Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be treated with chloros for >24 hours at >10% (10,000ppm). (Validated experimentally 100% kill) inactivated liquid waste will be disposed of in dedicated drains leading directly to sewer waste.

All solid waste will be soaked in chloros for >24 hours at 5% (5,000ppm), followed by autoclaving for 15 minutes at 120 C, followed by incineration. (100% kill).
All waste inactivation procedures will be carried out within the level 3 containment facility.

Psuedotyping with pVSV-G and insertion of SV40 large T antigen and other potential oncogenes raises this project to level 3. This work will be conducted in the UCL Jules Thorn Category 3 laboratory that is under the control of the Dept of Surgery local rules must be followed and Ludwig staff who use this facility must provide evidence of training for work in Category 3 environments to the LICR Biological Safety Officer.

Please enter comments on the GM safety committee on the risk assessment

**Project Additional Information**

**Purposes of the contained use**

This programme of work will use amphotropic retrovirus and adenovirus vectors to help study the functions of cellular and viral genes that affect the regulation of cell proliferation and cell survival.

**Recipient or parental organism**

Cell lines, such as QBI-HEK293A, which complement the E1A and E1B defect in adenovirus vectors, will be used to package the adenovirus. Once introduced into a complementing cell line that provides the E1 products in trans, adenovirus replication is possible.

Amphotropic or polytropic cell lines such as AmphoPack-293 or retroPack PT67 (BD Biosciences/Clontech) will be transfected with retrovirus, to produce virus capable of infecting human cells. Highly transfectable cell lines such as HEK293T and NIH3T3 cells will be used to package retroviruses.

Mammalian cells including U20s, Saos2, B cell lines will be used to transduce the recombinant viruses.

Cell lines are free of adventitious agents, and have a history of safe usage in the laboratory, equivalent to level 1.

**Host/vector system**

Adenoviruses (commercially available Adenovator or AdEasy or similar vectors that are commercially available). Adenoviruses can cause disease in humans, however, recombinant adenoviruses generated have their E1 and E3 region deleted. Such deletions prevent the recombinant viruses from replicating. The recombinant virus will be replication incompetent and non-pathogenic.

Retrovirus vectors based on non-human animal viruses such as Moloney murine leukaemia virus (Mo-MuLV), such as pMSCVpuro.

**Origin & function**

The following inserted genes cannot alter the pathogenicity of the recipient. The inserted genes to not encode for a pathogen or pathogenic determinant. As cancer development is a multistep process, transduction with such genes will not transform the infected cells.

* Cellular and viral genes that promote cell proliferation and/or decrease apoptosis - such genes are generally, but not exclusively oncogenes. This programme of work will not include viral oncogenes that have multiple oncogenic activities such as SV40 T antigen, nor will it include clusters of oncogenes such as HPV16 E6-E7. Genes encoding toxins will not be included in this work.

* Single growth-promoting (for example ras, E2F1, myc, E1A, mdmd2) and anti-apoptotic genes (for example iASPP, Bcl-XL).

* Tumour suppressor genes (for example p53, ASPP, RB, p130) and pro-apoptotic genes (for example Bax, Bik and Bad).

* SiRNAs: The SiRNA genes used in this work will be directed against regulators of cell growth and survival (e.g. oncogenes, tumour suppressor genes and pro-
anti-apoptotic genes). SiRNA's directed to tumour suppressor genes would be expected to promote cell growth, while those directed to oncogenes would be expected to inhibit cell growth. However, it is extremely unlikely that ablation of a single gene, as proposed in this project, would have major effects on cell growth and/or survival.

**Evaluation of foreseeable effects**

Adenovirus and amphotropic vectors are designed to infect efficiently cells of many different species and lineages. The two major foreseeable effects are accidental transduction of laboratory personnel and animal species such as mice. These vectors are replication defective and the risk is therefore limited to cells accidentally transduced with the packaged vector. The consequences for animal species are therefore negligible, since even in the extremely unlikely event that mice were exposed to the packaged vector, the virus could not propagate. Replication-competent retroviruses can be generated at low frequencies in packaging cell lines, albeit it seems likely that acquisition of viral replication functions by the vector would be at the expense of the inserted transgene. The use of these vectors will be restricted to transduction into cells in tissue culture, and the risk that infectious virus will be transmitted to animal species is minimal under Containment Level 2 conditions proposed for this project.

Retroviruses can cause pathogenicity, e.g. FeLV in cats. However, only severely deleted vectors will be used and recombination to generate WT virus will be impossible with the non-feline packaging systems used. MuLV is pathogenic in mice. Again the vector is severely deleted. Although there is a risk that low titres of replication competent MuLV can be generated during packaging, these will be insufficient to cause disease. In any event, mice have plentiful endogenous retroviruses which potentially are replication competent.

Exposure of laboratory personnel to packaged vectors containing growth promoting genes such as oncogenes or anti-apoptotic genes could result in some growth advantage of transduced cells. Similarly, transduction with retroviruses encoding siRNAs directed to growth inhibitory genes such as tumour suppressor genes and pro-apoptotic genes could also result in a growth advantage. The single genes targeted in these studies cannot by themselves result in cell transformation, even in highly responsive rodent cells. Targeting of combinations of genes with the potential to cause cell transformation has been specifically excluded from this programme of work. It should also be noted that with the scale of production to be used, it is extremely unlikely that accidental transduction will occur at stem cells at risk of carcinogenic development. Because of the very slight risk involved, it is proposed to carry out this activity under Containment Level 2 conditions.

Accidental exposure of laboratory personnel with packaged vectors carrying genes that inhibit cell proliferation and/or are pro-apoptotic is very unlikely to have any consequences. Similarly, transduction with retrovirus vectors encoding siRNAs directed to growth promoting genes such as oncogenes and anti-apoptotic genes would only inhibit the growth of the cells infected. In principle, transduction of stem cells could inhibit their growth and prevent them from participating in tissue maintenance. In practice, it is unfeasable that sufficient stem cells could be affected in this way to have any consequences for human health. Because of the very slight risk involved, it is proposed to carry out this activity under Containment Level 2 conditions.

It is noted that insertion of certain viral oncogenes (such as HPV16 E6 and E7 and some EBV genes) into E1a/E1B-deficient adenovirus vectors can complement their growth defect. Experimental observations show that rescue is incomplete (Steinwaerder et al., Mol Ther. 4:211-216, 2001) and replication of the recombinant is significantly less than that of wild-type virus. The recombinant virus would therefore be debilitated in its ability to spread in an infected human host. The risk associated with such recombinants is therefore no greater than that of the wild-type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Containment level 2**

In order to reduce the risk of infection of laboratory workers to an absolute minimum, this work will be carried out in an ACGM Containment Level 2 facility. All staff engaged in such work will wear protective clothing including gloves and goggles.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste will be treated with chloros for >24 hours at >10% (10,000 ppm). Validated experimentally 100% kill). Inactivated liquid waste will be disposed of in

Project Additional Information

Purposes of the contained use

This programme of work will involve the use of lentivirus vectors to aid analyses of the functions of cellular and viral genes involved in cell cycle regulation and cell survival.

Recipient or parental organism

Human 293 cells.

Host/vector system

Lentivirus vectors (non-replicating): Three separate plasmids will be transiently cotransfected into 293 cells to produce pseudotyped, packaged viruses. One plasmid will encode for the HIV-1 derived vector, one encodes the VSV-G and one provides functions in trans for packaging. Vectors are based on deleted/mutated HIV-1 genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope (VSV-G).

Origin & function

Vectors are based on deleted/mutated HIV-1 genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope (VSV-G). Lentivirus vectors provide an efficient means to transduce oncogenes and anti-apoptotic genes into human cells. The vectors can stably integrate into host cell DNA for sustained long-term expression of the cDNA transgene or siRNA. In these studies the cDNAs will encode for, and the siRNAs will be directed against, cellular or viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis, or inhibit cell proliferation and/or promote apoptosis.

Evaluation of foreseeable effects

The pseudotyped recombinant viruses have the ability to infect most cells with subsequent expression of the foreign gene or siRNA. Therefore all progeny cells will express the foreign DNA, but no new HIV-1 virions can be produced from the infected cell because the vectors (which carry deletions and/or mutations) are replication-defective.

There is a finite theoretical risk that if the virus infects a laboratory worker (eg by spillage in the eye) the transgene or siRNA will be expressed in the infected cells. Since the vectors cannot replicate to infect new cells, this significantly reduces the risk. There is also a theoretical risk of a worker being infected and expressing HIV Gag and Pol proteins (from the pAG132 vector or derivatives). However, since the recombinant virus cannot replicate, the number of expressing cells will be very small and the amount of protein expressed very restricted, the likelihood of an individual sero-converting is considered to be vanishingly small.

There is a theoretical risk of recombination with wild-type HIV-1 or HIV-2. However, there is no report of this ever happening. In any case, recombination restoring all HIV genes - which is necessary to produce a replication-competent virus - would delete the transgene, converting the recombinant virus to wild-type.
The recombinant viruses can only be packaged by cotransfecting the three plasmid components of the vector system into 293T cells. Transfected cells producing the recombinant virus must be maintained in tissue culture and cannot survive outside the laboratory. Although theoretically the lentiviruses would be able to infect other animal species such as rodents, the likelihood of this occurring accidentally is negligible. In the event that this did occur, the recombinant virus would be unable to propagate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Containment level 2

In order to reduce the risk of infection of laboratory workers to an absolute minimum, all work will be carried out in a tissue culture safety cabinet in an ACGM Containment Level 2 facility. All laboratory staff engaged in such work will wear protective clothing including gloves and goggles, and no sharps (glass or needles) will be used. Aerosol contamination will be minimised by confining the virus to closed containers during mixing and agitation procedures. Containers will only be opened in the safety cabinet.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste will be treated with chloros for >24 hours at >10% (10,000 ppm). (Validated experimentally 100% kill). Inactivated liquid waste will be disposed of in dedicated drains leading directly to sewer waste.

All solid waste will be soaked in chloros for >24 hours at 5% (5,000ppm), followed by autoclaving for 15 minutes at 120 degrees C followed by incineration. (100% kill).

All waste inactivation procedures will be carried out within the level 2 containment facility.

N

**Please enter comments on the GM safety committee on the risk assessment**

With a severely disabled virus, this would normally be a category 1 project but the use of inserts that promote cell proliferation raise it to category 2. In addition, the Category 2 containment laboratory on the third floor (where the work will take place) will operate as a sharps-free environment (no needles or glassware of any kind allowed in the facility).

Tick if confidential  

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum volume of culture is 12 litres.

All waste is autoclaved at 121 degrees C before disposal. The duration of the period of autoclaving is dependent on the volume or quantity of waste. Large volumes of waste eg. 12 L are autoclaved at 121 degrees C for 60 minutes. The autoclave used for large volumes is 'temperature logged' and aliquots of the liquid effluent will be plated out onto agar medium to check for viable organisms before discharge to the drains.

**Project Additional Information**

**Purposes of the contained use**
To improve understanding of plant metabolism, especially in legumes, by altering gene expression.

**Recipient or parental organism**
Lotus and Trifolium species
Agrobacterium rhizogenes strain C58C1 LBA9402
[Plant pathogen. Class 2. Use requires Plant Health license from DEFRA]

**Host/vector system**
Disabled E. coli/pUC/pIC/p Bluescript/pBin19 derivatives used to transform Agrobacterium rhizogenes
Agrobacterium rhizogenes is used to transform plants genetically eg Lotus and Trifolium.

**Origin & function**
The Genetically Modified Micro-organism Agrobacterium rhizogenes acts as a plant vector and the modifications do not involve manipulating its plant pathogenicity.

Genes isolated from a range of bacterial and plant sources will be introduced into A. rhizogenes, which will then be used to transform plants. None of the inserted genes will be expressed in A. rhizogenes. The inserted sequences include selectable marker genes, reporter genes and known genes or non-characterised plant sequences inserted in sense and antisense orientations that will potentially alter secondary metabolism and symbiotic interactions of the plants transformed with the sequences concerned. Inserted sequences will include
a) selectable markers for antibiotic resistance - kanamycin and hygromycin (from bacteria) - and herbicide tolerance - phosphophinothricin (PPT, bacteria).
b) reporter genes - glucuronidase (bacteria) and green fluorescent protein (jellyfish).
c) secondary metabolism genes from flavonoid pathway - chalcone synthase (plant), dihydroflavonol reductase (plant)
d) symbiotic genes - early and late nodulins, calcium binding protein (plant)
e) sequences isolated from plants, but whose role in the biochemical pathway is unknown, and is being determined.

**Evaluation of foreseeable effects**
Genetically Modified Microorganisms. A. rhizogenes:

**Risk to human health**

</tr>
</tbody>
</table>

The inserted bacterial and plant genes have no foreseeable effect on human health.

**Risk to Environment**

Agrobacterium rhizogenes is a soil-borne plant pathogen causing hairy root disease. Current information indicates that its pathogenicity has little economic impact on crop production. A rhizogenes is used as a plant vector and the modifications do not involve manipulating its plant pathogenicity. The inserted sense and antisense genes - antibiotic or reporter genes, known genes or non-characterised sequences related to metabolism in plants - are not expressed in the bacterium and are themselves unlikely to alter the pathogenicity of the bacterium.
While A. rhizogenes has the potential for a minor impact on the environment as a plant pathogen, the inserted genes are unlikely to increase that potential. In the unlikely event that genetically transformed A. rhizogenes were to escape and effect indigenous plants, the resultant hairy root tissue would contain and could express any of the inserted genes. However, any expression would be restricted to the hairy roots themselves and these hairy roots are unlikely to regenerate into new plants. Plant regeneration from roots usually requires very specific, controlled culture conditions, and then only occurs in a limited number of species.

The inserted gene would not be expected to confer any significant advantage on the hairy roots unless other unlikely conditions were also met. For example, hairy root tissue transformed with the PPT herbicide tolerance gene (as the result of accidental escape of A. rhizogenes) might be at an advantage if it came into contact with the herbicide. However, this herbicide is not used routinely in British agriculture and, normally, roots die without a shoot system. In a worse case scenario, these plants might be unusual and be able to regenerate shoots directly from the herbicide tolerant hairy roots.

The containment measures adopted will prevent escape of genetically manipulated A. rhizogenes. All bacterial and plant/bacterial work will be done in Class 2 safety cabinets. The bacterium will be maintained in sealed units, cultures will be contained within the laboratory and kept in growth rooms. A warning notice will be displayed next to bacterial cultures and plant cultures potentially containing A rhizogenes as agreed by DEFRA. Plant material will be rigorously tested for sterility to ensure that A. rhizogenes is removed prior to transfer to soil or equivalent in Plant Containment Level A growth rooms and glasshouses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The resulting GM plants will be grown under established facilities under agreed procedures for Containment Level A, in a locked, insect-proof compartment with no free drainage. All transgenic material will be free of Agrobacterium species before transfer to soil.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste is collected in labelled autoclave bags and autoclaved at 121 degrees C, 40 minutes, 15 psi
Autoclave is tested annually using a thermocouple and whenever autoclave is re-commissioned after maintenance work.
Autoclaved waste collected and disposed of by the local authority.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The local Genetic Modification Safety Committee (GMSC) considers that the risk assessment meets current regulations even though the comments on the original risk assessment were made under the regulations enforced in 1993. The agreed procedures state that all manipulations using A. rhizogenes will be done in a Class 2 hood.

The GMSC has now reclassified this activity as recommended by HSE as a Class 2 activity under the current regulations.

Waste is autoclaved to inactivate GMMs. A cycle of 121 degrees C at 15 psi for 30 mins is used to inactivate GMMs.

An in-load probe is used to monitor temperature in addition to the normal chamber temperature probe. To monitor the cycle, the loads are marked with autoclave indicator tape and each load carries a temperature indication tube. In addition, there is a chart recorder for load temperature throughout the cycle. Each run is logged.

Spore strips are included in a load on a monthly basis, to verify the autoclaves ability to inactivate microbes.

The autoclave is checked for performance and serviced at least on an annual basis and every 14 months for a pressure check.

The maximum culture volume of GMMs in any one vessel, which could potentially be released at any one time, would be no more than 400 ml. Please note, however, before autoclaving, this volume of culture would be aliquoted into several containers to ensure adequate heat penetration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Project Containment**
### Project Additional Information

**Purposes of the contained use**

A previously described cDNA for a vector based on tobacco-mosaic virus strains U1 and U5 will be genetically engineered to express various carrier proteins with peptide fusions. Plants belonging to the genus Nicotiana will be infected with in vitro transcripts produced from the genetically engineered cDNAs. Levels of in planta protein accumulation and stability of the genetically engineered viruses will be assessed. If adequate levels of recombinant proteins accumulate in planta, methods for purification of the recombinant proteins will be developed.

**Recipient or parental organism**

TMV is indigenous to the UK and the TMV based vector has been previously notified to HSE (GM 250/98.3). Although TMV is a major cause of disease in tobacco, this crop is not grown commercially in the UK. Extensive prior work has shown that GMOs derived from the recombinant TMV-based vector and in planta recombinants that arise for them are less pathogenic to plants than natural TMV (Rabindran S, Dawson WO Assessment of recombinants that arise from the use of the TMV-based transient...
### Host/vector system

- **Host:** Noctiana species
- **Vector:** Recombinant virus based on TMV

### Origin & function

The following proteins will be tested as carrier proteins for peptide immunogens expressed by the recombinant virus in plants:
- Mammalian immunoglobins (IgGs)
- Non-catalytic cholera toxin B-subunit (CTB)
- Non-catalytic E.coli heat labile toxin B-subunit (ETEC)
- VP1 structural protein of foot-and-mouth disease virus
- 3D polymerase protein of foot-and-mouth disease virus

### Evaluation of foreseeable effects

The viral proteins produced by the recombinant plant virus vector occur in nature and have no known risks to human health. Of the proteins that will be tested as carrier proteins IgGs, CTB, ETEC and VP1 have previously been tested as immunogens in mammals without adverse effect, and the 3D protein is present within currently used foot-and-mouth disease virus vaccines. These proteins are thus expected to present no risk to human health. Due to the genetic instability of the TMV-based vectors the sequences of foreign genes are rapidly lost and would not persist in the event of escape of the GMOs into the environment. Extensive prior experiments indicate the GMOs themselves do not present a threat to the environment, because of their genetic instability and the poor competitive fitness of such GMOs carrying foreign gene inserts relative to wild-type virus occurring in nature. The recombinants that will arise in planta from the GMOs will be fitter that the GMOs, however prior experimentation has shown that the recombinants arising in planta are still less pathogenic than wild-type TMV that occurs in nature. Therefore although the GMOs and recombinants have the capability to cause disease this is of little consequence as natural virus is more pathogenic and tobacco is not grown commercially in the UK.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Glasshouse benches resistant to acids etc. derogation applied for on basis that benches are made of wire mesh for ease of cleaning. Receptacles to prevent any run off will be included.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give a 100% kill. Contaminated surfaces will be disinfected with a proprietary virucide validated to give a 100% kill.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
Previous work has suggested that TMV constructs are very useable and inserts are likely to be lost within 2 passages. All the carrier proteins except FMDV 3D have been expressed previously in transgenic plants, so risks to human health are not predicted. The 3D protein is present in some, though not all foot-and-mouth disease vaccines, but has not been previously expressed in plants. However, there is no risk to the environment due to the likely instability of the construct.

### Project Ref 250/01.2

- **Date Ackn’d:** 01/11/2001
- **CU2 Project Title:** DEVELOPMENT OF PLANT VIRUS-BASED VECTORS FOR GENE SILENCING STUDIES IN MONOCOTYLEDONOUS HOSTS
- **Class:** Class 2
- **CultureVol:** < 1 litre
- **Class CultureVol:** Class 2
- **VolumeClass:** < 1 litre
- **Non-GMM:** Consent Granted
- **Project notified under transitional arrangements:** N

### Project Additional Information

**Purposes of the contained use:** The purpose of the project is the development of plant virus-based vectors and inoculation techniques for analysis of monocotyledonous plant gene function through silencing. Plant viral cDNAs, under the control of bacteriophage promoters for in vitro transcription, will be genetically modified through the insertion of genes for easily
detectable reporter proteins to monitor virus movement. The genetically modified viral cDNAs will be further placed under the control of plant promoter sequences to test biolistic and Agrobacterium-mediated inoculation of specific target tissues. The ability of the genetically modified viruses to induce silencing will be tested through the insertion of plant derived cDNA sequences.

**Recipient or parental organism**

- Barley stripe mosaic virus (BSMV), US isolate.
- Foxtail mosaic virus (FoMV), US isolate.
- Soil borne wheat mosaic virus (SBWMV), Japanese isolate.

**Host/vector system**

- **Host:** Escherichia coli strains XL1-Blue and DH5a.
  **Vector:** pUC-based plasmids containing plant viral cDNAs under the control of bacteriophage or plant promoters.

- **Host:** Agrobacterium tumefaciens strains LBA4404 and AGL-1.
  **Vector:** binary plasmids, ie. pBIN19 and pGREEN, containing plant viral cDNAs under the control of plant promoters.

- **Host:** Hordeum volgare
  **Vector:** Recombinant plant viruses based on BSMV, FoMV and SBWMV.

**Origin & function**

- Green fluorescent protein (GFP) from Aequorea sp., reporter protein.
- Red fluorescent protein (RFP) from Discosoma sp., reporter protein.
- B-glucuronidase (GUS) from Escherichia coli; reporter protein.
- Hordeum vulgare cDNAs, candidate genes for silencing.

**Evaluation of foreseeable effects**

The viral proteins produced by the recombinant viruses occur in nature and have no known risks to human health. The reporter proteins GFP, RFP and GUS have been expressed in a wide range of experimental systems and do not present a risk to human health. All three viruses to be used are non-indigenous plant pathogens and thus subject to legislative control. FoMV does not cause economically important disease and its natural hosts are not indigenous to the UK. SBWMV and BSMV are a cause of disease in wheat and barley. In order to provide robust biological containment portions of the coat protein genes of BSMV and SBWMV will be deleted to render them non-transmissible by mechanical and fungal routes respectively. The genetic modification required to disable their natural transmission routes will result in increased symptom severity on inoculated plants. Previous insertion of reporter protein genes into plant viral genomes has resulted in the creation of attenuated viruses and no mechanism for enhanced pathogenicity can be foreseen. The introduction of plant derived sequences into plant viral genomes and the induction of host gene silencing can affect the symptomatology of infections. However, previous experiments with vectors based on RNA plant viruses have shown introduced sequences to be very rapidly lost through in planta recombination events (for review of genetic instability in genetically modified RNA plant viruses see: Lacomme et al (2001) Plant Viruses as Gene Expression Vectors, in: Ring CJA and Blair, ED (Eds) Genetically Engineered Viruses: Development and Applications, BIOS Scientific Publishers, Oxford). Therefore, the genetically modified plant viruses are considered to present less risk to the environment than the natural progenitor viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Contaminated surfaces will be disinfected with a proprietary virucide validated to give 100% kill.

The committee discussed the following points:

The risk of whether silencing of genes could result in more severe symptoms was raised, but the committee were informed that introduced sequences are generally rapidly lost. DNA-based inocula were stated to pose no greater risk than DNA constructs for in vitro transcription. For agrobacterium inoculation of barley stripe mosaic and wheat soil borne mosaic viruses, mixed inoculums, with the genomes separated between 2 or 3 plasmids would be used to reduce risk in the event of an escape. The risk of escape would be greater for the monopartite foxtail mosaic virus, but there would be less effect to the environment. It was asked if any risk was foreseen to any UK horticultural crops, but confirmed not to be the case. The strict emphasis of pollen containment was reiterated by the committee.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 250/02.2

Date Ackn’d 17/09/2002

CU2 Project Title AGROINOCULATION OF SOLANUM SPECIES WITH RECOMBINANT PVX CONSTRUCTS IN A STUDY OF RESISTANCE/AVIRULENCE MECHANISMS

Class 3

CultureVolumeClass3-4 less than 1 litre

Non-GMM Consent Granted yes
The aim of this proposed research are to characterise functional roles for Phytophthora Exported Proteins (PEXs) in triggering different forms of resistance within potato. The experimental system proposed is the Agroinoculation of expressed sequence tags encoding proteins with a putative signal peptide into young potato plants and the assessment and RNA analysis of the resultant plant material.

**Recipient or parental organism**

Potato Virus X
A full-length cDNA clone of the potexviurus (pGR106), potato virus X (PVX), will be supplied by our collaborators. Individual cDNAs of unknown function (expressed sequence tags encoding proteins with a putative signal peptide) from Phytophthora infestans, Peronospora parasitica or P. sojae will be inserted into the PVX backbone in which their expression will be controlled by the duplicated PVX coat protein promoter.

