetics virus and a normal circulating influenza virus. In order to minimise the risk several containment measures have been implemented. All waste will arrive in sealed IBCs (Intermediate Bulk Containers) which will be incinerated during this process (not re-used).

Host/vector system
See above - generated by reverse genetics.

Origin & function
A/Puerto Rico/8/1934 (PR8) & A/Vietnam/1203/2004 (H5N1).

Evaluation of foreseeable effects
Extremely remote possibility of reassortment during simultaneous "infection" with rg A/Vietnam/1203/2004 X A/PR/8/34 6:2 and a circulating human flu virus generating a new pathogenic strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Derogation from the following measures specified in Table 2, Schedule 8 is applied for:
* Items 1, 2, 3, 4, 5 & 7 relate to closed systems, such as fermenters. This process involves extraction from a closed system (ie an IBC) to achieve optimal incineration capacity by injecting liquids into the Incinerator.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
See Operating Procedure and Risk Assessment

Onyx at Fawley does not have its own GMSC, but the site safety representatives, the local unions and H&S management have all been involved and made aware of this waste. This process will be overseen by the Chiron Vaccines GMSC and, discussed at Chiron Vaccines GMSC on 12 December 2005, and with Onyx on 13th December 2005. Planning has been conducted in consultation with Chiron and HSE. Work has been classified as Class 2 on the basis that no measures for Containment Level 3 are required. This is in line with WHO classification, and under advice from the HSE.

Give brief details of the genetic modification safety committee

The genetic modification safety committee consists of members of staff taken from Safepharm Laboratories Limited, Departments of Ecotoxicology and Genetic Toxicology, and Shardlow Business Parks Health and Safety Officer. The members of staff from Safepharm Laboratories Ecotoxicology and Genetic Toxicology Departments consist of the Head of each Department and Study Directors responsible for the conduct of studies using genetically modified organisms.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste produced from studies conducted using GMMs will be stored separately from non-GMM contaminated waste in clearly labelled waste containers prior to disposal by a licensed waste disposal company as clinical waste. All clinical waste generated will be incinerated and as such will result in greater than 99.999% kill.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The genetic modifications safety committee has reviewed the risk assessments conducted for the following study types.

i) Assessment of Estrogenic Activity using Saccharomyces cerevisiae expressing the human hER gene.
ii) Assessment of Androgenic Activity using Saccharomyces cerevisiae expressing the human hAR gene.
iii) Assessment of Mutagenic Activity Studies using Salmonella typhimurium strain TA1535 expressing a defective histidine biosynthesis gene and antibiotic resistance genes.
iv) Assessment of Mutagenic Activity Studies using Salmonella typhimurium strain TA102 and TA97 expressing defective histidine biosynthesis genes and antibiotic resistance genes.

The genetic modification safety committee agrees with the activity class assigned to each of the above study types.

Give brief details of the genetic modification safety committee

* The GMSC at Procognia comprises four members, one representing operations and three representing R&D.
* Areas of expertise held by the committee include post doctoral level biology with experience of prokaryotic and eukaryotic gene cloning and expression.
* The committee receive pre-circulated assessments of proposed GM work for comment.
* All comments are collated by the secretary for discussion and approval at the committee meetings.
* The newly formed committee is set to meet every 8 weeks to consider the approval of new assessments for GM work.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

- Biological waste will include, disposable plastic ware eg inoculating loops, Petri dishes and tubes), tissues, gloves, liquids and glassware.
- Disposable materials will be collected in plastic bags marked with the biohazard symbol and held in plastic waste bins. The waste will be double bagged prior to placing in a Morrison container for autoclaving.
- All liquid cultures will be sterilised with 1% ethanol.
- Biological waste awaiting sterilisation in the autoclave will be stored in closed plastic bins in the autoclave room.
- All biological waste will be sterilised by autoclaving (132 degrees C for 45 minutes). Waste is only considered to be sterile and ready for disposal if the printed record indicates that the machine was held 132 degrees for 45 minutes.
- Sterilised waste will be removed from the autoclave and stored in sealed plastic drums prior to incineration.
- All biological waste will only be handled by trained scientists up until the time it is in drums awaiting collection for off site incineration.
- Drums of sterilised biological waste will be collected by a waste management company fortnightly for incineration.

Bacteriology - All solid waste will be autoclaved prior to disposal. Chemical indicator strips (eg 3M Comply Thermalog Steam Chemical Integrator) will be used in with the load to ensure that the correct time and temperature conditions have been achieved. Records of the date and volume of waste autoclaved will be maintained. All liquid waste will be treated with 1.5% Virkon solution for at least 10 minutes prior to disposal into the foul sewer. The level of treatment has been proven to be 100% effective in killing bacteria: http://www.biosafetyusa.com/virkon/virkonifu.pdf; http://www.antecint.co.uk.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee (GMSC) is a sub-committee of the Infection Control Team (ICT). The ICT has been established at Simbec to ensure that all aspects of surveillance, prevention and control of infection are performed in accordance with recommendations made by the Infection Control Consultant and Biological Safety Officer (Consultant Microbiologist).

The ICT/GMSC collaborates with Simbec line management for approval, authorisation and implementation of necessary procedures. The ICT/GMSC is composed of the following personnel: Infection Control Consultant/Biological Safety Officer, Simbec Medical Director, Simbec Infection Control Officer (Senior Research Nurse), Health and Safety Committee Chairman, Quality Management Group Representative. Any appointed safety representatives may sit on the GMSC if they wish.

The following routine procedures will be followed at all times.
Simbec Standard Operating Procedure BD/324/1/03 - Hazardous Waste Management
Simbec Standard Operating Procedure BD/324/13/17 - Cleaning the Aseptic Unit

All materials that have been in contact with the vaccine or vaccination site will be disposed of into bins for autoclaving. The autoclave will be situated within a restricted laboratory. Autoclaved waste will be disposed of in yellow incineration bins provided in each laboratory/ward area as per routine hazardous waste management procedures. Syringes and needles will be disposed of into sharps bins for autoclaving before disposal by incineration. The remainder of the vaccine and vial will also be disposed of into bins for autoclaving before incineration.

On completion of immunisation and dressing procedures surfaces on which the vaccine vials have been placed will be cleaned with disinfectant.

Copies of SOPs attached.

Please enter comments of the GM safety committee on the risk assessment
The Biological Safety Officer, was absent due to annual leave. It was agreed that the minutes and all documentation relating to the HSE notification should be sent to him as soon as possible. Any feedback from him will then be forwarded to the HSE where necessary.

The committee reviewed the correspondence between MRC Human Immunology Clinic, and HSE. As the HSE has already agreed that the modified vaccine is Class 1 the risk assessment classification was approved.

Following review of the study protocol the following points were added to the risk management section of the risk assessment. Volunteers will be advised not to interfere with any dressings or scab formation on the site of inoculation. Concerns were raised regarding the volunteers leaving site without any dressing on the site of inoculation. It was suggested that volunteers be given a plaster to cover the site however it was decided that this would prevent the formation of a scab. Therefore it was agreed that as the risk to the environment is extremely low the site of inoculation should remain uncovered.

The choice of disinfectant to be used in each work area will be discussed further. The chosen disinfectant will be in accordance with routine Simbec Procedures. All staff, including ward orderlies, will undergo a training day to discuss procedures and protocols. This will also be an opportunity for staff to ask questions and raise any concerns they may have. This training session must be recorded in staff training records. All work performed within the Clinical Unit will be performed in a separate area from other studies to remain clear of other volunteers. Minutes of the first meeting of the GMSC enclosed.

The construction of class 1 GMMs will take place in the CEH laboratories in accordance with all CEH Oxford safety procedures. All waste will be autoclaved in central CEH Oxford facility prior to disposal - 100% kill. The autoclave is thermocouple-tested twice a year. Records are taken of each run to ensure sterilisation. All waste from the mobile unit will be disposed of in this facility. Derogation from containment level 1 requirement for autoclave required on site, when GM activities are undertaken off-site.

The GMM assay protocol, containment, waste management, and accidental spillage procedures are described in the supplemental notes attached.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

For activities involving GMMs, describe the waste management measures which will apply to the activity

Micro organism (cell kill by soaking overnight in Virkon 2% v/v of waste cell culture media) cell suspensions, for not less than 18 hours prior to disposal via drainage.

Disposal of all waste plastic cultureware, pipettes, eppendorf tips etc to double lined autoclave bags and sterilisation by autoclaving to 121 degrees C x 15 minutes.

Virkon 2% v/v has been experimentally determined to result in 100% kill of mammalian cell lines after overnight incubation, in the presence of 10% serum used for standard cell culture conditions. This will be confirmed by microscopy using trypan blue exclusion/haemocytometer count to look for viable cells post treatment and reinoculation of treated waste material into cell growth medium, with examination for viable cells after a suitable growth period.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Good microbiological practice.
Waste bacterial cultures are treated with disinfectant and then autoclaved at 121 degrees C for 20 mins before disposal down the drain. All biological solid waste such as agar plates and plastics are autoclaved at 121 degrees C for 20 mins and then incinerated off site. Contaminated glassware is autoclaved at 121 degrees C for 20 mins and then washed in accordance with normal laboratory practice (industrial dishwasher)

All lab work surfaces are regularly wiped with a disinfectant.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

---

Please enter comments of the GM safety committee on the risk assessment

The risk assessment has been approved by all members of the GMO safety committee and signed.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The modification committee comprises of a minimum of five members consisting of programme managers, project managers, scientists and a representative from the company health and safety organisation. The programme managers, project managers and scientists all possess expertise in the areas of microbiology, molecular biology, genetics, immunology and chemistry. They have combined at least 60 years of experience in these areas. The procedure for operating is as follows: A request for approval of a proposed GMM experiment is made by a proposer. He/She will be expected to complete a risk assessment using a defined template. The assessment will then be circulated to the members of the committee at least 3 days prior to a meeting. During the meeting a rigorous review of the risk assessment, a decision made on the containment category, whether HSE notification is required and if the experiment can go ahead. Comments are added to the risk assessment and the assessment is stored securely.

02/03/2022

Page 11787 of 15326
A GMM waste standard operating procedure (SOP) for treatment of waste has been written. Staff trained and are expected to adhere to it rigorously.

Liquid waste will be decontaminated by autoclaving at 121 degrees for 15 minutes. No more than 1 litre will be autoclaved in one vessel. Browning tubes will be used every 3 months to ensure sterilisation conditions are reached. The autoclave is serviced annually and a record of each autoclave run made. The decontaminated waste will then be disposed of down the drain.

Solid waste will be autoclaved at 121 degrees for 15 minutes. The autoclave is serviced annually and a record of each autoclave run made. The waste is then sealed within plastic bags and removed for incineration. All sharps waste will be placed in an autoclavable sharps bin. The sharps waste will be autoclaved at 121 degrees for 15 minutes and removed for incineration.

The small quantity of waste that does not withstand autoclaving will be decontaminated by placing in a 1% Virkon S solution with no air bubbles. This will be left overnight before disposal of liquids down the drain and the solids by incineration. Extensive validation of killing of microbes with Virkon S is provided on the Virkon manufacturer’s web site (http://www.atecint.co.uk/main/virkons.htm). 1% Virkon S overnight provides excellent disinfectant capacity.

Other(s) Molecular Biology techniques such as PCR

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment
The host strain E.coli JM109 is an E.coli K12 strain and is considered non-pathogenic. The JM109 strain was determined as disabled because it is RecA-and thi-. It was agreed that the pGEM vector should be classified as non-mobilisable, because it is Bom-, Tra-, Mob- and Nic-. It was noted that there were no pathogenic, toxic, oncogenic or cytokine sequences present within the vector. An overall access figure for the host/vector combination was 10e-9 under the Brenner scheme. The insert from Baccilus globigii is only 92 basepairs and is from the ribosomal DNA and is highly unlikely to be toxic. The sequence is short and there are no pathogenic, toxic, oncogenic or cytokine sequences present. Bacillus globigii is a class 1 organism. The expression level of the insert was discussed. There are T7 and SP6 promoters flanking the insert. It was noted that T7 and SP6 polymerases are not normally present in E.coli JM because they are from bacteriophages. Furthermore, there is no deliberately designed start codon, although potentially there could be one there fortuitously. A classification for expression of 10e-6 was considered appropriate. The damage factor for this GMM at 10e was agreed because the insert is derived from a gene sequence, but there is only a very short sequence of this gene present and any expressed protein is unlikely to be biologically active. An overall assignment of containment level 1 was agreed (overall value under the Brenner scheme was 10e-24). The risk to the environment was also determined as very low because 1 litre or less is to be cultured at one time, the disabled nature of the organism, the organism will be treated under good microbial practice and the waste treatment procedures instigated. The work with this GMM was approved at containment level 1. It was noted that GMM risk assessments should be stored as controlled documents, in both paper and electronic format.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Yes

Give brief details of the genetic modification safety committee:

- NBS Manchester Management Representative (Chair)
- Health & Safety Advisor NBS Manchester
- Senior Scientist Paterson Institute Union
- External Independent GM Advisor
- Senior Scientist/Biological Safety Officer NBS Manchester
- Safety Officer Paterson Institute
- Safety Representative NBS Manchester

The committee meets on a 6 monthly basis. New submissions or accepted submissions that require a new amendment for consideration are made electronically to the Biological Safety Officer who distributes the submission to the committee for review. Committee members are required to reply within 2 weeks. Any further amendments must be made and returned to the committee within 2 weeks for further review. After acceptance the risk assessment and approval is signed off by the Biological Safety Officer or the GM safety Committee Chair.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid and dry waste will be sent for incineration by White Rose Environmental Ltd. All material for disposal will be placed into 30 litre yellow containers which will be sealed prior to removal from the room where the class one material is being used. These will then be placed into wheelie bins for collection. The wheelie bin used to transport the GM waste will be clearly marked and contain only yellow containers with GM waste. Any minor liquid spillages (≤20ml) will be removed by soaking up with an absorbent wipe or for larger liquid spillages by the addition of absorbent granules and transfer into a yellow container. The area will then be sprayed with either Klericide A or B (a rotational disinfectant with demonstrated virucidal activity. Shield Medicare Ltd) for a minimum of five minutes as per the manufacturer’s instructions. After inactivation, the area will be wiped and the wipe placed into a yellow container. The area will then be sprayed and wiped with 70% isopropyl alcohol and the wipe placed into the yellow container. The container will then be sealed and sent for incineration as above.

There is an on site autoclave that can be used as a back up inactivation system in the event of a problem arising with the incineration procedure.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

A number of issues were raised by the GMSC and the risk assessment was modified to take account of the issues raise.

Give brief details of the genetic modification safety committee

The Safety committee is a sub group of the normal company safety committee, and consist of a range of staff considered experienced in biological work, and quality/regulatory issues.

The committee has been set-up specifically to ensure that the GMO work about to be started is carried out in a safe manner. The company previously operated a biologicals safety committee for the cell lines that we routinely cultivate, which are all Hybridoma cells (now removed from the level 1 classification, but controlled as such within the company).

All waste from this project is to be contained within plastic waste bags, and then held within a waste container. This is then removed from site by a contracted waste management company (Biffa). The waste is categorised for Biffa as Type A and B clinical waste. This is then transported to a site for incineration.

The route for waste management described above is to be used for all cell material and in-process solutions and containers.

Reuseable culture vessels will be disinfected and cleaned by the companies routine cleaning procedure, once any cell debris is removed for treatment by Biffa.

The fermenters used for large scale cultivation are 200l final volume. During final processing the cell material is removed and then sent for off-site incineration. All cell free supernatants are either chemically disinfected prior to disposal, or are used to manufacture the final finished product.

All surfaces that may contact the GMO are chemically disinfected with proprietary disinfectants, either chlorine, Hydroxide or Propanol based, dependant on the application.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The company has been operating with Hybridoma cells, both murine and human heterohybridomas, since 1985. During this period these cell lines were classified as requiring level 1 containment and control measures. The company's procedures and training have been designed around this classification, and the current Good Manufacturing Practice guidelines.

The GMO being considered as part of this new project is a class switched hybridoma, prepared for Serologicals by Bristol Institute for Transfusion. All genetic manipulation has been completed at Bristol, and Serologicals will then take this modified cell line for evaluation and large scale manufacture through the existing production facility. No genetic manipulation will be carried out at the serologicals facility.

The committee reviewed an assessment provided for the cell line by Bristol which indicated a Level 1 classification, and agreed that this was the correct classification for the material. The level of risk assigned to the GMO was then agreed to be similar to existing products.

The risk assessment was carried out and reviewed against the Guide to Genetically Modified Organisms (contained Use) Regulations 2000. The Committee agreed that the control measures in place meet the requirements of Table 1c and Table 2 for large scale manufacture.

Give brief details of the genetic modification safety committee

The Automation Partnership (TAP) GMSC includes:
- **TAP Biological Safety Officer.** The BSO has over 15 years experience of working with GMMs.
- **TAP Research and Development Manager,** whose team will be carrying out the processes involving GMMs.
- A representative from the TAP Project Management Group with responsibility for the project using GMMs.
- **TAPs H&S Consultant,** providing an overall H&S opinion and link with the TAP H&S Committee
- **TAP Operations Director,** representing Senior Management
- **TAP contracted Medical Officer.**

The Committee will meet as required by the nature of the work undertaken with GMOs in the company. Following the initial review meeting held 5 November 2003, there will be a 6 month formal review of practices at which further time-tableing of such meetings will occur. The BSO will maintain continuous review of practices at TAP using GMMs and will convene the GMSC for additional meetings as required for review of task assessments.

Liquid culture media:
Liquid media will be collected in a vessel and disinfectant powder eg Virkon added and dissolved in appropriate amount to the volume to provide a disinfecting solution. Other disinfectants may be used that have similar function. Disinfectant culture media will be disposed of through the general waste water system.

Disposable culture vessels/equipment:
Disposable equipment and labware used for culture of micro-organisms will be soaked in a solution of disinfectant for the period specified by the manufacturers. Followed the disinfectant soak, equipment will be rinsed with water, the rinse going to general waste, and the disinfected, rinsed equipment disposed of in the general waste system.

Non-disposable culture equipment:
Non-disposable equipment and labware used for culture of micro-organisms will be soaked in a solution of disinfectant for the period specified by the manufacturers, soaked in 70% ethanol or autoclaved. Following disinfectant/ethanol soak, equipment will be rinsed with water, the rinse going to general waste.

Solid culture media:
Solid culture media (of no more than 1cm thickness) will be either autoclaved or soaked in disinfectant fluid, followed by disposal in the general waste. Any disinfectant fluid will be disposed of in the general waste water system.

Additional items:
Other solid items, for example accidentally contaminated lab coats will be autoclaved or soaked in disinfectant liquid followed by disposal in the general waste. Any disinfectant fluid will be disposed of in the general waste water system. Solid material once disinfected will be disposed of in the general waste.

Monitoring:
Waste disposal processes will be based around standard disinfection processes using commercially available reagents and apparatus. The robustness of these process in relation to the GMO used in combination with the risk associated with the escape of this GMO lead us to consider continued biological monitoring unnecessary. The major risk revolves around the misuse of the reagents and equipment, as such efforts will be focused on training and assessing the execution of these procedures by staff, and review of the execution of these processes.

Tick to confirm that you are attaching a summary of the risk assessment

Purposes of the contained use

The goals of the project are to use bacterial reporter assays to compare concentrations of signalling molecules in samples treated with various signal-molecule inhibiting compounds. These results will help us to evaluate our compounds as novel treatments for bacterial diseases.

Recipient or parental organism

Chromobacterium violaceum and staphylococcus aureus

Host/vector system

Chromobacterium violaceum strain CV026 contains a double mini-Tn5 transposon insertion. Staphylococcus aureus strains RN6390B, and RN8463 all contain a reporter plasmid, pRN6683

Origin & function

Chromobacterium violaceum strain CV026 contains a double mini-Tn5 transposon insertion which renders it incapable of producing homoserine lactone signalling molecules. As a result, this strain does not produce the purple dye violacein, unless supplied with exogenous homoserine lactone. Therefore it can be used as a reporter strain for samples containing homoserine lactones. The mini-Tn5 transposon confers resistance to kanamycin as a selectable marker.

The pRN6683 reporter plasmid contains the E. coli blaZ (beta-lactamase) gene fused to the S.aureus agrP3 promoter, to allow determination of levels of S. aureus signalling molecules that activate the reporter construct. The plasmid also contains a gene for chloramphenicol resistance as a selectable marker, plus origins of replication for S. aureus and E.coli.

Evaluation of foreseeable effects

Expression of the mini-Tn5 transposon in Chromobacterium violaceum is unlikely to pose any serious hazard to human health; the strain CV026 has been widely used in these assays in other laboratories since 1997 with no reports of any adverse effects. The sites of the insertion have been mapped to a LuxI homologue (preventing synthesis of homoserine lactone) and a putative repressor locus. The transposon itself lacks the gene required for transposition, so it is unable to transpose to other loci in the genome. The likelihood of transfer to other organisms is virtually nil.

Expression of the pRN6683 plasmid in S. aureus is very unlikely to alter the pathogenicity of the organisms, and no change in the pathogenicity of these strains has been reported in the literature despite their widespread use in these assays since 1995. The pRN6683 plasmid is considered to be non-mobilisable. Again, the likelihood of transfer to other organisms is virtually nil.

Chromobacterium violaceum is not listed as Hazard Group II by the ACGM, but it is considered by most scientists as Group II and we intend to treat it as such. S. aureus is listed as Hazard Group II. The modifications contained by the strains we intend to use are not thought to alter the pathogenicity or Hazard Group classification of either organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid wastes: treated with 1% Virkon according to manufacturers instructions. Treated liquid waste will be disposed of down the main laboratory sink. We expect that Virkon treatment will be 100% effective, but this will be verified by plating out some of the treated waste to check for any viable bacteria.

Plasticware: will be autoclaved (121 degrees celsius, 15 minutes). Plastics are double-bagged before being taken in a robust plastic box with lids to autoclaves. We expect the autoclaving to be 100% effective in killing all viable bacteria.