**Host/vector system**

The viral genome will be cloned into Agrobacterium tumefaciens T-DNA and in planta synthesis of infectious recombinant PVX transcripts will be driven by the cauliflower mosaic virus (CaMV) 35S promotor. These transcripts will subsequently initiate the formation of virus particles that infect the tissue surrounding the inoculation site.

Plant species to be used initially will include later blight-resistant and susceptible accessions of Solanum papita, S. chacoense, S. verrucosum, and S. demissum. They would be expressed in a range of S. tuberosum differentials containing the full set of R. genes from S. demissum, singly and in combinations, to seek triggers of race-specific resistance to P. infestans. They would also be expressed in progeny derived from S. tuberosum cv. Stirling to seek the triggers of high-level field resistance to P. infestans. In addition, the GMO will also be inoculated onto Nicotiana benthamiana.

**Origin & function**

From an extensive set of P. infestans expressed sequence tags, our collaborators have identified many genes possessing predicted signal peptides, termed PEX (Phytophthora exported proteins). These genes have been individually cloned into a potato virus X (PVX) - Agrobacterium vector for expression in plants. These workers have then used these recombinant PVX constructs for inoculation of Nicotians sp. in a study of non-host resistance/avirulence mechanisms.

We can obtain these recombinant PVX constructs and propose to use them for Agroinoculation of Solanum sp. in a study of resistance/avirulence mechanisms at the species, and also cultivar level. If the P. infestans gene to be expressed from PVX in planta encodes an avirulence gene, we may expect to see localised necrosis (HR) at the point of inoculation, or systemic necrosis if the virus is able to spread through the plant. This response would be confined to one or few host plant genotypes; other host plant genotypes would show no visible response. Expression of putative pathogenicity factors in plants may be more difficult to detect or interpret. For instance, suppression of defence responses by the expressed gene may only be detectable by inoculation and infection with an incompatible P. infestans isolate, and subsequent host defence gene expression analysis. However, in many cases, the recombinant PVX will not lead to any change in the host plant, except for that caused by PVX.
Determination of both pathogenicity factor and avirulence genes from *P. infestans* will provide us with novel targets for both chemical and biotechnological control of late blight. It also will allow us to identify genetic components of more complex host resistance phenotypes such as field resistance to late blight, which can then be used in potato breeding programmes.

In our experiments, only very young plants will be used for inoculation, and inoculated plants will be kept for a maximum of 28 days. Therefore, spread of the virus through pollen dispersal will therefore not occur, as host plants will not be kept in the experimental system for sufficient time for flowering to occur, therefore seed will also not be collected.

Leaf samples will be taken for gene expression analysis. Samples will be immediately frozen in the glasshouse area and transferred in sealed, easily decontaminated containers to SCRI laboratories for RNA extraction. Potato tubers will be destroyed after experiments are completed. Plants will be destroyed by autoclaving after experiments have been completed. All material will be placed into sealable autoclavable receptacles within the glasshouse compartment and transported to the autoclave sited within the facility for destruction.

Plants infected with the GMO may be challenged with pathogenic *P. infestans*, or other non-pathogenic *Phytophthora* sp., to determine if any change to host resistance/susceptibility has occurred due to the expression of the GMO. These additional experiments would take a further 7 days, taking the total potential length of the experiments to 35 days. All material, with the exception of leaf samples retained for RNA analysis, would be destroyed by autoclaving at the conclusion of the experimental work.

**Evaluation of foreseeable effects**

**Risk to human health**

* Wild type PVX
PVX is not known as a hazard to human health and there is no evidence to suggest that it could be.

* Recombinant PVX
The foreign genes to be expressed in the recombinant PVX (the GMO) are of unknown function or biological activity. Transgenes will encode protein products from oomycete plant pathogens such as *P. infestans* (potato late blight), *P. sojae* (soybean root rot), or *Pe. parasitica* (downy mildew of Arabidopsis thaliana). The majority of transgenes to be tested will originate from *P. infestans*.

As the work will be strictly contained and no tubers will be produced from the experimental plants there will be no risk from consumption of novel potato material. Reports exist that consumption of blighted potatoes leads to birth defects of the nervous system, but these have not been proven, and have been largely refuted by Borman and Cryer (1990). Direct testing of *P. infestans* extracts on chick embryos has determined that there was no evidence for toxicity (Wu and Salunke 1978) and that any birth defects are caused by glycoalkaloids present in the potato tuber (Jelinek et al., 1976). No toxicology studies have been carried out on the related species *P. sojae* or *Pe. parasitica*, and there are no records to implicate either organism in human disease. In the extremely unlikely event that any of the expressed gene products are determined in other work elsewhere to be toxic to humans from other experiments, experiments with these genes will cease immediately.

* A. tumefaciens
Agrobacterium tumefaciens occurs naturally in soil and is not known to be a pathogen of humans. It has been used safely as a vector for transgene delivery into plants for many years. It is not expected to pose any threat to human health under the conditions to be used for experimentation. Generic risk assessments for manipulation of A. tumefaciens and agroinoculation are available at SCRI.

* Host plant species
None of the host plants (Solanum sp. or nicotiana sp.) to be used in our experimental system pose a threat to human health under the conditions to be used for experimentation.
* P. infestans
P. infestans occurs as an introduced pathogen on potato crops in the United Kingdom. It is not known as a human pathogen. It is not expected to pose any threat to human health under the conditions to be used for experimentation.

Risk to the environment

* Wild type PVX
Wild type PVX is transmissible by direct contact between infected plants or indirectly through mechanical transmission. PVX is not transmitted by aphids, and its host range is mostly limited to solanaceous plants. At worst, wild type PVX can cause yield losses in potato of up to 15%. In our experiments, the conditions for transmission of the virus will be prevented. Handling of infected plants will be minimised, disposable gloves will be worn for all handling of infected plants, and all materials that come in contact with the infected plants will be placed into sealable autoclavable receptacles within the glasshouse compartment and transported to the autoclave sited within the facility for destruction.

* A. tumefaciens
For agroinoculation of PVX into potato plants, it is highly unlikely that the A. tumefaciens strain would escape. Containment measures include: leaves are inoculated and subsequent watering of plants is from below so no water run off can occur from the leaves, any A. tumefaciens remaining on the leaf surface will be exposed to dessication, and A. tumefaciens does not spread beyond the site of initial inoculation. The glasshouse floor will be sealed, and the drains blocked off. In the highly unlikely event of flooding in the area the run-off will be routed into a holding tank and treated with an oxidising agent prior to release by manually-operated valves to mains drainage. As stated in the risk assessment, gloves will be worn at all times when inoculations are being performed and these will be autoclaved after use and before disposal. In addition, all soil, infected plant material, and any excess water in containment trays will be autoclaved at the conclusion of the experimental work.

* Recombinant PVX
The above actions are expected to prevent the escape of live A. tumefaciens carrying recombinant PVX. In the highly unlikely event of live A. tumefaciens carrying recombinant PVX escaping the containment measures in place, it is unknown whether the recombinant PVX construct could be transferred to other rhizosphere organisms, and hence into new host plants. Although numerous plant viruses can be spread by rhizosphere organisms, such as fungi and nematodes, PVX is not known to spread in this way. It is unlikely that the presence of the PVX constructs would confer any novel phenotype upon A. tumefaciens. This is due to the fact that the PVX constructs should be actively transcribed into infectious virus in the bacterial cell, being under the control of the CaMV35S promoter element, and the transgene itself is under control of the PVX coat protein promoter, both of which are transcribed only in planta. The combination of all of the above factors render the risk of escape of recombinant PVX via the A. tumefaciens route as negligible.

A further containment measure that could be applied to prevent the spread of recombinant PVX into potato fields, in the event of escape from the containment facility, would be to carry out the agroinoculations outside the usual potato growing season, such as the period September to April. Obviously we would wish to carry on these experiments year round but are willing to concede that it may be necessary to restrict the time for recombinant PVX research.

* Modifications to the host range of the GMO
For the majority of transgenes tested, there will be no effect on the infectivity, disease development, or host range of the GMO. However, the GMO may express genes that either cause more intense disease symptoms (necrosis) or suppress the host plant defence responses, thus leading to more rapid disease development and more intense disease symptoms. It is also possible that the expression of transgenes from the GMO may also alter the host range of the virus, leading to subsequent strong selection for the GMO in the unlikely event of escape.

However, in case of any viral escape, recombinant viruses often spontaneously delete the transgene from the viral genome (for example Chapman et al., 1992). This may occur due to viral packaging constraints being ‘overstretched’ with the insertion of the transgene.
In the highly unlikely event of any escape of the GMO, it should be noted that most major varieties of potato grown in the vicinity of SCRI, and throughout Scotland possess field immunity to PVX (for example varieties Maris Piper, Cara, King Edward, Pentland Dell, Pentland Javelin, Pentland Squire).

* P. infestans

Most potato varieties grown in Scotland are however susceptible to late blight, caused by P. infestans. Control of late blight is typically by frequent treatment of crops with fungicides active against P. infestans. It is very unlikely then, that infection of potato crops by escaped recombinant PVX would have any effect on the level or severity of late blight in those crops.

**Laboratory manipulation and analysis of the GMOs** will be performed in a laboratory equipped to containment level 2.

**Experiments on the GMO** will be carried out in the AN building at SCRI, a designated containment glasshouse facility designed to prevent any dissemination of the GMO. The facility is insect and vermin proof. Access is restricted to authorised personnel and the facility is equipped with two 'through the wall' autoclaves. To prevent escape of mechanically transmissible PVX, all handling of infected plants will be carried out with gloved hands and gloves disposed of appropriately. Designated laboratory coats are provided for work in the containment glasshouse and these coats are not removed from the containment facility unless in autoclave bags for sterilisation. Furthermore, any material that might be contaminated by PVX (plant material, pots, soil, labels, gloves) will be placed into sealable autoclavable receptacles within the glasshouse compartment and transported to the autoclave sited within the facility for destruction via accredited autoclave cycles.

The cubicle and benches (for which we apply for derogation as they are of wire-mesh) to be used for testing of the GMO will be cleaned and disinfected prior to commencement, and after completion, of experimental work. Initial analysis of the GMOs will be performed on no more than 50 plants at one time. However, larger numbers of plants will be required if the GMOs are to be screened across progeny derived from S. tuberosum cv. Stirling. In this instance, no more than 200 plants would be required. Escape of live A. tumefaciens will be prevented through the employment of procedures currently used at SCRI for agroinoculation, for which a generic risk assessment exists at SCRI (attached). SOPS include restriction of access to plants and watering only by licensed staff, control of water run-off through the use of trays, and watering from beneath. The glasshouse floor will be sealed, and the drains blocked off. In the highly unlikely event of flooding in the area the run-off will be routed via a default setting into a holding tank and treated with an oxidising agent prior to release by manually-operated valves to mains drainage.

Records of all glasshouse experiments will be maintained for inspection, including all details of plant disposal.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Glasshouse benches resistant to acids etc., derogation applied for on basis that benches are made of wire mesh for ease of cleaning. Receptacles to prevent any run off will be included. The glasshouse floor will be sealed, and the drains blocked off. In the highly unlikely event of flooding in the area the run-off will be routed via a default setting into a holding tank and treated with an oxidising agent prior to release by manually-operated valves to mains drainage.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Contaminated surfaces will be disinfected with a proprietary virucide validated to give 100% kill. All material from glasshouse will be bagged within the designated containment cubicle, prior to transportation in closed receptacles to autoclaves within the glasshouse.

**Is an emergency plan required according to regulation 20?**

### Project Additional Information

P. infestans is a hemibiotrophic comycete pathogen that predominantly infects the foliage of potato plants. Related oomycete pathogens such as P. sojae and
Peronospora parasitica have very different life styles to P. infestans; P. sojae is a hemibiotrophic pathogen of soybean that infects predominantly through the roots, and Pe. parasitica is a strictly biotrophic pathogen that infects Arabidopsis thaliana foliage.

From an extensive set of P. infestans expressed sequence tags, our collaborators have identified many genes possessing predicted signal peptides, termed PEXs (Phytophthora exported proteins). In addition, an extensive targeted gene discovery programme is underway at the Scottish Crop Research Institute (SCRI) aimed at identifying genes involved in the lifecycle stages of P. infestans prior to, and during, infection of potato. In the instance of P. infestans pathogenicity and avirulence genes, these will be genes that are either (or both) strongly up-regulated during infection of potato, or the P. infestans homologues of genes implicated in pathogenesis or avirulence of other plant pathogens. Many of the genes to be tested will have no homology to genes of known function. Our aim is to determine the phenotypic effects of constitutive expression, and/or silencing, of the discovered genes on specific pathogen cell types, pathogenicity, and avirulence. Our gene discovery programme also includes comparative analyses with the pathogens mentioned above, especially Pe. parasitica.

We aim to express avirulence genes from these related pathogens in P. infestans. The question we will address with this research is whether genes involved in avirulence in the named organisms have any role or effect in the P. infestans/potato interaction.

Determination of both pathogenicity factors and avirulence genes in P. infestans will provide us with novel targets for both chemical and biotechnological control of late blight. It also will allow us to identify genetic components of more complex host resistance phenotypes such as field resistance to late blight, which can then be used in potato breeding programmes.

Recipient or parental organism

Isolates of the wild-type oomycete plant pathogen P. infestans will originate from the SCRI Phytophthora culture collection. Details of constructs to be used for transformation of P. infestans are attached (Figure 1). Promoter and terminator sequences (hsp70, ham34) originate from regulatory genes in the lettuce downy mildew pathogen, Bremia lactucae. In vector pSam, the regulation of P. infestans gene elements will be tested. It would be used to drive expression of the green fluorescent protein gene (gfp) for cellular localisation of gene expression during all life cycle stages, including infection of potato. In vector pTor, inserted genes will be constitutively expressed under control of the ham34 promoter. Both transformation vectors contain the antibiotic resistance gene neomycin phosphotransferase (nptII) under control of the same B. lactucae promoters mentioned above.

We aim to express and silence genes involved in both pathogenicity and avirulence in P. infestans. In addition, we also aim to express in P. infestans, genes involved in avirulence originating from P. sojae (a soybean pathogen) and Peronospora parasitica (Arabidopsis downy mildew) to determine whether they will function as non-race-specific (and thus more durable) avirulence genes in the potato-P. infestans interaction. The precise sequence identity of each of the genes to be tested is not known, as the gene discovery phase of the research is still in progress. In the instance of P. infestans pathogenicity genes, these will be genes that are either (or both) strongly up-regulated during infection of potato, or the P. infestans homologues of genes implicated in pathogenesis of other plant pathogens. Many of the genes to be tested will have no homology to genes of known function. For P. infestans avirulence genes, these are being identified by map based cloning, or by a candidate gene approach. It is therefore not yet known what these genes will encode.

For studies into heterologous gene expression and function we aim to express genes in P. infestans from related plant pathogens P. sojae, and Pe. parasitica. The question we will address with this research is whether genes involved in avirulence in the named organisms have any role or effect in the P. infestans/potato interaction. The transgenic P. infestans from these experiments will have either the same phenotypes listed above, or will invoke a general, non-host response in all potato varieties, or no change from the wild type will be observed. Since the transgenes will originate from related pathogens (for which potato is a non-host plant), it is highly likely that functionally related genes are already present in P. infestans.

Host/vector system

Numerous methods for the transformation of P. infestans are available such as transfection of protoplasts, electroporation of zoospores, Agrobacterium tumefaciens transformation or microprojectile bombardment of germinating sporangia. We will use the latter technique initially as it has the potential to be the highest throughput. If microprojectile bombardment is unsuccessful, we propose using the other methods listed.
The GMMs would be tested for pathogenicity against Solanum tuberosum cvs Bintje and Stirling, as well as a range of S. tuberosum differentials containing the full set of R genes from S. demissum, singly and in combinations, to seek triggers of race-specific resistance to P. infestans. The GMMs will also be tested against key species and accessions from the Commonwealth Potato Collection (housed at SCRI) to seek triggers of race-non-specific resistance. Species to be used initially will include late blight-resistant and susceptible accessions of Solanum papita, S. shacoense, S. verrucosum, and S. demissum. They would also be tested against progeny derived from S. tuberosum cv. Stirling to seek the triggers of high-level field resistance to P. infestans.

Constitutive expression of candidate avirulence genes isolated from P. infestans will result in the tested transgenic P. infestans becoming avirulent (or incompatible) with potato varieties carrying specific matching resistance genes. In this case, the host range of the transgenic P. infestans is expected to be reduced from the wild type (with the wild type originally being virulent, or compatible, on the resistance genes tested). For a P. infestans avirulence gene to be expressed, we may expect to see localised necrosis (HR) at the point of inoculation. This response would be confined to one or few host plant genotypes (carrying the cognate R gene); virulence/avirulence specificity towards other host plant genotypes should remain unchanged.

We will also silence avirulence genes from P. infestans. The outcome from these experiments would be transgenic P. infestans that have gained virulence towards specific, cognate resistance genes. In this case, it should be noted that wild type isolates collected locally also display the same virulence/avirulence traits towards the same potato resistance genes. That is, the genes to be tested, and their phenotypic variants, occur naturally in local P. infestans populations.

A further experiment we propose is that of heterologous gene expression and function. We propose to express genes in P. infestans from related plant pathogens P. sojae, and Pe. parasitica. The question we will address with this research is whether genes involved in avirulence in the named organisms have any role or effect in the P. infestans/potato interaction. The transgenic P. infestans from these experiments will have either the same phenotypes listed above, or will invoke a general, non-host response in all potato varieties, or no change from the wild type will be observed. Since the transgenes will originate from related pathogens (for which potato is a non-host plant), it is highly likely that functionally related genes are already present in P. infestans. Therefore, it is unlikely that introduction of the heterologous genes will have any effect on the host range of the transgenic P. infestans. Indeed, the opposite effect of restricting the host range may be more likely, as the host plant may recognise the foreign gene product and initiate a resistance response.

Origin & function

Constitutive expression of candidate avirulence genes isolated from P. infestans will result in the tested transgenic P. infestans becoming avirulent (or incompatible) with potato varieties carrying specific matching resistance genes. In this case, the host range of the transgenic P. infestans is expected to be reduced from the wild type (with the wild type originally being virulent, or compatible, on the resistance genes tested). For a P. infestans avirulence gene to be expressed, we may expect to see localised necrosis (HR) at the point of inoculation. This response would be confined to one or few host plant genotypes (carrying the cognate R gene); virulence/avirulence specificity towards other host plant genotypes should remain unchanged.

We will also silence avirulence genes from P. infestans. The outcome from these experiments would be transgenic P. infestans that have gained virulence towards specific, cognate resistance genes. In this case, it should be noted that wild type isolates collected locally also display the same virulence/avirulence traits towards the same potato resistance genes. That is, the genes to be tested, and their phenotypic variants, occur naturally in local P. infestans populations.

A further experiment we propose is that of heterologous gene expression and function. We propose to express genes in P. infestans from related plant pathogens P. sojae, and Pe. parasitica. The question we will address with this research is whether genes involved in avirulence in the named organisms have any role or effect in the P. infestans/potato interaction. The transgenic P. infestans from these experiments will have either the same phenotypes listed above, or will invoke a general, non-host response in all potato varieties, or no change from the wild type will be observed. Since the transgenes will originate from related pathogens (for which potato is a non-host plant), it is highly likely that functionally related genes are already present in P. infestans. Therefore, it is unlikely that introduction of the heterologous genes will have any effect on the host range of the transgenic P. infestans. Indeed, the opposite effect of restricting the host range may be more likely, as the host plant may recognise the foreign gene product and initiate a resistance response.

Evaluation of foreseeable effects

Risk to human health

P. infestans occurs as an introduced pathogen on potato crops in the United Kingdom. It, and other Phytophthora species are not known as human pathogens. No Phytophthora species is expected to pose any threat to human health under the conditions to be used for experimentation.

The foreign genes to be expressed in the recombinant P. infestans (the GMM) are of unknown function or biological activity. Transgenes will encode protein products from oomycete plant pathogens such as P. infestans (potato late blight), P. sojae (soybean root rot), or Pe. parasitica (downy mildew of arabidopsis thaliana). The majority of transgenes to be tested will originate from P. infestans. Reports exist that consumption of blighted potatoes leads to birth defects of the nervous system, but these have not been proven, and have been largely refuted by Borman and Cryer (1990). Direct testing of P. infestans extracts on chick embryos has determined that there was no evidence of toxicity (Wu and Salunke 1978) and that any birth defects are caused by glycoalkaloids present in the potato tuber (Jelinek et al., 1976). No toxicology studies have been carried out on the related species P. sojae or Pe. parasitica, and there are no records to implicate either organism in human disease. In the extremely unlikely event that any of the expressed gene products are determined to be toxic to humans, experiments with these genes will cease immediately.

None of the host plants (Solanum sp.) to be used in our experimental system pose a threat to human health under the conditions to be used for experimentation.

Risk to environment

P. infestans is naturally transmissible by wind or splash dispersal of sporangia from infected leaves. P. infestans may also spread in saturated soils by dispersal of motile zoospores from heavily infected plants, or plant debris in soil. P. infestans exists as two mating types, designated A1 and A2. Mating between A1 and A2 types results in the formation of oospores, which are thick-walled resting spores that may persist for many years in soil. Most potato varieties grown in Scotland are susceptible to late blight, caused by P. infestans. Control of late blight is typically by frequent treatment of crops with fungicides active against P. infestans (oomaticides such as metalaxyl).
For the majority of transgenes tested, there will be no effect on the infectivity, disease development, or host range of the GMM. In the unlikely case of any GMM escape, little is known about the stability of transgenes in P. infestans. However, it has been demonstrated that transgenes in P. infestans may become silenced (Judelson and Shittaker 1995; van West et al., 1999b) and that the silenced state is persistent and transferable. For instance, an escaped transgenic P. infestans silenced for pathogenicity factors would either simply not spread, or would transfer the silenced pathogenicity state to wild type. P. infestans, rendering it less fit.

If the transgene confers a change in the aggressiveness or host range of the GMM, then there may be some selection for the retention and maintenance of the transgene. Again, this is an unlikely situation since pathogenicity in P. infestans is a complex process involving the up and downregulation of many genes, and the constitutive expression of only one of these genes is not likely to have a large impact on the overall aggressiveness of the GMM. Silencing of pathogenicity genes is more likely to yield useful information regarding the phenotypic effects of the gene(s) under study.

Should a GMM silenced for a pathogenicity gene escape, the possibility of its DNA being transferred to another environmental and non-pathogenic organism, or another pathogen, is remote. Pathogenesis in P. infestans, and oomycetes generally, is complex and probably employs many mechanisms differing to those known in the true fungi and bacteria. It is unlikely therefore, that the horizontal transfer of a single P. infestans gene to a fungus or bacterium would confer novel pathogenicity or host range. The only known organism that P. infestans can intercross with is P. mirabilis, and this plant pathogen is not known in the United Kingdom.

Regarding the proposed experiments on heterologous gene expression and function, we wish to express genes in P. infestans from related plant pathogens P. sojae, and Pe. prasitica. The question we will address with this research is whether genes involved in avirulence in the named organisms have any role or effect in the P. infestans/potato interaction. The transgenic P. infestans from these experiments will have either the same phenotypes listed above, or will invoke a general, non-host response in all potato varieties, or no change from the wild type will be observed. Since the transgenes will originate from related pathogens (for which potato is a non-host plant), it is highly likely that functionally related genes are already present in P. infestans. Therefore, it is unlikely that introduction of the heterologous genes will have any effect on the host range of the transgenic P. infestans. Indeed, the opposite effect of restricting the host range may be more likely, as the host plant may recognise the foreign gene product and initiate a resistance response.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In our proposed experiments, we will only use one mating type of P. infestans in any one experiment, to prevent the formation of any persistent propagules (oospores). Furthermore, the strains of P. infestans to be used in our experiments will be fully sensitive to the oomycicide metalaxyl.

P. infestans cultures will be maintained in sealed agar plates and the risk of escape from these vessels is minimal. It is standard practice in our laboratories to handle P. infestans cultures in a biohazard cabinet to prevent escape of the pathogen, and to protect the cultures from contamination. We propose to maintain and manipulate the GMMs in the same manner.

In our preliminary experiments, the conditions for transmission of P. infestans will be avoided where possible. For instance, whole plants grown in pots will not be used, whole plants (when used) will be in the form of micropropagated material in flasks under sterile conditions within laboratories. The preparation of inoculum in minimum quantities required for the experiment will use conditions to minimise/prevent the formation of aerosols, plants or detached leaves will be drop inoculated to prevent aerosols, the handling of infected plants will be minimised, disposable gloves will be worn for all handling of infected plants, and all materials that come in contact with the infected plants will be destroyed by autoclaving using validated procedures. Initial analysis of the GMMs will be performed on no more than 50 detached leaves at one time. Inoculated detached plant leaves in sealed containers, and whole plants in sterile flasks will also only be opened within the biohazard cabinet.

By using detached leaves in sealed containers and whole plants in flasks for inoculation experiments, the preliminary experiments will be entirely lab-based and contained. Records of all experiments will be maintained for inspection, including all details of plant disposal.

However, larger numbers of leaves will be required if the GMMs are to be screened across progeny derived from S. tuberosum cv. Stirling. In this instance, no more than 200 leaves would be required. Escape of live P. infestans can be prevented through the employment of procedures currently used at SCRI, and mostly through restriction of access to plants. Experiments on the GMM will be carried out in a designated containment glasshouse facility within the High Containment corridor of AN facility at SCRI.
To prevent any dissemination of the GMM. The facility is insect and vermin proof. Access is restricted to authorised personnel and the facility is equipped with a ‘through the wall’ autoclave. Designated laboratory coats are provided for work in the containment glasshouse and these coats are not removed from the containment facility. Further, any material that might be contaminated by the GMM (plant material, gloves, plasticware, flasks) will be placed into bags within the designated area, sealed and autoclaved prior to disposal. The cubicle and benches to be used for testing of the GMM (See part II below) will be cleaned and disinfected prior to commencement, and after completion, of experimental work. The floors of this area are sealed and in the highly unlikely event of flooding the drains are also capped and the default setting on the system would direct run-off to a holding tank where appropriate treatment would be applied to any release into mains drainage.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation is requested for Containment Measure 3 on the basis that the benches in the containment area of the glasshouse are made of wire mesh for ease of cleaning and to enable temperatures to be maintained consistently throughout the facility. Fully waterproof receptacles to prevent any run off from plant pots are routinely included in the SOPS for the Containment Facility. The floors of this area are also sealed and the drain capped. In the highly unlikely event of flooding the drains have an additional cap below the surface of the floor and, in the even less likely scenario of effluent getting past this, the default setting on the system would direct run-off to a holding tank where appropriate treatment would be applied prior to any release into mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material used in the laboratory manipulations (plates, tips, gloves) will be placed into autoclave bags in the lab prior to disposal in the validated autoclave in this laboratory. All culture media (less than 1 litre per experiment) will be inactivated, autoclaved and disposed of appropriately. All spillages will be dealt with by standard laboratory hypochlorite or alcohol-based agents which have been shown to be effective against the pathogen.

Initial analysis of the GMMs will be performed on no more than 50 detached leaves at one time, and this work will be done within the laboratory area. All leaves will then be autoclaved and receptacles autoclaved also or treated with bleach.

For glasshouse work, in this instance, no more than 200 leaves would be required. Any material that might be contaminated by the GMM (plant material, gloves, plasticware, flasks) will be placed into bags within the designated area, sealed and autoclaved prior to disposal. The cubicle and benches to be used for testing of the GMM will be cleaned and disinfected prior to commencement, and after completion, of experimental work. Receptacles to prevent any run off will be included routinely and treated with tepid solution between experiments. The floors of this area are sealed and in the highly unlikely event of flooding the drains are also capped and the default setting on the system would direct run-off to a holding tank where appropriate treatment would be applied prior to any release into mains drainage.

Records of all experiments will be maintained for inspection, including all details of plant disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Procedural practices must be strictly adhered to when handling GM Zoospores during inoculation to minimise the risk of aerosols. Although two forms of mating types (A1 and A2) exist for P. infestans, only one may be used in any one experiment to prevent the formulation of persistent oosporex. The committee recommend specialist training for glasshouse staff and the provision of an automatic irrigation system for this area to minimise entry.
The preliminary purpose of the project is the development of plant virus-based vectors and inoculation techniques for the analysis of plant gene function through silencing.

Stage 1 comprises plant viral cDNAs, under the control of bacteriophage promoters for in vitro transcription, which will be genetically modified through the insertion of genes for easily detectable reporter proteins to monitor virus movement. The genetically modified viral cDNAs will be further placed under the control of plant promoter sequences to test biolistic and Agrobacterium-mediated inoculation of specific target tissues. In the first instance VIGS enhancement directed against endogenous plant genes such as Phytoene desaturase (PDS) and transgenes such as green fluorescent protein (GFP) will be assessed by the comparison of viral based vectors carrying single gene cDNA inserts or the equivalent tandem inverted-repeat corresponding to the target sequences.
In the second stage of our programme, the ability of the genetically modified viruses to induce silencing will be tested through the insertion of plant derived cDNA sequences.

In order to trigger VIGS in dicots, non-coding short cDNA fragments in either antisense orientation and/or inverted-repeats will be cloned into the PVX and PLRV genome. The target cDNA are described in Section "Origins and intended functions of the genetic material involved".

For monocots selected cDNAs to be expressed as functional or non-functional proteins in barley are also listed in the appropriate section.

In conjunction with this programme is an investigation of the potential of virally expressed RNA secondary structure folding as dsRNA hairpins in their ability to enhance silencing of target genes once expressed from virus-derived expression vectors on their corresponding hosts.

The eventual objective of the research is to develop a more robust system to silence endogenous genes in roots, leaf and developing/germinating seed.

### Origin & function

**STAGE 1**

In order to trigger VIGS, corresponding homologous short cDNA fragments of (ranging from 40 up to 200 nucleotides) of the corresponding target plabnt gene will be...
introduced into the viral genome. These are most likely to be non-coding.

The targets are:

- Green fluorescent protein (GFP) from Aequorea sp., reporter protein.
- Red fluorescent protein (RFP) from Discosoma sp., reporter protein
- uidA, B-glucuronidase (GUS) from Escherichia coli, reporter protein
- phytoene desaturase (PDS)
- Genes involved in the biosynthesis of the anthocyanins: C1, b-Peru and A1 (dihydroflavonol-4-reductase gene)

To monitor silencing in vegetative and seed tissues, GFP fluorescence, GUS activity, photobleaching (as a consequence of PDS knock-out in foliar tissues), accumulation of red anthocyanins pigments in bombarded embryos or endosperm cells (following in situ transient expression of C1 and bPeru maize genes encoding transcriptional factors required for anthocyanins biosynthesis, Schweizer et al, 2000) will be evaluated according to which vector combination is being used.

STAGE 2

2.1 VIGS in dicots (solanum species and Nicotainae): (PVX mediated)

2.1.1 Target cDNAs related to disease resistance.

In order to trigger VIGS, non-coding short cDNA fragments in either antisense orientation and/or inverted-repeats will be cloned into PVX and PLRV genome. The target cDNAs are all related to disease resistance.

1. SGT1: A component of the ubiquitin ligase machinery that is involved in disease resistance in plants. Silencing of this gene in N. benthamiana inhibits the HR and thus it acts as a positive control in this experiment. Ref. Pear JR et al., (2002). Ubiquitin ligase-associated protein SGT1 is required for host and non-host disease resistance in plants. (PNAS 99:10865-10869.

2. Cathepsin B: The potato cathepsin B gene was identified as up-regulated specifically in R gene-mediated resistance to Phytophthora infestans (unpublished results) and, as such, is a candidate for having a role in the HR. Cathepsin B in mammalian systems has a regulatory role in apoptosis, a form of programmed cell death. REf: Guicciardi ME, et al., (2001) Cathepsin B knockout mice are resistant to tumor necrosis factor-alpha-mediated hepatocyte apoptosis and liver injury: implications for therapeutic applications. Am. J. Pathol. 159:2045-2054.

3. Adr1: The Adr1 gene (Activated Disease RESistance 1) was isolated from Arabidopsis in a gain-of-function screen for up-regulation of genes that increase resistance to a range of pathogens (unpublished). It is an NBS-LRR protein similar to R gene encoded plant proteins and is believed to coordinate pathway convergence from a range of R gene products.

4. St-WRKY1: The St-WRKY1 gene was isolated from potato and is up-regulated specifically during the early stages of R gene-mediated resistance to P. infestans (unpublished results and ref below). It encodes a transcription factor that binds to 'W' boxes found in the promoters of plant defence-associated genes. REf: Dellagi A, et al., (2000). A potato gene encoding a WRKY-like transcription factor is inducted in susceptible interactions with Erwinia carotovora subspp. atroseptica and Phytophthora infestans and is co-regulated with class 1 endo-chitinase expression. Mol Plant-Microbe Interact 13:1092-1101.

5. Oxysterol binding protein (St-OBP1): The OBP1 gene was identified as up-regulated specifically in R gene-mediated resistance to Phytophthora infestans (unpublished results) and, as such, is a candidate for having a role in the HR. OBPs have been found to play a role in apoptosis in mammalian systems.

No toxicity has been reported as a result of expression or knock-out of the abovementioned genes. The abovementioned genes are involved in specific resistance response (gene-for-gene) to plant-fungus interaction hence should not provide beneficial advantage to the recombinant virus vector.

2.1.2 to investigate the function of potato genes involved in carotenoid metabolism and the potato tuber life-cycle.

Selected cDNAs to be expressed in antisense orientation in potato (S.tuberosum and S.phureja) using the previously described PVX vector.

2.1.2A) carotenoid metabolism:

cDNA fragments cloned from S. phureja tuber encoding lycopene -cyclase (AF321537), lycopene -cyclase (97% identity with X86452 from tomato), -carotene hydroxylase (95% identity with Y14809 from tomato), zeaxanthin epoxidase (96% identity with Z83835 from tomato) and 9-cis epoxycarotenoid dioxygenase (AJ276244).

The genes we are studying are naturally occurring and functional in potato. The enzyme activities encoded by these genes form part of the carotenoid biosynthetic pathway. By modifying their expression level we hope to obtain information that may help us to understand how the carotenoid biosynthetic pathway is regulated. All these genes are well characterised in other plants. For some, stable antisense experiments have been carried out (eg zeaxanthin epoxidase in potato (Romer et al., 2002), -carotene hydroxylase in Arabidopsis (Rissler and Pogson 2001) or mutants have been studied (lycopene -cyclase in Arabidopsis, Pogson et al., 1996). There are no reports that we are aware of, that changes in carotenoid content result in increased or decreased susceptibility to plant pathogens or confer on the plant a selective advantage.

2.1.2 B) Partial cDNA clones isolated from a potato tuber meristem library:

</table>
We wish to investigate the function of these cDNAs in aspects of the potato tuber life-cycle by down-regulating their expression levels in an in vitro tuberisation system. We expect these genes to exert a regulatory function during tuberisation, dormancy and sprouting and wish to assess the in vitro system as a means to rapidly screen this type of candidate gene. The precise function of the encoded gene products is not known: several show sequence similarity with transcription factors, kinases, phosphatases or other activities that we suspect may be critical to the process such as tubulin genes, genes involved in polyamine biosynthesis (arginine decarboxylase) or channel formation (aquaporin).

We propose to test meristem genes solely in an in vitro system which has a high degree of containment.

We are unaware of any literature which suggests that this manipulation will confer a selective advantage on the plants subjected to VIGS however, for most, no data is available currently.

2.2 - VIGS in monocots (BSMV):

2.2.1): Oleosin, calesosin and steroleosin genes.

Based on the sequence homology to Arabidopsis, rice and sesame we have identified and isolated the following genes from the barley EST and BAC libraries:

* Five oleosin genes: ole1a, ole1b, ole1c, ole1b, ole2;
* Three coleosin genes: cal1, cal2 and cal3
* Two steroleosin genes: ster1, ster2.

The genes we are studying are naturally occurring and functional in the plant (barley) of our interest. By modifying their expression level and/or by expression of the parts of the genes as a GFP fusion protein we hope to obtain information, which may help us to understand the functions of these gene.

Oleosins were identified as a major protein constituent of the plant seed lipid bodies, while calesosins (calcium-binding protein) and steroleosins (sterol=binding dehydrogenase) comprised the minor fraction. The roles of these proteins have been associated with lipid body biogenesis, stabilization, trafficking and mobilization in desiccation tolerant seeds. But, tissue expression patterns, organisation of the genes encoding them and lipid profiles of different tissue types accumulating these proteins indicate that they are in fact multi-functional proteins playing important yet unknown roles in the whole plant development.

The BSMV vector system will be used to deliver untranslatable sequences of oleosins, calesosins and steroleosins into the barley leaves for silencing purposes. The barley leaf areas where the genes of interest are silenced will be determined by the real-time RT-PCR. The sub-cellular structures of the silenced leaves will be subjected to morphological and functional analysis using specific staining procedures (fluorescently labeled phallotoxins, lectins, DIOC6 and antibodies). Expected results are identification of the specific phenotypes associated with dynamics of cyto-skeleton, Golgi and ER.

In addition to their biological interest oleosins have recently been used in a biotechnological context as vehicles for overexpression in transgenic plants of a variety of fusion proteins.

2.2.2 Endogenous barley genes involved in resistance pathways to powdery mildew

The introduction of cDNA sequences into the viral genomes is hoped to induce silencing of endogenous barley genes involved in resistance pathways to powdery mildew. Inverted repeats of cDNA fragments up to 60 nucleotide will be cloned into BSMV genome. The targets cDNAs are Rar1, Mlo and cDNAs homologues to receptor-like kinase and oxysterol binding protein.
1. Rar1 encodes a 25.5-kDa zinc-binding protein interacting indirectly with ubiquitin ligase complex (Azevedo et al., 2002) required for multiple race-specific resistance to powdery mildew. Rar1 knockout should result in a shift from incompatible to compatible interaction of Blumeria graminis fsp hordei 983 on barley cv. Pallas (Mla13-near isogenic line11) variety and fungal growth.

2. Mlo encodes a 52-kDa-transmembranar protein representing a novel calmodulin-binding protein (Kim MC et al., 2002), acting most likely as a negative regulator of Blumeria graminis resistance. Mlo knockout should result in plant cell death control perturbations in the absence of pathogens leading to spontaneous necrosis (Devoto et al., 1999) and a shift from compatible to incompatible interaction of Blumeria graminis fsp hordei Tyne3 on barley cv. Pallas (Mla13- near isogenic line11).

3. cDNAs homologues to receptor-line kinase.

4. Oxysterol binding protein have been isolated in the context of the previously mentioned interaction and are rapidly up regulated during the incompatible interaction. They share homologies to respectively a receptor-like kinase and leucine-rich repeat protein (accession number DBJ: BAB03629.1) encoded by the rice disease resistance gene Xa21 (Song et al., 1995) probably involved in cell surface recognition of a pathogen ligand and subsequent activation of an intracellular defense response and an oxysterol-binding-ortein (accession number GB: AAL32781.1) probably regulating lipid and cholesterol metabolism recently considered as candidates in in vivo cytotoxicity (Colles SIM et al., 2001). If such genes play a predominant role in the outcome of the interaction, therefore either a shift from incompatible to compatible interaction or downstream alteration of plant defense response to challenge with the abovementioned Blumeria strains should be expected.

Once the VIGS system has been characterized in term of timing and localisation of knock-out of the targeted gene, leaf segments will be detached for monitoring fungal growth on petri dishes under contained laboratory conditions in order to minimize the manipulation of whole BSMV infected plants in glasshouse or growth rooms.

**Evaluation of foreseeable effects**

**VIRUSES:**

FoMV does not cause economically important disease, and its natural hosts are not indigenous to the UK.

SBWMV and BSMV are a cause of disease in wheat and barley. In order to provide robust biological containment, sections of the coat protein genes of BSMV and SBWMV will be deleted to render them non-transmissible by mechanical and fungal routes respectively. The genetic modification required to disable their natural transmission routes will result in increased symptom severity on inoculated plants.

TMVs natural host, tobacco, is not grown in Scotland, so the GMOs do not present a risk to the wider environment. The GMOs could present a risk to other plants grown in the institute, though no more than the wild-type virus. Therefore measures will be taken to minimize spread of the GMOs through mechanical transmission and dispersal of pollen or seed.

TRV-based vectors will be derived from RNA2-2b/2c deletion mutants, making them non-transmissible via nematode, and are not likely to have increased seed-transmissibility. Measures will be taken to minimize spread of the GMOs through mechanical transmission and dispersal of pollen or seed.

Potato Leaf Roll Virus (PLRV) and PLRV deletion mutants altered in movement and replication functions will be cloned into pGreenII binary vector driven by a 35S-promoter (Nurkiyanova et al., 2000. Tagging PLRV with the jellyfish green fluorescent protein gene. J. Gen. Virol. 81, 617-626) for Agrobacterium-based infection of Solanaceae. Risk assessments have already been prepared for PLRV and are covered by Plant Health Licences (Licence GM/183/2003, licence GM/183/2003).

Potato Virus X (PVX) genome (strain UK3) and PVX deletion mutants altered in movement functions will be cloned into binary-based (pGREENOOO) PVX-expression vector engineered from PVX strain UK3 driven by a 35S-promoter for Agrobacterium-based infection of in vitro grown potato (cross-reference: SEERAD licence GM 180/2003).
Maize streak virus (MSV), is a plant DNA virus classified in the Mastrevirus genus of the Geminiviridae family. MSV is a non-indigenous virus. No vectors (Leafhopper Cicadulina spp) have been identified in the UK. All known hosts are in the Gramineae, among which many species can be infected. It is not transmitted by mechanical inoculation nor by contact between plants, by seed or by pollen. The insertion of the sequence of interest into the Small Intergenic Region (SIR) using Asnl restriction site should generate constructs effective in replication and allow limited cell-to-cell movement (Shen and Hohn. 1995. Vectors based on maize streak virus can replicate to high copy numbers in maize plants. J. Gen. Virol. 76, 965-969). Maize streak virus clones exist as monomeric copies of the wild type genome in M13 and pUC based vectors, multimeric copies are present in T-DNA binary vectors (eg pBIN19) and pUC. Similar constructs exist for WDV. The binary vector constructs are used for agroinoculation. The pUC based constructs are used for microprojectile bombardment of tissue cultures.

Wheat dwarf virus (WDV) is a plant DNA virus classified in the Mastrevirus genus of the Geminiviridae family. WDV is present in Northern Europe and Scandinavia. Leafhoppers that could be vectors (Psamotettix spp) are not reported in the UK. Triticum aestivum (wheat) and Hordeum vulgare (barley) react differently to infection with the common and barley strains. The barley strain causes dwarfing, poor heads and yellowing in barley, but which is resistant to wheat strains. It is not transmitted by mechanical inoculation; nor transmitted by contact between plants, by seed or pollen. Such a vector has to be developed based on a barley isolate (in collaboration with Dr. M Boulton, JIC, Norwich, UK, WDV barley isolate obtained from Dr B Hohn, Friedrich Miescher Institute, Basel, Switzerland) and previous WDV-based vector development (Gooding P S et al., 1999. Plant cell-directed control of virion sense gene expression in wheat dwarf virus. Nucl. Acids Res. 27, 1709-1718).

These two geminiviruses (MSV, WDV) are maintained in the laboratory, as DNA clones in pUC-based vectors in E. coli, or binary vectors (pBIN19) in Agrobacterium.

General Comments:-
* The previous insertion of reporter protein genes into plant viral genomes has resulted in the creation of attenuated viruses and no mechanism for enhanced pathogenicity can be foreseen.
* The introduction of plant derived sequences into plant viral genomes and the induction of host gene silencing can affect the symptomatology of infections. However, previous experiments with vectors based on RNA plant viruses have shown introduced sequences to be very rapidly lost through in planta recombination events (for review of genetic instability in genetically modified RNA plant viruses see: Lacomme et al., (2001) Plant Viruses as Gene Expression Vectors, in: Ring CJA and Blair, ED (Eds) Genetically Engineered Viruses: Development and Applications, BIOS Scientific Publishers, Oxford).
* Therefore, the genetically modified plant viruses are considered to present less risk to the environment than the natural progenitor viruses.
* For Stage 1 work we propose containment levels appropriate to that of the wild-type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**GLASSHOUSE**

Stage 1 will be classified in two forms. Firstly, using vectors that, in some cases are well-characterized and expressing well-characterised genes which can be classified as no more than Containment Level 2. Secondly, in widening the spectrum of vectors to be used some cannot yet be described as well-characterised but will be expressing well-characterised genes, however, these will be subject, according to target, to Containment Level 3, until sufficient evidence is accumulated to re-classify them.

Stage 2 will use only well-characterised vectors, but in some cases to express less well-characterised genes. Thus this would constitute Containment level 3 especially in the case of genes involved in plant pathogen interactions, until sufficient evidence is accumulated to re-classify them.

Plants shall be grown in a designated greenhouse compartment or growth chamber, with access restricted to named personnel only. The plants shall be kept clearly labelled and physically separate from other plants. ALL PLANTS WILL BE BAGGED TO REDUCE POLLEN DISPERSAL.

To prevent escape of the mechanically transmissible GMMOs handling of infected plants will be performed with gloved hands. Designated laboratory coats are provided for work in the containment glasshouse and these coats are not removed from the containment facility unless decontaminated first. As a precautionary measure plants will not be allowed to flower. Further, any material that might be contaminated by the GMMOs (plant material, plant pots, soil, labels, gloves) will be autoclaved prior to disposal.

Escape of live Agrobacterium tumefaciens can be prevented through the employment of procedures currently used at SCRI for agroinoculation, for which a generic risk assessment exists at SCRI. That is, restriction of access to plants and watering only by licensed staff, control of water run-off through the use of trays, and watering from beneath. Records of all glasshouse experiments will be maintained for inspection, including all details of plant disposal.
On termination of experiments all plant material, soil and pots shall be transferred to autoclavable bags, sealed and autoclaved.

Any material removed from glasshouse (for experimental analysis, etc) to be carried in sealed container/plastic bags. All analysis to be performed in designated laboratory areas. Contaminated materials to be disposed of following autoclaving or sterilisation. Surfaces and floors in glasshouse compartment shall be cleaned after the experiments to eliminate any plant debris.

LABORATORIES

Laboratories are equipped to the requirements of containment level 2. Autoclaves are available within the building, obviating the need for further transportation. All contaminated materials will be autoclaved or treated with a proprietary virucide. Compliance with level 2 containment measures provides satisfactory environmental protection.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Request for derogation from Schedule 8, Part II, Table 1a(3) - Equipment - surfaces impervious to water etc...

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Contaminated surfaces will be disinfected with a proprietary virucide validated to give 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee discussed the following points:

1. The risk of whether silencing of genes could result in more severe symptoms was raised, but the Committee were informed that introduced sequences are generally rapidly lost. DNA-based inocular were stated to pose no greater risk than DNA constructs for in vitro transcription.

2. For Agrobacterium inoculation of barley stripe mosaic and wheat soil borne mosaic viruses, mixed inoculums, with the genomes separated between 2 or 3 plasmids would be used to reduce risk in the event of an escape.

3. The risk of escape would be greater for the monopartite foxtail mosaic virus, but there would be less effect to the environment.

4. It was asked if any risk was foreseen to any UK horticultural crops, but confirmed not to be the case.

5. The strict emphasis of pollen containment was re-iterated by the committee.

Project Containment
**Project Additional Information**

**Purposes of the contained use**

Experiments will be performed to express, from tobacco mosaic virus-based vectors (30B and 30B. CP)cDNA, libraries as fusions to GFP or mRFP for determination of the subcellular address of the expressed plant proteins. The work has three main themes:

* Libraries for subcellular addressing of expressed cDNA-GDP fusions
* Libraries to identify plant proteins involved in RNA splicing
* Libraries to identify protein - protein interactions in plants

Viral libraries will be screened through lesion-based assays on non-transgenic and transgenic plants by means of the observation of fluorescent reporter proteins and microscopic analysis. Library members of interest will be isolated and re-screened after passage; inserts will be recovered through RT-PCR and, after nucleotide sequence determination, reinserted into viral vectors for phenotype confirmation.
Recipient or parental organism

Tabacco Mosaic Virus

30B, hybrid vector based on TMV strains U1 and U5 (Shivprasad et al., 1999).

30B CP, a derivative of 30B in which the U5 derived sequences have been replaced with the 3’ untranslated region of strain U1.