After autoclaving, waste goes for Continuous Feed Auger processing.
Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Yes

Give brief details of the genetic modification safety committee

A genetic modification safety committee has been established composed of the laboratory Senior Scientist, (Biological Safety Officer), the Head of Proteinomics (Health & Safety Officer) and the Chief Operating Officer. The committee will meet not less than four times per year to review the use of GMOs and to advise on risk assessments and contained use activities. Minutes of the meeting will be recorded and circulated to all staff and the Board of Directors for approval; however, it is not anticipated that their will be any major changes in the types and varieties of GMOs in use.

02/03/2022
The GMMs that are currently made by Purely Proteins Ltd are completely destroyed by standard autoclaving. All laboratory waste (e.g. gloves, plasticware, pipette tips) and anything else contaminated will be subject to autoclaving before being discarded in the general refuse. In the case of liquids, a strong disinfectant (e.g. chlorox) will be used to disinfect samples prior to disposal down the drain. Regular testing will be carried out to gauge the level of killing. Work surfaces, such as bench tops, and equipment will be decontaminated with disinfectant or 70% ethanol - any solid waste from the decontamination process will be autoclaved as above.

The laboratory is designed so that it can be easily cleaned. Carpets and rugs are deemed inappropriate and laboratory furniture is capable of being easily cleaned by wiping. Spaces between cabinets and equipment are easily accessible for cleaning.

In accordance with Good Laboratory Practice, protective lab coats designed for lab use are worn while in the laboratory. This protective clothing is removed and left in the laboratory before leaving and entering other non-laboratory areas (e.g. administrative offices, kitchen). All protective clothing is either disposed of in the laboratory or laundered by the institution or appropriate laundry service; and is never taken home by any personnel. Gloves are worn when hands may contact any potentially infectious materials, contaminated surfaces or equipment. Gloves are disposed of when overtly contaminated, and removed when work with infectious material is complete. Disposable gloves are not washed, reused or used for touching "clean" surfaces (e.g. keyboards, telephones etc) and they are not worn outside the lab. Hands are washed following removal of gloves.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMSC has recommended that Purely Proteins work only with fully verified commercial sources of host strains and vectors to maintain all work at Hazard Level 1 and Containment Level 1.

Please enter comments of the GM safety committee on the risk assessment

Give brief details of the genetic modification safety committee

A genetic modification safety committee has been established by Crusade Labs comprising 6 representatives covering management, research and development, technical and administration. The committee includes a University of Glasgow representative. GM safety at Crusade was originally under the auspices of the local University of Glasgow GMSC at the Southern General Hospital and the Crusade committee will continue close contact with this committee.

The Crusade GMSC meets at least twice per year to review GM safety and on an ad hoc basis as the need arises.

All work involving genetic manipulations of bacteria, yeasts or mammalian cells will be performed aseptically either on the lab bench or in a microbiological safety cabinet. All solid waste including plastics will be autoclaved. Liquid waste will be either autoclaved or immersed in 5% Virkon or Chloros overnight. Non-disposable items will be either immersed in Virkon/Chloros overnight or autoclaved prior to normal cleaning. These methods are commonly used in microbiology and are known to result in complete deactivation. All work involves standard laboratory protocols with no unusual procedures that require additional containment measures.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All work to date at Crusade had been approved by the local University of Glasgow GMSC. A complete list of current bacterial and yeast strains, mammalian cell lines and plasmids with inserted genes of interest was prepared and approved by the GMSC. The risk assessment for Class 1 work was approved by the GMSC.

Project Ref 885/04.1

Date Ackn'd 04/02/2004
CU2 Project Title THE USE OF THE HSV-1 ICP34.5 DELETION MUTANT 1716 AND ITS
Class 2
CultureVol/Class 2 < 1 litre
CultureVolumeClass 3-4

02/03/2022
All Crusade’s activities are based on HSV-1 strains 17+ and 1716 with the emphasis on HSV 1716 as a tumour killing virus or gene therapy vector. Our research is based on an evolution of HSV 1716 from the basic first generation oncolytic virus with deletion of RL1 through second generation viruses either with enhanced tumour killing potential or as gene therapy agents for the expression of therapeutic proteins to a third generation of viruses with restricted tropism mediated by surface expression of targeting proteins.

Recipient or parental organism

Permissive tissue culture cell lines including BHK, 3T6, Vero, SK-N-SH and a range of tumour cell types, both primary and cell lines.

Host/vector system

The vector HSV 1716 and a varient of HSV-1 strain 17+ which has a deletion of the RL1 gene ablating the neurovirulence factor ICP 34.5. The RL1 locus is also the site of the transgene insertion.

Origin & function

The genes of interest include cell cycle proteins, hormones, growth factors, enzymes, transporters, anti-sense RNA and tumour targeting ligands/antibodies. They function either to improve the ability of HSV1716 to kill cells, to overcome genetic defects in cells infected with HSV1716 or to alter/restrict HSV1716 tropism.

Evaluation of foreseeable effects

When using human herpes viruses as vectors, consideration should be given to the nature and expression level of the novel gene insert. The HSV virus is an attenuated form and is selectively replication competent, only replicating in dividing cells, therefore the virus will be unable to replicate in the adult CNS. We do not expect that insertion of the genes of interest will affect the growth properties or pathogenicity of HSV 1716.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Lab coat, gloves and glasses will be worn when handling viral vectors. All work involving manipulation of the virus will be performed in a microbiological safety cabinet. All solid waste includinVirkon or Chloros overnight or autoclaved prior to normal cleaning. The work involves standard laboratory protocols with no unusual procedures that require additional containment measures. plastics will be autoclaved.
Liquid waste will either be autoclaved or inactivated by incubation in 5% Virkon or Chloros overnight. Non-disposable items will either be incubated in Virkon or autoclaved. 

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification) 

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated or equipment used will be either sterilised in Virkon or autoclaved. This will completely deactivate any virus and is a method which is commonly practised in virology. Solid waste is disposed of by incineration after autoclaving. All deactivated liquid waste can be disposed of down the sink with copious amounts of water. Sharps will be incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

All class 2 work currently undertaken by Crusade Labs has been approved by the local University of Glasgow GMSC. Following the establishment of its own GMSC, Crusade Labs extensively reviewed all its current risk assessments at a meeting attended by all Crusade personnel. Detailed consideration was given to all aspects of Crusade's research and development including vectors with improved cell killing, gene therapy vectors, variants with altered tropism and the genes of interest used in the production of all HSV1716 variants. The meeting concluded that none of Crusade's work used toxic genes/oncogenes or generated viruses with a greater risk than wild-type HSV-1 and all risk assessments were approved.

Project Ref 885/06.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Clinical trials using oncolytic herpes simplex virus HSV1716

Clinical testing of gene therapy agents based on herpes simplex virus, with the aim to develop and validate improved treatments for cancer.

The gene therapy agent, HSV1716, is a modified version of herpes simplex virus type 1 (Glasgow strain 17), that has been modified to be non-pathogenic in normal tissues. However, it retains the ability to undergo lytic replication in cancer cells. This virus has already been tested in Phase 1 human clinical trials and found to be safe when administered intracranially.

 HSV1716 is intended to replicate in cancer tissue, spreading through the cancer and killing the cancer cells. Because it is unable to replicate in normal tissues, it is deemed non-pathogenic. Therefore, it should not harm normal tissues, and would be unable to spread in the population.

 HSV1716 is expected to replicate in cancer cells, killing them by lysis, releasing identical progeny virus that can then infect surrounding cells. Therefore, the vector should spread progressively through a tumour, killing the cancer cells. Although some normal cells, eg at the tumour margins, may become infected, HSV1716 should be unable to replicate in these, and spread of the virus should cease. For example, in previous clinical trial work, no infection of ependymal tissue was detected and no infectious virus could be recovered. It is also thought unlikely that HSV1716 could reactivate from a latent state.

Transmission from the cancer patient to other humans will be prevented, by covering the injection site with occlusive dressings and the risk of infection is negligible in comparison to that of wild type HSV. HSV1716 does not shed, so no special post operative containment measures are required.
In the unlikely event that persons other than the cancer patient become contaminated with HSV1716, it will be unable to replicate and so it is most likely that no significant effects would be observed. HSV1716 will be unable to generate the "cold sore" lesions associated with the natural herpes simplex virus, because these result from virus replication in the normal skin, whereas HSV1716 is unable to replicate in normal tissue. A high proportion of the population has been naturally exposed to herpes simplex virus type 1, and has pre-existing immunity to the virus (up to 90% of the population). If seronegative individuals are infected with HSV1716, either deliberately (patient in trial) or through inadvertent self-inoculation at the time of administration, then seroconversion may occur.

Thus the effects of the HSV1716 infection in normal individuals are expected to be minimal. As an additional safety feature, HSV1716 retains the viral thymidine kinase gene, and thus infection can be controlled with the drug acyclovir and gancyclovir.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste materials contaminated with the GMM will include the vials in which it is supplied. Any vials that are dispensed will be held in a sharps bin for 8 hours at room temperature, conditions known to deactivate the virus, before following standard hospital disposal policy for such material (incineration). The disposable aspirate needle systems, contaminated dressings, latex/vinyl gloves, disposable aprons and eye protection with a risk of contamination will be placed into a sharps bin at the point of use, prior to disposal following standard hospital policy. The reusable needle systems will be placed in a standard Savlon solution (Clorhexidine 2-4%) for 5 minutes to deactivate the GMM, rinsed and then sterilised by autoclaving on-site, using fully validated and documented procedures, providing 100% kill.

We have also validated disinfection using 1-2% Virkon (a commercial disinfectant), to provide complete inactivation of HSV1716 as an alternative.

Decontaminated waste is disposed of as clinical waste, being removed by contractors for high temperature incineration off-site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agreed that HSV1716 is appropriately classified as a Class 2 organism and agreed that the containment facilities and procedures proposed here and in the risk assessment are suitable and fit for purpose. The GMSC recommended, as a precaution, that healthcare workers that are immunosuppressed, pregnant, or have active eczema, should take extra care not to come into contact with HSV1716, particularly in areas where the virus is administered.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMSC has reviewed the company’s GM procedures and the risk assessments performed. The GMSC confirmed the work to be carried out is Class 1 and were satisfied with the assessment of risks to both human health and the environment. The control and containment measures in place are appropriate for class 1 activities.

Give brief details of the genetic modification safety committee

The committee consists of two senior PhD qualified scientists who meet once every quarter. Both scientists have >10 years experience working within bacteriological, virological and cell maintenance environments. They also have experience in authoring risk assessments. Their role is to:

1. Oversee the design and implementation of all scientific research with NextGen Sciences Ltd with a view on biological safety.
2. Risk assess each specific project to ensure fit between facilities and required containment.
3. Ensure that the Management Committee at NextGen Sciences is fully aware of HSE notification and company infrastructure requirements.
4. Ensure the laboratory applies required biological safety standards.
5. Provide a reference point for all company employees who have concerns or issues regarding biological safety and manipulation.
6. Ensure completion and submission of the relevant Risk Assessments to HSE including any notification of premises required.

### Project Additional Information

#### Purposes of the contained use

To protect the user from exposure to bacterial strains carrying plasmid DNA sequences which encode potentially carcinogenic sequences under transcriptional control of a strong bacterial promoter. To protect the user from exposure to recombinant virus possessing DNA sequences which encode potentially carcinogenic sequences.

#### Recipient or parental organism

Bacterial strain BL21 (DE3) and derivatives of, which will harbour plasmid DNA containing potentially carcinogenic sequences under transcriptional control of a strong inducible promoter. Expression of protein requires the presence of the DE3 lysogen present in the above strain.

Recombinant baculovirus particles containing potentially carcinogenic gene sequences.

Further characteristics of the GMOs have been provided in the attached risk assessment.

#### Host/vector system

The above strain BL21 (DE3) and its derivatives are currently classified as CAT 1 but in conjunction with the plasmid backbone being used for expression (pET derivative) represents a plasmid mobilisation defective environment. Thus an element of risk exists in the potential for gene transfer between bacterial strains.

An element of risk in handling potentially carcinogenic sequences may exist with regards to tumor development, hence CAT II containment is envisaged to negate this risk.

Assessment of the danger involved with this host/vector relationship have been detailed within the attached risk assessment.

#### Origin & function

The genes identified as potential Breast Cancer targets have been listed with Appendix 2 of the attached risk assessment. It is possible that this list will be extended at which point a further risk assessment will be provided to cover these genes.

The genes have been isolated by a partner (Cytomyx Ltd, Cambridge UK) from human tissue using PCR based cloning methodologies. The ORF for each gene is then supplied to NextGen Sciences in a general cloning vector ie not suitable for protein expression purposes.
Expressed proteins will be purified in microgram quantities and used to attach to solid surfaces for testing of commercial antibodies to Breast cancer target proteins.

**Evaluation of foreseeable effects**

Once produced and purified as protein no foreseeable effects are likely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

1. All biological materials and disposable labware (except pipettes, see 2) associated with handling/manipulating the biological material will be disposed into autoclavable bags, then double bagged, sprayed with 70% alcohol and inactivated by autoclaving for 15 minutes at > 121 degrees C.
2. Within the CAT II laboratory environment, all disposable pipettes eg 5ml, 10ml and 50ml will be held within a plastic pipette container one quarter filled with appropriately diluted Virkon (1%). Attached micro-organisms will be inactivated in this environment for > 12hrs then disposed of as in 1.
3. All sharp material will be sprayed with 70% alcohol before being held within a standard yellow sharps disposal container. Once filled this container will be double bagged, sprayed with 70% alcohol and disposed into a large metal drum prior to collection for incineration.
4. All glassware used in culturing will be immersed in a large vat of fresh appropriately diluted Virkon (1%) and the microbiological material inactivated for > 12 hrs. The vat will then be sprayed with 70% alcohol and removed to wash-up facilities where the glassware will be washed, sterilised and prepared for reuse.
5. Liquid cultures will be inactivated by direct application onto solid Virkon such that within a 12hr period the concentration to Virkon solution will be greater than or equal to 1%.
6. All bagged autoclaved waste will be disposed into large metal drums and removed by an external vendor for incineration.

NB See Appendix 3 to Risk assessment which details operational procedures within the CAT II environment including waste management.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

- **Y**

Give brief details of the genetic modification safety committee

Committee Members:
- From Novacta: Research Director (Company Safety Officer)
- Fermentation Group Leader (Biological Safety Officer)
- Molecular Biology 1 Group Leader, Molecular Biology 2 Group Leader and Molecular Biologist.

The committee will meet annually to review all risk assessments and HSE notifications. Additional meetings will be held to consider new risk assessments and notification requirements as required. All assessments and notifications will be circulated by email and comments from the committee taken into account prior to any new procedures being adopted. Any assessments will fall outside the expertise of more than three of the committee will be sent to external advisors.

</tbody>
</table>
Solid biological waste will be placed in unsealed bags and sterilised within the Novacta facility by autoclaving. If the waste is to be deactivated by the University central services, the unsealed bag will be placed in a lidded but unsealed boxes and removed from the laboratory to the central autoclave service where it will be sterilized. The autoclave cycle will include heating the material to at least 120 degrees C for 15 minutes to ensure 100% kill for all material.

Liquid waste and contaminated glassware will be treated in one or two ways:
1) Autoclaving: The autoclave cycle will include heating the material to at least 120 degrees C for 15 minutes to ensure 100% kill for all material.
2) Hycolin disinfectant: Hycolin disinfectant, diluted according to the manufacturers instructions, overnight at room temperature.

In either case an initial check will be carried out the first time the process is carried out to check that no culturable cells remain before disposal. This check will be repeated periodically depending on classification of risk and whenever waste from different cell types or quantities of culture are produced to ensure that the procedure results in a 100% kill.

Members of the Genetic Modification Safety Committee have read the attached risk assessment and have agreed with its conclusions.

### For activities involving GMMs, describe the waste management measures which will apply to the activity

For GMMs (disabled strains of E. coli): render non-viable with Virkon or equivalent, dispose as liquid waste or render non-viable by autoclaving, dispose as liquid or solid waste, as appropriate. For GM invertebrates: kill by freezing (< 10 degrees Celsius, >20 hours, or as required to kill), then dispose as solid clinical waste.

### Please enter comments of the GM safety committee on the risk assessment

The GMO Safety Committee has considered all aspects of the Health & Safety Implications of the proposed work. It has not identified any risks that are greater than working with non-GM versions of the species: these risks are primarily the risk of allergy from working with insects and the normal laboratory hazards of using glassware, equipment and reagents. Waste will be inactivated as described in the risk assessment, and disposed of using a professional waste disposal service. We unanimously believe that the research should be classified as Containment Level 1. Virtually identical research has been carried out in the University of Oxford, Department of Zoology, and the Departmental GMO Safety Committee has come to a similar conclusion.

Page 11837 of 15326
For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste and all plastic disposable solid waste will be decontaminated in a final concentration of >5% Trigene overnight. The manufacturers of Trigene, The Hygiene Corporation Ltd, state that it exhibits a kill rate (virucidal, bactericidal and fungicidal) of >99.999% after contact with 1% Trigene for 5 minutes under clean conditions, and 5% Trigene for 5 minutes in the presence of 25% protein. Decontaminated waste, and paper waste/gloves, will be sealed in autoclave bags and placed in a one-way burn bin for incineration. Incineration will be undertaken by S Grundon (Waste) Ltd (Lakeside Road, Coinbrook, Slough, SL3 OEB). The company has been approved by the HSE for the incineration of GM waste.

Tick to confirm that you are attaching a summary of the risk assessment

Project Additional Information

Purposes of the contained use

The process of haematopoietic lineage commitment, megakaryopoiesis and platelet production is poorly understood, but necessary for improved clinical management and therapy in platelet disorders. A number of candidate genes of potential importance have been identified. This project aims to characterise such genes by over-expression or knock-down/knockout in primary human cells or cell lines, and subsequent biochemical analysis. For studies using primary human cells, retroviral (lentiviral) vectors are needed to obtain significant levels of gene transfer.

Recipient or parental organism

Recipient of genetic material (first GMO) is a replication-incompetent retrovirus (lentivirus; see information below). This will be used to infect (transduce) various murine and human cells in culture, particularly those of haematopoietic origin and including sem cells. The unmodified cells are fastidious and non-harmful, unable to colonise or cause disease (Hazard group 1). Primary human cells are derived from screened healthy donors. However, as there is a possibility that material may contain adventitious infectious agents, it will be handled at Containment Level 2.

Host/vector system

Vectors are defective lentiviruses (i.e. Replication incompetent, 'third gneration' derivatives of HIV-1) in which the helper genes are located on separate blocks of DNA. Such vectors may infect human cells and integrate into the cellular DNA, but when unmodified are considered class 1 GMMs. The SACGM guidance on 'pseudotyped' vectors suggests they should be considered as class 2 GMM's. When modified with genes of interest they will be treated as class 2.

Origin & function

The 'insert', or donated, genetic material consists of human genes proposed to be involved haematopoiesis, particularly platelet/megakaryocyte function. These include known human leukaemia genes including MEIS1, as well as other factors involved in transcriptional regulation. These will be overexpressed in various cell types to observe effects such as altered growth, differentiation, self-renewal and apoptotic response. In addition, short hairpin RNAs that inhibit expression from transcripts pf the above genes (giving 'knock-down') will be inserted.

Evaluation of foreseeable effects

The viruses used for introduction of the transgene are replication-incompetent. The components required for viral production are present on separate vectors, transfected
into the 'packaging' cell line, so that newly formed viral particles contain only the transgene and the minimal viral genes required for its genome integration and expression. They do not contain all the factors necessary for reproduction of that virus. In addition, virulence genes have been completely removed from the system. The possibility of sequential recombination events in the packaging cell line giving rise to replication-competent virus is extremely unlikely, and recombination with wild-type virus is prevented by regular screening of the packaging cell line for wt HIV-1 by PCR. High titre viral stocks will not be produced in-house but commercially from constructs we supply. Stocks will be stored in lockable freezers in areas of restricted access. Thus the vectors do not present a risk to the wider human population or the environment. The viruses will be VSV-G 'pseudotyped'. This coat protein confers a wider tissue tropism than for the natural virus. The vectors may be transmitted by contact/aerosol as well as the natural percutaneous route. Lentiviruses are able to infect non-diving cells unlike other retroviruses; the range of cells and modes of transmission are thus significant. Such chimaeric particles exhibit a greater physical stability but are more sensitive to the complement system. Considered class 2. On infection, these viruses insert their DNA into the cellular DNA and so are capable of expression for the life of the cell. Insertion itself could lead to a deleterious mutagenic event but this is of low probability. Long term expression of some of the genes/inserts of interest could result in cell transformation or oncogenesis. However, it is unlikely that a single expression event would result in any clinical manifestation and VSV-G pseudotyped virions have been shown to be relatively ineffective at entering via the apical surface of cells of the airway epithelium. These factors combine to greatly reduce the risk of harmful effects from such viruses. The risks from the proposed inserted genes is not considered to significantly increase the overall risk therefore vectors with inserts are class 2. The human cells transduced by such viruses may become transformed/oncogenic; however they would remain fastidious and would be incapable of colonising/causing disease; cells could present a genuine risk to corresponding donor, but there will be no opportunity of donors to be so exposed. Class 1

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A derogation from the requirement for an autoclave in the building is sought. We are embedded within the National Blood Service and our waste is handled as per their national policies; disposal of clinical waste is under contract to Whit Rose (see below)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All medical sold waste is currently destroyes by incineration under site contract (while Rose Environmental (Now SCRL), authorized/validated to carry/destroy hazardous material of GM Class 2). Disposable labware exposed to Viral GMO's will be treated with 1% Virkon for at least 16 hours, then placed in a toughened plastic autoclave bag within 20L, sealable sharps bins used for commercial incineration: 100% kill. Culture fluids will be exposed to 1% Virkon for at least 16 hours before sink disposal: effectively 100% kill. Work surfaces will be wiped with 1% Trigene followed by 70% ethanol: effectively 100% kill Virkon has been extensively validated for viral inactivation by manufacturers(Antec)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

06/01/09: Departmental GMSC met to discuss proposed work
19/01/09: GMSC agreed that the specific work can be conducted subject to terms of the risk assessment, and following the allocated period (45 days) after acknowledgement by HSE of this notification.
Hepatitis B virus (HBV) and hepatitis C (HCV) infections remain a major global public health problem despite the availability of effective antiviral treatments and anti-HBV vaccine. HBV- and HCV-related chronic hepatitis are the main causes of cirrhosis and hepatocellular carcinoma (HCC) that are responsible for a high rate of morbidity and mortality. In addition, despite continuous technical improvement in blood donation testing, hepatitis virus infection is still a major risk of transfusion/transplantation-transmitted viral infection. It is critical to increase our knowledge about the replication properties of these hepatitis viruses.