Host/vector system

- Arabidopsis thaliana cDNAs
- Nicotiana tabacum cDNAs
- N. benthamiana cDNAs
- Gene for green fluorescent protein
- Gene for monomeric red fluorescent protein (Campbell et al., 2002)
- Gene for circularly permuted enhanced yellow fluorescent protein (Baird et al., 1999)
- Hordeum vulgare CaM3 gene (Link & Zielinski, 1989)
- Hordeum vulgare Mlo gene (Blueshges et al., 1997)
- Potato mop-top virus triple gene block protein 2 and 3 (TGBp2 and TGBp3, 13kDa and 21kDa) genes (Cowan et al., 2002)
- N. plumbaginifolia RNA-binding protein 45 (Lorkovic et al., 2000)
- N. plumbaginifolia uracil-binding protein 1 (Lambermon et al., 2000)

Origin & function

1. Libraries for subcellular addressing of expressed cDNA-GFP fusions

Experiments will be performed to express cDNA libraries as fusions to GFP or mRFP for determination of the subcellular address of the expressed plant proteins. The vector 30B has been described previously. This vector is a hybrid of tobacco mosaic virus (TMV) strains U1 and U5, and has been genetically engineered to express foreign proteins from a duplicated subgenomic promoter. Derivatives of 30B (30B.GFP & 30B.mRFP) will first be produced in which the initiating methionine codon or the stop codon of the gene encoding the fluorescent protein is replaced with a polylinker sequence. Subsequently cDNA will be produced primarily from Arabidopsis thaliana, but also possibly from N. tabacum and N. benthamiana, will be cloned directionally into these polylinkers to produce vectors capable of expressing plant cDNAs as fusions to the amino- or carboxy-termini of the fluorescent proteins. Populations of viral vectors containing the cDNA libraries will be inoculated after reassembly with purified TMV coat protein to non-transgenic N. benthamiana or N. tabacum, less than forty eight plants per experiment, or transgenic N. benthamiana or N. tabacum 35SS::30K (TMV) plants (CB lines 7-11), in order to enhance infectivity. As each fluorescent infection focus is initiated by a single clone from the population the subcellular distribution of the fluorescent protein in individual lesions on inoculated leaves will be determined, within three weeks of plant inoculations, by confocal laser scanning microscopy (CLSM). Infection foci showing subcellular distributions of interest will be passaged to N. benthamiana or N. tabacum to confirm the phenotypes by CLSM of the fluorescent lesions on the inoculated leaves. Subsequently RNA will be extracted and used in RT-PCR to recover the portions of the genetically modified viral genomes that encompass the plant derived sequences. The RT-PCR products will be cloned into 30B.GFP or 30B.mRFP to recheck the phenotypes of CLSM of fluorescent lesions on inoculated plant leaves.

2. Libraries to identify proteins involved in splicing.

We wish to develop a high-throughput viral-based screen for identification of genes involved in splicing. To do this transgenic N. tabacum plants will be used that carry an m-gfp5-ER transgene (Haseloff, 1999) with an internal mini-exon (Simpson et al., 2002) under the control of a 35S promoter. Enhancement of alternative splicing will be monitored through the visual observation of increased fluorescence resulting from increased GFP expression and the observation of GFP expression. To test the system candidate genes UBP1, RBP45 and PTB, which have previously been shown to affect splicing efficiency, will be cloned into 30B CP. The constructs produced will be inoculated onto the transgenic tobacco plants and enhancements in GFP expression sought. If this proves successful, N. tabacum cDNA libraries will be cloned into the
same vector and libraries inoculated to the same transgenic plants. Any infection foci showing enhanced fluorescence will be used for RNA extractions. The extracted RNA will be used for RT-PCR and the amplification products cloned prior to nucleotide sequence determination. Inserts of interest may be cloned back into viral vectors to confirm observed enhancements in alternate splicing.

3. Libraries to identify protein-protein interactions in plants.

We wish to develop a high-throughput viral based screen for identification of interacting protein pairs in plants. To do this, use will be made of a circularly permuted form of enhanced yellow fluorescent protein (cp-EYFP) whose level of fluorescence is dependent on the interaction between protein pairs fused to its carboxy- and amino-termini. To test the feasibility of this system genes encoding known protein pairs will be fused to the 5’ and 3’ ends of cp-eyfp, and the gene fusion inserted into 30B. CP. The engineered viruses will be inoculated to the leaves of non-transgenic N. benthamiana or N. tabacum plants or transgenic N. benthamiana or N. tabacum 35S::30K(TMV) plants (CB lines 7-11), in order to enhance infectivity. Protein interactions will be monitored through visual observation of fluorescence, microscopy and fluorimetry of plant extracts. Test pairs will include H. vulgare CaM and Mlo, and Mlo mutants encoding amino acid substitutions within the CaM-binding peptide. This protein pair have been previously shown to interact in vitro and in vivo (Kim et al., 2002A) and the barley MLO protein is involved in pathogen and stress responses (Piffanelli et al., 2002; Kim et al., 2002b). The other pair of proteins that will be tested are TGBp2 and TGBp3 of PMTV, which have previously been shown to interact in a yeast two-hybrid system (Cowan et al., 2002). These two viral movement proteins have previously been expressed independently as GFP fusions from the 30B vector without enhancing viral pathogenicity. The two proteins act in concert with TGBp1 to traffic viral RNA. If the aforementioned experiments prove successful it is would be out intention to create vectors containing genes encoding fusions between selected bait proteins, cp-EYFP and libraries of plant proteins. Interacting pairs would be identified through the inoculation of viral libraries to plants, isolation of infection foci showing enhanced fluorescence and recovery of the expressed target sequences through RT-PCR and cloning of the amplified products.

**Evaluation of foreseeable effects**

**Tobacco Mosaic Virus**

TMV forms very stable rod-shaped particles in infected tissues. It is readily mechanically transmissible, but not seed or pollen transmissible. Further, TMV is not transmitted by arthropods, nematodes or fungi. TMV has a world-wide distribution, including the UK, and is a cause of disease in tobacco. TMV has a wide experimental host range including many members of the family Solanaceae, predominantly from the genus Nicotiana. In comparison to wild-type virus, hybrid U1/U5 gectors and the recombinants that arise in plants from them are attenuated and restricted in host range.

For Part 1. Such TMV-based vectors have been shown to be competitively unfit in comparison to wild-type TMV and to rapidly undergo recombination events in plants to delete foreign sequences, resulting in the formation of pseudo wild-type viruses that are also unfit in comparison to wild-type TMV (Rabindran, S. and Dawson, W.O., 2001).

For Part 3. Although the combination of the two viral proteins is not expected to enhance the movement characteristics of the TMV-based vector, a possibility exists. However, the use of 30B. CP, which lacks a viral coat protein gene, provides biological containment and renders the GMMOs non-transmissible.

**Inserted gene produce**

The fluorescent proteins have been expressed in a wide range of experimental systems previously and there are no known risks associated with them. The plant cDNAs and a viral movement proteins that will be expressed from the plant viral vectors occur in nature, thus no novel toxicological effects are predicted. However, the levels of expression achieved with a viral vector may be greater than occur naturally. There is a possibility that this may lead directly to increased levels of possibly allergenic proteins (Krebitz, M. et al., 2000) and indirectly to altered levels of metabolites (Kumagai, et al., 1995; Kumagai et al., 1998)

**Alteration of existing pathogenic traits.**

The insertion of the PMTV gene sequences into 30B. CP are, in the absence of TGBp1, not predicted to have any effect on the intracellular movement properties of the TMV-based vector. The effect of over-expression of known and unknown plant cDNAs on vector accumulation cannot be predicted, for instance calmodulin genes are both
up and down regulated during TMV infection (Yamakawa et al., 2001) and many other genes are up or down regulated (Itaya et al., 2002). However, in all previous studies with TMV-based vectors the pathogenicity of these has been reduced in comparison to the progenitor virus.

The inclusion of plant derived sequences in a plant virus-based vector gives rise to the possibility of gene silencing and the insertion of a partial phytoene desaturase (PDS) sequence from Lycopersicon esculentum in a TMV-based vector, in sense of antisense orientations, and magnesium chelatase subunit H sequences from N. benthamiana have been shown to induce gene silencing and symptom alteration in N. benthamiana (Kumagai, M. H. et al., 1995; Biriart, J.-B. et al., 2003). Depending on the source of the cDNA inserts silencing rates of between 1% and 10% have been observed in N. benthamiana, which is not indigenous to the UK, based on novel phenotypic symptoms (Large Scale Biology Corporation, unpublished data). However, attempts to cause VIGS with vectors carrying Nicotiana pds sequences have not resulted in visible VIGS phenotypes on the related species N. excelsior, N. clevelandii, N. excelsior or N. tabacum cultivars (LSBC, unpublished data). Further, the efficacy of TMV-based VIGS in N. benthamiana has been shown to be dependent on the cDNA insert size and the presence of such inserts leads to substantial decreases in viral titre (Hiriart et al., 2003). The inclusion of complete cDNAs from Capsicum annuum, Lycopersicon esculentum, Oryza sativa and Betula pendula in TMV-based vectors had led to protein over-expression rather than gene silencing (Kumagai et al., 1995; Kumagai et al., 1998; Kumagai et al., 2000; Krebitz et al., 2000).

Recently it has been shown that silencing of NbEDS1 in N. benthamiana transgenic for the resistance gene N compromised the N-mediated resistance against TMV (Peart et al., 2002). However, to achieve this effect it was necessary to establish silencing by inoculation of a Tobacco Rattle Virus-based VIGS vector three weeks in advance of TMV challenge and further VIGS of twenty other genes putatively involved in N-mediated resistance did not produce any consistent loss of TMV resistance. In another study prior silencing with TRV-based vectors of resistance-related genes permitted a TMV-based vector to escape N gene mediated resistance (Liu et al., 2002). More recently silencing of genes, the products of which interact with the TMV RNA replicase, has resulted in both decreased and increased viral accumulation, the latter phenotype being mimicked by herbicide treatment (Abbink et al., 2002).

However, as before, silencing was achieved through prior inoculation with a TRV-based vector. Experiments with TMV-based vectors carrying pds sequences have only shown photo-bleaching in non-inoculated leaves and photo-bleaching occurs at least seven days post inoculation, after the appearance of systemic viral infection. Therefore, how silencing of an endogene by a TMV-based vector could alter the pathogenic traits of that vector is not perceived.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**GLASSHOUSE**

Experiments on the GMMOs will be carried out in a level 2 containment glasshouse facility to prevent dissemination of the GMMOs. Individual clones from the population will be represented by single lesions or by single plants for the subset chosen for phenotypic confirmation (<100 at a time) and plants will not be propagated for extended periods (<3 weeks). The glasshouse facility is insect and vermin proof. Access is restricted to authorized personnel and the facility is equipped with a "through-the-wall" autoclave.

To prevent escape of the mechanically transmissible GMMOs handling of infected plants will be performed with gloved hands. Designated laboratory coats are provided for work in the containment glasshouse and these coats are not removed from the containment facility unless decontaminated first. As a precautionary measure plants will not be allowed to flower. Further, any material that might be contaminated by the GMMOs (plant material, plant pots, soil, labels, gloves) will be autoclaved prior to disposal. Where samples need to be transported to the laboratory for analysis this will be done in secure containers.

**LABORATORIES**

Laboratories are equipped to the requirements of containment level 2. Autoclaves are available within the building, obviating the need for further transportation. All contaminated materials will be autoclaved or treated with a proprietary virucide. Compliance with level 2 containment measures provides satisfactory environmental protection.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Contaminated surfaces will be disinfected with a proprietary viricide validated to give 100% kill.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project Ref 250/04.1

Date Ackn’d 29/12/2004

Date Project Ceased 04/05/2018

CU2 Project Title The insertion of cauliflower mosaic virus into host genomes during natural viral infections.

Class 3

CultureVolClass2 Class

Consent Granted Yes

Project notified under transitional arrangements N
The aims of the project are to study:
1. Whether Cauliflower mosaic virus (CaMV) inserts into plant genomes that are genetically modified (GM) to express genes under the control of the CaMV 35S RNA promoter.
2. The consequences of such insertion events for the use of GM plants and how this compares to the situation in non-GM plants that are infected with CaMV.

Modified versions of CaMV will be prepared to facilitate the analysis. These will be inoculated to GM and non-GM plants of four species, Arabidopsis thaliana, Brassica napus, Nicotiana benthamiana and Nicotiana tabacum, which will be assessed for evidence of CaMV integration and for effects on the stability and expression of the transgene.

Transgenic Arabidopsis plants will also be generated that contain inserted CaMV genomes, thus permitting assessments of the consequences of germline integration, even in the event that few or no CaMV integrants are found to result from CaMV infection. These plants will be studied to assess whether transcription, reverse transcription or episomal disease occurs, in the presence or absence of conditions of stress. The plants will also be used to assess the effect of CaMV integration on a range of vital plant functions.

Wild-type CaMV is found world-wide in temperature regions. Its host range includes species in the families Brassicaceae, Solanaceae and Resedaceae. Natural transmission is by aphid vectors and the virus is also mechanically transmissible, but is not reported to be seed transmissible. CaMV infection of brassicas grown as food crops is widespread and is not associated with any risk to human health.

Modified versions of CaMV will be prepared for use in determining whether CaMV sequences integrate into plant genomes of non-GM and GM host plants of CaMV. The first of these modified CaMV involves replacing CaMV Gene II (encoding a protein required only for the aphid transmission of CaMV) with a smaller gene encoding dihydrofolate reductase (dhfr), derived from the bacterial plasmid R67. The modified virus will therefore no longer be aphid-transmissible. A similar construct made 20 years ago was shown to provide resistance to methotrexate in CaMV-infected plants (Brisson et al., 1984). Our construct differs from the earlier one in including upstream sequences encoding the 20 bp RNA promoter sequence from the phage T7 (T7pol). This would allow the dhfr gene to be expressed in bacteria that contain and express the T7pol. This construct is required to maximise the chances of detecting integration of CaMV sequences into non-GM and GM plants which are hosts of CaMV.

Other modified CaMV involves the strains of CaMV designated H7 and W260. CaMV H7 is a recombinant virus composed of elements from strains D4 and CM1841 (Schoelz and Shepherd, 1988). CaMV W260 is a strain that, unlike other CaMV strains, which show no movement in Nicotiana tabacum, will replicate and move cell- to cell.
cell in N. tabacum, but will not move long distance in this host.

These strains will be modified by insertion of a novel PCR-tag sequence into the Gene VI of CaMV. This sequence will be used to facilitate detection of integration into plant genomes that already contain other CaMV sequences. Insertion of a similar PCR tag has been noted to have no observable effect other than slightly slowing the rate of viral infection (Dr J E Schoelz, personal communication).

Host/vector system

Construction of modified CaMV will be carried out in plasmid vectors in Escherichia coli.

To initiate infection, viral DNA will be excised from the vector at the cloning site and mechanically inoculated to Brassica compestris cv. Just right, which will serve an inoculum source for further studies.

The modified CaMV produced in Stage 1 will be used to inoculate four plant species:

- Arabidopsis thaliana
- Brassica napus
- Nicotiana benthamiana
- Nicotiana tabacum

This will provide an assessment in three different host species and none non-host species, respectively. Inoculation will be to both unmodified and GM plants of each species. To determine whether CaMV infection affects the expression and atability the transgene, the four GM species will be assessed. The GM plants will all express the gene encoding the jellyfish green fluorescent protein (GFP) under the control of the CaMV 35S promoter (Haseloff et al., 1997; Ruiz et al., 1998; Halfhill et al., 2001; Harper & Stewart, 2000).

A determination of whether CaMV integration affects transgene expression and stability or vital plant functions requires having plants in which integration has been shown to occur. If the frequency of integration is quite low, it is conceivable that integration will not be detectable in the germline of the plants inoculated above, but may occur at a significant frequency in the hundreds of thousands to millions of plants present in field situations. Therefore, it is necessary to establish the consequence of germline integration, should such occ ur. To this end, we will generate GM A. thaliana plants that contain inserted CaMV genomes. These plants will allow assessment of the consequences of germline integration; in the absence of detecting such events by infection of non-GM and GM plants.

Origin & function

A. thaliana plants will be transformed with three types of CaMV genomes:

1) a single full-length CaMV genome;
2) two, tandem full-length copies of the CaMV genome;
3) a cDNA copy of the 35S RNA, containing repeated sequences at the ends of the cDNA.

As it is not known in which form the CaMV genome itself could naturally integrate, nor which form is able to permit episomal replication, it is necessary to examine the three most likely forms in which the entire genome of CaMV could integrate. The genome forms will be introduced into commonly used binary plasmids, such as pBIN19 and pGREEN, and transformed into disarmed, non-tumorigenic A. tumefaciens strains (LBA4404 and AGL-1) prior to transformation.

To determine the effects of the integration of the CaMV genome on the expression and stability of a transgene pollen from the above transgenic lines will be used to fertilise transgenic A. thaliana expressing the gene encoding the GFP, under the control of the 35S promoter. The progeny plants will be examined to confirm the presence of both the GFP transgene and the inserted CaMV genome.

Progeny plants derived from these plants will be used for analyses involving examination of the effects of CaMV insertion on the expression and stability of the transgene. This analysis will be done as described above for the A. thaliana, B. napus, N. benthamiana, and N. tabacum plants, transgenic for GFP under the control of the 35S promoter, and infected with CaMV. These data will determine the effects of CaMV integration on the expression and stability of a GFP transgene.
To determine whether CaMV integration affects vital functions, two approaches will be taken. In the first approach, several key parameters will be measured. These include:

I) levels of starch accumulation;
ii) levels of Rubisco accumulation;
iii) plant size
iv) root weight
v) number of seeds set
vi) time to seed set and senescence
vii) germination frequency of seeds.

The GM plants containing integrated CaMV genomes will be compared to non-GM plants, and GM plants expressing the GFP gene. Fifty plants of each will be inoculated and the plants will be incubated for either 30 days (A. thaliana and N. tabacum) or 90 days (B. napus and N. benthamiana). If there is an effect on the level of GFP expression, representative plants will be assessed further to determine whether the effects are due to silencing of the transgene (by examining the level of expression of the transgene mRNA) or modification of the transgene (by examining the expression of the transgene in the next generation). If the latter occurs, then the transgene will be cloned out of representative plants and the sequence analysed, to determine the nature of the modification to the transgene. In addition, the experiments with N. tabacum will assess whether limited (W260) or no (H7) movement of CaMV in the inoculated leaves only will still result in systemic silencing of the 35S RNA promoter-driven transgene. These assays will permit a determination of whether and to what extent infection by CaMV affects expression of a transgene and the stability of the transgene in an infected plant.

To determine whether integration occurs in the somatic tissue, leaves from 10 infected plants of each species will be harvested 30 days after inoculation for A. thaliana, and N. tabacum, and at 30, 60 and 90 days after inoculation for B. napus and N. benthamiana.

To determine whether integration occurs in the germline, seeds from the above infected plants will be collected and germinated, and leaves will be processed as for the leaves from the parent plants. PCR will then be used and a series of primer pairs to determine whether integration can be detected. The nature of the PCR products will be confirmed by cDNA cloning into E. coli and nucleotide sequence determination. In the first instance, primer pairs will be used to determine whether tandem or nearly tandem insertion occurs of two copies of the CaMV genome. In the second instance, a different strategy will be used to detect single copy insertion events.

If the integration occurs with a high frequency, then many of the sector should result in the positive detection of CaMV sequences. If no PCR products are detected by this assay, then it suggests that the incidence is low or nil. To determine whether integration occurs with a very low frequency, DNA will be extracted from the above plants infected with CaMV containing the dhfr gene. This DNA will be cut with restriction enzymes not present in the modified virus and the DNA fragments will be ligated into a plasmid vector and transformed into E. coli expressing the T7pol and spread onto plates containing methotrexate. The only E. coli cells that will grow are those that contain the CaMV sequences with the dhfr gene under the control of the T7pol. The plasmids from E. coli cells that are able to grow under these conditions will be analysed to verify the presence of the CaMV (and dhfr gene) sequences, as well as flanking plant DNA sequences. These combined approaches will determine whether CaMV sequences can integrate into the genome of their hosts and with what frequency.

To assess whether transcription, reverse transcription (RT) or episomal disease occurs in CaMV-integrated plants, both the progeny of plants containing CaMV inserted into the germline following infection (if they occur), as well as the transgenic A. thaliana plants transformed with CaMV genomes will be analysed. These analyses will enable us to determine whether integration of the CaMV genome leads to episomal expression and disease, or transcription and RT of the integrated CaMV DNA.

Specific changes in environmental conditions may result in transcription, RT, or episomal expression and disease from the integrated CaMV genomes. The specific environmental conditions that will include pathogen attack. In the last case, the plants will be infected by Cucumber mosaic virus (CMV), which can infect any of the above species, does not have a DNA phase to its replication, and has no relationship to CaMV. Moreover, CMV has a well-characterised suppressor of gene silencing, and gene
silencing may be important to prevent expression of the integrated CaMV genome. Infection by CMV will itself induce symptoms, as may any of the other environmental effects. Thus, the environmentally altered and CMV-infected plants would have to be examined for expression of CaMV RNAs and DNAs as described above. These analyses will be made at various times during the life of the plant and should establish whether environmental conditions can affect the propensity of the integrated sequences to become expressed or produce replicating virus.

Evaluation of foreseeable effects

Wild-type CaMV is found worldwide in temperate regions. Natural transmissions is by aphid vectors and the virus is also mechanically transmissible, but is not reported to be seed transmissible. CaMV infection of brassicas grown as food crops is widespread and is not associated with any risk to human health.

To determine whether integration of CaMV affects expression and stability of the transgene, GM plants that show integration into the germline will be assessed for effects on GFP expression and stability, as described above. Similarly, the progeny of such plants also will be assessed for effects on GFP expression and stability. Plants with low somatic integration frequencies will be examined, but the effects would be expected to be negligible to non-detectable. Plants with high levels of somatic integration would be expected to show some effects.

The previous insertion of reporter genes into plant viral genomes has resulted in the creation of attenuated viruses and no mechanism for enhanced pathogenicity can be foreseen.

Assessment of the possible properties of the GM CaMV, the GM host plants and the possibility and likelihood that they could cause harm to the environment.

Stage 1. MODIFIED VIRUSES. These will be kept in either the laboratory or in a contained glasshouse and have little-to-no risk of escape. The H7 and dhfr-expressing variants of CaMV are not transmissible by aphids, the natural vector of CaMV and thus these viruses cannot be transmitted to other plants. Gene II encodes the protein needed for aphid transmission and has been replaced by the dhfr gene in that construct, while H7, which contains Gene VI from strain D4 (Schoelz et al., 1986) is derived from CaMV strain 1841 and contains Gene II of strain CM1841, which was shown to be not transmissible by aphids (Woolsten et al., 1987).

In addition, CaMV is already endemic to the UK environment, found in both crops as well as cruciferous weeds (Raybould et al., 1999; Thurston et al., 2001; Pallet et al., 2002).

Stage 2. INOCULATED PLANTS. The W260 variant will be used only for the experiments involving examination of integration into N. tabacum vs. N. benthamiana in the inoculated leaves, in the first 30 days after inoculation and thus will have little opportunities for escape. The effects of escape of virus from the plants are the same as from the laboratory which has already been covered above. The escape of seeds from transgenic plants in which the virus has been integrated into the germline is considered unlikely, since (a) we have never seen such examples of escaped seeds growing near the glasshouse, (b) except for B. napus, the others are not crop plants grown in Scotland, and B. napus seeds are too large to be wind-borne; and (c) it is unlikely that we will see many plants with natural integration into the germline. The effects of such escape, if it could occur, on the release of CaMV into the environment should also be negligible, as specified above.

Stage 3. TRANSFORMED PLANTS. Only arabidopsis thaliana plants will be transformed, and these will be transformed with CaMV-dhfr, which does not have the aphid transmission gene. A. thaliana is not a crop plant, but an annual weed. These plants have a short life cycle and are not considered a reservoir for insects or viruses for spread to crop plants. If some plants escaped and propagated virus, the virus would not be transmissible to other plants for the reasons given above. Moreover, if the escaped plants crossed with wildtype ecotypes of A. thaliana, these plants would not have a selective advantage, but most likely would become infected from episomal replication of the integrated CaMV sequence, be less competitive than the wild ecotypes, and be eliminated in competition situations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GLASSHOUSE

Plants shall be grown in a designated Containment Level 3 greenhouse compartment or growth chamber, with access restricted to named personnel only. The plants will be clearly labelled and physically separated from other plants. All plants will be bagged to reduce pollen dispersal and a strict pollen and seed management regime will be implemented. The seeds harvested in Stage 2 and 3 will be clearly labelled and stored in a locked cabinet within the containment area. For handling pollen during the
pollination stage full body disposable overalls will be worn.

To prevent escape of the mechanically transmissible GMMOs, handling of infected plants will be performed with gloved hands. Designated laboratory coats are provided for work in the containment glasshouse and these coats are not removed from the containment facility unless decontaminated first. Any material that might be contaminated by the GMMOs (plant material, plant pots, soil, labels, gloves) will be autoclaved prior to disposal.