Recently, a relatively large number of infected, apparently healthy blood donors escaping HBV surface antigen (HBsAg) detection but with so-called occult HBV infection/carriage (OBI) were identified. OBI is characterized by undetectable HBsAg in the presence of very low levels of viral DNA in blood. The mechanism(s) explaining the transient low levels of virus in OBI donors are largely unknown. We have identified mutations affecting different critical regulatory elements in the HBV genome. These
mutations are assumed to negatively impact viral replication possibly explaining low viral load and HBsAg yield below detection threshold. This hypothesis will be explored in vitro by comparing replication ability of HBV variants and wild type strains from naturally infected individuals. OBI variant strains with significant reduced replication abilities will be 'repaired' by site-directed mutagenesis of the genomic position studied, and the corresponding OBI mutations will be introduced in wild type control genomes in order to definitively link OBI-specific mutations to reduced viral replication.

Over the past years, we collected indirect evidences that HCV particles may carry at their surface a particular cellular protein embedded in the viral envelope. If confirmed, the presence of this cellular protein may or not play a role in the virus replication. Our objective is to purified viral particles from culture supernatants to test for the presence of the cellular protein at the virus surface by using electron microscopy and labelling with specific antibodies.

Recipient or parental organism

- PCR- amplified HBV genome of fully characterized OBI strains and wild type HBV controls. HBV virus can cause both acute and chronic liver disease potentially evolving to cirrhosis or liver cancer on the long term in humans. The virus is transmitted through contact with the blood or other body fluids of an infected person, not through casual contact. HBV is classified as hazard group 3. HBV infection is preventable with a safe and effective vaccine and several effective antiviral drugs are available for treatment. However, the infectious viral particles will not be cultured and only non-replicating viral DNA directly extracted from low titre plasmas will be used

- The pJFH1 plasmid (Wakita et al., 2005, Nat Med, 11: 791-96) containing JFH-1 HCV genotype 2a full-length DNA construct will be directly supplied by, Heidelberg University, Heidelberg, Germany. HCV is classified as a hazard group 3 pathogen and HCV infection can lead to chronic liver infection, liver cirrhosis and hepatic carcinoma. HCV is transmitted through contact with the blood or other body fluids of an infected person. Less common but possible sources of HCV infection are needle-stick or injury with other contaminated sharp instruments, contamination of open wounds, contamination of skin lesions (eg eczema), and splashing of the mucous membranes of the eye, nose or mouth. The HCV genome is under T7 promoter control in the plasmid and consequently requires T7 polymerase for transcription. The latter is a bacteriophage polymerase found in bacteria infected with bacteriophages. It is extremely promoter-specific and only transcribes DNA cloned downstream of a T7 promoter. In the DNA form, the HCV replicon in the pJFH1 plasmid is not infectious and requires transcription by the above bacteriophage polymerase to its RNA form. E. coli strains containing T7 promoter will not be transformed.

Overall risk: Effectively zero.
group 3 and is transmissible by direct contact through percutaneous inoculation (from sharps, including needles, scalpels, broken glass, etc including contamination of exposed skin or pre-existing cuts and abrasion etc) contamination of conjunctivae by inadvertent contact with eyes. The amount of potentially infectious virus produced in culture will be limited by (1) the low volumes of cultures (5-10mL), (2) except for wild type controls, the HBV strains studied have impaired replication properties, and (3) viral particles produced in culture supernatants cannot directly infect HUH-7 and Hep G2 cells and no high viral stocks will be produced. Culture supernatants and transfected cells will be inactivated after final testing. All workers are vaccinated against HBV with documented levels of anti-HBV neutralizing antibodies and antiviral drug therapies are available.

The resulting HBV will not differ radically from the parental virus. Mutations introduced by site directed mutagenesis would either restore a wild type sequence in HBV natural variants or introduce mutations present in naturally infected individuals with evidence of impaired viral replication and no clinical symptom. Consequently, the resulting GMM is not expected to have enhanced replication ability or to be more infectious. Site directed mutagenesis should not affect viral genes involved in antiviral drug resistance or vaccine/immune escape.

- The full length HCV RNA will be transcribed in vitro from the pJFH1 plasmid. In vitro transcribed RNA is highly fragile, susceptible to cleavage and destruction by nucleases ubiquitously present in skin, hands and nails. Transfection into mammalian cells needs special procedures using appropriate transfection reagents. Quantity of RNA for transfection of Huh-7 or HepG2 cells will be 5-10 micrograms. HCV RNA transcript is capable of producing infectious HCV particles upon transfection into mammalian hepatocyte cells (Huh-7 cells and HepG2 cells). HCV is ACDP hazard group 3 and its routes of transmission are similar to the ones described above for HBV. One human plasma, the source of the HCV-H77 (genotype la) genomic consensus sequence, had a chimpanzee infectious dose (CID) tier of about 10e6.5/ml. This was in good agreement with results from the branched DNA probe assay, which demonstrated that the ratio of HCV RNA genome equivalents to CID of ,10e2/ml and a genome equivalent CID ratio of greater than 10000:1. Reasons for these differences are not clear, but could reflect a high level of defective genomes or immune complexes in the plasma of this subject (Walker 1997, Springer Seminars in Immunology, 19:85-98).

The sequence of the HCV strain inserted in pJFH1 plasmid will not be changed during the whole process and the virus produced in culture will be identical to the parental strain.

**Evaluation of foreseeable effects**

- The resulting GMMs will not differ radically from the recipients. The sequences inserted in the plasmids are unlikely to be transcribed efficiently in bacterial cells and any background transcripts would lack the translation signals to engage bacterial protein synthetic machinery. Any viral proteins would not be expected to have any effect on the properties of the bacterial host and there is no mechanism to excrete these proteins. Even if human cells were exposed to the viral proteins, they would not be expected to have any effect.

The modification is not expected to overcome disablement of the host organism, nor affect host specificity, tissue tropism or susceptibility to host defence mechanisms.

- The viral genome is disabled in plasmid and cannot replicate in bacteria.
  - HBV: non-replicative naked linear viral DNA with disrupted viral promoter controlling viral polymerase and core protein gene expression as well as synthesis of the pregenomic viral RNA both essential for HBV replication.
  - HCV: viral genome under the control of T7 promoter and needs transcription by T7 polymerase. The latter is a bacteriophage polymerase not present in uninfected bacteria. E. coli strains are available that contain viral T7 polymerase in their genome (egBL21(DE3)), and care will be taken not to transform these strains.

- Stability of the cloned viral genome:
  - HBV: stability of linear non-replicative HBV double stranded DNA ensures by the addition of Dapl sequences of both termini to prevent release and self re-assembly. HCV: without the T7 promoter, the inserted HCV DNA would not be transcribed and generate a coding genomic RNA (+) strand.

- Analytical scale quantities of HBV linear DNA or in vitro transcribed HCV RNA (total yield ,5 microgram DNA/RNA) to be undertaken at containment level 1 with Good Microbiological Practice and Good Occupational Safety and Hygiene. This work will be conducted at the NHS Blood & Transplant Centre, Long Road, Cambridge, Purification of larger quantities of viral DNA or RNA (up to 10 microgram) for transfection of hepatocyte cell lines will be conducted in the Containment Level 3 laboratory at Lab 21 Ltd, Science Park, Cambridge. Only non-infectious plasmids will be transported in sealed adequate containers between NHS Blood & Transplant Centre and Lab 21 Ltd facilities.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Control measures
Control of HBV genome and site directed mutagenes: containment level 1 with Good Microbiologicval Practice and Good Occupational Safety and Hygiene. Disposal of GM waste is into sealed plastic bins for incineration under NHS Blood & Transplant site rules.

Step 2 - HBV replication in hepatoma cell line cultures: All disposable solid culture/lab waste will be treated with 1% Virkon for at least 16 hours, then autoclaved, and incinerated: 100% kill. Culture fluids will be exposed to 1% Virkon for at least 16 hours, then autoclaved, and incinerated: 100% kill. Culture fluids will be exposed to 1% Virkon for at least 16 hours and disposed to drains: effectively 100% kill. Bench/cabinet surfaces will be wiped with 70% ethanol: effectively 100% kill. Spills will be sprinkled with Virkon powder. Virkon has been extensively validated for viral inactivation including HBV and HCV by the manufacturer (Antec). All waste to be disposed of according to Lab 21 site rules.

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

On 01/04/2011, members of the safety committee and a representative of the NHSBT visited Lab 21 to discuss the proposed use of the facility under their procedures. We met the Compliance Officer, Biological Safety Officer and the CL3 Supervisor and were satisfied with the operational arrangements, the induction, storage and waste management procedures of Lab 21.

University and NHSBT employees involved in this project are experienced scientists, and have been inducted at Lab 21.

On a review of the original draft of the risk assessment (RA), we sought further clarification about the possible enhanced risk resulting from generation, in vitro, of higher viral titres than encountered in naturally occuring material. This was more fully addressed in the final RA, which was approved by the GMSC on 15/11/2011

For activities involving GMMs, describe the waste management measures which will apply to the activity

- Solid media and contaminated plastics will be contained in approved biohazard waste bags until removal and incineration by an approved contractor.
- Used pipette tips, tubes will be totally immersed in a fresh effective 'use'dilution' of Chloros overnight and the disinfected materials transferred safely to an appropriate container as described.
- Contaminated sharps will be disposed of in approved biohazard incinerator cartons until removal and incineration by an approved contractor.
- Liquid media will be treated overnight with a fresh effective 'user-dilution' of Chloros, storage in a leakproof container until removal and disposal by an approved contractor. The premises to be used consist of one purpose-built laboratory within the unit and has no provision for an autoclave.

All volumes of bacterial suspensions will be small and pose no risk outside the appliance of good laboratory practice. In case of spillage, liquid will be mopped up with absorbent paper and chloros and disposed of in a biohazard bag as above.

Give brief details of the genetic modification safety committee

The genetics modification safety committee consists of the following people:
The Health & Safety coordinator for the company,
Two scientists with at least 10 years each experience in Molecular Biology,
A member of the management committee,
Normally the decision manager.

At least four members of the committee must be present.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid waste will be treated by autoclaving at 121 degrees, 1 bar pressure per 30 minutes in an autoclave. The waste will then be removed for incineration by specialist in waste disposal contractors. The autoclave is present within the laboratory and is serviced annually by the suppliers.

Sharps waste (including pipette tips) will be collected in specialist 'sharps bin' which will then be treated by autoclaving at 121 degrees, 1 bar pressure for 30 minutes in an autoclave. The waste will be removed for incineration by specialist waste disposal contractors. The autoclave is present within the laboratory and is serviced annually by the suppliers.

Liquid waste will be treated by autoclaving at 121 degrees, 1 bar pressure for 30 minutes in an autoclave. The waste will be removed for incineration by specialist waste disposal contractors. The autoclave is present within the laboratory and is serviced annually by the suppliers.

Alternatively liquid waste will be treated by putting enough Virkon S Powder in the liquid waste to make up 1% Virkon solution and left overnight. According to the manufacturer's website http://www.antecint.co.uk/main/virkons.htm a 100% decontamination of an E. coli culture was observed after 60 seconds.

Minutes of the meeting.

* The agreed scale of growth of the GMM, is under 1 litre for Research & Development
* The vector, pSP64, has no Bom-, Nic-, Mob- and Tra- and is therefore non-mobilisable.
* The E.coli strain JM 109, because it is recA and needs added thiamin, is unlikely to survive outside of the laboratory.
* Given the above, the access factor for this host / vector combination of 10-9 was considered appropriate.
* The insert, an intergenic sequence from Saccharomyces cerevisiae was reviewed. A BLAST search to determine if any substantial homology to human sequences was requested. This has been carried out and no substantial homology was detected DH.
* The insert is inserted into the Smal site of pSP64. Therefore, the sequence is downstream of a SP 6 promoter, although the host bacteria does not carry this polymerase. Therefore 10-6 for the expression as under the Brenner scheme is considered appropriate.
* The insert does not code for any known proteins, so the Damage figure of 10-9 is appropriate.
* Handling this GMM under containment level 1 was considered safe by the committee.
* Filing of the Risk Assessment will be both electronically and on paper. The Risk Assessments needs to be signed by at least 4 committee members.
Recipient or parental organism

Mouse embryonic stem cells

Host/vector system

Mouse embryonic stem cells
Mammalian expression vectors e.g. pEGFP were used by our collaborators in order to introduce the GFP tag into the mouse ES cell line via homologous recombination.

Origin & function

GFP reporter genes are inserted in the mouse embryonic stem cell line for the four genes of interest for single cell analysis. The cell line to be received has already had the GFP tag introduced into the cell line by our collaborators. No genetic manipulation of this cell line will take place on the premises of Oxford Gene Technology. The cell line has been fully risk assessed by our collaborators and by ourselves.

GFP tagged cells will allow identification of cells positive for the genetic markers of interest and will concentrate our single cell analysis to only cells of interest amongst a largely heterogenous population of cells.

Evaluation of foreseeable effects

The stem cell line carries genetically modified endogenous genes created by homologous recombination.
Manipulated genes are not involved in or anticipated to have any effect on pathogenicity.
The stem cell line is not expected to survive outside of controlled culture conditions.
No micro-organisms used are listed in ACDP hazard groups 2, 3 or 4 or controlled by DEFRA.
pEGFP is not mobilisable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable - All work carried out within the premises of Oxford Gene Technology will be on mouse embryonic stem cell lines that have genes tagged with GFP.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cell culture flasks in which the cell lines are maintained will be exposed to 10% Virkon for a minimum period of 2 hours. Flasks will then be autoclaved and subsequently incinerated. All lab waste is collected as clinical waste by a professional management company (LAB3) and incinerated.
This is expected to cause 100% death to the cells within the flasks.
In order to ensure that all cells have been killed by exposure to 10% Virkon a “kill” control measure will be carried out. This will entail taking a flask that has been exposed to 10% Virkon and refeeding the cells within the flask. It is expected that the Virkon exposure will prevent any cell growth. Upon receipt of cells this will be carried out immediately and will subsequently be carried out once a month to ensure that 10% Virkon continuously and sufficiently causes cell death even before autoclaving and incineration.
A further control measure will entail removing an aliquot of Virkon from the flask and this will be placed in a fresh flask and re-fed with excess media and left in the incubator for 24 hours. The flask will be analysed the following day to ensure there is no cell growth.
cell culture utensils (such as glass pasteur pipettes) will be autoclaved and subsequently incinerated as described above.
All excess cells following experimentation will also be treated in the manner outlined above.
The safety committee has passed the proposed work following the review of the attached risk assessment.

Please enter comments on the GM safety committee on the risk assessment

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee at IDIS consists of the following committee members:
- **Title:** Financial & Corporate Affairs Director
  **Positions:** Responsible person
  **Representative Functions:** Leader of integrated risk management committee and member of Health & Safety committee, responsible for the overall supervision and safety of GM activities at the premises.

- **Title:** Quality Assurance Specialist
  **Positions:** Quality Assurance representative on risk management committee
  **Functions:** Responsible for ensuring all GM activities are proceduralised and adequately implemented.

- **Title:** Logistics Manager
  **Positions:** Health & Safety Manager at address of premises.
  **Representative Functions:** appointed as IDIS Biological Safety Officer and representative of management with responsibility for the work in genetic modification. Also responsible for ensuring compliance of Safety Representatives and Safety Committee Regulations.

- **Title:** Pharmaceuticals Service Manager
  **Positions:** Qualified Pharmacist
  **Representative Functions:** Management representative and liaison for technical enquiries

- **Title:** New Product introduction (NPI) Co-ordinator
  **Representative Functions:** Employee representation responsible for co-ordinating the internal progress of GMSC and act as liaison between GMSC and internal departments.

IDIS have agreed that the GMSC will initially meet on a monthly basis, however this will be open to review at a later date.
This is a small premises where no autoclave is available, however, a third party contractor Adchem Environmental Services Limited (www.adchem-ltd.co.uk) will remove waste for remote disposal (incineration). Waste will be stored by IDIS in 60 litre sealed plastic One-way burn bins. The bins are removed by the contractor for incineration at 1000°C. This method will guarantee complete destruction. The company Adchem have confirmed that they are compliant with the Contained Use 2000 Regulations and are monitored by the Environment Agency.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The genetic modification committee (GMSC) has been set up to ensure the safe use of the ER-CALUX Bioassay. The ER-CALUX assay uses genetically modified cells. It is the responsibility of the GMSC to ensure that controls on the contained use of the GMO are followed as stated in the Genetically modified organisms (contained use) regulations 2000. The GMSC committee as of 5th July 2004 are composed of:

- Chairman
- Site safety officer
- Laboratory Manager
- Operations Manager
- Biological Safety Officer
- ER-CALUX Project Manager

For activities involving GMMs, describe the waste management measures which will apply to the activity

All material that has come into contact with or may have come into contact with the genetically modified cells either directly or indirectly is to be placed in an autoclave bag. At the end of the working day the bag is to be sealed ready for autoclaving. The bag will be autoclaved and the autoclaved bags will be placed in bin liners, the top secured and stored in a suitable place. When sufficient bags have been collected they will be disposed via a recognised waste disposal company.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The WRc-NSF Genetic Modification Safety Committee (GMSC) have now met on two occasions to consider the risk assessments and safety precautions that have been implemented at WRc-NSF Medmenham to undertake the estrogenic potency testing using the ER-CALUX bioassay. The GMSC is satisfied that all risk assessments needed to carry out the bioassay have been completed and the committee agrees with the conclusions of these documents that the use of ER CALUX meets the category, Provisional Containment 1. The Committee is also satisfied that the safety procedures implemented meet the requirements on risk minimisation of a Class 1 activity.

Chairman, GMSC

Y

Give brief details of the genetic modification safety committee

The duties of the GMSC are fulfilled by the standing Environment Agency, Ecosystems and Human Health Science Group Health & Safety Committee. The committee is comprised from members of the sections that make up the Ecosystems and Human Health Science Group.

H&S Co-ordinator & Chair, Principal Scientist (Chemicals Assessment Unit), Senior Scientist (Chemicals), Senior Scientist (Human Health), Senior Scientist (Biological Effects), Scientist (Ecosystems) and a Technical Assistant (Chemical Assessment Unit).

OPERATING PROCEDURES AND FREQUENCY OF MEETINGS:-

1. Chair invites members to a quarterly meeting to discuss H&S matters and to review either new, or current, risk assessments.
2. Risk Assessments are circulated prior to the meeting.
3. During the meetings the relevant risk assessments will be discussed and any amendments required will be made by the Chair after liaison with the staff involved in drafting the original risk assessment.
4. The amended risk assessment will then be circulated to all staff in EHH for further comments/suggestions.
5. Finalised risk assessments are passed to the Head of the Environment & Human Health Science for formal approval.

</tbody>
</table>

Level 1 (GMMs)

Level 2 (GMMs)

Level 3 (GMMs)

Level 4 (GMMs)

Non-microbial
The GMM proposed for use in this study is an especially-disabled strain of Saccharomyces cerevisiae (FF18984), ACDP Classification - Class 1: Gentronix Greenscreen EM™. The Environment Agency's Biological Effects laboratory is a UKAS accredited ecotoxicological testing facility. Standardised Working Procedures will be adopted when handling Class 1 GMMs, consistent with, and often exceeding, those required for Class 1 containment (See the attached working practices document).

* GMMs will be handled, wherever possible, within a contained working area (re-circulating chemical fume hood) equipped with HEPA exhaust filters.
* Routine inactivation and disposal of items contaminated with Class 1 GMMs.
* All disposable items contaminated with Class 1 GMMs, such as polypropylene pipette tips, sample vials, cells culture plates and gloves will be sealed in small ‘biohazard’ bags containing absorbant material and inactivated via autoclave (see note 2) before appropriate disposal. Final disposal of items after inactivation will be as either general laboratory waste, recyclable waste (pipette tips/cell culture plates), or hazardous waste - depending on chemical contamination of the items by hazardous substances.
* All re-usable items contaminated with Class 1 GMMs, such as laboratory glassware, will be disinfected by total immersion in freshly prepared 1% (w/v) Virkon solution (Antec International) in a sealed container for 24 hours (see note 1). Items will then be washed and autoclaved (if required) following standard laboratory practices.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
procedures prior to re-use (EA, Biological Effects Laboratory AQC procedures 9 and 5 respectively).
* Laboratory coats that could potentially have been contaminated with class 1 GMMs must be sealed in large 'biohazard' bags and subject to inactivation by autoclave (see note 2), before normal laundering.
* Stock cultures of class 1 GMMs, when no longer needed, will be sealed in small 'biohazard' bags containing absorbent material and inactivated via autoclave before disposal as general laboratory waste (see note 2).
* Work areas (fume hoods, incubators etc) will be disinfected after use using 70% Ethanol solution (see note 3).
* Hands and wrists of laboratory staff using Class 1 GMMs will be washed immediately using Day-Impex LabGuard (see note 4) if contamination by viable Class 1 GMMs is suspected. In addition, hands and wrists will always be washed using Day-Impex LabGuard (see note 4) before leaving the laboratory after performing any procedure involving viable Class 1 GMMs, even if no contamination is suspected.

Spillage Containment
* Liquid spills of class 1 GMMs on the bench or floor will be contained with absorbent paper tissue, or Virkon powder. Absorbent paper and powdered Virkon waste will be inactivated by autoclave before appropriate disposal (see note 1 and 3). The affected floor/bench area will be disinfected with 70% ethanol/water solution (see note 3). Final disposal of inactivated paper tissue/virkon will be as either general laboratory waste, or hazardous waste - depending on chemical contamination of the liquid spill with hazardous substances.
* Contaminated broken glass will be inactivated by autoclave (see note 2) before appropriate disposal. The affected bench/floor area will be disinfected with 70% ethanol/water solution (see note 3). Final disposal of inactivated broken glassware will be as either general laboratory waste, or hazardous waste - depending on any chemical contamination of the glassware by hazardous chemicals.
* Liquid spills >5ml will be recorded in the Laboratory's GMO activities log and reported to line managers. Areas will be swabbed and suspension tests performed to ensure that disinfection was effective.

Note 1 - Virkon is a peroxynitryl system that is widely used for laboratory disinfection, and is effective against bacteria, viruses and yeast. In addition, Virkon was found to be effective against 3 strains of Saccharomyces cerevisiae (the Host organism proposed for use in this study) after 5 minutes contact time at 1% using a suspension test (Alegente et al). 99.999% degree of kill is assumed after 24 hours contact with 1% Virkon solution.

Note 2 - Items inactivated via autoclave (LTE Scientific, Osprey - EA, Biological Effects Laboratory Inventory number E220) are subject to a temperature of 121ºC for a duration of 20 minutes. The temperature probe used in the autoclave, the autoclave cycle chart recorder and the temperature variation within the autoclave chamber are assessed and calibrated annually by a UKAS certified calibration agent. 100% degree of kill would be achieved.

Note 3 - Alcohols give a very rapid kill of micro-organisms, but do not provide sustained microbial action. 99.999% kill would be achieved.

Note 4 - Day-Impex LabGuard is an antimicrobial handsoap containing 0.5% p-Chloro-m-xylene (PCMX), a bacterial and anti-fungal agent that is effective in destroying a broad spectrum of organisms including Saccharomyces spp. (Day-Impex, 2004) 99.999% kill would be achieved.

Oxonica Waste management for class 1 activities.

The principle method of waste disposal is via incineration for solid materials, and chemical treatment for liquid waste. However, solid waste samples are also pre-treated via autoclaving on-site to incineration.

The maximum culture volume of bacterial cells is 2 litres at any one time. Waste from such cultures is treated, following manufacturer's instructions, with Virkon powder or solution (Antec International Limited, UK). Efficacy of this treatment is tested every six months by treating a volume of viable culture in this manner and establishing percent kill by subsequent growth on an agar plate. Records of testing are maintained by the GM Safety Officer.

Disposable, solid waste is autoclaved at 134 degrees C for 15 minutes before removal to clinical waste storage. This is collected and incinerated by Select Environmental Services, Reading.

The autoclave (LTE Osprey 40) is serviced and calibrated annually by LTE Scientific, Oldhal. In addition, efficacy is monitored every three months using a Geobacillus stearothermophilus SporAmpule biological safety indicator (SPS Medical, New York, USA, distributed in the UK by Medical Engineering Technologies, Folkestone). Records of this procedure are maintained by the GM Safety Officer.

For activities involving GMMs, describe the waste management measures which will apply to the activity

GMSC requested that Permit to Work system be extended to the Biological lab and that fridges and freezers be lockable as best preventive measure against accidental out of hours exposure.

Give brief details of the genetic modification safety committee

VP Research, Director Discovery Sciences, Director Biochemistry (Biological Safety Officer) and Senior Scientist.

Individual scientists will present written risk assessments TO THE MEMBERS OF THE gmsc FOR PRIOR EVALUATION. The GMSC will meet on a quarterly basis and/or whenever necessary to review risk assessments and procedures. The GMSC will be empowered to approve level 1 activities and will identify any activities that are deemed to warrant level 2 categorisation and which will therefore require advance notification to the HSE.

Culture medium/liquid waste will be decontaminated by treatment with Trigene prior to disposal via the drain (2% (v/v) final for a minimum of 1h for routine use; 10% (v/v) final for a minimum of 1h under high organic load eg serum). Any re-usable glassware will be soaked in 2% Trigene for a minimum of 1h prior to washing.

Trigene (Medichem International Limited, PO Box 237, Sevenoaks, Kent, TN15 0ZJ; www.medichem.co.uk) is a non-toxic, non-hazardous, biodegradable agent with broad spectrum activity (bacterial, fungicidal, virucidal, mycobactericidal and sporicidal) recommended for medical, veterinary and environmental use at 2% under soiled/ high risk conditions and at 10% under conditions of very high soilage (blood, faeces etc).

Disposable solid waste (eg plasticware, gloves) will be discarded into 60 litre one-way burn bins, sealed and sent for incineration by S Grundon Waste Management Limited. The company has been approved by the HSE for incineration of GM Waste.

Routine disinfection will use 1% Trigene. Any substantial bio-spills will be treated with the Trigene Body Fluid Response Kit.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The programme of work involves the expression of a human protease for functional and structural studies. The GMSC has examined the potential impact of the GMMs that will be generated in terms of hazard to human health and potential damage to the environment.

The protease itself is considered to represent no greater risk than that of many other proteases commonly used in a laboratory environment eg trypsin and is considered to offer negligible risk of increasing the survivability or fitness of any cell that is induced to express it. All bacterial manipulations will be performed in K12 strains of E.coli or (for expression purposes) within strains that have a long history of safe use in a laboratory environment. The insect and mammalian cells used are considered non-pathogenic and will show a negligible ability to survive outside the cell culture environment.

All vector/host combinations are considered to show negligible likelihood of transfer to other hosts. The GMSC has recommended that this work be carried out under containment level 1 conditions.

02/03/2022
All waste material and contaminated plastic ware are autoclaved at 121 degrees for 15 minutes. This will have an efficiency of 100% kill. Autoclaves are tested with indicator strips to validate the process.

Virkon is used to decontaminate liquid waste. This is a broad spectrum virucidal and bactericidal disinfectant cleaner routinely used to inactivate biological material in liquid cultures. Adding Virkon to liquid waste at a concentration of greater than 1% for two hours will give 100% kill. To confirm decontamination, Virkon is added to a concentration of 1% to a flask containing cells in culture medium. Incubation at 37 degrees for an overnight period confirms 100% kill.

1% Virkon solution and 70% industrial methylated spirit are readily available for disinfection of areas of work and for the event of any spillages.

The safety committee confirm that the risk assessment is a fair and accurate description of the work to be carried out.

Y

Give brief details of the genetic modification safety committee

The Faculty of Archaeology and Anthropology Safety Policy Committee is comprised of faculty and academic staff and researchers, and meets once every academic term to discuss issues related to University, Departmental and Faculty safety including GMM safety.

Each of the laboratories where GM work will be carried out (see 2) is represented on the Safety Policy Committee by a tenured member of staff from each department responsible for that laboratory. GM Safety and GMM issues are on the agenda as a standing item.

Yes

All solid and liquid waste and contaminated disposable plastics ware generated is placed in autoclavable biohazard bags, sealed and autoclaved using a Prestige Omega 121 degrees C laboratory autoclave.

Once autoclaving is complete, solid waste is sealed inside waste bag and placed in the general waste bin. Disposal of liquid waste subsequent to autoclaving is via a dedicated sink to the drains.

Contaminated glass and plasticware are either autoclaved or decontaminated by soaking over night in a 1-3% Virkon solution.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Give brief details of the genetic modification safety committee:
The GMSC consists of the CEO of Idna Genetics (20 years practical experience of GMOs), Prediction Manager of Idna Genetics (4 years practical experience GMOs), Sales and marketing Manager of Idna Genetics (4 years practical experience GMOs), Manager of the Norwich Bioincubator (10 years practical experience GMOs, serves on 2 other biological safety committees), Managing Director of Plant Biosciences Limited (20 years practical experience in plant biotechnology). The committee transacts most of its business by email, and will meet annually to review all assessments. The committee exists to assess risks to people and the environment due to Idna Genetics Limited activity with respect to genetic modification.

Level 1 (GMMs)
Level 2 (GMMs)

Transgenic Birds
Microbiology Research
The activity does not involve GMMs. The activity is restricted to non-notifiable activities involving genetically modified plant material. It is not envisaged that the company will be undertaking genetic modification itself, but will be handling genetically modified plant material produced by other parties. The majority of samples will be grain (or occasionally leaves) for destructive laboratory testing. Before disposal all material will be rendered non-viable by grinding to a fine powder, or autoclaving as appropriate. In order to monitor the efficiency of grinding or autoclaving in order to render the samples non-viable, for each new type of sample ground or autoclaved material will be tested for germination in the laboratory.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The comments received from the GMSC indicated that the risk assessment was satisfactory.

Project Additional Information
### Purposes of the contained use

The purpose of the project is to use the plant viruses, Potato virus X (PVX) and Tobacco mosaic virus (TMV), as tools for the expression of foreign genes in plants, with the aim to investigate potential of the PVX and TMV vectors as tools for foreign protein production.

### Recipient or parental organism

Both PVX and TMV are endogenous viral pathogens and neither is considered to have any serious consequences on infected plants. Both viruses are transmitted in nature by mechanical means, generally plant-plant contact and neither virus is known to be transmitted by arthropod or nematode vectors. In the unlikely event of release of the modified virus to the environment a rapid selection for "wild type" virus is observed and recombinant viral progeny lacking foreign genetic sequences rapidly arise and dominate quickly dominate the viral population.

### Host/vector system

The modified PVX and TMV cDNA's with a duplicated viral coat protein subgenomic promoter is cloned in plasmid pBluescript KS (M13-) for propagation in suitable Escherichia coli K12 strains. Nucleic acid sequences of interest will be inserted into vector using standard molecular biology procedures. Gene expression will be under the control of the coat protein promoter and the expression level will not exceed that of the viral coat protein.

### Origin & function

The gene encoding the human endostatin protein will be inserted into cDNA copies of the PVX and TMV viral genomes in such a way that infection of plants with in vitro synthesized viral RNA transcripts will permit the infection of host plants and production of recombinant endostatin. Endostatin is a protein that acts as a negative regulator of angiogenesis and therefore has a potentially important role as a therapeutic agent to prevent tumour growth and metastases.

### Evaluation of foreseeable effects

Endostatin is normally produced in humans and animals (e.g. during wound healing processes) and therefore neither endostatin-coding sequences nor endostatin are considered to pose any health threat to humans and animals. It is unlikely that introduction of the endostatin gene into the PVX or TMV genome will alter the routes of viral vector transmission. The modified PVXs or TMVs are likely to be less fit than wild type. It is unlikely that expression of human endostatin, a protein that is not normally expressed in plants, will make PVX or TMV pollen or seed transmissible. It is also very unlikely that the modified PVX or TMV will become a vector transmissible (e.g. by insect, mite, fungal or nematode vectors) and that the host range of the modified PVX will be altered. Therefore, the genetically modified PVX or TMV will not be any more harmful than its parent. Inoculation of plant material may be performed in a Unigro Gro Dome The construction method means that the facility is virtually airtight. The compartments can be negatively pressurised (to approx 40 pascals) to ensure that insects or pollen do not escape and an air exhaust bag filter will be used. The method of construction also means that the steel superstructure and polycarbonate dome can withstand winds up to 120mph and resist impact from flying objects produced by such winds. Close adherence to standard operating procedures, training of staff, and rigorous implementation of containment measures should protect the environment. Furthermore, the isolated location of the growth room inside a building in the middle of a very large field of perennial fruit crops (which PVX or TMV is not able to infect), should prevent the modified viruses from escaping to infect any susceptible natural host plants. Gene expression vectors based on PVX and TMV have been used for well over a decade in the UK under containment conditions that are inferior to those of the GroDome without any evidence of escape to the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Infection of whole plants with modified PVX will be undertaken in a compartment of the Unigro Gro Dome Containment Facility. The facility is designed to meet containment level II and is therefore suitable for the proposed research. Access to the facilities (growth room) will be restricted to authorised personnel only.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Disposal of all inoculated plant material is by autoclave in laboratories located close to the GroDome House. The plant viral particles, plant tissues and their recombinant products are easily destroyed by normal autoclaving temperatures and pressures. Experimental material will be placed in sealable autoclavable bags and then into
sealable plastic bins before being transported to the labs nearby.

In the laboratory all media in contact with GM materials as well as GM cultures and plants will be placed in identified containers and autoclaved prior to disposal. Infected plants will be grown in compost in pots in waterproof trays in a containment growth room inside a building. Only a limited amount of water will be used daily for watering plants. There will be no run-off water. Accidentally contaminated water will be contained. Plant material and other solid waste will be transported from the Unigro GroDome compartment in secure closed containers, for autoclaving and disposal. Following recommendation from Defra Plant Health Division, liquid waste and condensate from the cooling coils will be collected, treated with Virkon to give a final concentration of 1% (or another suitable disinfectant at an appropriate concentration) and then autoclaved.

Is an emergency plan required according to regulation 20?

Give brief details of the genetic modification safety committee

- Committee comprises four members - MD and 3 Project Managers
- Meetings held on a monthly basis
- GM issues are raised and discussed with decisions and action points being documented in the meeting minutes.
- Both safety and GM issues are disseminated to board members (at board meetings) and all employees (via line managers and monthly company meetings)

For activities involving GMMs, describe the waste management measures which will apply to the activity

Culture media and cells to be disinfected/deactivated in a solution of at least 1% v/v Trigene (Medichem International) overnight before disposal down drain with plenty of water.

Pipettes, culture flasks and any other plasticware will be disinfected in a solution of at least 1% v/v Trigene overnight and then sent for incineration.

All other waste material will be autoclaved on site before being sent for incineration.

Trigene has been validated by the manufacturer and meets the following standards at the concentration used:
EN 13704, EN 14204, EN 12634, EN 13727.

Further information can be found at http://www.medichem.co.uk/mainmedical.html

Trigene has also been shown to deactivate genetic material (http://www.medichem.co.uk/dna.html; copy of personal correspondence attached)

Project Additional Information

**Purposes of the contained use**

This work aims to create human organoid cell lines expressing reporter genes including GFP or RFP and firefly luciferase for monitoring our cells in in vivo and in vitro assays. We will transduce our human organoid cell lines with second generation amphotropic recombinant HIV-1 lentiviral particles generated in-house, containing our transgenes of interest—e.g., RFP and firefly luciferase.

**Recipient or parental organism**

2. Lentiviruses—HIV-1 derived, replication defective, amphotropic
3. Mammalian cells (human primary cells and cell lines)—considered as especially disabled
   - HEK293T (human kidney cells)
   - cholangiocyte organoids
   - hepatoblast organoids
   - pancreas organoids
   - pancreas and liver tumoroid lines
   - LX2 hepatic stellate cells.

**Host/vector system**

1. E.Coli (DH5 α derivative - NEB 5 α) - K12 derivative / plasmids: pLL-EF1α-rFluc-T2A-mRFP-mPGK-Puro, pWPT-GFP, psPAX2, pMD2.G
   K-12 derived strains of E.Coli are non-colonising and disabled. Having auxotrophic requirements that are unlikely to be satisfied outside the laboratory they are not considered pathogenic to humans or animals.
2. HEK293T - plasmids: pLL-EF1α-rFluc-T2A-mRFP-mPGK-Puro, pWPTGFP, psPAX2, pMD2.G
   This is a second generation lentiviral system where no structural genes are present and as a consequence no replication-competent virions can be produced. pLL-EF1α-rFluc-T2A-mRFP-mPGK-Puro co-expresses rFluc and...
mRFP from the EF1α promoter, which delivers moderate expression in most cell types (including primary and stem cells), and co-expresses the puromycin resistance gene for selection in vitro. pWPT-GFP allows for constitutive expression of eGFP driven by a EF1α promoter. HIV-1 virulence genes Vif, Vpr, Vpu and Nef have been deleted in the helper plasmid. The vector plasmid has the 3'LTR U3 region that encompasses the native viral promoter and enhancer deleted resulting in a self-inactivating vector. Packaging vector - psPAX2 - codes for Gag, Pol, Rev, and Tat but lacks both LTRs and has no viral packaging signal. Envelope (VSV-G) is expressed on a separate vector - pMD2.G

3. Human primary cells and cell lines (holangiocyte organoids, hepatoblast organoids, pancreas organoids, pancreas and liver tumoroid lines, LX2 hepatic stellate cells) / pseudotyped recombinant lentiviral particles

The lentiviral particles will be used to transduce organoid cell lines to induce stable over expression of the factor of interest (e.g. GFP and luciferase) in the transduced cell. The production of fluorescent proteins and luciferase will have no biological effect.

**Origin & function**

Inserts carried by lentivirus will express mRFP, rFLuc or eGFP

**Evaluation of foreseeable effects**

The reporter genes GFP, RFP and luciferase are not believed to harmful when expressed in mammalian cells. Lentivirus do however integrate into the host cell genome and this is associated with a risk of insertional mutagenesis. These systems are not believed to show an integration bias toward the transcriptional start site regions of DNA like other viral systems therefore the risk from this is minimal.

The vectors are all amphotropic (VSV-G pseudotyped) recombinant HIV-1 lentiviral particles that are replication defective. The viral vector system has been disabled by removal of the HIV-1 virulence genes Vif, Vpr, Vpu and Nef in the helper plasmid. The vector plasmid has the 3'LTR U3 region that encompasses the native viral promoter and enhancer deleted resulting in a self-inactivating vector. Key elements for AAV replication are deleted in the packaged viral particles which renders the vectors incapable of selfreplication. In the event of accidental contamination (sharps, aerosol) the amount of cells transduced will be much lower than that of cultured cells as the protocols are optimised for this system. The VSV-G pseudotype of this lentivirus results in complement sensitivity which increases the likelihood of an immune response against it. This means that only a low number of cells may be transduced through accidental contamination. Environmental stability tends to be increased by VSV-G pseudotyping compared to retroviruses displaying the native envelope. However, retroviral particles remain sensitive to air, temperature and pH and will have short lifespan in an open environment.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

CL2 waste is autoclaved in-house prior to disposal. Bags and Biobins containing CL2 waste should be clearly labelled and should always be sealed using autoclave tape prior to disposal. When a CL2 waste container is full the lid should be sealed using autoclave tape and taken to the autoclave for autoclaving followed by incineration. Waste bags, autoclave tape and Biobins are supplied by the department and should be collected from the distribution points.

Pipette tips can be collected in beakers containing Virkon or Distel. When full, drain the fluid and place the tips in a Biobin. When the Biobin is full put the lid on and seal for disposal.

CL2 liquid waste can be aspirated if it does not contain any chemicals that cannot be disposed of down the sink. Empty aspirator bottles should have Virkon added to them prior to use. If they are more than ¾ full when you finish please empty the contents down the sink and add fresh Virkon.

Chemicals that cannot be disposed of down the sink should be collected in bottles, treated with Virkon or other validated disinfectant compatible with the chemical being used, and put into the Chemical Fume Hood for disposal.

Sharps use must be kept to a minimum in CL2 and must be thoroughly risk assessed. Sharps should be decontaminated (by soaking in Virkon, avoid wiping) and placing in sharps bins. Sharps bins should not be filled past the lid. Once they are full pull the lid across, label as CL2 and place them in the designated collection point.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

This work was considered as part of the Department of Surgery Safety Committee Meeting held on 1st October 2020. Whilst the committee felt that the workers should be encouraged to consider third/fourth generation lentivirus systems for their work, it was acknowledged that the prior experience of the researchers and familiarity with the second generation system provided a compelling argument to use this approach. Risk Assessment Designated Class 2, Containment 2 Activity.

Give brief details of the genetic modification safety committee

Fisher Clinical Services provide a packaging, storage and distribution service for clinical studies to the pharmaceutical industry and as such do not process GMOs in any way. The site is licensed by the MHRA and the licence number is MA(IMP)18693. Processes are conducted according to current GMP 2003/94/EC.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
With regard to waste management, the process has been designed at Fisher so that we are only handling 1 vial at any time. The clean up will follow the specific clean up as stated in the MSDS provided by the manufacturer.

In the unlikely event of a vial being damaged the procedure will be followed and the waste will be separately bagged and labelled as GMO waste for disposal via our licensed contractor.

I have attached the MSDS and our internal SOP for clean up and spillage.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

We have an H&S committee on site here who review H&S matters. COSHH assessments are carried out primarily by myself with an independent review and sign off by a H&S professional. Risk assessments are performed in a similar way.

The COSHH assessment for this product was handled in the same way as above using information supplied by the client.

Give brief details of the genetic modification safety committee

The STL GMSC has been set up to address Health and Safety requirements associated with the use of the ER-CALUX bioassay. This assay uses genetically modified mammalian cells. The GMSC is composed of a range of STL staff whose responsibility it is to ensure that the controls documented in the Genetically Modified Organisms (Contained Use) Regulations 2000 are followed. The GMSC committee (April 2005) is comprised of: Laboratory Manager, Biological Safety Officer, Technical Development Manager (Chair), Principle Scientist (ER-CALUX Project Manager), Site Safety Coordinator, Health, Safety and Environment Manager.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All material and solutions that have been in contact with genetically modified cells, both directly and indirectly will be placed in a discrete autoclave bag. The bag will then be carefully sealed, autoclaved and then stored in a secure place until disposal via a recognised waste disposal company.

Please enter comments of the GM safety committee on the risk assessment

The STL GMSC met on 06/04/05 to consider the risk assessment and safety precautions implemented at STL Bridgend to undertake oestrogenic potency testing using the ER-CALUX bioassay.

The GMSC is satisfied that all associated risk assessments have been completed and the committee agrees with the conclusions of these documents that the use of ER-CALUX meets the category, Provisional containment 1. The committee is also satisfied that the safety procedures implemented meet the requirements on risk minimisation of a Class 1 activity.

Give brief details of the genetic modification safety committee

The VASTox GMSC consists of four members, the COO, and heads of biology and invertebrate biology. All are experienced scientists directly supervising any proposed GM work. All members have previous hands on experience of the GM regulations.

The committee also includes a lay person.

The committee meets every three months with the provision for additional meetings to assess new proposals in order to expedite work.