Records of all glasshouse experiments will be maintained for inspection, including all details of plant disposal. On termination of experiments all plant material, soil and pots shall be transferred to autoclavable bags, sealed and autoclaved.

Any material removed from the glasshouse (for experimental analysis, etc) to be carried in sealed containers/plastic bags. All analysis to be performed in designated laboratory areas. Contaminated materials to be disposed of following autoclaving or sterilisation.

Surfaces and floors in glasshouse compartment shall be cleaned after the experiments to eliminate any plant debris.

LABORATORIES
Laboratories are equipped to the requirements of containment level 2. Autoclaves are available within the building, obviating the need for further transportation. All contaminated materials will be autoclaved or treated with a proprietary virucide. Compliance with level 2 containment measures provides satisfactory environmental protection.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Schedule 8. Part II, Table 1a(3)
For C3 glasshouse containment we apply for derogation for the requirement of impervious bench surfaces, and request that our alternative which is the use of impervious trays for control of run-off water, in conjunction with sealed drains be considered.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Contaminated surfaces will be disinfected with a proprietary virucide validated to give 100% kill.

Is an emergency plan required according to regulation 20?  
N

If yes, tick to confirm that it is attached to this form  
N

Tick to confirm that you have attached a risk assessment to this form  
Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  
N

The committee discussed the following points:
1. The level of containment for the pollen work was discussed at length and a strict pollen and seed management was deemed necessary.
2. The BSO further questioned the number of plants needed, but were assured by the proposer that such numbers were required for experimental purposes.

Project Containment
**Project Ref** 250/05.1

**Non-GMM Consent Granted** Not Applicable

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To test the utility of TRV- and TMV-based vectors for the expression of fluorescent proteins, nematicidal, fungicidal/oomyceticidal or aphidical proteins in plants. The aim of the project is (1) to test a TMV-based system for aphid (Myzus persicae MP1) uptake of virally expressed fluorescent proteins, (2) to evaluate the expression of selected fungicidal/aphidical peptides by a TRV-based vector, and (3) test their efficacy in protecting plants from pest attack.

**Recipient or parental organism**

Recipients. K20.RNA2.A2b. A previously described vector based on the PpK20 strain of tabacco rattle virus (TRV) (MacFarlane and Popovich) will be modified to express nematicidal or fungicidal/oomyceticidal proteins. The vectors produced will lack the 2b gene, which is required for nematode transmission (MacFarlane, 2003) 30B. A hybrid vector based on TMV strains U1 and U5 (Shivprasad et al., 1999) will be modified to express aphidical proteins.

**Host/vector system**
Lycopersicon esculentum for expression of fungicidal/oomyceticidal proteins.

Nocotiana benthamiana for expression of fluorescent reporter proteins or candidate insecticidal proteins.

Arabidopsis, tomato and potato plants for expression of nematicidal proteins.

**Origin & function**

Temporin A is a small cationic antimicrobial peptide originating from the European red frog (Rana temporaria) and is a non-cysteine-containing, linear, alpha helical peptide that has both antibacterial and antifungal activity and will be tested for fungicidal activity.

The mannose-specific lectin protein from Allium sativum (garlic) has known anti-microbial and anti-insect activity and plants infected with virus expressing the lectin are expected to be more resistant to insects.

Chicken egg white cystatin is a protein inhibitor of cysteine proteinases and it is expected that it will affect nematode life-cycle making plants expressing it more resistant to nematode infection.

Lepista nuda mannanase is a protein from the edible fungus Agaricus nudus with high homology to a mannanase of the cultivated mushroom Agaricus bisporus, which is a ligninolytic leaf-litter degrader and is also expected to affect nematode life-cycle.

A fifteen amino acid peptide identified in phage display assays that binds to and exerts an adverse effect in vitro on Globodera rostochiensis (V. Blok, unpublished data) also expected to affect nematode life-cycle.

GFP: green fluorescent protein from Aequorea victoria, and mRFP: monomeric red fluorescent protein from Discosoma sp. Both used as marker genes.

**Evaluation of foreseeable effects**

TRV is indigenous to the UK and has a broad experimental host range including Solanaceae, Cruciferae and Leguminosae. TRV is mechanically transmissible and seed transmissible (from 1% to 40% respectively for Capsella pastoris and Viola arvensis), but is not transmissible by inter plant contact and requires a specific nematode (Paratrichodorus pachydemus) for transmission between plants. Prior experiments have shown TRV-based expression vectors to be attenuated relative to the progenitor virus and that foreign inserts are lost through recombination.

TRV-based vectors have been shown to be efficient at silencing endogenous plant genes in various Solanaceous species (Ryu et al., 2004), however this is not pertinent as plant genes will not be introduced.

TMV forms very stable rod-shaped particles in infected tissues. It is readily mechanically transmissible, but not seed or pollen transmissible. Further, TMV is not transmitted by arthropods, nematodes or fungi. TMV has a world-wide distribution, including the UK, and is a cause of disease in tobacco. TMV has a wide experimental host range including many members of the family Solanaceae, predominantly from the genus Nicotiana. The vector 30B has been described previously. This vector is a hybrid of TMV strains U1 and U5, and has been genetically engineered to express foreign proteins from a duplicated subgenomic promoter. Such TMV-based vectors have been shown to be attenuated, restricted in host range and competitively unfit in comparison to wild-type TMV and to rapidly undergo recombination events in planta to delete foreign sequences, resulting in the formation of pseudo wild-type viruses that are also unfit in comparison to wild-type TMV. TMV-based vectors are poor inducers of silencing and have only been shown to do this in the non-indigenous species N. benthamiana.

Viral expression of temporin A may affect the microfauna of the infected leaf surface.

The mannose-specific lectin is expressed naturally in plants and is unlikely to be cytotoxic to plants and there is no known effect on human health. No expected effect on TRV pathogenicity is expected from the nematicidal proteins or peptide which may increase nematode fitness and alter their life-cycle.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For aphid challenges it is proposed to transport infected plants in sealed containers to a lockable controlled environment room in an insectary where the infected plants will be placed with aphids in aphid-proof Perspex boxes. These boxes are water impervious and a watering system allows external watering of the plants. Any analyses will be performed in Class 2 laboratories. At the end of experiments any material that might be contaminated by the GMOs (plant material, plant pots, soil, matting) will be autoclaved in a Class 3 facility prior to disposal or treated with a proprietary virucide, ie propagator and insect boxes.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material that might be contaminated by the GMOs (infected plant material, plant pots, soil, labels, gloves) will be autoclaved prior to disposal. Propagator and insect boxes will be treated with a proprietary virucide.

Is an emergency plan required according to regulation 20? [ ]

If yes, tick to confirm that it is attached to this form [ ]

Tick to confirm that you have attached a risk assessment to this form [ ]

Tick if you are claiming exemption from disclosure for section of the risk assessment [ ]

Please enter comments on the GM safety committee on the risk assessment

Note was made of the point that no silencing of plant genes was likely given that the expressed genes were of non-plant origin nor that it was likely that any effect on virus pathogenicity or transmissibility would occur. Note was also made of the requirement for a derogation for experiments to be carried out in the insectary facility.

### Project Ref 250/07.1

**Date Ackn'd:** 10/01/2007

**CU2 Project Title:** Use of Potato Mop-Top Virus (PMTV) (Swedish and Scottish isolates) full-length clones to study virus movement, host specificity and transmission.

**Class:** Class 3

**CultureVol:** < 1 Litre

**Non-GMM Consent Granted:** Yes

**Withdrawn:** No

**Tick if notifying a connected programme of work:** No

**Project notified under transitional arrangements:** No
**Project Additional Information**

**Purposes of the contained use**

With the help of the fluorescently tagged constructs the cell-to-cell movement of PMTV will be studied, and the localisation and function of the viral proteins will be elucidated. Constructs with mutations in the triple gene block proteins and in the coat protein (CP) readthrough protein will also be used to pinpoint important domains in these proteins.

Another area of study will be the acquisition and transmission of PMTV by Spongospora subterranea. The acquisition and transmission of PMTV and the interaction between different S. subterranea "strains" identified by sequence variation and/or aggressiveness traits in various host systems, will be studied by infecting plants with both S. subterranea and PMTV under controlled environmental (pot test or nutrients cycling system) conditions.

**Recipient or parental organism**

Recipient: Potato Mop-Top Virus (PMTV) Swedish and Scottish isolate full-length clones. PMTV is a plant pathogen infecting potato. The virus is transmitted by Spongospora subterranea in soil and water and is poorly manually transmissible to potato but can infect experimental hosts this way. Tagging of the virus proteins with fluorescent proteins is not expected to alter its characteristics, transmission or pathogenicity. Mutations in the triple gene block proteins are expected to affect the cell-to-cell movement of the virus and possibly its distribution in the host plant. These experiments do not involve Spongospora subterranea and the virus will not be transmissible in soil or water. Mutations in the coat protein/readthrough protein are expected to affect the interactions with Spongospora subterranea. Experiments involving Spongospora subterranea will result in the GMM becoming water-borne.

**Host/vector system**

Nicotiana benthamiana, N. tabacum, Lycopersicon esculentum and Solanum tuberosum for GMM growth, cell-to-cell movement and vector transmission experiments.

Spongospora subterranea will also be used as the virus vector in experiments studying the virus acquisition and transmission processes.

**Origin & function**

DNA encoding fluorescent proteins such as GFP or RFP or other fluorescent proteins will be introduced into a cDNA clone of PMTV RNA 1, 2 or 3 as fusions to virus genes. Transcript RNA will be synthesized from the cDNA and mechanically inoculated to the test plants (N. benthamiana, N. tabacum). The vectors are based on previously described full-length clones of PMTV (Sacenko et al., 2003 Journal of General Virology 84, 1001-1005). The final constructs will contain the gene for a fluorescent protein introduced to different parts of the full-length clones in order to localise fluorescent protein-viral gene product fusions in the infected plants, monitor virus advance and transmission and the infection process.
PMTV (Swedish isolate) is not indigenous to the UK and differs from the indigenous Scottish PMTV in the sequence of the coat protein-read through domain. The Swedish isolate also has a 109 nucleotide extension at the 3'end of the read-through domain. The read-through domain has been implicated in the transmission by the Spongospora vector, but the function of the 3'end extension in the Swedish isolate is not known. Constructs containing mutations in the read through protein will be used to study its function in acquisition and transmission by the vector.

Mutations in the triple gene block proteins are expected to inhibit cell-to-cell movement of the virus. Mutant versions of the GMM that are characterised as defective in cell-to-cell movement will be inoculated to transgenic plants expressing the cognate triple gene block protein, either native or fused to a fluorescent protein to determine if the defect in cell-to-cell movement can be complemented in this way.

Evaluation of foreseeable effects

Addition of fluorescent proteins to the virus is not expected to change the properties of the virus. Mutations in the triple gene block proteins are expected to inhibit cell-to-cell movement of the virus. Mutations in the read through protein are expected to abolish vector transmission. The modifications are unlikely to increase the pathogenicity or alter the host range of the virus. The genetic stability of the constructs containing foreign genes is predicted to be low and modified viruses are likely to replicate within infected plant cells, but lose inserted sequence during propagation and passage leading to reversion to wild type or near wild type as experienced with other virus-derived vectors, e.g. Ziegler et al., 2000 (Molecular Breeding 6, 327-335). The RNA transcript from the Swedish isolate full length clones cannot be mechanically transmitted to Solanum tuberosum (unpublished results, E Savenkov). Experiments that involve inoculation of only the virus to host plants will be carried out at containment level 2.

Spongospora Subterranwa, the vector for PMTV, is a plasmodiophorid organism, able to infect roots of a wide range of plant genera. However, infection of non-Solanum host species has only been seen to produce zoosporangial inoculum, which is relatively short-lived (a few hours at most). Long-lived sporeballs which would be a threat to subsequent potato or tomato crops produced in these hosts. In potato and tomato infections, there is a possibility that PMTV infected sporeballs could be produced, and infected natural hosts would be therefore destroyed at an early stage of infection before sporeball formation to eliminate this risk. S.subterranea is water and soil-borne and will not be transmitted by aerial means. The GMM is associated with S.subterranea is a water-borne pathogen and water run-off will be prevented; consequently these experiments will be carried out at containment level 3.

PMTV is a plant virus and not known to be harmful to humans. Human consumption of potatoes from PMTV or S.subterranea infected plants is not known to be harmful. There are no known harmful effects of GFP or RFP or other fluorescent proteins either. The virus constructs are not likely to be pathogenic or harmful to humans.

The GMO constructs will replicate and form particles. The probability of displacement of other isolates of PMTV, in particular the indigenous Scottish isolate is very small as the GMO will not have any competitive advantage, and in the case of mutations to the readthrough or triple gene block proteins will be at a disadvantage.

The GMO is not known to be pathogenic to animals, only to host plants. There is no known toxicity of the viral products or of the expressed foreign genes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material that might be contaminated by the GMM (infected plant material, plant pots, soil, labels, gloves) will be autoclaved prior to disposal and this will give a 100% kill. The autoclaves used have been validated for the destruction of tobacco mosaic virus (TMV) which forms much more stable particles than PMTV does. Conditions are used that result in no detectable TMV being recovered from plant material after autoclaving as assessed by inoculation to sensitive local and systemic host plants.
The GM Safety Committee noted that the work involved a non-disabled plant pathogen and that experiments that involved the fungus host would result in the GMM becoming water-transmissible albeit for a relatively short period of time as the viruliferous zoospores are short-lived. Experiments involving the fungus will be carried out at containment level 3 to prevent run-off water from plants. Experiments looking at cell-to-cell movement that do not involve the fungus host can be carried out at containment level 2 as the virus alone is not spread in run-off water.

**Project Ref** 250/07.2

**Date Ackn’d** 05/11/2007

**CU2 Project Title** Pectobacterium atrosepticum as a delivery vector in screening for effector function in secreted proteins from Pectobacterium atrosepticum and Phytophthora infestans.

**Class** Class 3  
**Culture Vol Class 2** < 1 Litre  
**Culture Vol Class 3-4** < 1 Litre

**Non-GMM Consent Granted** Yes

**Date Project Ceased**

**Withdrawn** N

**Tick if notifying a connected programme of work** N

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**
Pectobacterium atrosepticum (syn. Erwinia carotovora ssp. atroseptica) causes blackleg disease on potato, and disease is restricted to that host. P. atrosepticum is indigenous to the UK. The genome of P. atrosepticum has recently been sequenced and this has revealed that numerous factors such as pectolytic enzymes and phytotoxic compounds, are required for full pathogenicity in this organism. Also pathogenicity determinants (effector proteins) such as DspE are secreted by a type III secretion system (T3 SS) and some effector proteins in plant pathogens may suppress host defence responses such as the hypersensitive response. The ability of plant pathogens to actively target components of host defence responses can in part define the host range of the pathogen.

Host range in plant pathogens is also mediated by avirulence gene products. The expression of these genes by the pathogen is recognised by the host plant. A resistance response (the hypersensitive response (HR), a form of programmed cell death) is initiated by the plant, and the infection is contained. The pathogen is termed incompatible with that host, Absence of the avirulence gene products will lead to compatibility, and development of disease. Avirulence genes can operate at the host species level, as well as the variety, or cultivar level. At the cultivar level, each avirulence gene is matched by a cognate resistance gene, the so-called gene-for-gene interaction, For instance, potato resistance gene R3a is matched by Phytophthora infestans avirulence gene allele Avr3a. Interaction of P. infestans carrying Avr3a with a potato carrying R3a results in recognition of infection, and a resistance response; the pathogen is incompatible. Compatibility, or successful infection, results where the pathogen carries avr3a (virulence allele) and is not recognised by the host plant carrying R3a.

The discovery of a functional T3 SS in P. atrosepticum, a frill genome sequence for potato pathogens P. atrosepticum and P. infestans, and defined pathogenicity deficient mutants for P. atrosepticum provides an opportunity to use P. atrosepticum to study the delivery and effect of putative pathogenicity factors from both organisms in host (potato) and non-host (Nicotiana benthamiana) plants. The genes to be tested will be those that are either (or both) strongly up-regulated during infection of potato, or the homologs of genes implicated in pathogenesis or avirulence of other plant pathogens. Many of the genes to be tested will have no homology to genes of known function. Our aim is to determine the effect of delivery into host plant cells on the host ability to respond either in terms of non-host or innate immunity, or resistance gene mediated response (hypersensitive response). Determination of both pathogenicity factors and avirulence genes in P. atrosepticum and P. infestans will provide us with novel targets for both chemical and biotechnological control of potato diseases. It also will allow us to identify genetic components of more complex host resistance phenotypes such as field resistance, which can then be used in potato breeding programmes.

The question we will address with this research is whether genes involved in avirulence or pathogenicity in the named organisms have any role or effect in plant/pathogen interactions. The GMMs from these experiments will either invoke a resistance response in N. benthamiana or potato, or no change from the wild type will be observed.

Recipient or parental organism

Isolate SCRI-1043 of P. atrosepticum represents the wild type genetic background to be used in these experiments. Isolate SCRI—1043 was originally isolated from potato in Scotland. The GMMs from these experiments will either invoke a resistance response in N. benthamiana or potato, or no change from the wild type will be observed. Since the transgenes will originate from a pathogen that is itself restricted to potato hosts, it is unlikely that introduction of the heterologous genes will have any effect on the host range of the GMM. Indeed, the opposite effect of restricting the host range may be more likely, as the host plant may recognise the gene product as an avirulence protein and initiate a resistance response.

P. atrosepticum occurs as an endemic pathogen on potato crops in the United Kingdom. Although an enterobacterium closely related to Escherichia coil, P. atrosepticum has never been recorded as a human or animal pathogen. P. atrosepticum is not expected to pose any threat to human health under the conditions to be used for experimentation. P. infestans occurs as an introduced pathogen on potato crops in the United Kingdom. It and other Phytophthora species are not known as human pathogens. P. infestans is not expected to pose any threat to human health under the conditions to be used for experimentation.

For the majority of transgenes tested, there will be no effect on the infectivity, disease development, or host range of the 0MM. In the unlikely case of any 0MM escape, little is known about the stability of transgenes in P. atrosepticum. However, the transgenes are located on non-integrative plasmids that are unlikely to persist for long periods of
time without ampicillin selection in P. atrosepticum. Since the potato pathogen P. atrosepticum is to be used, and the transgenes to be tested originate from a pathogen restricted to potato hosts, it is highly unlikely that the host range of the GMM would be extended. An emerging consensus from the study of many bacterial, fungal and oomycete plant pathogens (including P. atrosepticum and P. infestans) is that pathogenicity is a complex process involving the action of many genes; the addition of only one of these genes is not likely to have a large impact on the overall aggressiveness of the GMM. In bacteria, where horizontal gene transfer is well documented as is considered to have had a role in changes in pathogenicity, this has often been due to the transfer of entire operons (clusters of several genes) such as for toxin biosynthesis or Typelli secretion. Should a GMM expressing a pathogenicity gene escape, the possibility of its DNA being transferred to another environmental and non-pathogenic organism, or another pathogen, is remote. In addition to the plasmid harbouring the effector transgene having a high probability of loss from P. atrosepticum, pathogenesis in many pathogens is typically complex and probably employs many mechanisms. It is unlikely therefore, that the horizontal transfer of a single P. infestans gene to a fungus or bacterium would confer novel pathogenicity upon a non-pathogen or increase host range of an existing pathogen.

Host/vector system

Vectors are based on the commonly used non-integrative pOEM series of plasmids, which are also functional in P. atrosepticum; the plasmid vectors therefore contain an ampicillin resistance gene. The T3SS effector DspE from P. atrosepticum is an orthologue of AvrE from Pseudomonas syringae and shows the bias towards high serine (20%), low aspartate (2%) in the first 50 amino acids of T355-translocated effectors in P. syringae. The promoter region, containing the hrp box for HrpL-dependent induction, along with the first 100 amino acid encoding region of dspE, will be fused to P. infestans effector genes, minus the signal peptide-encoding sequences. Potato resistance genes will be expressed from A. tumefaciens strain AGLO.

Origin & function

We aim to express P. infestans candidate pathogenicity and avirulence genes from P. atrosepticum in different assays. The precise sequence identity of each of the genes to be tested is not known, as the bioinformatics analyses of the P. infestans genome sequence for candidate genes are still in progress. In the instance of P. infestans pathogenicity genes, these will be genes that are either (or both) strongly up-regulated during infection of potato, or the P. infestans homologues of genes implicated in pathogenesis of other plant pathogens. Many of the genes to be tested will have no homology to genes of known function, Initial experiments will use Avr — R gene pair of Avr3a and R3a, both of which have been isolated. Overexpression of the Avr3a gene in stable transformants of P. infestans has not led to any increase in the aggressiveness of that organism. For defined or candidate avirulence genes from P. infestans where the cognate resistance gene from potato has been cloned, the transgenic P. atrosepticum will be coinfiltated into plant leaves with A. tumefaciens strain AGLO expressing the cognate resistance gene. Delivery of both components (AVR and R) is expected to trigger the hypersensitive response. These experiments will be carried out in either potato or N. benthamiana. For candidate effector genes, transgenic P. atrosepticum will be infiltrated first into N. benthamiana leaves followed later by infiltration with wild type Erwinia amylovora, for which AL. ben/hamiana is a non-host. Where a candidate effector is acting to suppress defence responses, the HR triggered by B. amyllovora will be inhibited.

Evaluation of foreseeable effects

The GMMs from these experiments will either invoke a resistance response in N. benthamiana or potato, or no change from the wild type will be observed. Since the transgenes will originate from a pathogen that is itself restricted to potato hosts, it is unlikely that introduction of the heterologous genes will have any effect on the host range of the GMM. Indeed, the opposite effect of restricting the host range may be more likely, as the host plant may recognise the gene product as an avirulence protein and initiate a resistance response. For defined or candidate avirulence genes from P. infestans where the cognate resistance gene from potato has been cloned, the transgenic P. atrosepticum will be coinfiltated into plant leaves with A. tumefaciens strain AGLO expressing the cognate resistance gene. Delivery of both components (AVR and R) is expected to trigger the hypersensitive response. Expression of candidate avirulence genes isolated from P. infestans will result in the GMM becoming avirulent (or incompatible) with potato varieties carrying specific matching resistance genes. In this case, the host range of the GMM is expected to be reduced from the wild type (with the wild type originally being virulent, or compatible, on the resistance genes tested). For a P. infestans avirulence gene to be expressed, we may expect to see localised necrosis (HR) at the point of inoculation. This response would be confined to one or few host plant genotypes (carrying the cognate R gene); specificity towards other host plant genotypes should remain unchanged.

Risk to human health
P. atrosepticum occurs as an endemic pathogen on potato crops in the United Kingdom. Although an enterobacterium closely related to Escherichia coli, P. atrosepticum has never been recorded as a human or animal pathogen. P. atrosepticum is not expected to pose any threat to human health under the conditions to be used for experimentation. P. infestans occurs as an introduced pathogen on potato crops in the United Kingdom. It and other Phytophthora species are not known as human pathogens, P. infestans is not expected to pose any threat to human health under the conditions to be used for experimentation. A. tumefaciens occurs naturally in soil and is not known to be a pathogen of humans. Disauned A. tumefaciens strains have been used safely as a vector for transgene delivery into plants for many years. It is not expected to pose any threat to human health under the conditions to be used for experimentation.

The foreign genes to be expressed in the 0MM are of unknown function or biological activity. Transgenes will encode protein products from P. atrosepticum or P. infestans (potato late blight). No toxicology studies have been carried out on P. infestans or P. atrosepticum, and there are no records to implicate either organism in human disease. In the extremely unlikely event that any of the expressed gene products are determined to be toxic to humans, experiments with these genes will cease immediately.

Risk to the environment
P. atrosepticum is spread in saturated soils by dispersal from heavily infected plants, or plant debris in soil. P. atrosepticum can also persist on roots of alternate host plants such as Brassica sp. Almost all potato varieties grown in the UK are susceptible to P. atrosepticum. There is no effective chemical control against P. atrosepticum. It is simple to maintain P. atrosepticum in sealed agar plates and the risk of escape from these vessels is minimal. It is standard practice in our laboratories to handle P. atrosepticum field isolate cultures in a class 2 biohazard cabinet to prevent escape of the pathogen, and to protect the cultures from contamination. We propose to maintain and manipulate the GMMs in the same manner.

In our experiments, the conditions for transmission of P. atrosepticum will be avoided where possible. For instance, preparation of inoculum will use good microbiological practice, small plants will be inoculated by infiltration to prevent aerosols, inoculated plants will be kept in sealed propagator boxes, handling of infected plants will be minimised, disposable gloves will be worn for all handling of infected plants, and all materials that come in contact with the infected plants or cultures will be destroyed by autoclaving.