Solid biological waste is collected in clear autoclave bags in laboratory waste bag holders e.g. Bacterial contaminated disposables. This waste is treated by Autoclaving for 30min@136°C (12mins free steaming), it is then removed to Yellow UN registered sacks and taken for incineration. All records of waste removal are kept for a minimum of 2 years.

Liquid biological waste and associated glassware is disinfected at source by the addition of 11% by volume. The mixed solution is left to stand for a minimum of 1 hour before being discarded down a laboratory sink with cold running water which is left to run for at least 1 minute. The glassware is rinsed before being placed in the designated glassware collection tray located in each laboratory prior to cleaning and autoclaving.

All liquid waste from bacteriological and cell-line work will be treated with Chemgene disinfectant (from Medimark Scientific). This has been tested for bactericidal, viricidal, fungicidal and sporicidal activity by the manufacturer and working dilutions recommended (see http://medi-mark.co.uk/products/product/chemgene-hld4h-ce-marked-high-level-medical-surface-disinfectant).

The recommended dilution for bio-hazard contamination (blood, urine, vomit etc) dilute to 1:20 (5%), for high risk disinfection of organisms in dirty conditions dilute at 1:50 and for general disinfection dilute at 1:100 (1%), (see http://medi-mark.co.uk/images/uploads/CHEMGENE_HLD4H_EN_TEST_SUMMARY.pdf).

All solid biologically contaminated waste will be collected in 30 L or 60 L sealable, leak-proof waste bins prior to incineration. All solid biologically contaminated contained waste is collected by Babraham Research Campus waste management and taken to an off-site facility at the Cambridge Pet Crematorium for incineration.

All solid waste will be autoclaved prior to incineration. An autoclave provided as a central service by the Babraham Institute will be used. This autoclave is tested on an annual basis for an insurance pressure test and serviced at six monthly intervals. The next service and pressure test is due 2/6/05. Autoclaved waste is then taken to an off-site incineration facility at the Cambridge Pet Crematorium for incineration. Information form the crematorium is attached to this form.

The risk assessments have been reviewed and deemed appropriate for the activities to be undertaken.
The cloning and mutagenesis of diptheria toxin, modified diptheria toxin with the membrane targeting domain replaced by human IL-2, and mutants thereof.

E. coli strains: XL1-blue, TG1, BL21 (DE3)

XL1-blue and TG1 are multiple auxotrophs that cannot survive outside a laboratory environment. BL21 (DE3) is disabled and has limited survivability in the environment.

The following vectors will be used with the above hosts:
- pUC derived plasmids - these are non-mobilisable.
- pET51b+, or similar. This vector is also non-mobilisable.

The genetic material will be made by gene synthesis. The diptheria toxin gene will be mutated and tested for retention of function in in vitro and cellular assays. Successful mutants will be modified by replacement of the membrane targeting domain with human IL-2. The modified protein is ultimately intended as an anti-cancer therapeutic.

Both whole toxin and modified toxin and mutants thereof will be expressed using the pET system in small cultures. It is anticipated that the toxin will be secreted to the periplasmic space in an active form. Accidental short-term exposure
To small amounts of native or mutant toxins is likely to cause minimal risk, considering the small amounts of protein being used. In addition, the modified toxin is anticipated to be less toxic than the native toxin since it will be targeted to a much narrower tissue range, i.e. those cell types expressing the IL-2 receptor. Accidental exposure is likely to be at the body surface tissues, e.g. skin and mucous membranes, whereas the most severe effects of the toxin and modified toxin are manifested upon blood exposure. Therefore the use of good microbiological practice in association with PPE will minimize exposure and consequent risk. The use of sharps should be avoided.

The cloned protein is unlikely to alter the host-range or tissue tropism of the GMM since these traits are complex and conferred by more then one protein. However, this enteric bacterium could have additional toxicity, compared to wild-type, if it were able to become established in a human host. However, this risk is negligible due to the disabled nature of the bacterial strain being used. The vectors being used are considered to be non-mobilisable, Gene transfer is thus a very remote possibility. The host organism does not express 6. cili pathogenic determinants and has been shown to be unable to persist in the guts of experimental animals. It is unable to adhere to and colonize the gut and therefore would not be able to accumulate to sufficient levels to cause harm. Contamination is most likely to occur through aerosols and low level splashes, therefore exposure can be minimized by using good microbiological practice in conjunction with PPE. In addition, to minimize the risk from aerosols, all procedures likely to generate these will be carried out in a class II microbiological safety cabinet.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GM will be handled according to good microbiological practices at containment level 2. All liquid waste will be treated with 1% Trigene for at least 30 min prior to disposal down the sink. Contaminated glassware and plasticware will also be disinfected as above. Contaminated solid waste will be double bagged and autoclaved prior to incineration. Spillages will be contained using absorbant material that will then be treated as solid waste. The contaminated area will be wiped clean with 1% Trigene. Trigene has been certified by the manufacturer to effectively kill E.coli at concentrations of 0.5% (see http://www.medichem.co.uk/trigenelab-laboratory.html).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

#### Date of Significant Change

### Project Additional Information

**Purposes of the contained use**  
To create toxin fusion proteins with potential therapeutic use

**Recipient or parental organism**

E. coli strains XL1-blue, DH5alpha, TG1, BL21 (DE3) and derivatives, Origami2(DE3) and derivatives.  
XL1-blue, DH5alpha and TG1 are multiple auxotrophs that cannot survive outside the laboratory. BL21(DE3) and Origami2(DE3) derivatives are disabled and have limited survivability in the environment

**Host/vector system**

The following vectors will be used with the above hosts:  
pUC derived plasmids - non-mobilisable  
pET series plasmids - non-mobilisable

**Origin & function**
The ribotoxins are naturally found in various species of fungi; however for the purposes of this project, the genes will be synthetic. The genes will be cloned into bacterial expression plasmids for the production of mutant proteins for testing for their ability to kill mammalian cell lines.

Y

**Give brief details of the genetic modification safety committee**

A GMSC has been composed to reflect the balance of the workforce at Geneservice Ltd (GSL). The main duties of the committee are to ensure that the facilities are adequate for the purpose and that equipment is correct and properly maintained. Relevant training will be provided to all of the staff concerned, and local rules have been drawn for all procedures. Finally, emergency plans have also been drawn. The committee has reviewed the risk assessments.

The following members of staff constitute the GMSC:

- Chief Operations Officer
- Resource Development Manager
- Biological services
- Biological Reagents & Credit Control

Disposal of biohazard waste

Used tips, tubes, and inoculating loops are to be placed in 'sweetie jars', these are then taped shut with biohazard tape and placed in the yellow biohazard bags. Items such as disposable gloves or paper tissues contaminated with low hazard waste should be disposed of as Biohazard waste. Solid microbial waste will be placed in yellow bags (double bagged), these are then sealed and then autoclaved prior to collection via a designated waste disposal agent for incineration. The agent used is: Vetspeed Limited.

Disposal of microbial cultures

Aqueous microbial cultures are to be treated with Virkon at a final concentration of 1% w/v, left for a minimum of overnight before discarding via the drain with copious amounts of water.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Risk assessment Tomlinson doc and Clone doc

The host vector systems and constructs satisfy the requirements for Group 1. The host strains are all K12 disabled, and the vectors are non-mobilisable. The likelihood of the hazard is therefore negligible and the environmental risk effectively zero.

Risk assessment Sequencing doc

This service aims to sequence already cloned DNA templates, which are sent in by customers. The cloned DNA is effectively random, as far as the service is concerned, but will already have been cloned into the appropriate host/vector system. Once received, the service grows up small volumes of the cells, to obtain a sufficient quantity to extract the DNA and then sequence it. The host/vector systems are all standard and since the inserts are highly unlikely to enhance the pathogenicity, the work is correctly assessed as Class 1. One additional factor is that some DNAs could be potentially hazardous and it is recommended that all naked DNA should be handled appropriately to cover this hazard, ie DNA should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10; ie gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

Clearance has been given by the GMSC that work can be started, pending receipt from the HSE.

The principle method of inactivation of cultures of GMMs will be by treatment in an autoclave (heat inactivation) at 120 degrees C, 15 psi, 20 minutes to achieve effective 100% kill, and following the manufacturer's recommendations for use. All cultures whether in glass or disposable containers will be autoclaved before disposal or recovery of containers. Liquid medium from which micro-organisms have been recovered and contaminated plasticware (Petri dishes, Eppendorf tubes, disposable pipettes and culture tubes etc) will also be sterilised in the autoclave prior to disposal. Day to day monitoring of the autoclave's effectiveness will be checked by inspection of records of each autoclave run. Electronic and printed records of each autoclave run will be retained. The autoclave will be regularly services and tested for effectiveness by the manufacturer.

Apills and leakages of contaminated liquids are to be treated with a suitable disinfectant (eg Virkon) according to manufacturer's recommendations and in accordance with appropriate COSHH guidelines. Disposable tissues used for mopping up disinfectant-treated spills will be autoclaved prior to disposal.

Contaminated sharps will be collected in an approved designated sharps container and disposed of by incineration.

All equipment used in GM procedures including glassware for re-use, and waste materials are autoclaved on site at 121 degrees C for at least 15 minutes, with full steam penetration. The procedure ensures 100% kill and inactivation of the GMO and sterilisation of equipment.

Validation of autoclave conditions is undertaken twice yearly by service testing. Between scheduled service checks confirmation of correct functioning is carried with each load using a steam-chemical integrator device. In event of unsatisfactory operation the load is retained pending suitable repair of the autoclave.

After autoclaving waste material is disposed to landfill with consignments of general waste arising from the laboratory.

Please enter comments of the GM safety committee on the risk assessment

The proposal and risk assessments were distributed to members of the Burnham health and safety panel and discussed at a meeting on 14th October 2004. The risk assessments were subsequently updated to include ergonomic factors for operators of pipettes and discussed again at a meeting in January 2005. The committee were content with the assessments and endorsed the Notification of Intention to use premises for contained use activities.

Risk assessments updated, reviewed by Divisional Risk Assessment Champions and accepted as ‘HS16 AHH-EAH-ECORA RA-18 YES-YAS Assays’ in January 2013.

# Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

GM risk assessments will be considered by the already established GM safety committee of the MRC Laboratory of Molecular Biology (HSE ref. GM20).

This committee includes management, staff and user representatives, together with the Biological Safety and Medical Officers and also external representation.

| Level 1 (GMMs) | Yes | Level 2 (GMMs) | Yes | Level 3 (GMMs) | Yes | Level 4 (GMMs) | Non-microbial | Laboratory | Animal Unit | Growth Room | Glass House | Large Scale |
|----------------|-----|----------------|-----|----------------|-----|----------------|---------------|-------------|-------------|-------------|-------------|-------------|-------------|

Page 11951 of 15326
Solid waste is collected and transferred in secure containers to an incinerator, which is notified for Class 1 GM work, and then incinerated. This is considered to give 100% killing.

Liquid waste will be inactivated by autoclaving, which is considered to give 100% killing, or else will be inactivated by validated chemical means. The disinfectant used will be chosen depending upon the host cells involved, but in all cases will be validated for the purpose.

Work on human genes (including primary cell cultures) for cancer or nutritional studies.

For activities involving GMMs, describe the waste management measures which will apply to the activity

This work involves the growth and screening of a commercial yeast library in which individual genes have been knocked out. The aim is to identify genes involved in ubiquinone transport from mitochondria. The host is disabled and there is nothing to increase its hazard. The work is therefore correctly assessed as Class 1.
Project Additional Information

Purposes of the contained use
Overproduction of the V-ATPase of E. hirae into which the V-ATPase operon has been cloned. (This work is self-cloning and the GMM has already been constructed and characterised elsewhere.)
The overproduction is wanted to allow purification of the V-ATPase for structural studies.

Recipient or parental organism
Enterococcus hirae (formerly Streptococcus faecalis), ATCC9790 and 25D.

Host/vector system
E. hirae (as above) as host; pHY300LK vector.
This is a commercially available, mobilisation defective vector from Yakuruto Co. (Japan). It is one of the smallest hybrids of a series of chimeric plasmids using the parental plasmids pACYC177 of E. coli and pAM-a of Streptococcus faecalis. This shuttle vector for E.coli and B. subtilis contains an RNA primer gene for ori-177; the R-Tc gene; the R-Ap gene; Rep-alpha-1 gene, which is the plasmid replication gene; two replication origins, one for E. coli and the other for B. subtilis; and a polylinker.

Origin & function
The genetic material cloned is derived from E. hirae and is cloned back into the micro-organism as host, i.e. the work is self-cloning. The resultant construct has already been characterised elsewhere (in Japan) and the work within the UK will involve growth, cell lysis and purification of the cloned protein.

Evaluation of foreseeable effects
Enterococcus hirae is a human commensal, which occurs in the intestine of normal healthy people and only occasionally causes disease due to getting into the wrong environment (e.g. the bloodstream). Since it can cause disease, it is classified as a Hazard Group 2 pathogen - in the same way as Eschericia coli.
The genetic modification involves self-cloning of an operon from E. hirae, in order to obtain increased yields of the protein product from this operon. The protein is membrane bound and will not increase the pathogenicity of the host (which it naturally).
The only foreseeable affect is the disabling of the E. hirae, due to overproduction of one protein rather than the appropriate amount being made as in the wild-type cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Only micro-organisms involved in this work.
Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After growth, the micro-organisms will be centrifuged and collected. The culture supernatant will be disinfected with a clear phenolic disinfectant. During the initial experiments the optimum disinfection conditions will be determined, to obtain <1 viable cell/ml, and these conditions then be applied to all supernatants before discharge down the drain into the public sewer. The cell pellet will be resuspended and the cells lysed to prepare the protein. Any substantially solid residues will be inactivated by autoclaving at 135 for 15min, which is expected to give - 100% killing.

### Project Additional Information

**Purposes of the contained use**

To study the pathways regulating differentiation of human cells, in particular how stem cell fate is regulated.

**Recipient or parental organism**

Human and mouse tissue culture cell lines.

**Host/vector system**

Laboratory strains of E. coli K12.  
Phoenix-ecotropic and amphotropic retroviral producer cells.

**Origin & function**

Inserts used are all derived from mouse, human and Xenopus cDNA libraries and comprise wild type and mutated forms of Notch ligands, Notch receptors, suppressor of hairless homologues, mastermind homologues, and Notch target genes including the hairy/enhancer of split family of transcription factors. In addition mutant Xenopus beta catenin and mutants of MAP kinase will be expressed to determine how the Notch pathway interacts the wnt and Map kinase signalling pathways. Cell cycle inhibitory proteins such as p21Cip1 and Geminin will also be used.

In addition reporter constructs derived from the pGL3 series of vectors will be used; these consist of Notch and wnt responsive promoter elements, driving expression of the firefly and renilla luciferase genes.  
In some experiments green fluorescent protein will be expressed as a reporter.

The intended use is to study how these genetic elements control the cell development.

**Evaluation of foreseeable effects**

The main hazard arises directly from the recombinant retroviruses produced from the packaging cells. These yield both ecotropic and amphotropic retrovirions, depending upon the envelope protein supplied by the cell.
The packaging cell lines used to generate the retrovirus have either ecotropic or amphotropic envelope proteins, and the retrovirus therefore can either infect only mouse cells, or have a wider host range including human cells. Their infectivity is unstable and infection is only obtained by co-cultivation of the packaging cell line with their recipient cells. The retrovirus is self-inactivating and there is thus no possibility of further transfer. With the ecotropic packaging cell line, there is therefore negligible risk to the worker or the environment.

With the amphotropic packaging cell line, the risk of infection of a worker during the packaging/infection step is small, but still not negligible. Although the inserted genes are not known to be oncogenic, they have this potential and it is considered that this part of the work is Class 2. In view of the, at worst, low-oncogenic nature of the inserted genes and also the self-inactivating nature of the retroviruses, there likelihood of any hazardous replication competent virus being generated is negligible and is no need to test for such RCV.

The single non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of some of the inserts. This risk can be controlled if DNA grown up from such clones is handled appropriately; ie gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 mins), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

Is an emergency plan required according to regulation 20? No

Tick to confirm that it is attached to this form No

Tick确认 that you have attached a risk assessment to this form Yes

Tick if you are claiming exemption from disclosure for section of the risk assessment No

Please enter comments on the GM safety committee on the risk assessment

This work involved the cloning of some potentially oncogenic genes into disabled retrovirus vectors, with the use of packaging cell lines which have an amphotropic envelope protein.

From the ACGM Compendium of Guidance, Part 2B, Annexe III, particularly para. 30, this requires Class 2 (as already concluded in the risk assessment).

The Committee noted that the risk of the potentially oncogenic DNA had already been considered in the assessment.

**Project Containment**
PROJECT REF 20/02.4

FUNCTIONAL SILENCING OF GENES INVOLVED IN DNA REPAIR AND CELL CYCLE: 2

Date Ackn'd: 02/08/2005
Date Project Ceased: 03/09/2013

Class 2
Culture Volume Class 3-4

Consent Granted: Not Applicable

Tick if notifying a connected programme of work: N

Historical Significant Changes: Transferred from GM20 on 02/08/2005, Project transferred to GM3201 03/09/2013

Project Additional Information

Purposes of the contained use
To functionally silence genes whose inactivation in cancers gives rise to genetic instability, using a recently developed stable RNA interference approach, to ascertain the molecular basis for the abnormal division of cancer cells and their increased genetic instability.

Recipient or parental organism
Tissue culture cells of human origin.

Host/vector system
Laboratory strains of E. coli K12 derivatives; tissue culture cells of human origin.
pUC-based plasmid vectors with RNA polymerase III promoter (e.g., pSUPER);
Phoenix-amphotropic retroviral producer cells.

Origin & function

The plan is to use vectors based on pSUPER in which an RNA polymerase III promoter drives expression of a short (~25 mer) interfering RNA from a synthetic DNA insert. Details of the categories of interfering RNAs to be inserted are as follows:

A) RNAs which target DNA double-strand break repair pathways: The proteins encoded by BRCA1, BRCA2, RAD51 and its paralogs, Nbs1, ATM, ATR, Ku70, Ku80 and DNA-PK are nuclear molecules which participate in the sensing and repair of DNA double-strand breaks. In mice, homozygosity for null mutations in these genes leads to cell death, embryonal lethality and a DNA repair defect accompanied by genetic instability.

B) RNA which target cell cycle regulators: The proteins encoded by the mammalian cyclin/CDK genes, the mitotic kinases Pik1, nek1, Aurora-A/B/C, Bub1/BubR1 and the chromatid cohesion molecules Scc1, SMC1/3 and Eco1, are required for cell cycle progression and mitosis.

C) RNAs which target regulators of the G1, S and G2/M checkpoints: These inserts will include proteins encoded by checkpoint regulators such as p53, chk1/chk2 and chfr, or proteins involved in the downstream enforcement of these checkpoints (including cdc14, ranGAP, cyclin G, cdc25 or PP1).

Evaluation of foreseeable effects

The inserts encode short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

A non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras 8-10, in which the potential hazard is specifically considered.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

It is expected that these will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
This work involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNA. The genes targeted in this work are those for sensing and repair of DNA double-stranded breaks, cell cycle progress and mitosis, and checkpoint regulators or downstream enforcement proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled retroviral vectors, which require a helper t.c. line to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse emphotropic cell lines, with the packaging construct in more than one component, to produce the disabled retrovirus with an amphotropic envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras 21-30, it was agreed that Class 2 is appropriate for this work. If cell lines are being maintained for a long time, consideration should be given to testing them for the presence of replication competent virus.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

**Project Additional Information**

**Purposes of the contained use**

The project aims to determine the molecular basis of the differentiation of human and mouse epithelial cells. Pathways regulating differentiation include Notch, wnt and the MAP kinase signalling cascade. In addition we wish to explore the interaction of Notch with cell cycle regulators such as p21 Cip1 and Geminin.

**Recipient or parental organism**

Tissue culture cells of human or murine origin.

**Host/vector system**

Laboratory strains of E. coli K12 derivatives; tissue culture cells of human origin.

pUC-based plasmid vectors with RNA polymerase III promoter; Phoenix-amphotropic retroviral producer cells.

**Origin & function**

The expression of inserts encoding siRNAs, consisting of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA, in human primary epidermal keratinocytes, mouse primary keratinocytes and mouse and human cell lines, including squamous carcinoma cells and telomerase immortalised keratinocytes. Once expressed the siRNA oligonucleotides are expected to decrease levels of RNA encoding the target protein by over 70%.

Target genes are those of the pathways regulating epithelial stem cell fate, including Notch receptors, suppressor of hairless homologues, mastermind homologues, and the hairy/enhancer of split family of transcription factors. In addition components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins such as p21 Cip1 and Geminin will also be targeted.

Control siRNAs directed against enhanced green fluorescent protein and luciferase will be required for some experiments.

**Evaluation of foreseeable effects**

The inserts encode short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not
enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

Purposes of the contained use
To use somatic cell line knockout technology to generate assay reagents for combinatorial libraries of potential therapeutic compounds and for pathway analysis of potential new therapeutic targets.
This project requires gene disruption through homologous recombination in human epithelial cells in vitro; rAAV (adeno-associated virus) vectors permit such knockouts in human cells.
Inserts will encode LoxP sites, human genomic targets and positive selectable marker genes (eg neomycin or hygromycin). Target cells are human epithelial cell lines, including HCT-116, DLD1, A549, CAL51 and MT3 cell lines. These cells will be infected with rAAV (eg AAV-293).
Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

Origin & function
Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

Evaluation of foreseeable effects
The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.
The one significant hazard arises from the rAAV produced from the packaging cells. This is capable of infecting human cells and contains inserts designed to knockout target genes in the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3. Their effect is therefore considered as potentially oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The work involves the cloning of inserts to knockout various genes, their incorporation into recombinant adeno-associated virus (rAAV) and the subsequent infection of human epithelial cell lines, in order to establish stable cell lines with the appropriate genes knocked out. The target genes are those in the pathways regulating DNA repair, apoptosis and histone acetylation, including BRCA2, HDCA1, SITR1 and ADA3. The host cells are all highly disabled and the modifications will not increase their pathogenicity. With the exception of the rAAV, the vectors are non-mobilisable and present no risk. The exception is the AAV, which can infect human cells.