For the majority of transgenes tested, there will be no effect on the infectivity, disease development, or host range of the 0MM. In the unlikely case of any 0MM escape, little is known about the stability of transgenes in P. atrosepticum. However, the transgenes are located on non-integrative plasmids that are unlikely to persist for long periods of time without ampicillin selection in P. atrosepticum. Since the potato pathogen P. atrosepticum is to be used, and the transgenes to be tested originate from a pathogen restricted to potato hosts, it is highly unlikely that the host range of the 0MM would be extended. An emerging consensus from the study of many bacterial, fungal and oomycete plant pathogens (including P. atrosepticum and P. infestans) is that pathogenicity is a complex process involving the action of many genes; the addition of only one of these genes is not likely to have a large impact on the overall aggressiveness of the GMM. In bacteria, where horizontal gene transfer is well documented as is considered to have had a role in changes in pathogenicity, this has often been due to the transfer of entire operons (clusters of several genes) such as for toxin biosynthesis or TypeIII secretion. Should a GMM expressing a pathogenicity gene escape, the possibility of its DNA being transferred to another environmental and non-pathogenic organism, or another pathogen, is remote. In addition to the plasmid harbouring the effector transgene having a high probability of loss from P. atrosepticum, pathogenesis in many pathogens is typically complex and probably employs many mechanisms. It is unlikely therefore, that the horizontal transfer of a single P. infestans gene to a fungus or bacterium would confer novel pathogenicity upon a non-pathogen or increase host range of an existing pathogen.

As an additional containment measure, staff carrying out these experiments will not visit potato fields or SCM potato glasshouses (other than the containment glasshouse) on the day of experiments involving the 0MM.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Glasshouse benches resistant to acids etc: derogation applied for on the basis that the benches in the containment area are made of wire mesh for ease of cleaning and to enable temperatures to be maintained consistently throughout the facility. Fully waterproof receptacles to prevent any run off water from plant pots are included routinely in the SOPs for the facility. By using small plants (less than 20 cm height) in sealed containers, there will be no water run off. By keeping all inoculated plant material in sealed vessels, there is no possibility of water ingress as a result of flooding. The floors of this area are also sealed and the drain capped. In the highly unlikely event of flooding...
the drains have an additional cap beneath the floor and if this should fail the default setting on the drainage system would direct the effluent to a holding tank where chemical disinfection could take place before release to mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material including flasks or plates used for growth of cultures, inoculated plant material plant pots, compost, labels, gloves etc. that might be contaminated by the GMOs will be autoclaved before disposal. A 5 log reduction in the number of microorganisms will result and will be validated by plating out of a liquid culture before and after autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This was an amended version of a proposal that had been submitted previously (December 2006) suggesting a lower containment level and which had been rejected by the committee. The committee was now satisfied with the containment measures suggested and are now happy for this work to proceed. Institute Safety Office indicated that dedicated freezers should be made available for this work and that material should not be stored beside other GM material,

Project Ref 250/07.3

Date Ackn’d 05/11/2007

CU2 Project Title Study of interactions between plants and bacteria pathogenic for humans.

Date Project Ceased 02/03/2022

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM Consent Granted Not Applicable
To investigate the interactions that occur between plants and human pathogens: pathogenic Escherichia coil (including nonverotoxigenic (non-VTEC) serotypes 0157, 026 and 0111 and uropathogenic strain CFT073), Salmonella enterica serovar Typhimurium and Kiebsielia pneumoniae. The work will make use of comparative genomic analyses based on the genome sequence of Pectobacterium atrosepticum and these pathogens to analyse gene orthologs between the different pathogens that may be involved in association and survival on plants. Genes of interest will be analysed by (i) mutation in the wild type background of K coil, S. Typhimurium or K pneumoniae and complementation (plasmid-based or single copy via alleleic exchange); (ii) cloning into plasmid-based vectors and over-expression in a negative control background; (iii) fusion to reporter genes (both plasmid-based and single copy chromosomal fusions).

The bacterial strains in the proposal are pathogenic to humans and are all defined by the HSE as Category 2 classification. NonVTEC K coil strains are attenuated by deletion of the shiga-toxin genes and are derived from the well-characterised sequenced isolates EDL933 and Sakai, or from field isolates. Loss of the verotoxigenic genotype and phenotype has been confirmed by PCR and/or vero cell assay in the source laboratories (Centre for Infectious Diseases, the University of Edinburgh) E. coil CFT073, S. Typhimurium (e.g. strains SL1344 and LT2) and K pneumoniae (e.g. Kp 342 and ATCC 700721) are all wild type strains that do not require attenuation for Category 2 classification. K coil K-12 (Category 1 classification) will also be used as an intermediate strain for cloning DNA of interest into plasmids. It will also be used as a control organism in experimental work, as it represents a negative control, Genes targeted for manipulation will be those potentially involved in survival on plants and not those associated with pathogenesis on either plants or humans, Any risks associated with pathogenesis on either of these hosts will thus be extremely unlikely. The manipulations and modifications will focus on deletions of virulence determinants, and comparison to wild type parent strains. None of the GMMs will carry insertions of ‘foreign’ virulence factors, i.e. from one species to another. If foreign DNA is inserted it will be in the form of reporters (such as LacZ, GnsA or fluorescent proteins), antibiotic marker genes (listed above). As these bacteria are not pathogenic on plants, there is no risk to plants associated with spread to the wider environment. An increased risk to humans is unlikely.

Manipulation requires the use of both transposons (mTn5, delivered on the plasmid pUT APR), and plasmids. All manipulations will be carried out under antibiotic selection, Removing selective pressure results in dilution of the plasmid by bacterial growth. The plasmids will be transferrable to enteric bacteria. Lysogenic bacteriophage specific to E. coil (P1) or S. Typhimurium (P22) will be used to mobilize marked (with antibiotics) mutations or reporters into wild type backgrounds.

Genes and regulatory DNA possibly involved in adherence to, and persistence within, plant tissue from K coil strains EDL933, CFT073 and Sakai, or from field isolates, or from S Typhimurium (e.g. strains SL1344 and LT2) and K pneumoniae (e.g. Kp 342 and ATCC 700721) will be manipulated by mutagenesis, complementation or
Evaluation of foreseeable effects

Genes targeted for manipulation will be those potentially involved in survival on plants and not those associated with pathogenesis on either plants or humans. Any risks associated with pathogenesis on either of these hosts will thus be extremely unlikely. Modifications which result in mutagenesis of a particular gene will reduce that characteristic of the GMM. Complementation of mutants will restore phenotypes to wild type levels. Manipulation of the factors will not alter the normal route of transmission of E. coli or S Typhimurium GMM to the human host. Although manipulation requires the use of antibiotics, the wild type susceptibility to antibiotic treatment will not be affected as the antibiotics used in treatment have superseded those used in manipulations by several generations- For the majority of enteric infections, fluoroquinolones are effective. Furthermore, this work will not use strains that carry multi-thug resistance, such as S. Typhimurium DTIO4. In particular, specific guidelines (HPA) for E. coli 0157 indicate that there is no convincing evidence to suggest that antimicrobial agents alter the natural history of VTEC infection or the duration of faecal excretion of the organism. Small-scale studies have investigated co-trimoxazole, aminoglycosides, or beta-lactam antibiotics rather than the fluoroquinolones. The work in this proposal will only make use of verotoxin-negative strains, which means that even if sub-inhibitory concentrations of antibiotics were administered, it will not lead to lysis and release of verotoxin associated with wild type strains of VTEC.

No DNA transfer between pathogens will take place but, as is commonly carried out, F. coil K-12 will be used to transfer genetic material for mutagenesis etc. Any inserted DNA sequences will not increase the virulence of the GMM over that of wild type. The manipulations should not affect the survival of the GMM over that of wild type, Manipulation requires the use of both transposons (mTn5, delivered on the plasmid pUT APR), and plasmids. All manipulations will be carried out under antibiotic selection. Removing selective pressure results in dilution of the plasmid by bacterial growth. The plasmids will be transferable to enteric bacteria. Lysogenic bacteriophage specific to F. coil (P1) or S Typhimurium (P22) will be used to mobilize marked (with antibiotics) mutations or reporters into wild type backgrounds. The likelihood of the 0MM establishing an infection in a human host is no greater than the wild type. The probability of this happening is no greater than if the work focused on wild type bacteria. The manipulations listed above in (2) will not affect pathogenicity, infectivity, toxicity, virulence, allergenicity, colonization, parasitism, symbiosis or competition over the wild type and should not render the 0MM detrimental for natural flora and fauna or alter the capacity of the GMM to cause harm to the environment. None of the manipulations (deletions or insertion of reporter cassettes) will confer a selective advantage, if either transferred to enteric bacteria already in the environment or if the GMM were released into the environment. Chromosomal mutations (random or defined) and insertion of reporter systems into the chromosome will be stable. Even if the 0MM were to revert to wild type, it poses no greater risk than the parent wild type strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material including flasks or plates used for growth of cultures, inoculated plant material plant pots, compost, labels, gloves etc. that might be contaminated by the GMOs will be autoclaved before disposal. A 5 log reduction in the number of microorganisms will result and will be validated by plating out of a liquid culture before and after autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The minutes of the GM safety committee that discussed the project are below:

- (BSO) took the opportunity to discuss this submission with the HSE inspectors on their recent visit and they seemed satisfied with the Risk Assessment and the Category 2 classification.

(Institute Safety Officer) had contacted the Biological Safety Officer at the Moredun Research Institute regarding this submission and she was happy with the RA although made a few suggestions regarding SOPs (These have been incorporated into the risk assessment).

i.e. Dedicated lab coats or gowns will be required and kept in the cat 2 lab, indicated that these labcoats will be of a different (style to identify them from "ordinary" labcoats.

Staff should be trained and written records of staff training will be required. pass training records to These documents must identify individuals by name.  -

SOPs for daily work as well as for dealing with accidental spillages should be available in the lab.

(Deputy BSO) emphasized the need for care when handling human pathogens. A dedicated laboratory should be identified for this work. All lab users should be aware of the Category 2 work being carried out in the laboratory. A list of authorized users should be posted on the designated laboratory door.

needs to notify HSE and should liaise with him regarding this matter.

### Project Additional Information

#### Purposes of the contained use

Plant pathogens (bacteria, oomycete or fungi) will be transformed with vectors directing the expression of marine invertebrate-derived fluorescent proteins with a β-barrel structure (either native or fused to proteins derived from the pathogen to be transformed) and localisation of the pathogen or pathogen-derived protein in plants infected with the pathogen will be determined by fluorescence microscopy or confocal microscopy. Recombinant viruses will also be generated containing fluorescent protein genes and similar localisation studies performed on plants infected with single viruses.

#### Recipient or parental organism

**Viruses**

Infectious clones of plant pathogenic viruses will be used to either make infectious transcripts in vitro, or infectious clones in agrobacteria binary vectors will be applied by agroinoculation. Viruses will include:

1. Aphid transmissible viruses: Potato virus A, Potato virus Y, Potato leafroll virus, Black raspberry necrosis virus, Cucumber mosaic virus, Cauliflower mosaic virus.
2. Nematode transmitted viruses: Tomato black ring virus, Tobacco ringspot virus, Tomato ringspot virus, Tobacco rattle virus
3. Mite-transmitted viruses: Raspberry green leaf blotch virus, Blackcurrant reversion virus
4. Manually-transmitted viruses: Tobacco mosaic virus, Potato virus X, , Barley stripe mosaic virus, Turnip vein chlorosis virus, Tomato bushy stunt virus, Groundnut rosette virus, Pea enation mosaic virus 2
5. pollen transmitted virus: Raspberry bushy dwarf virus
6. beetle transmitted virus: Rubus Chlorotic mottle virus
7. Oomycete transmitted virus: Potato mop-top virus

The viruses are pathogens of plants and cause a variety of disease symptoms in plants. Addition of fluorescent proteins is not expected to affect their pathogenicity, host range or mode of transmission. Containment level 2 will normally be applied except where it is suspected that either pollen-transmission or water-borne transmission of a virus via a vector can occur in which cases containment level 3 will apply in the glasshouse.

**Fungi and Oomycetes**

Fungi will include the cereal pathogens: Rhynchosporium secalis, Ramularia collo-cygni, Phaeosphaeria nodorum, Mycosphaerella graminicola, Magnaporthe grisea, Oculimacula yallundae, Pyrenophora/Drechslera, Gaeumannomyces graminis, Bipolaris sorokiniana, Claviceps purpurea, Fusarium spp, Pyrenophora tricirepentis, Pyrenophora graminea, Pseudoseptoria stomaticola, Ustilago spp and Rhizoctonia solani.

Oomycetes will include the potato-infecting Phytophthora infestans, Spongospora subterranea and Phytophthora erythroseptica; soft fruit-infecting Phytophthora fragariae and Phytophthora idaei; Arabidopsis thaliana-infecting Phytophthora brassicae and Hyaloperonospora arabidopsis (syn. H. parasitica); woody host-infecting Phytophthora ramorum, Phytophthora alni and Phytophthora kernoviae; soybean-infecting Phytophthora sojae and broad host range Phytophthora andina, Phytophthora capsici, Phytophthora cinnamomi, Phytophthora palmivora, Phytophthora cryptogea, Phytophthora cactorum, Phytophthora cambivora, Phytophthora dechleri, Phytophthora nicotianae, Phytophthora megasperma, Aphanomyces eutiches, Pythium ultimum and Pythium oligandrum.

These cause a variety of symptoms on host plants including: leaf and tuber blight, root, stem and fruit rot, stem canker and downy mildew. Pythium oligandrum is plant associated and also infects and lyases fungi and other oomycetes. Addition of fluorescent proteins is not expected to affect their pathogenicity, host range or mode of transmission. Containment level 2 will apply in the glasshouse except were water-borne transmission is suspected in which cases containment level 3 will apply.
Viruses

Infectious clones of plant pathogenic viruses will be used to either make infectious transcripts in vitro, or infectious clones in agrobacteria binary vectors will be applied by agroinoculation. Viruses will include:

i. Aphid transmissible viruses: Potato virus A, Potato virus Y, Potato leafroll virus, Black raspberry necrosis virus, Cucumber mosaic virus, Cauliflower mosaic virus.

iii. Mite-transmitted viruses: Raspberry green leaf blotch virus, Blackcurrant reversion virus.

v. pollen transmitted virus: Raspberry bushy dwarf virus.

vi. beetle transmitted virus: Rubus Chlorotic mottle virus.

The viruses are pathogens of plants and cause a variety of disease symptoms in plants. Addition of fluorescent proteins is not expected to affect their pathogenicity, host range or mode of transmission. Containment level 2 will normally be applied except where it is suspected that either pollen-transmission or water-borne transmission of a virus via a vector can occur in which cases containment level 3 will apply in the glasshouse.

Fungi and Oomycetes

Fungi will include the cereal pathogens: Rhynchosporium secalis, Ramularia collo-cygni, Phaeosphaera nodorum, Mycosphaerella graminicola, Magnaporthe grisea, Oculimacula yallundae, Pyrenophora/Drechslera, Gaeumannomyces graminis, Bipolaris sorokiniana, Claviceps purpurea, Fusarium spp, Pyrenophora triciribirentis, Pyrenophora graminea, Pseudoseptoria stomaticola, Ustilago spp and Rhizoctonia solani.

Oomycetes will include the potato-infecting Phytophthora infestans, Spongospora subterranea and Phytophthora erythroseptica; soft fruit-infecting Phytophthora fragariae and Phytophthora idaei; Arabidopsis thaliana-infecting Phytophthora brassicae and Hyaloperonospora arabidopsis (syn. H. parasitica); woody host-infecting Phytophthora ramorum, Phytophthora alni and Phytophthora sojae and broad host range Phytophthora andina, Phytophthora capsici, Phytophthora cinnamomi, Phytophthora palmivora, Phytophthora cryptogea, Phytophthora cactorum, Phytophthora cambivora, Phytophthora dechleri, Phytophthora nicotianae, Phytophthora megasperma, Aphanomyces eutiches, Pythium ultimum and Pythium oligandrum.

These cause a variety of symptoms on host plants including: leaf and tuber blight, root, stem and fruit rot, stem canker and downy mildew. Pythium oligandrum is plant associated and also infects and lyases fungi and other oomycetes. Addition of fluorescent proteins is not expected to affect their pathogenicity, host range or mode of transmission. Containment level 2 will apply in the glasshouse except were water-borne transmission is suspected in which cases containment level 3 will apply.

Bacteria

These will include the following plant pathogenic bacteria:

i. Pectobacteria atroseptica which is endemic in Scotland and causes disease only in potato, but may survive on plants including other crops without disease symptoms. It is transmitted via contaminated vegetative material.

ii. Pectobacteria carotovora which is limited to potato in Scotland but has wider host range in warmer countries. It is transmitted via contaminated vegetative material. It lives in soil as a saprophyte and is endemic in Scotland.
iii. Dickeya species (D. dadantii, D. dianthicola, D. chrysanthemi, D. zeae, D. paradisiaca and D. dieffenbachiae) cause disease on different plants including some crops in warmer countries. D. dianthicola and possibly other species are present on potato in Europe. They are transmitted via contaminated vegetative material but there is some evidence that the Dickeya species are water-borne in transmission at least in some instances.

iv. Pantoea ananatis is a pathogen of eucalyptus in South Africa but can also cause disease on maize and onion.

v. Erwinia amylovora, causes disease of apples and pears.

vi. Streptomyces scabies infects potatoes and other root crops including beets, radish, turnip, carrot and parsnips. It survives in soil and infected plant material and is transmitted as spores

vii Pseudomonas aeruginosa

vii Burkholderia cepacia

Containment level 2 will apply in the glasshouse except for the Dickeya species where there is evidence of water-borne transmission and for which containment level 3 will apply in the glasshouse.

Host/vector system

The transformation vectors for fungi, bacteria and oomycetes are based on non-integrative pGEM bacterial plasmids or transposons (mTn5, delivered on the plasmid pUT ApR).

Origin & function

Genes encoding fluorescent proteins with a β-barrel structure from marine invertebrates such as green fluorescent protein gene (GFP), yellow fluorescent protein (YFP), red fluorescent protein (mRFP or dsRED), or tandem dimer tomato fluorescent protein (tdTomato) will be added to the plant pathogens either in their native form or fused to other genes of the pathogen. This will allow localisation of the pathogen (or pathogen-derived protein) by detection of fluorescence under ultra-violet light.

For fungi and oomycetes promotor and terminator sequences originate from the Aspergillus nidulans glyceraldehyde-3-phosphate dehydrogenase gene. The vectors also contain the antibiotic resistance gene hygromycin phosphotransferase (hpt) under control of the same promotor mentioned above to allow for selection in fungi and the ampicillin resistance gene to allow propagation of the plasmid in the bacterium Escherichia coli.

Evaluation of foreseeable effects

There is a long history of the safe use of genes encoding marine invertebrate-derived fluorescent proteins with a β-barrel structure such as green fluorescent protein gene (GFP), yellow fluorescent protein (YFP), red fluorescent protein (mRFP or dsRED), or tandem dimer tomato fluorescent protein (tdTomato) either in their native form or fused to other proteins. We expect to see that, following transformation, transformants will become fluorescent under specific light wavelengths. No increase in aggressiveness is expected, as these fluorescent tags have been used extensively in other virus, fungal, oomycete, and bacterial plant pathogens without increasing the pathogenic capabilities of the pathogens. Indeed, the opposite effect of reduced aggressiveness is more likely as constitutive overexpression of a heterologous gene is likely to place a metabolic burden on the pathogens. It is also common for plant pathogens kept in culture (as would be the GMMs) to become attenuated in virulence or lose the ability to produce spores (where appropriate). It is not expected that addition of such a gene will affect the pathogenicity, host range or aggressiveness of a pathogen, nor is it expected that plants infected with pathogens expressing these genes will behave any differently from those infected with unmodified pathogens.

Risk to human health

Most of the pathogens are restricted to plants and present little hazard to human health. Two of the bacteria (Pseudomonas aeruginosa and Burkholderia cepacia) opportunistically infect humans and are in ACDP group 2.
Addition of genes encoding fluorescent proteins is unlikely to make the resulting GMMs any more harmful than the parental pathogens. Infection of the host plants with pathogens should present no greater risk than plants infected with unmodified pathogens. Expression of fluorescent proteins will not affect the ability of the plants to survive or diseminate, instead infection with the GMMs should decrease the fitness of the plants. Expression of fluorescent proteins should not increase the multiplication of the pathogens and infected plants should not become greater reservoirs for pathogens. Spread of the genes encoding fluorescent proteins to other organisms will cause them to fluoresce under ultra-violet light but no other adverse or beneficial effects are expected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Glasshouse benches resistant to acids etc: derogation applied for on the basis that the benches in the containment area are made of wire mesh for ease of cleaning and to enable temperatures to be maintained consistently throughout the facility. Fully waterproof receptacles to prevent any run off water from plant pots are included routinely in the SOPs for the facility. The floors of this area are also sealed and the drains capped. In the highly unlikely event of flooding the drains have an additional cap beneath the floor and if this should fail the default setting on the drainage system would direct the effluent to a holding tank where chemical disinfection could take place before release to mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material including flasks or plates used for growth of cultures, inoculated plant material plant pots, compost, labels, gloves etc. that might be contaminated by the GMOs will be autoclaved before disposal. A 5 log reduction in the number of microorganisms will result and will be validated by plating out of a suspension of GMM before and after autoclaving. For viruses autoclaves have been validated for killing of tobacco mosaic virus by inoculation of autoclaved infected plant material onto sensitive local and systemic host plants and no infection of test plants was observed.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The committee noted that the purpose of the risk assessment was to determine the localisation of a number of different plant pathogens. An increase in the number of people expressing an interest applying such approaches had been seen and this risk assessment was to allow a single application to be made for consent to carry out the work. An email enquiry to HSE had indicated that inclusion of a number of different pathogens as a linked programme of work should be acceptable.

The role of protein transport in the pathogenicity of Streptomyces scabies

Genes of S. scabies known or thought to be involved in secretion of bacterial proteins have been replaced by targeted mutagenesis by a collaborator at the University of Dundee. We now wish to obtain these strains and investigate whether the protein secretion systems that have been deleted contribute to the virulence of S. scabies by performing basic plant virulence assays on Arabidopsis, potato and radish plants.

One protein secretion system that we know contributes greatly to virulence is the Tat system. We wish to carry out confocal laser scanning microscopy (CLSM) to look at how plant roots are infected by wild-type and tat mutant strains. To this end, constructs have been introduced into the bacteria that express green-fluorescent protein to label the bacteria so that they may be visualised. The pathogen-infected plant material will be transported to the microscopy suite in a sealed container and the microscope cleaned with 70% ethanol after use.

We also wish to investigate the role of individual proteins that are secreted by the Tat system. Knockout mutants of these will be constructed and assessed in virulence assays. Those found to contribute to pathogenicity will be fluorescently labelled and their localisation in the plant roots visualised using CLSM to give an indication of their plant cell target and helping to elucidate the role of the Tat system in the disease process.

Similar work is proposed for a second secretion system, the Esx system. This has not been examined previously in S. scabies although plays a role in pathogenesis of other Gram-positive bacteria, including Mycobacterium tuberculosis and Staphylococcus aureus.
Streptomyces scabies, an opportunistic pathogen causing common scab of potato and other tuber crops.

**Host/vector system**

S. scabies cosmid library constructed in SuperCos pSET152 derived plasmids that integrate into the chromosome at the phage phiC31 site. Both must integrate into the chromosome in order to be maintained as they cannot replicate in Streptomyces (suicide vectors).

**Origin & function**

n-frame gene deletions are marked with antibiotic resistance genes. It is expected that these will prevent secretion of a sub-set of bacterial proteins and possibly affect virulence of S. scabies. Constitutive expression of green-fluorescent protein allows for visualisation of strains during microscopic examination.

**Evaluation of foreseeable effects**

Mutations in the Tat system of protein secretion cause attenuation in virulence of S. scabies. The effects of other mutations are uncertain, although they are also expected to lead to a reduction in virulence. This is yet to be ascertained.

S. scabies is an opportunistic plant pathogen that causes scab on root vegetables. Scab causing Streptomyces sp are already endemic in the UK and do not cause economically significant damage on crops other than potatoes. S.scabies is potentially transmissible in run-off water. No reports of adverse effects of S. scabies on human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Glasshouse benches resistant to acids etc: derogation applied for on the basis that the benches in the containment area are made of wire mesh for ease of cleaning and to enable temperatures to be maintained consistently throughout the facility. This work requires glasshouse Containment Level 3 as this is potentially a water-borne pathogen, and will require notification to the HSE. For work in the microscopy laboratory, as with other work on potentially water-borne pathogens, safe transport and disinfection of all equipment in contact with infected material will be required. The proposal was approved subject to those amendments.