Knocking out the target genes is potentially oncogenic and, while this is highly unlikely to increase the pathogenicity of the intended host cells, it does present a risk to workers who might become infected with the rAAV.

For this reason the packaging and infection steps are considered as Class 2, while the preliminary cloning steps and subsequent propagation of any modified cells are Class 1.

(Note from BSO: I have taken advice from HSE and the Inspector, to whom I was referred, agreed with this assessment.)

Project Additional Information

Purposes of the contained use

Cancer cells exhibit abnormalities in cell cycle progression, chromosome structure and segregation and in the capacity to repair DNA damage that are central to transformation. These abnormalities are often the result of mutations in tumour suppressor genes, such as the breast cancer gene BRCA2. The overall goal of our studies is to ascertain the molecular basis for the abnormal division of cancer cells, and their increased genetic instability.

Recipient or parental organism

Murine-embryo-fibroblasts and HeLa and other cancer cell lines.

Host/vector system

E.coli laboratory K12 derivatives/pUC based vectors; Vertebrate tissue culture cells including 293T cells, murine-embryo-fibroblasts and HeLa and other cancer cell lines/Lentiviral vectors, with polytropism through viral
pseudo-typing using VSV-G protein.

Lentiviral system:  The viral system to be used employs a well-characterised lentiviral vector and packaging cell lines(Refs below). A number of safety features are incorporated to eliminate or very greatly reduce the possibility of generating productive recombinants. The vector lacks gag, pol, env, tat, rev, vpr, vpu, vif and nef functions. A chimeric LTR offsets the requirement for Tat in expressing genes transcribed from the LTR. The Rev function is provided in trans from a separate plasmid in the packaging cells, as are the Gag/Pol functions. The viral vectors are self-inactivating due to deletions in both the LTRs, and thus incapable of replication after one round of infection of target cells. The packaging cell lines are effectively helper-free, since the rev, gag/pol and env (in this case, pseudo-typed with VSV-G protein) genes are expressed from separate plasmids. Rubinson et al Nat Genetics 34:231 (2003); Dull et al., J Virol 72:8463 (1998); Myoshi et al J. Virol 72:8150 (1998).

Origin & function

Specific aims with details of the categories of inserts to be used are as follows:

A)  BRCA2-deficient cells exhibit defects in DNA repair (1). The defect is likely related to the inability of mutants BRCA2 to form functional complexes with RecA homologs in the Rad51 family (eg Rad51, xrc2 & 3, Rad51B-D). The molecular basis for this phenotype will be studied by functional and biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

B)  Abnormalities of chromosome structure and number are abundant in BRCA2-deficient cells (2-4). To investigate the molecular basis for these phenotypes, the function of genes controlling chromatin structure (eg histones, histone-modifying-enzymes, HP1), the cell cycle (eg cyclins A, B, D, E; cdks 1, 2 & 4, polo-like kinases), chromosome number and structure (eg SMCs1 & 3, scc1, Ecol), cytokinesis (eg chromokinesins, INCENP, surviving) and the centrosome cycle (eg nek1, nap, g-tubulin, aurora kinases) will be investigated by functional & biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

C)  We have shown that mutations inactivating mitotic checkpoint genes including Bub1 or Mad3L (BubR1), are necessary for the neoplastic transformation of cells lacking the BRCA2 tumour suppressor (5). Besides these, we will test the possibility that genes (eg chk1/chk2, cdc14A/cdc14B, PP1delta, cdc25C, m TERT or h TERT, ranGAP & cdt1) whose normal function is to regulate cell cycle progression and chromosome stability, particularly during the S phase and in mitosis, will be targets for inactivation by secondary genetic changes during tumour evolution in cells that lack genes such as BRCA2, using studies of transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

D)  To identify novel genes that regulate these processes, cells will need to be transfected with pools (libraries) of vertebrate cDNAs or short-hairpin RNA molecules that interfer with the expression of vertebrate genes, for phenotypic screens. Here, the precise nature of the insert cannot be specified in advance.

In A-C above, fusions of wild-type & mutant genes to GFP or other fluorescent tags will be used to determine intracellular localisation.

3)  Yu et al., Genes Dev 14:1400 (2000)
5)  Lee et al., Molecular Cell 4:1-10 (1999)

Evaluation of foreseeable effects

Possible changes in the behaviour of cells in tissue culture, helping to elucidate the abnormal division of cancer cells, and their increased genetic instability.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge doen the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

## Project Additional Information

### Purposes of the contained use
The project aims to determine the molecular basis of the function of EMSY in mammalian cell lines. EMSY binds to the tumour suppressor protein BRCA2, inhibiting its function and is over expressed in breast and ovarian cancer.

### Recipient or parental organism
Target cells will be established mammalian cell lines, including human cells.

### Host/vector system
Target cells will be established mammalian cell lines, including human cells. Replication incompetent lentiviral supernatants from commercial sources, typically packaged with VSG or an amphotropic receptor. If it is found necessary for sufficiently stable siRNA production, a WPRE element may be incorporated in the vector.

### Origin & function
Inserts will encode RNA silencing constructs directed against the EMSY protein. Typically the inserts consist of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA. Control siRNA constructs directed against housekeeping transcripts or reporter genes and non functional mutant siRNAs may also be expressed. Vectors may also encode reporters such as EGFP or selectable markers such as puromycin.

### Evaluation of foreseeable effects
EMSY is amplified in breast and ovarian cancer. Knockdown of EMSY is not predicted to have any oncogenic effects. The aim of this study is to see what effect such knockdown does have on mammalian cell lines.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Only micro-organisms involved in this work.

- For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
  
  Full CL2 will be used, with no derogation.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Containment level 2 waste will be autoclaved (136°C for 10min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Page 11970 of 15326
This work involves the use of purchased replication incompetent retroviral vectors, with amphotropic envelope proteins, which contain and express siRNAs against the mRNA for EMSY. In view of its involvement with BRCA2, it is considered that this may be potentially oncogenic. The recombinant retrovirus will be used to infect mammalian (including human) cell lines. In view of the potentially oncogenic nature of the insert into amphotropic disabled retrovirus, it was agreed that classification as Class 2 was correct. It was noted that this classification would also allow the use of vectors containing the WPRE element, should this prove desirable.

### Project Additional Information

**Purposes of the contained use**

Kid protein is toxic to mammalian cells and Kis protein protects from this effect. When they are expressed together in mammalian cells, death or cell survival depends on the ratio between Kid and Kis that cells are able to sustain. This is potentially a therapeutic or experimental tool. The ratio can be controlled at the level of transcription,
mRNA stability and protein stability. We want to exploit the genetic differences between normal cells and cancer cells to regulate, differentially, the Kid-to-Kis ratio in these cells, so that cancer cells are killed and normal cells are protected from toxicity.

Recipient or parental organism

Murine and human cells (primary cells, cancer cell lines and immortalized cell lines)

Host/vector system

1) E. coli, laboratory K12 derivatives/pUC based vectors;

2) Vertebrate tissue culture cells, human and mouse, including as examples 293T cells, murine-embryo-fibroblasts and HeLa and other human cancer cell lines and immortalised normal cells; and primary cultures of human and mouse cells.

3) Adenoviral vectors and Lentiviral vectors (the latter with polytropism through viral pseudo-typing using VSV-G protein)

3.1.) Adenoviral system: The adenoviral system to be used employs a well-characterised vector and packaging cell lines (Refs below). Second generation replication defective human adenovirus serotype 5 derived adenoviral vectors will be used for expression of Kis and/or Kid proteins. Vectors are rendered replication defective by the deletion of the E1 and E3 genes. The E1 gene is essential for the assembly of infectious virus particles and is complemented in vivo by an adenovirus packaging cell. The E3 gene encodes proteins involved in evading host immunity and is dispensable (Luo et al, Nature Prot., 2 (5): 1236 (2007))

3.2.) Lentiviral systems: The two types of viral system to be used employs two well-characterised lentiviral vector and packaging cell lines (Refs below).

3.2.1.) Type A (eg. pLenti6-UbC-V5DEST from Invitrogen):

- The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replicant-competent virus (Dull et al., J Virology 72 8463-8471 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTR's or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced,
- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes from pLP1 has been rendered Rev-dependant by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.
- A constitutive promoter (RSV promoter) has been placed upstream of the 5 LTR in the lentiviral vector to offset the requirement for Tat in the efficient production of viral RNA. The 3LTR region has a deletion that promotes self inactivation of the viral genome upon integration in the host genome.

3.2.2.) The lentiviral packaging systems mentioned above (type A) is a third generation versions that utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-por sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbors the sequences required for independent replication. Type B (Clontech’s Lenti-X HT) Packaging System also uses a split-gene packaging strategy, but adds another level of safety by further uncoupling pol (RT and IN) from gag-pro. The result is that gag, pol and env reside on three physically distinct entities, rather than the standard two. This approach further reduces the possibility of creating RCV to a level below that of standard 3rd generation packaging systems, because extra recombination events are required to create such viruses. In fact, the emergence of RCV is undetectable from systems using this approach (Wu, X., et al. (2000) Mol. Ther. 2 (1):47-55.). These improvements significantly increase the safety profile of our Lenti-X HT Packaging System.

Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All
essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix (described above).

In brief, the number of genes from HIV-1 that are used in type B system has been reduced to four (i.e. gag, vpr-pol, rev and tat).

. Genes encoding the structural and other components required for packaging the viral genome are separated onto five plasmids. This reduces the incidence of replication competent lentivirus to levels below that of the system A above.

. Although the four packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain HIV-1 LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.

. The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

. Expression of the gag, tat and rev genes from the packaging plasmids is directed by tetracycline dependant promoters (PrTRE). Therefore their expression requires supplying TetR- VP16 in trans, and it is only active in the absence of doxycycline in the growth medium.

. In this system, expression of tat is required in the packaging cell line, because the lentivirus vector contains an intact HIV-1 5LTR, which allows very high titers in viral preparations.

Origin & function

The overall purpose is to introduce Kis and Kid protein expression into mammalian cells, control that expression and monitor expression. Inserts will encode reporters, such as EGFP, Ds Red; transcriptional regulators such as TetR; prokaryotic genes encoding ribonuclease Kid and its counteracting protein Kis; and transcription and post-transcription-regulating sequences of prokaryotic and mammalian origin.

Genes Kis and Kid will include wildtype, inactive mutants and fusion variants (e.g. fused to unstable protein domains), and they will be expressed under the control of viral and mammalian promoters, both constitutive (e.g PrCMV, PrUbC, PrEF-Ialpha) and/or repressible (e.g regulated by TetR).

Evaluation of foreseeable effects

Some of the virus vectors will kill infected mammalian cells, so some of the vectors will be toxic to human and mammalian cells. Also because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMS - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136º C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Adenovirus vectors: (Risk assessment H2008-009)

This individual RA H2008-009 is an assessment for adeno vectors, and so the main issue is whether, and in what way, the inserts are hazardous to human cells. Oncogenic inserts would be Class 2, most other inserts Class 1. As some of the inserts are toxic, we have chosen precautionary Class 2 containment for the active toxic insert work only. The majority of the work proposed will be concerned with establishing control of expression and this can be done with inactive mutants, in Class 1.

The principal concern here is that, for some of the inserts, the virus generated and the packaging/producer cells are effectively toxins that could kill one human cell per virus particle, though the act of killing the cell would disable the virus. Handling and storing the producer cells and supernatants is therefore similar to handling cholera toxin, ricin, or phalloidin. Those involved must be made aware of this.

A subsidiary concern would be propagation of the virus, but the virus is sufficiently disabled to eliminate this. E1/E3 deleted adenovirus is generally accepted as disabled and, with wild-type adeno being HG2 this allows the mutant to be HG1. Once the virus has infected a target cell those cells pose no particular hazards, since the toxin involved is intra cellular.

Lentivirus (RA H2009-002)

The issues in this work are (i) the expression of the toxin Kid in lentiviral vectors, and (ii) the lentivirus vectors themselves, which, if they carry the complete WPRE, are potentially oncogenic and current guidance is to use them in CL2 regardless of their tropism. Both these have been considered by us before. (i): toxin-expressing human host range virus is toxic to cells in a similar way to a strongly toxic lab reagent and should be treated as such. They are borderline CL1/CL2 but we have previously chosen to recommend CL2. (ii) The lentivirus work does require CL2 when the vectors incorporate the putatively-oncogenic complete WPRE element. The E.coli work raises no particular issues as the vectors do not express in bacteria.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

The construction work in E. coli is correctly assessed as Class 1.

Project Additional Information

Purposes of the contained use

We aim to identify genes that could play a significant role in the transformation of human oesophageal epithelium towards cancer via the development of Barrett's oesophagus and the acquisition of a malignant phenotype. Several candidate genes have been identified in literature as potential regulators for this switch in phenotype. Most of them are transcription factors, they include HoxGenes (identified in a current project in the lab), NHF4a, p63, CDX2 and C/EBP and they are potential oncogenes.

Recipient or parental organism

Packaging cells HEKs93
Oesophageal cells:
1. Primary cells will be isolated from human squamous oesophageal resection specimens and processed to obtain single cell suspension (separate Risk Assessment RCF 041 for human tissue). For this purpose freshly isolated, cultured cells will be used.
2. Other established human oesophageal cell lines (normal and from cancer).

Host/vector system

HEK293 (human embryonic kidney) cells, that, by producing the adenovirus E1 gene in trans, allow the production of infectious virus particles when cells are transfected with E1- deleted adenovirus vectors such as the pAdEasy-1.

Vector:
Purified recombinant Ad plasmid DNA is digested with the restriction enzyme Pac I to expose its inverted terminal repeats (ITR), and then used to transfect AD-293 (or HEK293) cells which have complemented in vivo viral assembly genes are:

Oesophageal cells/Adenoviral particles
Hosts:
1. Primary cells will be isolated from human squamous oesophageal resection specimens and processed to obtain single cell suspension (Risk Assessment RCF 041). For this purpose freshly isolated, cultured cells will be used.
2. Other established human oesophageal cell lines (normal and from cancer) might be used.
Vector:
The adenoviral particles generated as above. The regions E1 and E3 of the viral genome have been deleted. E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cell); the E3 region encodes proteins involved in evading host immunity. Therefore the host cells which do not have the E1 region cannot replicate the virus or integrate it into the genome.

Origin & function
Inserts will be from Human genomic DNA and cDNA sequences cloned in bacteria. These inserts will be genes thought to be relevant to the transformation of human oesophageal epithelium.

Evaluation of foreseeable effects
The bacterial construction system cannot generate hazardous particles from the cloned inserts and for this reason a Cat I containment level would be adequate and this part of the work is not described here.

The target cells (human oesophageal cannot replicate the virus or integrate its DNA in the genome. However, it is possible that the pathogenicity of the host cells would be enhanced by the inserts. In addition, the nature of the host cells (untested human primary cells) requires a containment level (Cat II) adequate to this risk.

Furthermore, the regions E1 and E3 of the viral genome have been deleted. E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cell); the E3 region encodes proteins involved in evading host immunity.

HEK293 contain the E1 gene that allows gene replication and therefore also the "amplification" of the viral stock solution requires an adequate (Cat II) containment level.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Cat II containment level is adequate.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Only micro-organisms and tissue culture cells are involved

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Please enter comments on the GM safety committee on the risk assessment
This is a relatively typical case of adenovirus vector transduction of human cells in culture, and should be Class 2. The lab concerned already is familiar with Class 2 working, as the target cells are human primary material. The application specifically acknowledges the need to take care when storing adenovirus stocks outside the Class 2 lab, as discussed by the Hutchison-MRC safety committee.

### Project Additional Information

**Purposes of the contained use**

The project aims to investigate strategies to modulate the differentiation of human and mouse embryonic stem cells, differentiated cells and tumour cells by introduction of genes including transcription factors and cell cycle regulators using lentiviral vectors.

**Recipient or parental organism**

...
Murine and human cells (packaging cells, primary cells, cancer cell lines and immortalized cell lines).

**Host/vector system**

1) E.coli, laboratory K12 derivatives/pUC based vectors;

2) Vertebrate tissue culture cells including 293 T cells, embryonic stem cells, human cancer cell lines, and cells including fibroblasts and neuroblastoma and glioblastoma cell lines derived from patient samples.

3) Lentiviral vectors

3.2) Lentiviral systems: the two types of viral system to be used employs two well characterised lentiviral vector and packaging cell lines.

3.2.1) Type A (e.g. pFUV and tet-ON derivatives thereof), 3rd generation:

. The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
. Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural and other components required for packaging the viral genome are separated onto four plasmids.
. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
. The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
. In some cases expression of our gene insert of interest will be drive expression off a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

3.2.2) Type B (e.g. LentiX0HTX from Clonetech), 4th generation

The lentiviral packaging systems mentioned above are 3rd generation versions that utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Type B (Clontech’s Lenti-X HT) Packaging System also uses a split gene packaging strategy, but adds another level of safety by further uncoupling pol (RT and IN) from gag-pro. The result is that gag, pol and env reside on three physically distinct entities, rather than the standard two. This approach further reduces the possibility of creating RCL to a level below that of standard 3rd generation packaging systems, because extra recombination events are required to create such viruses. In fact, the emergence of RCL is undetectable from systems using this approach (Wu, X, et al. 2000) Mol. Ther. 2(1):47-55.) These improvements significantly increase the safety profile of our Lenti-X HTX Packaging System.

Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix (described above).

In brief, the number of genes from HIV-1 that are used in type B system has been reduced to four (i.e. gag, vpr-pol, rev and tat).

. Although the four packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293 T derived producer cell lines, none of them contain HIV-1 LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

In this system, expression of tat is required in the packaging cell line, because the lentivirus vector contains an intact HIV-1 5LTR, which allows very high titers in viral preparations.

In some cases expression of our insert gene of interest will be driven expression of a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard.

**Origin & function**

Genes and mutant derivatives thereof, usually of human, mouse or Xenopus frog origin, encoding both growth control proteins and transcription factors, along with marker genes such as GFP and antibiotic resistance genes.

**Evaluation of foreseeable effects**

Some of the virus vectors will lead to growth arrest and differentiation of mamalian cells, while there is potential to promote cell proliferation. Because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Cat II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms and tissue culture cells are involved.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

**Is an emergency plan required according to regulation 20?**

**Project Additional Information**

The project aims to determine how candidate genes may function in tumour progression or stromal cell function (e.g. gp38). We will study their phenotypic and functional changes following modification: e.g. a) in cancer cells: the acquisition of malignant features such as increased motility and invasive capacity, b) in stromal cells: changes to junctional properties and interaction with infiltrating immune cells.
Recipient or parental organism

a) Murine cells (for example, isolated tumour and stromal cells and commercially available, immortalized well-established cell lines).
b) Human cells (including packaging cells e.g. HEK293, established well-characterised cancer and stromal cell lines).

Host/vector system

1) E. coli, laboratory K12 derivatives/pUC based vectors;
2) Mammalian tissue culture cells including human cancer and mouse cell lines. Human hosts include for example, HEK293T packaging cells, well-established human cancer and stromal cell lines. Examples of mouse hosts include stromal cells such as fibroblasts (normal dermal, lymph node stromal and tumour-associated) and tumour cells either isolated or purchased as commercially available cell lines.
3) Viral vectors: The viral systems to be used employ well characterized vector systems packaging line
   3.1) Lentiviral systems:
   3.1.1) Commercially available, verified transduction ready viral transduction particles e.g. MISSION sequence verified shRNA lentiviral transduction particles (pLKO.1-puro).
   3.1.2) Third generation lentiviral particle generation using the 3-plasmid method
   ● The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
   ● Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
   ● Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
   ● The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Virally transduced cells will not leave Class II containment until negative results are obtained from HIV-1 p24 ELISAS. This measures viral titres and ensures no residual viral proteins are present in the supernatant of transduced cells.

3.2) Adenoviral systems expressing Cre recombinase (AdCMV-Cre) or fluorescent marker proteins
   3.2.1) Commercially sourced, pre-titred replication deficient virus constructs
   ● The Adenoviral particles purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.
   3.2.2) Assembly of virus using the AdEasy system (or similar)
   ● Cre recombinase is a Type I topoisomerase from P1 bacteriophage that catalyzes site-specific recombination of DNA between loxP sites. P1 sequences are not found in the human genome, therefore cre-recombinase expression would be expected to have no impact on the cell
   ● Recombinant adenoviruses exhibit a wide tissue tropism and could potentially infect a range of mammalian cells, however, the particles being used are replication deficient due to elimination of E1 and E3 genes.
   ● The Vectors do not integrate into the genome.

Origin & function

Gene constructs and mutant derivatives thereof, usually of human or mouse origin, a) encoding candidates genes deemed important in tumour progression and stroma function e.g. gp38, b) cre recombinases to mediate specific recombination events, along with marker genes such as GFP and antibiotic resistance genes.

Evaluation of foreseeable effects

Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.
The main Hazard is potential of persons working in the lab by the GM virus, for which a Class II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Once negative viral titres have been measured, work with these genetically modified cells can be undertaken at a Class I level of classification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Micro-organisms and tissue culture cells are involved

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class 1 level of classification.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

As per Hutchinson /MRC research Centre standard practice guidelines (unless the risk assessment demands more stringent measures)

CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus)

Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.

Bacterial Plates are autoclaved in the building.

Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contractor (Novus).

It is expected that these measures will give effectively 100% killing.

This is a fairly standard proposal to use lentivirus (for various genes) and adenovirus (for cre) to genetically manipulate murine and human cells. The inserts proposed do not seem particularly hazardous.

**Project Containment**

02/03/2022
### Project Additional Information

**Purposes of the contained use**

We plan to use viral vectors to insert or delete candidates identified by transcriptomics or metabolomics analyses as being important in cell metabolism of both epithelia and stromal cell during tumorigenesis. We will study their phenotypic and biochemical changes following modification: e.g. a) in cancer cells: the changes of their malignant features such as increased motility and invasive capacity and changes in core metabolic pathways, b) in stromal cells: changes of core metabolic pathways and transdifferentiation into cancer associated stromal cells.

**Recipient or parental organism**

Murine fibroblasts and murine kidney epithelial cells obtained from Fumarate Hydratase deficient mice, primary and immortalised cell lines and tissues from other genetically engineered mice and well characterised human normal and cancer cell lines (including HEK293T that will be used as packaging cells for virus production).

**Host/vector system**
1) E. coli, laboratory K12 derivatives/pUC based vectors;

2) Mammalian tissue culture cells including human and mouse cell lines. Human hosts include for example, HEK 293T packaging cells, well-established human cancer and stromal cell lines. Examples of mouse hosts include epithelial cells, stromal cells such as fibroblasts and tumour cells either isolated or purchased as commercially available cell lines.

3) Viral vectors including retrovirus, lentivirus and adenovirus as follows:

**RETROVIRUS:** Modified cell lines will be created by the transduction with retroviral particles generated from appropriate packaging cell lines (see below) after their transduction with retroviral plasmids and will be based mostly on the following backbones:
1. The pBABE vector is derived from the Moloney murine leukemia virus (MMLV).
2. The pRETROSUPER vector is derived from the Murine Embryonic Stem Cell virus (MSCV).

**LENTIVIRUS:** Modified cell lines will be created by the transduction with lentiviral particles generated from appropriate packaging cell lines (see below) after their transfection with lentiviral plasmids and will be based mostly on the following backbones:
2. TRC1 and TRC2 pLKO.1-puro
3. pGIPz
4. pTripz
5. Transduction ready particles generated from the above and purchase directly from the suppliers

**ADENOVIRUS:** modified cells will be obtained by direct infection with commercially available adenoviral particles of adenoviral particles generated as follows.

1) Commercially sourced, pre-titred replication deficient virus constructs
   - The Adenoviral particle purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.
2) Assembly of virus using the AdEasy system (or similar)

**Origin & function**

Gene constructs and mutant derivatives thereof, usually of human or mouse origin, a) encoding candidates genes deemed important in cell metabolism, b) cre recombinases to mediate specific recombination events, along with marker genes such as GFP and antibiotic resistance genes. c) fluorescent markers targeted to different subcellular compartments.

**Evaluation of foreseeable effects**

**ADENOVIRUS**

The adenoviral particles purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.

Cre recombinase is a Type 1 topoisomerase from P1 bacteriophage that catalyzes site-specific recombination of DNA between loxP sites. P1 sequences are not found in the human genome, therefore cre-recombinase expression would be expected to have no impact on the cell.

Cells isolated from murine tissues with loxP sites will be from normal or tumour-associated tissues and are expected to be similar in nature to established fibroblast cell lines. Therefore, these cells are not anticipated to pose a hazard to human health.

Recombinant adenoviruses exhibit a wide tissue tropism and could potentially infect a range of mammalian cells, however the particles being used are replication deficient.
To elimination of E1 and E3 genes.

These Vectors do not integrate into the genome.

RETROVIRUS AND LENTIVIRUS

The main hazard arises directly from the recombinant viruses produced from the packaging cells. These yield both ecotropic and amphotropic lentivirions and ecotropic and amphotropic retrovirions, depending upon the envelope proteins supplied by the cell. Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Retroviruses and lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. To further reduce the risks of virus utilization, we will

1. Use retroviral infections targeted to murine cell or human cells designed to express ecotropic receptors

2. Use third generation lentiviral expression vectors, where genes encoding the structural and other component required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

Some of the indicated vector might contain the WPRE (Woodchuck hepatitisB virus post transcriptional regulatory element). This element is used to increase lentiviral vector titre and gene expression. It includes the promoter for the X-protein and the part to the coding sequence for such protein, which may have oncogenic properties. Whenever possible we aim to use WPRE-less vectors such as the TRC-1-pLKO.1, thus limiting the oncogenic potential of the viral particles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Micro-organisms and tissue culture cells are involved

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2 will be applied only in specific circumstances such as:

1. The use of lentivirus containing the WPRE elements
2. The modulation of the expression of known or suspected oncogenes or tumour suppressors.
3. The expression of toxic or inflammatory (e.g. cytokines) genes

Other infection and virus production work will be carried out in class l.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class 1 level of classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

As per Hutchinson/MRC Research Centre standard practise guidance (unless the risk assessment demands more stringent measures).

CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus).

Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.

Bacterial Plates are autoclaved in the building.
Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contractor (Novus). It is expected that these measures will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This is a fairly standard proposal to use lentivirus (for various genes) and adenovirus (for cre) to genetically manipulate murine and human cells, but the human host range virus work falls on the borderline between class I and class II: innocuous inserts may be transduced in class I, but toxic, pathogenic or oncogenic inserts or vector components require class II.

Since we discourage use of Class II where it is not necessary - to minimize the number of people exposed to more hazardous material particularly clinical material - we consider that it is helpful to identify much of this work as acceptable in class I.

Most of the inserts are not overly hazardous, being marker genes or genes involved in metabolism, so in these cases use of lentivirus that lacks the WPRE element in class I seems acceptable. However, class II is required for experiments involving vectors with the WPRE element, or with inserts that might be oncogenic (including knockdown constructs for a tumour suppressor gene) or toxic or inflammatory (such as cytokines, peptide hormones).

02/03/2022
The overall aim of the lab is to study genes that are altered by structural rearrangement of the cancer genome: these can be inactivated tumour suppressor genes or fusion genes analogous to those traditionally associated with leukaemias.

This project is to investigate the functions of these candidate genes by manipulating their expression using siRNA or expression of cDNAs in cultured cells. We plan to use a number of human cancer and normal cell lines, principally breast and ovarian, that can be particularly difficult to transfect by standard methods. We therefore plan to use viral vectors. The work will be carried out in vitro.

Description of procedure: cDNAs or shRNAs that target the gene of interest will be cloned into retroviral and lentiviral vectors. Recombinant retro/lentiviral vectors carrying the gene or shRNA of interest will be packaged in virus packaging cells. The viruses harvested will be used to infect human or mouse cell lines. The transformed cell line will be used in vitro for functional assays such as cell cycle, apoptosis and cell-mobility assays.

E. coli and established human and mouse cell lines in vitro. We may also use human cell lines engineered to express the ecotropic receptor (but such lines will not be constructed under the risk assessment).

Recipient or parental organism

The host/vector systems are (i) plasmids in E. coli for construction steps; (ii) transfection of retrovirus or lentivirus vector into packaging cell line systems to generate virus; and (iii) infection, with the packaged retroviral or lentiviral constructs, of human or mouse cell lines. Retrovirus/lentivirus and the packaging lines will be chosen to match the target cells and to repeat published experiments. Broadly, lentivirus will be used on less vigorous human cancer cell lines.

i) Generation of the construct to express the genes of interest.

INSERT: the insert is chosen to modulate the expression levels of genes of interest by overexpression or downregulation. We will begin for example with NRG1, which has been proposed as both a tumour suppressor gene and an oncogene. However, we will apply this technology to other known and candidate cancer genes. We will include knockdown of the known tumour suppressor gene, p53, and overexpression of the known oncogene, Ras, as controls.

a) Constructs for overexpression: these constructs are engineered using cDNAs that will encode for candidate cancer genes and rearranged forms of these genes, such as fusions of these genes, internal partially duplicated mutants and deletion mutants. These inserts will be either purchased or designed ad hoc and inserted into lentiviral or retroviral vectors.
b) Constructs for downregulation of gene expression: these constructs are shRNAs that will downregulate the expression of chosen target genes. These constructs will be purchased or designed ad hoc and inserted into lentiviral or retroviral vectors. For custom design of shRNAs, to be cloned into the MSCV-miR30 vector, we will use the Hannon lab shRNA retriever (http://katahdin.cshl.org/siRNA/RNAi.cgi?type=shRNA). We will also use microRNA-adapted shRNAs constructs already cloned into appropriate plasmids (see below) mostly, but not exclusively from Open Biosystems (thermoscientific) (http://www.openbiosystems.com/RNAi/LentiviralshRNAmir/) or Cellecta (http://www.cellecta.com/products-services/pooled-shRNA-libraries/) and Santa Cruz. We will also use shRNAs in vectors designed by others to replicate their work, notably constructs of Sheng et al Cancer Cell 2010;17, 298.

VECTOR: the vectors described here will be used to express the insert in proliferating and non-proliferating mammalian cells by means of viral transduction and could be either retrovirus- or lentivirus -based.

RETOVIRAL
The retrovirus vectors to be used are derived from Moloney murine leukaemia virus (MMLV) and its relative Murine Embryonic Stem Cell virus (pMSCV). Currently, these are pBABE, MSCV-miR30, pRETROSUPER and LPC. For all the vectors, the env genes, provided by the packaging plasmid, determines host range.
Vectors mainly for cDNAs.
1. pBABE (Morgenstern & Land) is derived from Moloney murine leukaemia virus (MMLV). The vector provides the viral package signal, transcription and processing elements, and a target gene. Transfection into a packaging cell line, such as Phoenix, produces high titer replication-incompetet viruses.
2. LPC system. The LPC vector was constructed at CSHL by S L (Cold Spring Harbor Lab) for efficient expression of cDNAs.
Vectors Specifically designed for shRNA inserts:
3. The MSCV-miR30 vector (also developed by S L’s lab) is derived from the Murine Embryonic Stem Cell virus (pMSCV), closely related to MMLV. The vector contains the mir 30-styled shRNA expression cassette expressed from the U6 promoter. The vector has a specifically designed 3’LTR that has a deletion in the LTR promoter elements. This deletion results in inactivation of the LTR mediated transcription upon retroviral integration. The phosphoglycerate kinase (PGK) promoter drives the expression of the puromycin resistance gene for selection in eukaryotic cells. The MSCV-miR30 plasmid can be propagated in E. coli under ampicillin (AMP) selection.
4. pRETROSUPER vector is also derived from the Murine Embryonic Stem Cell virus (pMSCV) and is commercially available.
Either cDNA or shRNA:
5. pOZ-FH-C is a retrovirus vector that has been used to coexpress an insert of interest with IL-2, so that infected cells can be affinity purified by IL-2 antibody (Nakatani and Ogryzko, 2003).
6. pWZL, a commercially available retroviral vector available with various selection markers, made by J M, the maker of pBABE.
7. Related established retroviral vectors to achieve coexpression with marker genes.

LENTIVIRAL
For cell lines where proliferation is limited we may need to use lentiviral vectors. We will use metabolisation-defective lentivirus (third-generation lentiviral vectors). One packaging plasmid lacks both LTRs, viral packaging signal (y) and viral genes (env, tat, rev, ypr, vpu, vif and nef). Rev is supplied in-trans on a second plasmid. Envelope is expressed on a third plasmid. The vector to be packaged has a self-inactivating LTR and expresses no viral gene products.
Lentiviral vectors used include:
1. PLKO vector is widely used and commercially available - see below.
Specifically designed for shRNA inserts:
2. Lenti-miR30 is a vector adapted by CSHL to express shRNAs as part of simulated microRNAs. Other lentiviral vectors in current use by our colleagues may also be used. They include:
1. pRSI-U6-(sh)-UbiC-RFP-2A-Puro: HIV-based lentiviral shRNA cloning vectors with H1, U6, or H1 tet-regulated promoters for expression of shRNA and a choice of a single or dual selection marker (GFP, RFP, PuroR, BleoR, NeoR, Hygro-HK, etc.) expressed from a single CMV EF1α, PGK, UbiC, or other promoters. It contains 18-nt bar code compatible with the Illumina HT Sequencing platform.
2. pLKO1-puro: The viruses generated using these plasmids were used to generate the TRC1 and TRC2 collection of commercially available shRNAs. This construct contains a 3' self-inactivating long terminal repeat. pLKO-puro is available in two forms. The TRC1-pLKO vector does not contain WPRE (Woodchuck hepatitis B viruspost-transcriptional regulatory element), while the TRC2-pLKO vector does not contain it.

3. pGIPz: this vector contains a TurboGFP expressed by an IRES in tandem with the shRNA. These constructs contain a WPRE.

4. pTripz-inducible shRNAs plasmids with TurboRFP that marks inducible shRNAmir expression

5. Transduction ready particles generated from the above and purchased directly from the suppliers.

Generation and expansion of plasmids carrying construct/gene of interest

cDNAs and shRNA plasmid constructs will be generated by subcloning cDNAs and shRNAs of interest into the empty backbones indicated above.

VECTOR: Recombinant lentiviral and retroviral plasmids will be transformed and amplified in laboratory strains of E. coli after selection with the appropriate antibiotics. Lentiviral and retroviral plasmid DNA will be purified by maxi prep.

HOST: E. coli: laboratory TOP10 chemically competent E. coli will be used for selection and amplification of plasmid DNA.

(ii) Transfection of retrovirus or lentivirus vector into packaging cell line systems to generate virus.

RETROVIRUS

Cell lines such as Phoenix cells (http://www.stanford.edu/group/nolan/retroviral_systems/phx.html) will be used as packaging cell lines. Phoenix, based on the 293T cell line, is a second-generation retrovirus producer line for the generation of helper free ecotropic and amphotropic retroviruses and has stably integrated three plasmids that provide the retrovirus proteins in trans. In order to infect human cell lines we will use the packaging cells Phoenix Ampho. Also, well characterised and commercially available PT67 cells with appropriate tropism would be used if the Phoenix system proves inadequate.

Virus will be packaged by transient transfection.

LENTIVIRUS

Lentivirus will be packaged by co-transfection of lentivirus vector and packaging plasmids into 293T cells.

(iii) Infection, with the packaged retroviral or lentiviral constructs, of human or mouse cell lines.

VECTOR: Replication deficient lentiviral or retroviral transduction particles harbouring construct/gene of interest and appropriate resistance gene or fluorescent marker. These particles can be obtained as indicated above or purchased as 'Ready-to-use lentiviral particles' from certified sources.

HOST: Well characterised human normal and cancer cell lines, mouse cell lines, or human cell lines engineered to express the ecotropic receptor. Successfully transduced cells will be selected with appropriate antibiotics and in the case of inducible of an inducible system activated by doxycycline.

Determination of viral titre in packaging cells and GM-cells supernatant

Generally, we will determine the viral titre of transducing particles suspension only if a specific MOI is required for the infection. We will determine the viral titre in the supernatant of the genetically-modified cells to assess the suitability to transfer infected cells from CL2 to CL1, when CL2 tissue culture has been used for the infection. To determine the viral titre of cell supernatant we will use well characterised methods such as the Molecular Probes' EnzChek® Reverse Transcriptase Assay, a convenient, efficient and inexpensive assay for measuring reverse transcriptase activity, a direct readout of the presence of viral particles

Genes will be genes that are mutated or rearranged in cancers, from human or mouse, and may be in normal form or mutant/rearranged variants of the genes, such as fusion genes. cDNAs-either cloned or synthesised- or shRNAs that target the gene of interest will be cloned into retroviral and lentiviral vectors
HAZARD IDENTIFICATION: Host

MODIFIED BACTERIA TO AMPLIFY THE CONSTRUCTS
Laboratory strains of modified E. coli K12 such as TOP10 are recognised as non-colonising and may be considered to be ACDP hazard group 1.

CELL LINES
Phoenix cells are widely used and they have a history of safe usage. The gag-pol and env genes are expressed from non-moloney promoters to minimise recombination potential. Different promoters for gag-pol and envelope were used to minimise their inter-recombination potential. Amphotropic Phoenix cell lines have been extensively tested for helper virus production and established as being helper-virus free. The 293T cell line, in addition to other well characterised human normal and cancer cell lines, has a history of safe usage and is not expected to represent a hazard to human health.

HAZARD IDENTIFICATION: Vector

RECOMBINANT RETRO/LENTIVIRAL VECTORS
Retroviruses and lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission.

1. The retroviral vectors used are replication defective. To produce a replication-competent retroviral genome three recombination events are required between the vector of interest, the gag-pol regions of the packaging cell line and introduction of the split genome packaging cell lines.

2. We will use third generation lentiviral expression vectors, which contain multiple safety features, as follows;

   • The majority of lentiviral genes have been eliminated (Δ vpr, vif, vpu and nef). The number of genes from HIV-1 that are used in this system has therefore been reduced to three (i.e. gag, pol, and rev).
   • Genes encoding the structural and other components required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al J Virology 72 8463-8471 1998).
   • Although the packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gag,pol, rev, env) in the 293T derived producer cell lines, none of them contain 3’ LTRs. This results in elimination of the promoter-enhancer region, which avoids promoter interference issues and further negates the possibility of viral replication.
   • No single plasmid contains all the genes necessary to produce packaged lentivirus. None of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
   • The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Some of the indicated vector might contain the WPRE (Woodchuck hepatitis B virus post-transcriptional regulatory element). This element is used to increase lentiviral vector titre and gene expression. It includes the promoter for the X-protein and the part to the coding sequence for such protein, which may have oncogenic properties.

The main hazard arises directly from the recombinant retroviruses and lentiviruses produced from the packaging cells. These yield amphotropic lentivirions and retrovirions.

HAZARD IDENTIFICATION: Insert

Our genetic experiments will include knockdown of known (p53) and potential tumour suppressor genes (e.g. NRG1) and overexpression of known (Ras) and potential oncogenes (e.g. NRG1 again). However, at least 4 different genes should be expressed for tumorigenesis in human tissues (W.C. Hahn et al., Nature 400, 464) and we expect that a contamination of more than 4 virus supernatants would be extremely unlikely.

None of the cell lines used is capable of colonising a healthy individual and we do not expect any of our proposed manipulations to change this. The amphotropic retrovirus and lentivirus would be able to infect human but could not replicate unless the improbable event occurs that it recombines with endogenous retroviruses. Even then, it is
unlikely that expression of a single oncogene or suppression of a tumour suppressor could cause tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and safeguard mechanisms exist impeding the accumulation of these alterations in the organisms.

HAZARD IDENTIFICATION: Lab Personnel
The principal hazard is gene transfer to human cells when using the human host-range packaged viruses. Attention should be paid to staff awareness of this and to storage and labelling of any stocks. Virus will be removed from the lab Cat II rooms only for storage and kept in designated -80°C freezers according to the agreed guidelines and SOPs in the Hutchinson/MRC Research Centre. Work will therefore be done in:
Class II: production and infection work with lentivirus and amphotropic retrovirus.
Cell lines produced by infection that are virus-free after infection using the methods indicated above will be transferred to Class 1
Class I for work with plasmids in E. coli.

HAZARD IDENTIFICATION ENVIRONMENT
The prokaryotic and eukaryotic cells and cell lines are highly disabled and the possibility of competent virus being generated is negligible. Therefore they should be unable to propagate in the environment. The plasmid vectors are non mobilisable, therefore neither has any possibility of further spread.
The viruses are replication-incompetent and no live virus should reach the environment.
The risk to the environment is therefore effectively zero

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2 will be applied to work packaging and infecting with the human host-range viruses.
Infection and virus production of ecotropic retrovirus will be carried out in class 1.
After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will be transferred to class 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus).
Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.
CL1: Liquid waste is disinfected with Virkon to final concentration of 1%; contact time of 30 minutes minimum before disposal to drain.
Bacterial Plates are autoclaved in the building.
Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contactor (Novus).
It is expected that these measures will give effectively 100% killing

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
This is similar to many RAs for using non-replicating lentivirus and retrovirus vectors to express genes and shRNAs in human cell lines in vitro, with Class II for production and infection by human host-range virus vectors. It is quite broadly based as a variety of genes and host cells may be used, but raises no particular issues.

Since the applicant group leader is the BSO (competent person) note that the committee that has considered this risk assessment includes two others with long experience of GM risk assessment. Dr P B, formerly of MRC-LMB, and Dr P J, the previous BSO for this building.

Project Additional Information
Purposes of the contained use

We wish to study the role of mitochondrial proteins in human disease. Respiratory chain structural subunits and assembly factors as well as proteins involved in mitochondrial gene expression and maintenance will be our primary subjects. This necessitates the use of human and mouse cells, both established continuous cultures and primary cultures from patients and/or mice. After a certain passage number, primary cells become senescent and stop dividing. To avoid this, it is possible to transform them into immortal cell lines by transfection of the SV40 T Antigen. Moreover, the cells to be analysed often need to undergo genetic modification as part of the research, in particular to allow stable knock-down expression or to overexpress a protein of interest. Lentivirus systems allow highly efficient transfection of the shRNA or cDNA for the gene of interest and its stable integration into the host cell. We will then be able to study the phenotypic and biochemical changes produced by these modifications and their relationship to mitochondrial disease. Lentiviral vectors can be exploited to produce iPSCs from both human and murine primary cultures, by using vectors expressing reprogramming proteins such as Oct-4, Sox2 etc. A further application of lentiviral vectors is the possibility to rapidly produce transgenic mice by injection of high titer virus into the embryos.

Recipient or parental organism

Mammalian cells and cell lines and bacterial cells that are disabled (non-colonising) and unable to survive or propagate outside of laboratory culture, even when transformed.

Host/vector system

The following bacterial strains will be used:
E. coli K12 derivatives such as DH5α or XL-10 gold.

The following mammalian cells will be used:
Human and murine primary fibroblast cells, murine primary cultures such as muscle cells or neurons, or cell lines expressing the SV40 T Antigen, cell lines such as L929, HEK293T (packaging), HeLa, 143B, A549 cells (stably expressing the protein of interest).