Project Additional Information

Purposes of the contained use

Rhynchosporium secalis and Ramularia collo-cygni are important fungal pathogens of barley in the UK. Leaf scald (R. secalis) is classified as the most damaging disease of barley and is a major reason for fungicide use. The severity of epidemics varies between seasons, regions and crops. These diseases are accredited for losses to farmers in yield and quality estimated at £6.7M in 2000, despite fungicide applications to 95 % of crops.

R. secalis grows symptomlessly under the cuticle, especially where walls of adjacent cells are joined before producing new conidia and finally, visual symptoms. R. secalis may also complete its infection cycle asymptptomatically. To invade and grow within the host plant, it must produce a range of secreted effector proteins to suppress host innate immunity triggered by pathogen associated molecular patterns (PAMPs) such as chitin. Populations of R. secalis can change rapidly, defeating new barley resistance genes after just several seasons of widespread commercial use.

Infection by Ramularia can result in a yield decrease of 0.6 tonnes per hectare and has been shown to cause yield losses of 20 %.

Despite the damage that R. secalis and R. collo-cygni inflict on barley crops, knowledge of their pathogenicity factors is almost non-existent. The challenge is therefore to gain a greater understanding of novel and essential pathogenicity determinants, as these represent good targets for host plant recognition to protect itself. Some pathogenicity determinants essential for the core biology of the pathogen during infection may also represent efficient fungicide targets.

One of the most revealing strategies to elucidate gene function is to remove its activity through mutagenesis, knockout, or gene silencing. R. secalis and R. collo-cygni, like most fungal plant pathogens, are haploid which allows the use of knockouts. R. secalis and R. collo-cygni transformation has already been used at SCRI to successfully introduce genes encoding fluorescent proteins.
Selected R. secalis and R. collo-cygni gene sequences will be prioritized for functional analysis through targeted gene disruption by bioinformatic analyses such as predicted location (e.g., secreted or membrane bound), Pfam domains, or knowledge of structure (e.g., C-rich). RERAD funded R. secalis genome and interaction transcriptome sequencing will provide further information about the extent of pathogenicity gene families as well as a subset of genes expressed during barley colonization by R. secalis. The R. secalis genome sequence will allow identification of candidate pathogenicity factors (including effectors) specific to R. secalis. It also provided the R. secalis sequence of KU70 gene allowing creation of KU70 deletion transformant with increased targeted gene replacement frequency.

The aim of this project is functional characterisation of R. secalis and R. collo-cygni pathogenicity factors including their effect on pathogenicity through targeted gene knockouts, complementation, localisation using fluorescent protein tagging, and identification of functions for R. secalis or R. collo-cygni secreted proteins during barley pathogenesis and/or resistance response.

Recipient or parental organism

Endemic isolates of the wild-type fungal plant pathogens R. secalis and R. collo-cygni will originate from the SCRI culture collection.

For cloning Barley stripe mosaic virus (BSMV) genomes and R. secalis genes we will only use disabled E. coli strains e.g., XL1-Blue, DH5α, SURE, etc. and disarmed A. tumefaciens strains e.g., C58C1 (pCH32), GV3101 (pMP90), etc. These microorganisms are unlikely to persist in the human lungs or the gut, or indeed survive outside culture medium.

The ND18 strain of BSMV that will be used in this study is not indigenous to the UK and thus is subject to legislative (plant health) control. We have a license to move and keep this pathogen. BSMV is not known as a hazard to human health and nor is there any reason to suppose that it could be unless specifically modified to express toxic proteins or proteins that produce toxic products. BSMV has no known arthropod, fungal, or nematode vectors. The main route of natural spread of BSMV seems to be by plant to plant contact. The only natural hosts of BSMV known are barley and wheat. Wild oats (Avena fatua) can also be infected occasionally. BSMV infection is already widespread but does not cause serious agronomic problems even in susceptible cultivars. BSMV is also known to be transmitted through seed to 90% of the offsprings depending on the virus strain. This virus is also pollen-borne and can infect pollinated plants. However, this is not a major problem in barley and wheat as both are self-pollinated within the closed floret. To eliminate this potential hazard due to accidental release of recombinant BSMV the experimental plants will be discarded before they reach the flowering stage.

Host/vector system

The transformation vectors are based on non-integrative bacterial plasmids containing different antibiotic resistance genes. pCAMBgf must contains the antibiotic resistance gene hygromycin phosphotransferase (hpt) under control of the Aspergillus nidulans tryptophan synthase C (TrpC) promoter for constitutive expression together with the SGFP gene under the control of the Pyrenophora tritici-repentis TOXA gene promoter. pAB8-1 contains the bleomycin resistance-encoding gene (ble) from Streptoalloteichus hindustanus, under the control of promoter (gpdA) from Aspergillus nidutans genes; pFBT009 contains nat1 cassette conferring resistance to nourseothricin.

Origin & function

The inserted DNA will contain an antibiotic resistance gene: hygromycin phosphotransferase under control of the Aspergillus nidulans tryptophan synthase C (TrpC) promoter, bleomycin resistance-encoding gene (ble) from Streptoalloteichus hindustanus, under the control of promoter (gpdA) from Aspergillus nidutans genes, or nat1 cassette conferring resistance to nourseothricin for selection of transformants, and a marine invertebrate fluorescent protein gene (e.g., GFP), for localisation of viable hyphae and other fungal structures during infection of barley, flanked by the partial sequences of R. secalis gene to be disrupted.

In case of complementation or transient overexpression the inserted DNA will contain the endogenous R. secalis gene, which might restore R. secalis pathogenicity to that of wild type, and an antibiotic resistance gene. In case of fluorescent proteins tagging the inserted DNA will contain the endogenous R. secalis gene with fluorescent protein sequence at its C or N terminus and an antibiotic resistance gene.

The function of R. secalis genes coding for secreted proteins, which we propose to investigate during this project are unknown but are most likely play roles in the
communication events between R. secalis and barley leaves. As R. secalis is a pathogen of barley we do not anticipate much activity towards other plant species, including wheat. In fact, BSMV virus has a much broader host range than the fungus. The possibility exists that the fungal proteins under study might trigger the death of barley leaves due to them functioning as host-specific or non-host-specific effectors or toxins. As yet none of these proteins are currently known to be plant toxins. As the fungus from which these proteins originate is a barley pathogen, should any toxins or defence suppressors be identified they are likely to function primarily against barley and will not impact upon other plants nor any animals. The worst case scenario might be that barley leaves inoculated with the viral transgene might display a trailing necrosis response. All the genes to be tested originate from this fungus primarily infecting barley and therefore no change in host specificity of the virus is anticipated. Neither virus nor fungus are airborne, therefore there is no risk of breach of containment through airborne particles. All the genes are predicted to function at the host-pathogen interface (in communication events) and none have anticipated enzymatic activities, as they possess no known functional domains (e.g. for enzymes or transporters etc.), and will not influence sensitivity to antifungal compounds.

**Evaluation of foreseeable effects**

**Risk to human health**

None anticipated.

R. secalis and R. collo-cygni occur as endemic pathogens on barley crops in the UK. These and other fungal pathogens of cereal species are not known as primary human pathogens. Neither fungal species is expected to pose any threat to human health under the conditions to be used for experimentation.

BSMV is also exclusively a plant pathogen. There are no reports of the virus, or reasons to believe the fungal genes under study, pose any risk to humans or animals.

The precise sequence identity of each of the fluorescent protein genes to be used is known. These genes and their encoded proteins have been expressed in a wide variety of organisms, including fungal, oomycete and bacterial plant pathogens, with no adverse effect on human health.

Transformation of fungal material is not expected to pose any risk to human health under the conditions to be used for experimentation. Transformation of protoplasts and Agrobacterium-mediated transformation are common laboratory method of gene delivery in fungal/oomycete genetics and have been used for many years (including at SCRI) without adverse effect to human health.

**Risk to the environment**

R. secalis is naturally transmissible by splash dispersal of spores from infected leaves; spores are produced within a mucilage matrix. To reduce this risk the R. secalis inoculated plants will never be watered from the top. Fungal conidia are not airborne, so there is no risk of airborne breach of containment during these studies. It is also possible that R. secalis and R. collo-cygni may be spread by infected seed, but the role of this form of transmission is not fully understood. These experiments will not involve plants which are flowering so no seed borne issues will occur. All plants used in the experiments will be destroyed before the flowering stage.

Most barley varieties grown in Scotland are susceptible to R. secalis and R. collo-cygni. Control is typically by frequent treatment of crops with fungicides. Furthermore, the strains of R. secalis and R. collo-cygni to be used in our experiments will be fully sensitive to common fungicides.

It is simple to maintain R. secalis and R. collo-cygni cultures in sealed agar plates and the risk of escape from these vessels is minimal. It is standard practice in our laboratories to handle fungal cultures in a Class II biohazard cabinet to prevent escape of the pathogen, and to protect the cultures from contamination. We propose to maintain and manipulate the GMMs in the same manner. Inoculated detached plant leaves in sealed containers will also only be opened within the Class II biohazard cabinet. Containers holding infected leaves from whole glasshouse grown plants will also only be opened inside the Class II biohazard cabinet or containment level 2 laboratory.

In our experiments, the conditions for transmission of R. secalis and R. collo-cygni will be avoided where possible. For instance, preparation of inoculum will use conditions to minimise/prevent formation of aerosols, plants or detached leaves will be drop inoculated to prevent aerosols, handling of infected plants will be minimised, infected plants will be watered from below; disposable gloves will be worn for all handling of infected plants, and all materials that come in contact with the infected plants will be destroyed by autoclaving.
It is not expected, or likely, that expression of gene encoding fluorescent proteins would alter the host range of R. secalis. Disruption of R. secalis pathogenicity genes will make it less or non-pathogenic. We expect to see that, following transformation, transformants will become fluorescent under specific light wavelengths. No increase in aggressiveness is expected, as these fluorescent tags have been used extensively in other fungal, oomycete, and bacterial plant pathogens without increasing the pathogenic capabilities of the pathogens. Indeed, the opposite effect of reduced aggressiveness is more likely as constitutive overexpression of a heterologous gene is likely to place a metabolic burden on the pathogens. It is also common for plant pathogens kept in culture (as would be the GMMs) to become attenuated in virulence or lose the ability to produce spores.

Complementation with the plasmid caring the disrupted gene can restore R. secalis pathogenicity to wild type level. Should a GMM expressing a pathogenicity gene escape, the possibility of its DNA being transferred to another environmental and non-pathogenic organism, or another pathogen, is remote. Pathogenesis in many pathogens is typically complex and probably employs many mechanisms. It is unlikely therefore, that the horizontal transfer of a single gene to a fungus or bacterium would confer novel pathogenicity upon a non-pathogen or increase host range of an existing pathogen.

To minimize risk of transmission, glasshouse work will be carried out under containment level 3, since the work involves barley seedlings infected with a GM fungal pathogen which produces spores on the leaf surface, and little is known about potential water-borne spread.

It has been previously shown (Pogue et al., 2002, Annu. Rev. Phytopathol. 40: 45-74; Bruun-Rasmussen et al., 2007, Mol. Plant Microbe Interact. 20: 1323-1331) that sequences inserted into BSMV vector are unstable as the virus replicates. That means passaging the recombinant virus more than once to another plant usually results in either complete loss of the heterologous sequence or its significant shortening. Therefore, accidental release of recombinant BSMV may cause disease on the initially infected plants. However, due to instability of the insert the hazard would be eliminated in any secondarily infected plants and the virus would be no more severe than wild type virus. BSMV infection is already widespread but does not cause serious agronomic problems even in susceptible cultivars (Jackson & Lane, 1981, Handbook of Plant Virus Infections and Comparative Diagnosis, ed. E Kurstak, pp. 565-625, Amsterdam: Elsevier).

Recombination of wild-type and genetically modified BSMV is possible, though the resulting recombinants are likely to be less virulent than the wild-type viruses. Recombination between BSMV and genomes of the other known Hordeiviruses, Anthoxanthum latent blanching virus (ALBV), Lychnis ringspot virus (LRSV), and Poa semilatent virus (PSLV), is theoretically possible. However, ALBV, LRSV and PSLV, are rare and they are not known to cause diseases of cultivated cereal crops. Therefore, a risk of gene transfer from BSMV to other Hordeiviruses is negligible.

The fungal strain to be used in these experiments is non-transgenic and already possesses all the genes this project aims to study. It very unlikely that this fungus would acquire genes from the virus as there is no known interaction between the two organisms. In the very unlikely scenario that the fungus were to acquire the viral encoded transgene as a second copy it might become more aggressive towards barley if the gene were to encode a strong virulence factor. Therefore no fungal material would be re-isolated alive from infected leaves.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Glasshouse benches resistant to acids etc: derogation applied for on the basis that the benches in the containment area are made of wire mesh for ease of cleaning and to enable temperatures to be maintained consistently throughout the facility. Fully waterproof receptacles to prevent any run off water from plant pots are included routinely in the SOPS for the facility. The floors of this area are also sealed and the drain capped. In the highly unlikely event of flooding the drains have an additional cap beneath the floor and if this should fail the default setting on the drainage system would direct the effluent to a holding tank where chemical disinfection could take place before release to mains drainage.

Containment Level 3 facilities sealable for fumigation: derogation applied for on the basis that fumigation for plant pathogens is not routine. Glasshouse cubicles within the facility will be disinfected by power-washing with a mixture of
Hortisept and Verritex. Hortisept is a horticultural disinectant that is effective against most fungi, viruses and bacteria, and which has been formulated for use in glasshouses and polytunnels. Verritex is a horticultural cleaning fluid that is used in conjunction with Hortisept to facilitate the removal of biofilms from glasshouse surfaces.

Containment level 3 facilities - HEPA filters: derogation applied for on the basis that R. secalis and R. collo-cygni are regarded as splash transmitted rather than aerosol transmitted. Spores are produced in a mucilage matrix and the outlet fans in the glasshouse cubicles are fitted with Primary Grade Panel Filters G4 which should retain these if they were to be dispersed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any material including flasks or plates used for growth of cultures, inoculated plant material, plant pots, compost, labels, gloves etc. that might be contaminated by the GMOs will be autoclaved before disposal.

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment

The committee expressed concern that there may be a possibility of sporulation and questioned if the plasmids used are mobilisable. The proposer will be requested to clarify this on the Risk Assessment. The committee agreed that there was little potential hazard posed by expression of the fluorescent proteins in the pathogens. It was noted that the pathogens are spread on leaf surfaces by splash inoculation. Little is known about the possibility of water-borne transmission; roots of plants do become infected but it is not known if this happens directly or by spread of pathogen through the plant. It is possible that the pathogen could survive for short periods of time in run-off water but it is not known if it could be infective by that route. Questions were also raised about containment of fungus spores on the surface of plants grown to maturity in the glasshouse and it was felt that plants should be maintained in a cubicle under negative pressure. Containment level 3 was recommended for growth of plants to maturity due to the uncertainties over possible water-borne spread of the pathogens and to contain fungal spores present on the surfaces of plants.

Project Ref 250/11.2
We are interested in whether specific host plant genes can influence susceptibility to disease. Consequently we intend to infect Nicotiana benthamiana transgenic plants which either over-express or have compromised expression of these genes with a variety of Pseudomonas strains. Pseudomonas syringae pv. Tomato DC3000 (Pst DC3000) is unable to replicate in Nicotiana benthamiana as it encodes HopQ1-1, a protein which activates hypersensitive cell death defence mechanisms in this plant. Subsequent deletion of HopQ1-1 in this P. syringae strain renders it virulent as the plant no longer mounts the same level of antimicrobial defence (however the plant may still initiate a basal defence mechanism which may slightly lower bacterial titres in planta). Pst genes such as HopAA1-2 and HopG1 play similar roles in plant defence modulation to HopQ1-1.

We would like to use Pst DC3000 and mutant strains in these Hop genes to identify the plant pathways which are important in hypersensitive and basal defence mechanisms. Furthermore, we would like to test the applicability of P. syringae mutants (e.g. HopQ1-1 and others) to act as 'effector – detector vectors'. These mutants could, for example, be used to express other pathogen effectors (e.g. Phytophthora infestans or Potato Cyst Nematode- PCN) in Solanaceae such as potato, tomato and Nicotiana species to study their effects on virulence and/or avirulence.

Candidate pathogen effectors will be selected based on transcription profiles and those specifically induced during infection will be prioritised. Furthermore, effectors that contain matches to Pfam domains or have shown to interact with important virulence targets will also be included.

In parallel, we also aim to exploit the genetic resource of Arabidopsis, in order to identify key genes involved in these defence pathways. Pst DC3000 is able to replicate and cause disease in Arabidopsis, however Pst DC3000 expressing AVRBS induces a plant defence response which limits infection. We aim to use several "on-site" Arabidopsis mutants and transgenics which have altered defence responses in order to gain a better understanding of the pathways involved in mediating resistance to Pseudomonas.
Origin & function

AVRB, an avirulence protein derived from pathovar glycinea (Staskawicz, B., et al, 1987, Journal of Bacteriology). Candidate pathogen effectors from P. infestans and potato cyst nematode selected based on transcription profiles and induced during infection including effectors that contain matches to Pfam domains or have shown to interact with important virulence targets.

Evaluation of foreseeable effects

Pseudomonas syringae pv. tomato DC3000 is not pathogenic to mammals but does cause bacterial speck diseases in tomato and Arabidopsis. The bacterium exists as an epiphyte and invades appropriate plant tissues via stomata or wounding. HopQ1-1 and HopAA1-2, HopG1 mutants of Pst have an increased host range that include Nicotiana benthamiana does not affect the disease state in tomato or Arabidopsis. It is currently unknown if other Solanaceae including potato and Nicotiana spp. are also infected by these mutant Pst lines but we would like to establish this.

Expression of AVRB in Pst DC3000 induces a necrotic response in several hosts, most notably Arabidopsis. This response severely restricts host range of this pathogen and, as such, is less hazardous to the environment.

No effects on human health are foreseen.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Investigation of the function of plant proteins targeted by plant pathogen effectors through Tobacco Rattle Virus induced silencing

Purposes of the contained use

To promote disease many plant pathogens deliver sets of effectors inside their hosts. These effectors interact with host target proteins to modify their function to the benefit of the pathogen. We have identified plant proteins that putatively interact with Phytophthora infestans (potato late blight), Phytophthora capsici and Potato Cyst Nematode (PCN) effectors from Solanum tuberosum, Solanum lycopersicum and Nicotiana benthamiana. We aim to silence plant targets of pathogen effectors in N. benthamiana to examine their role in disease susceptibility and plant immune signalling.

Small, untranslatable, cDNA fragments (150-350bp), corresponding to selected host plant genes, will be cloned in anti-sense orientation in to a Tobacco Rattle Virus (TRV) – based vector to induce silencing in plants. The small fragments will be from N. benthamiana orthologues of genes encoding proteins known to interact with pathogen effectors or other proteins known to be involved in plant immunity. Host effector targets under examination for the role in plant immunity may also play a role in a range of plant processes.

Silencing of one target of the P. infestans effector Avr3a, the defence –associated E3 ligase CMPG1, has been shown to decrease the cell death triggered by some plant receptors and make N. benthamiana less susceptible to P. infestans. The effector Pi02860 interacts with two potato proteins, a 14-3-3 protein involved in protein stability and another E3 ligase (NRL). As with CMPG1, silencing of NRL has been shown to decrease the susceptibility of N. benthamiana to P. infestans. In contrast silencing of another E3 ligase, NbPUB17, which has a role in plant defence, has been shown to enhance P. infestans leaf colonization. Thus silencing of such effector targets can both decrease and increase plant susceptibility to the pathogen that produces the effector.
The effector PiAvr3a is known to interact with thirteen potato proteins including components of the plant exocyst pathway (Sec3 and Sec5) and the hypothetical protein Kipi30. PexRD2 is an RXLR effector that interacts with potato MAPKKK ε, a positive regulator of cell death. Pi17316 interacts with a different MAP3K, known as VIK1 (VH1-interacting kinase), which has role in vascular development in Arabidopsis. These and other effector targets will be silenced to investigate their function and the extent of their roles in cell death and defence.

Recipient or parental organism

Tobacco Rattle Virus occurs widely, including in the UK. It can infect more than 400 plant species and can cause diseases of crop plants including potato, tomato, sugar beet, tobacco and ornamentals. TRV causes spraing in potato, which makes tubers unmarketable for human consumption. Many common weed species are hosts of TRV and act as a reservoir of the virus in the field. TRV is spread naturally by root-feeding nematodes, but can be spread mechanically, by pollen and by seed. The genome consists of two positive-sense RNA molecules. The larger RNA 1, which is capable of autonomous replication, encodes genes required for replication and cell-to-cell movement. The smaller RNA 2 encodes the capsid protein required for transmission and other non-structural genes such as 2b, which is involved in nematode transmission. RNA 2 by itself is not infectious. A genetically modified UK strain will be used.

Host/vector system

The plant species Nicotiana benthamiana will be used as a host for silencing experiments. This species originates from tropical / sub-tropical regions of Australia. It is not found in the UK and is expected to be incapable of establishing in the external environment. Like its relative tobacco it contains toxic alkaloid compounds, e.g. nicotine, and is not consumed.

Agrobacterium tumefasciens-delivered, binary vectors containing TRV genome components have been used extensively over the last fifteen years to induce gene silencing in various TRV host plant species for basic plant science studies. Agrobacterium strains containing binary vectors with kanamycin selectable markers will be used in the proposed studies. The T-DNA portions of these binaries will contain a wild-type RNA1 cDNA or modified RNA2 cDNAs under the control of Cauliflower Mosaic Virus 35S promoters. The modified RNA2 forms will lack the non-structural genes involved in the natural nematode transmission mechanism and hence will be partially disabled. The TRV-based system that will be used in these studies has been shown to be incapable of establishing infections and silencing in potato, which is bred at the institute and grown commercially widely in the surrounding area.

Origin & function

Sequence fragments from Nicotiana benthamiana genes will be inserted in anti-sense orientation in to the RNA 2 component of the TRV-based system to induce silencing of endogenous N. benthamiana genes. The fragments will not be expressed in planta. The choice of genes to be silenced will be based on whether the proteins encoded by them, or orthologues from other plant species, interact with effector proteins from the above mentioned plant pathogens. The specific sequence choice will be guided by efficacy of silencing and avoidance of cross-silencing of other N. benthamiana genes and genes in other plant species. The genes that will be silenced are expected to be involved in plant immunity and responses to pathogens, but may also be involved in other plant processes. Publications in the literature show that silencing of such genes can result in both increased and decreased susceptibility of N. benthamiana to pathogen attack.