The following systems of Lentiviral transduction will be used:
1. pLOX-Ttag-iresTK+ psPAX2 + pMD2.G (Didier Trono lab). This system will be used for immortalisation of primary fibroblasts. The pLOX-Ttag-iresTK lentiviral vector (Tronolab) contains the SV40 Large T antigen and HSV1-TK as inserts. The plasmids have been derived from the HIV-1 genome. HIV lentiviral vectors however have been modified so they are safe to use in research labs. The lentiviruses are replication defective, using separate plasmids encoding various HIV genes and require multiple separate recombination events to generate replicating virions. To further prevent these recombination events, the system includes a large deletion of the 3’ LTR in the transfer plasmid (SIN system).
2. The RNAi Consortium, TRC + pMISSIONgagpol (Sigma) + pMISSIONvsrg (Sigma).
3. pWPXLd (pWPXLd-ires-Puro/Neo) + psPAX2 + pMD2.G (Didier Trono Lab).
All the above systems (including pLOX-Ttag-iresTK) are considered “Second-Generation” because they use one packaging plasmid containing: Gag, Pol, Rev and Tat and one packaging plasmid encoding VSV-G. These vectors contain the woodchuck hepatitis B virus (WHV) post-transcriptional regulatory element (WPRE) to increase viral vector titre and enhance expressions of the transgenes.
4. pLenti6.3/V5-TOPO + pLP1 + pLP2 + pLP/VSVG (Invitrogen).
The pLenti6.3/V5-TOPO+pLP1+pLP2+pLP/VSVG system is considered “Third-Generation” because the use two packaging plasmids pLP1 containing: Gag/Pol and pLP2 containing Rev and one packaging plasmid encoding VSV-G. The proteins to be expressed are not believed to have oncogenic or other pathogenic properties. It also contains the woodchuck hepatitis B virus (WHV) post-transcriptional regulatory element (WPRE).

Origin & function

The genes targeted for overexpression and knockdown are involved in aspects of mitochondrial function including, but not limited to, respiratory chain structural subunits.
and assembly factors as well as proteins involved in mitochondrial gene expression and maintenance. They are not expected to be toxic or oncogenic.

**Evaluation of foreseeable effects**

Mammalian primary cells or cell lines and bacterial cells are unable to survive or propagate outside of laboratory culture.

The genes targeted for over-expression and knockdown are involved in aspects of mitochondrial function and are not expected to be toxic or oncogenic. The SV40 large T antigen which is used to immortalise cell lines, and the reprogramming genes used to produce iPS may have oncogenic properties.

The lentiviral vectors used will be self-inactivating (SIN). A deletion inactivates transcription from the proviral LTR, so reducing the potential for transcriptional activation of cellular genes and also prevents mobilization of any RCL. However as the virus integrates into the host cell DNA there is still a potential for insertional mutagenesis to occur.

The WPRE is similar to the post-transcriptional regulatory element found in human Hepatitis B (HBV), which is closely related to WHV and may have oncogenic properties.

A plasmid encoding the envelope protein from vesicular stomatitis virus envelope protein G (VSV-G) increases the host cell range/tissue tropism and makes it able to infect a variety of human and other mammalian cells, including quiescent cells. Such particles are also physically more stable. The genes or other sequences of interest will be delivered by an integrative process leading to potential long-term expression for the life of the target cell. The results of such expression for most of the sequences will not be severe and will be limited to the cells targeted and no further. VSV-G enables the vector virus to infect a wide variety of mammalian cells. There may also be enhanced environmental stability. However, the viruses are replication disabled; they cannot produce progeny virus and so cannot spread to the wider human population or other animals. The possibility of RCL being generated and released is negligible. The lentiviruses have unstable infectivity and efficient infection generally requires forced contact with the virus and so the risk is extremely low.

None of the modifications will alter the broad properties of the vectors. They will remain replication disabled and so are biologically contained.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

N

02/03/2022
Even though the lentivirus can enter human cells the overall risk is low. The SV40 large T Antigen and the reprogramming genes for iPS may have oncogenic properties and therefore the associated work is Class 2. All work with lentiviral vectors using an WPRE, such as the pWPXLd system is Class 2 regardless of the insert. Therefore the final classification is Class 2 (Containment Level 2).

Purposes of the contained use

We wish to study the role of mitochondrial proteins in cellular function and human disease. The genes of interest are involved in, or thought to be involved in mitochondrial function and include respiratory chain structural subunits, assembly factors, mitochondrial dynamic regulators,
### Recipient or parental organism

Mammalian cells and cell lines and bacterial cells that are disabled (non-colonising) and unable to survive or propagate outside of laboratory culture, even when transformed

### Host/vector system

1. **Vectors:**
   (a) Recombinant Adenovirus:
      (i) Ad Easy Adenoviral vector system (Agilent Technology) Backbone: pADEasy 1, Adenoviral type S dE1/E3 including pShuttle and pShuttle-CMV
   
   Description of the recombinant Adenovirus: Both recombinant Adenoviruses are replication defective by the deletion of the E1 and E3 genes. The E1 gene is essential for the assembly of infectious virus particles and is complemented in vivo by an adenovirus packaging cell line (e.g. AD-293). The E3 gene encodes proteins involved in evading host immunity and is dispensable. Not only do these deletions render the virus incapable of replicating itself, but they also create space for up to 7.5 kb of foreign DNA.

   The plasmid pAdEasy-1, containing most of the human adenovirus serotype S (AdS) genome, is deleted for the genes E1 and E3. The removal of these two viral genes creates space for foreign DNA and eliminates self-replication capabilities. The E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cell); the E3 region encodes proteins involved in evading host immunity and is dispensable. The deletion of both genes creates room for up to 7.5 kb of foreign DNA that can be inserted into the AdS genome. The E1 gene, which is necessary for production of viral particles, is provided in trans by AD-293 cells. pAdEasy-1 carries the ampicillin resistance gene, which is lost after recombination with a shuttle vector. The vector pShuttle-CMV contains a multiple cloning site sandwiched between the CMV promoter and the SV40 polyadenylation signal and is suitable for insertion of a large cDNA (up to 6.6 kb). pShuttle contains only a multiple cloning site. This allows for the insertion of an entire expression cassette, including specialized promoters and termination signals (up to 7.5kb). The regions indicated as arms are the stretches of sequence homology with pAdEasy-1 where the homologous recombination occurs. The R-ITR and L-ITR regions are short inverted terminal repeats (Left and Right) which have a role in replication of the viral DNA.

2. **Hosts for amplification and production**
   (a) Bacterial strains: E.coli K12 derivatives such as XL 10 Gold, BJ5183 (Addgene)
   (b) Mammalian cell lines: Established human cell lines such as HEK293 and AD-293 (Agilent)

3. **Hosts for infection and experiments**
   Classical mammalian cell lines: HeLa, Cos-7, mouse and human fibroblast

### Origin & function

Inserted cDNA coding for human proteins involved in mitochondrial function including respiratory chain structural subunits, assembly factors, mitochondrial dynamic regulators, mitochondrial and ER markers, as well as proteins involved in mitochondrial gene expression and maintenance mitochondrial dynamics and functions will be used. None of these proteins are known to be biological toxins, oncogenes or prion-type agents.

### Evaluation of foreseeable effects

The recombinant virus elements used are replication deficient due to deletions in the E1 and E3 regions. The E1 gene is essential for the assembly of infectious virus particles and is complemented in vivo (in trans) by an adenovirus packaging cell line (e.g. AD-293). The E3 gene encodes proteins involved in evading host immunity and is dispensable. These deletions render the virus incapable of replicating itself. Since the mammalian cells used possess...
integrated human AdS DNA, there is a low frequency of homologous recombination between the E1-deleted vector and the host DNA resulting in the production of some replication competent adenovirus (RCA). The frequency of occurrence is very low, but the percentage of RCA in a given virus stock goes up with each amplification of that stock. Because the recombinant adenovirus remains epichromosomal in the human host cell, there is only a remote possibility of activation or inactivation of host cell genes resulting from interruption by the transfected gene(s). Infection of bacterial cells with the recombinant Adenovirus elements presents no risk for human health and environment since at this stage the virus is still deleted of the E1 and E3 regions, and is not replicative. Following transfection, production and amplification of Adenovirus in AD-293 or HEK293 are considered as Hazard Group2/Containment Level 2: since cells possess integrated human AdS DNA, there is a low frequency of homologous recombination between the E1-deleted vector and the host DNA resulting in the production of some replication competent adenovirus (RCA). The frequency of occurrence is very low, but the percentage of RCA in a given virus stock goes up with each amplification of that stock. Therefore there is a potential risk to the worker at this stage. Adenoviridae are classified as Hazard Group 2 by the ACDP. Wild type, replication competent adenoviruses provoke cold symptoms and strong immune responses in healthy individuals and generally do not cause serious illness.

The mammalian cells infected for the experiements are established cell lines with history of safe use and could be classified as Hazard Group 1. These cells do not contain the E1 and E3 regions required for the virus replication. Infection in those cells and the corresponding experiments are classified as Class2/Containment Level 2 due to Adenovirus infection; whilst the Adenovirus within these cells is uncoated therefore non-infectious, the virus in the supernatent may be infectious for some time. However, after at least one passsage, the supernatent will be discarded and the cells washed to eliminate all the viral particules. As the uncoated Adenovirus inside the cells is not infectious the subsequent experiments will be considered as Class1/Containment Level 1. None of the modifications will alter the broad properties of the vectors. They will remain replication disabled and so are and unable to propagate in the environment. For the RCA, Adenoviruses are generally species specific; AdS infects humans and does not naturally infect other animals (but can experimentally infect cotton tail rats, which are not endogenous in the UK). Therefore there is no risk to other organisms. The host cell lines, even when transformed, are highly disabled and unable to propagate in the environment. The overall risk to the environment is therefore effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The risk assessment seeks to identify those strains, vectors and insertsto be used during the designated project and to identify any potential hazards. This includes hazards to both human health and safety, but also environmental consequences. In the context of this particular risk assessment there is negligible risk associated with a total breach of containment and consequently the project can be designated class 1.

Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity
Containment and control measures:
Fungal cultures shall not leave the laboratory (except as waste in dedicated sealed containers)
Lab coats used in the laboratory shall not leave the laboratory.
A record shall be kept of every culture generated and shall include information on:
Location, number, vial type, organism, strain type (including donor vectors), date of generation, expiry date and date of disposal (by autoclaving).
New and existing staff be training in necessary procedures.
Records shall be monitored by the Senior Scientist.
Waste:
Disposable plasticware will be used wherever possible. Non sharps waste (including gloves and cleaning materials) will be retained in autoclave bags in dedicated waste bins. These shall be autoclaved on site in sealed containers, in a licensed autoclave facility. Lab coats shall be autoclaved before cleaning. GMM Sharps waste and toxic waste will be disposed on through a licensed waste disposal company.
Spillages of biological nature are to be cleared with Virkon (5%). Safety cabinet and benches are to be wiped down with Virkon/70% suitable alcohol eg ethanol at the end of each day. Gloves and cleaning materials to be discarded to autoclave waste bins.
The GMM strains will not remain viable (100% kill) after autoclaving. Indicator tape shall be used to ensure the autoclave is performing as required. Autoclaved material shall then be disposed of through normal domestic channels.
The autoclaving process shall be described in a standard operating procedure to ensure it is carried out in a reproducible manner.
Autoclaving shall be carried out within 10 days of waste being generated to minimise the risk of container breakage and contamination.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Health and Safety training to be given to new and existing employees. This is to include:
1. Location of first aid equipment eg eye wash, fire-fighting equipment, Risk assessment forms, COSHH information and safety procedures (eg dealing with spillages).
2. Filling in and use of risk assessment forms.
3. Record keeping of GM strains including generation and disposal of material.
Generation of fungal biosensors. This involves expressing marker proteins eg fluorescent and luminescent proteins in a range of wild type and mutant (deleterious mutations such as those used for DNA repair or oxidative stress) …

Recipient organisms:
E. coli strain XL1 (Stratagene). (non-pathogenic). Class 1 organism.
Neurospora crassa, Aspergillus nidulans, Aspergillus niger, Magnaporthe grisea etc. wild type and mutant (deleterious mutations) strains (obtained from Fungal genetics stock Centre). Spores and mycelia to be transformed.

Vector:
Based on BlueScript (Stratagene)
Commercially sensitive.
Contain luminescent and fluorescent proteins obtained from deep sea organisms under the control of various fungal promoters.

Genetic material:
Fluorescent and luminescent proteins. Derived from marine coelenterates (non-pathogenic). No homology to known human genes.
A variety of promoters, mainly isolated from filamentous fungi. Including constitutive and inducible promoters.

Selection systems:
Bacteria: ampicillin, chloramphenicol, kanamycin
Fungi: hygromycin, and auxotroph selection

Cloning protocol:
Digestion of insert from commercially available vectors.
PCR amplification of above inserts
Insertion of PCR fragment of new vector, containing appropriate fungal selection (eg hygromycin/auxotrophic selection) and fungal promoters.
Transformation.

Note, these experiments are small scale <100ml

Foreseeable effects:
No hazards associated with insertion of gene. None of the genes are involved in pathogenesis and instead act as luminescent of fluorescent markers for assessment of promoter-driver gene expression.

No change from non-pathogenic to pathogenic state or increased virulence is expected.

The genes inserted pose no danger to health and in the unlikely event of transmission to other organism would not be expected to cause damage or health/environmental dangers.

It is HIGHLY unlikely that the GMM could cause human infection.

The fitness of GMM is likely to be comparable, or slightly reduced compared to unmodified strains.

No consequences for the environment following accidental release of modified XL1 bacteria are forseen. Previous genetic manipulations of N. crassa and other fungi tend to show some reduction in fitness compared to wild-type.

Host/vector system
Using E. coli to generate plasmids.
Transformation of fungi using an electroporation or protoplasting protocol.

Origin & function
E. coli strains: commonly used in molecular work. Obtained from commercial company eg Stratagene or Invitrogen. For use only in lab, not for general release.

Fungi are to be transformed with fluorescent and luminescent markers. These are derived from marine coelenterates (non-pathogenic). Most are commercially available from Nanolight (www.nanolight.com). They have no homology to known human genes.

Transformed fungal strains shall be used in laboratory-based assays for drug screening and environmental testing. They are NOT for general release.

Evaluation of foreseeable effects
Neurospora crassa, Aspergillus nidulans and A. niger are saprotrophic (non-pathogenic) organism. No cases of pathogenic behaviour of unmodified or modified N. crassa reported. Please see article 'Evidence for Safety of Neurospora species for Academic and Commercial Uses' (Perkins and Davis, 2000, Applied and Environmental Microbiology) for more details.

Antibiotic reporter genes used in vectors: ampicillin, kanamycin, hygromycin and chloramphenicol. Safety procedures will be followed when using such antibiotics eg gloves, mask and goggles. Used in microbiological safety cabinet level 1.

No hazards associated with insertion of gene. None of the genes are involved in pathogenesis and instead act as luminescent of fluorescent markers for assessment of promoter-driver gene expression.
No charge from non-pathogenic to pathogenic state expected.

The gene inserted pose no danger to health and in the unlikely event of transmission to other organism would not be expected to cause damage or health/environmental dangers.

It is highly unlikely that the GMM could cause human infection.

The fitness of the GMM is likely to be comparable, or slightly reduced compared to unmodified strains.

No consequences for the environment following accidental release of modified XL1 bacteria N. crassa or Aspergillus strains are foreseen. Previous genetic manipulations of fungi tend to show some reduction in fitness compared to wild-type.

Health and Safety
First aid kits, eye wash and fire-fighting equipment provided.
Risk assessment forms, for each procedure undertaken in lab are available in the lab and contain information regarding appropriate steps following spillages and for correct wast disposal.

Signs for information on coping with spillages and contact details are provided.

Labs are locked when not in use and signs forbidding unauthorised entry are clearly visible, to prevent unauthorised personnel entering labs.
All members of staff are trained in working with GMMs and general lab safety.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment and control measures:
Fungal cultures shall not leave the laboratory (except as waste in dedicated sealed containers)
Lab coats used in laboratory shall not leave the laboratory
A record shall be kept of every culture generated and shall include information on: location, number, vial type, organism, strain type (including donor vectors), date of generation, expiry date and date of disposal (by autoclaving).

Records shall be monitored by Senior Scientist.

Waste:
Disposable plasticware will be used wherever possible. Non sharps waste (including gloves and cleaning materials) will be retained in autoclave bags in dedicated waste bins. These shall be autoclaved on site (in sealed containers), 121°C> 15 min. Lab coats shall be autoclaved before cleaning. GMM sharps waste and toxic waste will be disposed of through a licensed waste disposal company.

Spillages of biological nature to be cleared with Virkon (5%). Safety cabinet and benches to be wiped down with Virkon/70% ethanol at the end of each day. Gloves and cleaning materials to be discarded to autoclave waste bins.
The GMM strains will not remain viable (effectively 100% kill) after autoclaving. The autoclave shall be serviced annually and indicator tape shall be used to ensure the autoclave is performing as required. Autoclaved material shall then be disposed of through normal domestic channels.

The autoclaving process shall be described in a standard operating procedure to ensure it is carried out in a reproducible manner. Autoclaving shall be carried out within 10 days of waste being generated to minimise the risk of container breakage and contamination.

For activities involving GMMs, describe the waste management measures which will apply to the activity
Solid waste will be placed into autoclave bags within dedicated biological waste bins in the laboratory. These bags will be closed with autoclave indicator tape before being transported to the autoclave for sterilisation.

To decontaminate equipment and liquid waste precept will be used at 1,000 pm for 20 minutes. Following decontamination liquid waste will be disposed of via a sink. Glass-ware will be cleaned via the normal washing procedure.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee (GMSC) consists of all competent personnel directly involved with the company (currently 3 people). All three members of the Helperby Therapeutics GMSC have at least 10 years experience in molecular biology/microbiology and have a track record in handling genetically modified organisms. One member of the Helperby GMSC was previously a member of the GMSC of St George’s, University of London. The Helperby Therapeutics GMSC will convene whenever a new project needs to be reviewed or changes to a current project will occur.

Helperby Therapeutics Limited is currently renting its laboratory space from St George’s, University of London. Therefore all risk assessments regarding the work with genetically modified organisms will also be presented to the GMSC of St George’s University of London for their evaluation.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
Helperby Therapeutics rents its laboratories from St George's University of London within the Medical Microbiology Department. As part of this agreement Helperby therapeutics has access to the waste disposal facilities of St George's University of London.

All biological waste will be autoclaved prior to disposal.

When autoclaving is not feasible the biological material will be inactivated by soaking the material in 2% hycolin for at least 24 h (>5.29 log10 reduction after 5 min contact time according to the manufacturer validation procedure).

Laboratory equipment that cannot be autoclaved will be disinfected using Vikan sanitising agent according to the manufacturers recommendations.

All other laboratory waste will be disposed of through the clinical waste route within St. George's University of London.

---

Please enter comments of the GM safety committee on the risk assessment

The GMSC did not have any specific comments regarding the risk assessment for the project entitled "E. coli strains expressing proteins of the chaperonin regulon of M. tuberculosis and M. leprae". The GMSC was satisfied with the information provided and approved of the project and its classification as class 1.

02/03/2022
Waste disposal procedure at the Institute of Food Research (IFR) site

1. Introduction

This code of practice (COP) covers the disposal of biological waste at Algentech Ltd in accordance with Institute of Food Research general procedure. Biological waste is defined here as that contaminated with micro-organisms (ACDP Hazard Groups 1 and 2 and ACGM Genetically Manipulated (GM) Organism Classes I and II, mammalian cells, human body fluids/wastes or transgenic plant material. All such waste will be inactivated before final disposal, i.e. release to the environment. The inactivation procedure will be one (or more) of chemical treatment, autoclaving or incineration.

2. Inactivation by autoclaving

Waste in re-usable items such as glass bottles will be placed in the stainless steel containers available from the Media Laboratory of the Institute of Food Research. These containers will be labelled with the number of the room generating the waste, and will be collected by support staff for autoclaving.
Non-reuseable solid or semi-solid wastes (e.g. Petri dish culture) will be put in a transparent/blue autoclave bag (the recognised colour coding for biohazard waste for autoclaving), and contained within a white polypropylene bucket. Care will be taken that no sharp items that might penetrate the bags are included. Such items will be placed in a dedicated ‘sharps’ container in a separate autoclave bag. Buckets will be labelled on a piece of tape with the number of the room generating the waste, and the lid clipped on to the bucket ready for collection. Buckets will be routinely collected from the laboratory by support staff. After sterilisation, waste in autoclave bags will be further bagged by the support staff using yellow incinerator bags (see below), and dispatched for incineration.

Note that other safety requirements, such as COSHH, will also be met.

3. Chemical inactivation

Chemical inactivation will use an approved disinfectant such as alcohol at concentration 70-85% for 10-30 minutes, VIRCON at concentration 1% for 10 minutes, and chlorine compounds like bleach or hypochlorite at the concentrations 5-10% for 15-20 minutes. Although chemically-inactivated waste no longer presents a biological hazard, other requirements of COSHH will be met when considering further disposal.

4. Inactivation by incineration

Waste for incineration will be double-bagged and the outer bag will be yellow (The recognised colour coding for biohazard waste for incineration). Sharp items will be placed in a dedicated ‘sharps’ container in a separate bag. Bags will be sealed with tape, and will then be routinely collected from the laboratory by support staff. Bags of waste for incineration will be transported by a licensed contractor in secondary containment appropriate for transport on public roads.

Note that other safety requirements, such as COSHH will also be sent.

5. Transgenic plant material

As noted in 1 above, in general, waste containing genetically modified material will be inactivated prior to leaving the laboratory site. However, as an exception, genetically modified plant waste originating from IFR glasshouses, and which IFR Genetic Manipulation Safety Committees consider to be Containment Level A or B, will be sent off-site direct for incineration without prior inactivation, via an approved contractor, using yellow bags held inside rigid transport bins.

6. General Administration

All waste bins will be clearly labelled. All staff (particularly visiting workers) will be instructed on the disposal procedures for biological waste, particularly the differences between biological waste for autoclaving and ordinary non-hazardous waste e.g. office materials (black bags).

Waste Disposal Procedure at the John Innes Centre (JIC) Site.

Only genetically modified plant waste originating from JIC glasshouses, and which JIC Genetic Manipulation Safety Committees consider to be Containment Level A or B, will be disposed at JIC site. All JIC genetically modified plant waste will be autoclaved and subsequently composted on the site in accordance with JIC Safety Procedure.
More details on genes and bacterial strains will be used for research should be introduced;

Nicotiana spp have a commercial crop in the UK as ornamental varieties, and this issue should be taken in consideration.

The final version of the risk assessment was modified in accordance with comments and was accepted as adequate for the project.

---

### Project Additional Information