Evaluation of foreseeable effects

The disabled E. coli strains, disarmed Agrobacterium tumefasciens strains and Tobacco Rattle Virus that will be used in these studies are not pathogenic to humans and thus the risk to human health is minimal. Instead the greater foreseeable risk is to the environment. The GMOs are expected to induce silencing in N. benthamiana making it more or less susceptible to pathogen attack, however this species is not present in the external environment or of any economic importance. The most easily foreseeable detrimental effect is that the genetically modified TRV form could transiently induce silencing in other Solanaceous species with adverse consequences on pathogen susceptibility. Aside from potato, which is not infected or silenced by the TRV vector to be used in these studies, such species, e.g. tomato, are disperse in the external environment and of little economic importance lowering the risk. In the event of escape the genetically modified form of TRV would be as a competitive disadvantage relative to wild-type forms already present in the external environment as it is partially disabled through the removal of the genes involved in the natural nematode transmission route. However, there is a need to minimize dissemination to the external environment. Transmission by nematodes, as in nature, is precluded by the disablement and control of pathogens in the glasshouse; mechanical transmission of the virus will be controlled by use of gloves and dedicated labcoats; escape of pollen and seed will be controlled by prevention of flowering, though there are no plants in the external environment to receive pollen and this species is not adapted to the Scottish climate. In an imaginary scenario a nemtode transmissible form of the GMO might be reconstituted through recombination with wild-type viurs in the external...
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

As in previous notifications a derogation is requested for containment measure 3 in glasshouses, i.e. impervious and easily cleaned benching. The glasshouses at the institute have metal mesh benching to allow air circulation and facilitate temperature control. Instead, water-impervious, easily-disinfected, polypropylene trays / boxes will be used to allow disinfection and minimize run-off. Further, experiments will be carried out in glasshouse compartments in which the drains have been sealed. In addition, when the drains from these compartments are opened the water is collected in a holding tank which could be chemically disinfected prior to discharge to mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Material contaminated with the GMMs (e.g. cultures, culture vessels, gloves, plasticware, plants, plant pots and compost) will be routinely autoclaved to give 100% kill. An exception to this is the plastic trays used in the glasshouse, which will be treated with 2% Virkon overnight to give a greater than six log reduction in viable Agrobacterium and also inactivate Tobacco Rattle Virus. In addition to thermo-metric testing of autoclaves, inactivation of the relatively thermo-sensitive E. coli, Agrobacterium tumefaciens and TRV will be monitored by the inclusion of Class 5 steam chemical integrator strips (121°C, 15 minutes) in all autoclave waste loads. Inactivated cultures will be discarded to mains drains and autoclaved plasticware etc sent for incineration.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
In this submission the use of TRV-based vectors for studies of genes involved in resistance responses was proposed. The form of the vector used means that the GM virus is not transmissible by nematodes as found in nature. However, it is still mechanically transmissible, and transmissible by pollen and seed. The GMSC thought that silencing of endogenous N. benthamiana genes involved in resistance presented a negligible hazard for human health. The use of Agrobacterium for delivery gave rise to another possible escape route. However, escape down the drains was unlikely to bring the GMO in to contact with plants and the fact that the two components of the viral genome were separated between two bacterial strains made it extremely unlikely that an infection would be established in the external environment by this route. If the GM virus were to escape in to the external environment it might infect a wide range of plant species. The sequences inserted to induce silencing are derived from N. benthamiana. While the GM virus can efficiently induce silencing in this highly susceptible host, published data shows this vector would not be capable of inducing silencing in the field in the economically important crop of potatoes. The GMSC thought silencing in others members of the Solanaceae, e.g. tomato, could be possible in the event of escape and suggested that sequences used for silencing should be checked against tomato and potato genome databases to ascertain the likelihood of this. The GMSC recognized that removal of the genes involved in nematode transmissibility provided a level of biological containment and that such transmissibility was unlikely to be re-acquired in the event of an escape without the loss of the sequences responsible for inducing silencing. The GMSC’s opinion was that the GM viruses would be less consequential disease causing agents than the progenitor virus and expected inserted sequences to be lost during virus propagation. The BSO informed the GMSC that the use of such a TRV-based vector had previously been notified to the HSE as part of a wide-ranging Class 3 application and though some genes involved in resistance had been specified in this application there was not such a wide range and TRV had not been specified. Containment Level 2 is automatically required for work with GM pathogens and it was thought a new notification to the HSE should be made to cover this work. To control the risks to the environment the GMSC thought that the Containment Level 2 measures were suitable to reduce the risks to the environment to negligible with the additional control measure of plants being disbudded to prevent seed set and precluding this route as a means of escape. The GMSC provisionally approved the proposal at Containment Level 2. However, the GMSC thought that the proposal should be re-written to more lucidly present the case, there being excessive repetition of facts in multiple locations. The inclusion of a more appropriate reference for TRV vector instability was suggested. It was noted that work should not start until the HSE have been notified and acknowledged receipt of the notification. A revised version of the risk assessment was submitted to the GMSC and approved.

Project notified under transitional arrangements N

02/03/2022
Purposes of the contained use

The overall aim of this project is to define the biological role of the Type 6 secretion system (T6SS) in the recruitment and functioning of the bacterial communities thriving at the root-soil interface, designated the rhizosphere microbiota. The T6SS is used widely throughout gram-negative bacterial species in injecting effector proteins and virulence factors (such as proteins, toxins, or enzymes) from across the interior (cytoplasm or cytosol) of a bacterial cell into a target cell. In Agrobacterium, the T6SS confers a competitive advantage over other bacteria during the colonisation of plant habitats (e.g., leaves; [Ma et al., 2014 Cell Host Microbe, 16:94]. In this project we will use available Agrobacterium tumefaciens strains impaired in the functioning of the T6SS and we will combine them with other non-pathogenic taxa to generate bacterial consortia of known composition. These consortia will be used to inoculate barley seedlings grown in autoclaved soil and monitor their impact on plant performance (e.g., by determining seedling dry weight fluctuations on inoculated specimens) and microbiota formation (e.g., by using next-generation sequencing approaches and colony count).

Recipient or parental organism

Agrobacterium tumefaciens is a widespread, including in the UK, gram-negative, non-spore forming, motile, rod-shaped, soil bacterium. It is the causal agent of crown gall disease in over 140 species of eudicots. Economically important disease is restricted to a limited number of horticultural species like perennial fruit, nut, ornamental and vine crops. Barley is a non-host for this pathogen and studies indicated that A. tumefacies can be retrieved from the rhizosphere microbiota of ‘symptomless’ barley plants. The strain that will be used originates from the USA and as a non-indigenous plant pathogen is held under licence from Scottish Government.

Host/vector system

pJQ200SK. This vector was used to induce mutations in components of the T6SS. This is a suicide vector permitting gene replacement and mobilization into a wide range of Gram negative bacteria (Quandt and Hynes, 1993, Gene 127:15). These mutants were constructed at Academia Sinica, Taipei, Taiwan, by creating markerless in-frame deletion mutant instead of inserting any antibiotics resistance gene by double homologous recombination in all the tssL deletion mutants. Therefore, backbone plasmid sequences will not be left on the mutant strain (Prof Erh-Min Lai, Academia Sinica, Taipei, Taiwan, personal communication).

Origin & function

The DNA inserted during the construction of the GMOs caused a site directed deletion in certain components of the T6SS. In the final constructs that have been obtained from the external source there is no residual foreign sequence, merely a deletion of native sequence and this has been confirmed by sequencing.

Evaluation of foreseeable effects

The resulting GM A. tumefaciens is not disarmed and still has the potential to be pathogenic to plants. Unmodified Agrobacterium tumefasciens is commonly occurring in the external environment. Although the GMO still has the potential to be pathogenic to plants, it is impaired in a biological function that is required to successfully compete with other bacteria in soil. Therefore, their persistence in the natural environment is likely reduced (Ma et al., 2014 Cell Host Microbe, 16:94). The genetic modifications made are deletions in the bacterial chromosome and thus are expected to be stable. Although, crop species that the GMOs could cause disease in are not grown commercially in the vicinity, the strain of Agrobacterium tumefaciens used to generate them is not indigenous and held under licence. Therefore, there is a need to control dissemination of the progenitor organism and its GM derivatives to the environment. Possible routes of escape are known and managed.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

It is intended that experiments will be carried out in plant growth chambers, plant growthrooms and possibly in glasshouses. These are not fitted with impervious, easily-cleaned benching, e.g. the glasshouses at the institute have metal mesh benching to allow air circulation and facilitate temperature control. Therefore, as in previous notifications a derogation is requested for containment measure 3, i.e. impervious and easily cleaned benching. Instead plant pots will be placed in water-impervious, easily-disinfected, polypropylene trays / boxes to minimize run-off and allow disinfection. In the case of growth cabinets, any water escaping from these trays will be collected for inactivation. In the case of growth rooms, the trays will be placed on steel mesh above drip trays so that any escaping water can be inactivated and the growth room drains will be sealed. If glasshouse compartments are used the plastic trays will be placed on absorbent matting that can be autoclaved at the end of experiments. Further, experiments would be carried out in glasshouse compartments in which the drains have been sealed. In addition, when the drains from these compartments are opened the water is collected in a holding tank which could be chemically disinfected prior to discharge to mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Material contaminated with the GMOs (e.g. cultures, culture vessels, gloves, plasticware, plants, plant pots and compost) will be routinely autoclaved to give 100% kill. An exception to this is the plastic trays used in the glasshouse, which will be treated with 2% Virkon overnight to give a greater than six log reduction in viable Agrobacterium. In addition to thermo-metric testing of autoclaves, inactivation of the relatively thermo-sensitive Agrobacterium tumefasciens will be monitored by the inclusion of Class 5 steam chemical integrator strips (121°C, 15 minutes) in all autoclave waste loads. Inactivated cultures will be discarded to mains drains and autoclaved plasticware etc sent for incineration. Equipment for the preparation of root specimens for downstream analysis will be autoclaved or decontaminated in Virkon before being re-used.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The type 4 secretion system is intact in the Agrobacteria and thus they have the capacity to be pathogenic. However, the literature indicates that mutations in the type 6 secretion system make Agrobacterium competitively less fit relative to other microbiota in the rhizosphere. This will be tested under controlled conditions with a non-host plant, barley. The method used to generate the GM bacteria means there is no residual foreign inserted sequence, only deletions of native sequence. Experiments will be carried out in a dedicated growth cabinet that is being purchased. The GMSC expected that the GM bacteria would be less fit than the progenitor, non-disarmed organism, but this was an exotic, pathogenic strain requiring a Plant Health Licence. It was thought that run-off could be easily controlled in a plant growth cabinet to avoid exposure of the environment to this non-indigenous strain. Agrobacterium is not pathogenic to humans so the hazard to human health is negligible and instead the greater hazard is to the environment. The GMSC thought that Containment Level 1 measures in the laboratory and Containment Level 2 measures for the plant growth cabinet were appropriate to control the hazard to the environment. It was thought that the risk assessment should be amended to indicate that run-off will be collected for inactivation and that the cabinet will be disinfected with Virkon after use. As this is novel work a notification will have to be submitted to the HSE and work cannot start until they have acknowledged receipt of this. Should indicate in risk assessment that a MSC is not required and request a derogation from requirement for solid benching as not included in cabinet.

**CultureVolumeClass**: Class 2

**Non-GMM Consent Granted**: Yes

**Project notified under transitional arrangements**: No

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

## Project Additional Information

**Purposes of the contained use**

The purpose of the research is to screen soil and in-stream water samples from rural catchment areas for the presence of antibiotic resistance genes in bacteria from within these environments and subsequently characterise these genes using selection (growth) in the presence of a range of antibiotics and PCR. Genes which are present on mobile genetic elements, such as those conferring antibiotic resistance, can spread from one species of bacteria to other, unrelated bacteria using natural horizontal gene transfer mechanisms, such as conjugation. This can result in the recipient strain acquiring new traits such as resistance to antibiotics. Only isolates expressing the GFP and showing antibiotic resistances will be characterised.

**Recipient or parental organism**

Non-pathogenic GM strains of Pseudomonas putida and E.coli engineered to express GFP will be used: P. putida
strain KT2442 (GFP+, kanR, rifR) and Escherichia coli strain CV601 (GFP+, kanR, rifR). Strain KT2442 is a spontaneous rifampicin resistant mutant of P. putida strain KT2440, which was originally an environmental isolate, that promotes plant growth and is used as a biocontrol agent for plant pathogens. It is not considered pathogenic for humans (ATCC 47054, BSL1) and was the first Gram-negative soil bacterium to be certified as a safety strain by the Recombinant DNA Advisory Committee. E. coli CV601 is a disabled (Thr-, Leu-, Thi-) E.coli K-12 derivative which does not possess the toxin gene(s) and is auxotrophic.

### Host/vector system

The intention is to allow bi-parental mating on 2-5 cm filters using natural process such as conjugation to transfer natural genetic elements, from environmental soil/water bacteria to the GM, GFP-expressing recipient strains. The genes for GFP and antibiotic resistance (kanamycin, rifampicin) are chromosomal and are not transferred.

### Origin & function

The origin of the (new) inserted genetic material is from the natural bacterial flora present within the soil/water environment. Selection will be for a range of antibiotic resistances on growth media and expression of GFP.

### Evaluation of foreseeable effects

The GM recipient strains present a minimal hazard to human health or the environment. Transformed derivatives of the GMMs that have gained additional antibiotic resistance genes may grow on media containing the antibiotics and will express GFP. The acquisition of additional antibiotic resistance genes is not predicted to affect the pathogenicity of the recipient, GM strains and would impose a genetic load, but could reduce treatability. In theory, other genes present on mobile elements, such as toxins, might also be transferred to the recipients. The acquisition of toxin genes is not predicted to make the recipient GM strains pathogenic, but could increase the hazard they present if toxins are expressed. However, toxin genes are normally chromosomal and the likelihood of co-acquisition of plasmids carrying toxin genes along with plasmids carrying antibiotic resistance genes is considered very low as this has not been noted in previous research. Thus, this is not an expected hazard, but in theory could occur.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations required

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid culture and solid waste will be autoclaved (123°C/60 minutes) to give 100% kill prior to disposal. Autoclaved liquid waste will be disposed to drain. After autoclaving solid waste will be sent for commercial incineration. Monitoring of the effectiveness of the autoclaving of the liquid waste will be done by subculturing and Class 5 steam chemical integrator strips (123°C, 60 minutes) will be included in all autoclave waste loads to monitor autoclave processes.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form
The GMSC noted that Containment Level 2 measures were required on account of microbiological work with environmental samples, rather than on account of the genetic modifications. The GMSC did not perceive a risk to human health or the environment from the genetically modified recipient strains and thought they should be classified as Class 1. The GMSC noted that only the environmental bacteria with the antibiotic resistances selected for would be propagated to the level of single colonies and only trans-conjugants derived from the HG1 GMMs would be propagated beyond this. The GMSC thought that if the HG1 GMMs acquired toxin genes that this would not convert them into pathogens, but would increase the hazard. The GMSC thought that the probability of obtaining transconjugants with toxin genes was probably very low, but could not be excluded. The GMSC thought that, although it might be argued that the proposed work could be classified as Class 1, as Containment Level 2 was required for work with the environmental, non-GM, bacteria the proposed work should as a precaution be classified as Class 2 and notified to the HSE.

Historical Significant Changes
The purpose of the contained use is to test the utility of the Tobacco Rattle Virus (TRV) - based system described in a paper by Ellison et al. (Multiplexed heritable gene editing using RNA viruses and mobile single guide RNAs. Nature Plants 6, 620–624 (2020). https://doi.org/10.1038/s41477-020-0670-y) for Virus Induced Gene Editing (VIGE) in Nicotiana benthamiana and Solanum tuberosum plants carrying a Cas9 nuclease transgene with the purpose of generating CRISPR/Cas9 genome edited progeny plants. Initial studies will be aimed at editing phytoene desaturase (PDS) genes, commonly used as a visible reporter, in N. benthamiana and potato. If these experiments are successful the objective would be to extend the use of the TRV-based system to edit other genes of interest through the use of transgenic plants of these species as a research tool for analysis of plant gene functions. If successful this system could allow faster, targeted, precise knock-out or modification of plant genes of interest than is currently possible.

The plant species Nicotiana benthamiana and Solanum tuberosum are not native to the United Kingdom. The former originates from drier sub-tropical/tropical regions and is probably incapable of establishing in the UK. It is a species widely used in experimental plant research. Potato is a commercial crop widely grown in the UK. Its cultivation is achieved through planting of tubers rather than through the use of true seed. It is unlikely to be able of establishing outside cultivation. Both species contain toxic compounds, but toxic parts of the plants are not consumed.

Tobacco Rattle Virus is distributed around the world and is present in the UK. It can infect more than 400 plant species and can cause diseases of crop plants that include potato, tomato, beets, tobacco and ornamentals. TRV causes spraying in potato, which makes tubers unmarketable for human consumption. TRV is spread naturally by root-feeding nematodes, but can be spread mechanically and by seed. The genome consists of two positive-sense RNA molecules. The larger RNA 1, which is capable of autonomous replication, encodes genes required for replication and cell-to-cell movement. The smaller RNA 2 encodes the capsid protein required for transmission and other non-structural genes such as 2b, which is required for nematode transmission. RNA 2 by itself is not infectious. Plant virus vectors based on TRV have been used extensively over the last 25 years as tools in plant research, in particular in gene silencing studies.

N. benthamiana and S. tuberosum plants carrying a Cas9 nuclease transgene will be produced by stable transformation using disarmed Agrobacterium tumefasciens. Transformations will be accomplished with a standard binary vector in which the Cas9 gene will be under the control of Cauliflower Mosaic Virus (CaMV) promoter and Nopaline Synthase (NOS) terminator sequences, with antibiotic resistance genes for kanamycin selection in bacteria and plants.
Plants infections by the genetically modified TRV-based vector will be initiated by agro-infiltration with disarmed Agrobacterium tumefaciens transformed with binary vectors containing segments of the viral genome under the control of CaMV and NOS promoter and terminator sequences for transient transcription in plant cells. These binaries will also include antibiotic resistance genes for selection in bacteria, but not markers that can be selected for in plants. The two components of the viral genome, RNA 1 and RNA 2, will be provided by separate binary vectors transformed in to separate A. tumefaciens bacteria that will be mixed prior to agro-infiltration of plant leaf tissue.

**Origin & function**

The cDNA for the RNA 2 of TRV RNA 2 has previously been modified by removal of the 2b and 2c genes, the former of which is required for nematode transmission, to disable the virus in nematode transmission. Further, it has been previously modified to include a subgenomic promoter sequence from a related tobravirus to direct transcription of inserted sequences in planta.

In this case a synthetic single guide RNA (sgRNA) will be placed under the control of the subgenomic promoter to direct gene editing in Cas9 transgenic plants. The sgRNA comprises a short, 20 nucleotide, guide RNA that directs the Cas9 nuclease to the specific target for gene editing and a tracrRNA that provides a scaffold for binding of the Cas9 nuclease. The short guide RNA will in the first instance be specific for PDS genes.

The new TRV-based vectors also include plant derived sequences to increase the efficiency of gene editing by the virus in Cas9 transgenic plants. The plant derived sequences are from the Arabidopsis thaliana Flowering Locus T (FT) open reading frame or a tRNA for isoleucine sequence. FT is a phloem mobile signal molecule that promotes the transition to flowering, while the isoleucine tRNAs has a central role in protein synthesis. Both of these sequences have been identified as phloem mobile sequences.

**Evaluation of foreseeable effects**

The introduction of the Cas9 gene into N. benthamiana and S. tuberosum is not of any perceived benefit to the transgenic plants and will not make them weedier. The Cas9 protein is not in itself toxic or allergenic. Hence, the transgenic plants are not perceived to prevent a greater risk to human health or the environment than the progenitor plants.

The inclusion of the single guide RNA sequence in the TRV-based vector will lead to gene editing of the target gene, but the length of the plant gene specific sequence is such that it should not lead to gene silencing. Thus this sequence should only have an effect on transgenic plants. Editing of the PDS gene is expected to be detrimental to the host transgenic plant causing bleaching and possibly dwarfing. In the case of PDS gene edited progeny seed are not expected to give viable plants. Virus induced gene editing of other target genes would be likewise limited to Cas9 transgenic plants, but depending on the target might result in progeny plants that are fitter than the progenitor wild-type plant and such larger GMOs would need to be separately risk assessed.

The inclusion of the A. thaliana FT sequence in the TRV-based vector was reported not to cause silencing in N. benthamiana, but its inclusion might be expected to result in silencing of FT in host plants in the Brassicaceae. This would delay floral development and be detrimental to infected / silenced plants.

The inclusion of the FT and tRNA mobile sequence elements in the TRV-based vector has been shown to enhance genome editing in Cas9 transgenic plants. However, the inclusion of these elements has also been shown to enhance systemic spread / accumulation of the virus vector over the progenitor vector. This change could increase the mechanical transmissibility of the new virus vector and it is not known how it compares with natural, wild-type virus. However, the new virus vector is still disabled in nematode transmission, the most important natural route of transmission, due to the deletion of the 2b gene. A recombination mechanism by which the 2b gene and nematode transmissibility could be reacquired without loss of the foreign, introduced sequence is not apparent. Previously TRV-based vectors have been found to be unstable with introduced sequences being lost through recombination. Whether this will be true for the mobile RNA sequence elements is not known, as their retention may have a selective advantage for the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The larger GMOs, i.e. the N. benthamiana and S. tuberosum plants with Cas9 transgenes and any derived progeny, will be used in combination with the Class 2 GMMs. Therefore, the same containment measures required for containment of the GMMs will be used for containment of the LGMOs.
As in previous notifications a derogation is requested for containment measure 3 in glasshouses, i.e. impervious and easily cleaned benching. The glasshouses at the institute have metal mesh benching to allow air circulation and facilitate temperature control. Instead water-impervious, easily-disinfected, polypropylene trays / boxes will be used to allow disinfection and minimize run-off. These trays will be placed on mesh benches that have been covered with plastic sheet and absorbent matting that can be autoclaved after use. Further, experiments will be carried out in glasshouse compartments in which the drain covers have been sealed. In addition, when the drains from these compartments are opened the water is collected in a holding tank which could be chemically disinfected prior to discharge to mains drainage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Material contaminated with the GMMs and LGMOs (e.g. cultures, culture vessels, gloves, plasticware, plant pots, compost and plants) will be routinely autoclaved to give 100% kill. An exception to this is the plastic trays used in the glasshouse, which will be treated with 2% Virkon overnight to give a greater than six log reduction in viable Agrobacterium and also inactivate Tobacco Rattle Virus. In addition to thermo-metric testing of autoclaves, inactivation of the relatively thermo-sensitive E. coli, Agrobacterium tumefasciens and TRV will be monitored by the inclusion of Class 5 steam chemical integrator strips (121°C, 15 minutes) in all autoclave waste loads. Inactivated cultures will be discarded to mains drains and autoclaved plasticware etc sent for incineration.

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The GMSC did not perceive a risk to human health in the proposed experiments. The GMSC thought that, while the use of TRV to deliver sgRNAs for gene editing was novel and differed significantly from the use of TRV for VIGS, this was little risk to the environment as gene editing could only occur in transgenic plants carrying a Cas 9 transgene. While the inclusion of A. thaliana FT sequences had not affected flowering in N. benthamiana its inclusion in the vectors might induce VIGS and have detrimental effects on flowering in other host species. That the inclusion of the mobile plant RNA sequences in the new TRV based vectors increased systemic spread / accumulation over the progenitor vector was of concern to the GMSC as this was an increase in virulence that made the vector more mechanically transmissible. It was not clear how the virulence of the modified vector compared to wild-type virus found in the external environment, but the GMSC did not see that this change could restore nematode transmissibility to the disabled vector. The GMSC thought that considering earlier publications it was quite unlikely, but not impossible, that the new TRV-based vectors would be able to infect the economically important potato crop. The GMSC thought that escape should be prevented to preclude the possibility of possible environmental harm. The establishment of infections in the environment through water-borne escape of Agrobacterium was considered highly unlikely due to the separation of the two viral genome components between different bacteria, but possible glasshouse run-off to drains needed to be controlled. The GMSC thought that the proposed containment measures were suitable to control the possible risks to the environment and approved the proposal at Class 2. Because of the novelty of the work and perceived possible increase in virulence the GMSC thought this had to be notified to the HSE.

The GMSC indicated that the sponsor needed to clarify what laboratory would be used to do the work as those in AF were not suitable and would need to import viral clones and possibly GM seed under a Plant Health License.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Y

Give brief details of the genetic modification safety committee

The established safety committee of the company will also take on the role of GM safety. Meetings are currently held once a month.
The GMSC subgroup will consist of: Chief Operations Officer (Chairman), Quality, Health and Safety and Environment Officer, Biological Safety Officer and research scientist, Safety Officer and research scientist (with relevant experience), Facilities Manager.

Laboratory  Animal Unit  Growth Room  Glass House  Large Scale

Level 1 (GMMs)  Yes

Level 2 (GMMs)
**For activities involving GMMs, describe the waste management measures which will apply to the activity**

The GMM will only be cultured on a small scale (10-200ml maximum). Work areas will be disinfected after every use with Virkon. Any spill will be treated with disinfection (Virkon) according to manufacturers’ instructions immediately after spillage. All waste, solid and liquid, will be autoclaved at 121 degrees C, 15 psi for 20 minutes and then disposed by normal routes. The normal functioning of the autoclave will be monitored to estimate the “degree of kill” on a regular basis (sterilisation indicator strips/temperature recorder). External contractors (SW Scientific) service the autoclave annually.

</tr>
</tbody>
</table>
PLASMIDS CONTAINING MYCOBACTERIAL AND CYTOKINE GENES

The aim of this project is to clone a number of DNA constructs expressing mycobacterial antigens and cytokine genes into attenuated Salmonella typhimurium for use in immunogenicity studies. The constructs have already been used in other related studies within the laboratory. Initially the mycobacterial antigens to be tested will be ESAT-6, 65Kda antigen and MPT-83; cytokine genes of interest will initially be Interleukin 12 (IL-12) and Granulocyte Macrophage Colony Stimulating Factor (GM-CSF). This study may be expanded in the future as other DNA constructs become available.

Bacteria to be used will be the attenuated (aro) strain of Salmonella typhimurium. This bacteria has a defined mutation in the prechorismate biosynthetic pathway and is therefore unable to generate aromatic amino acids. This strain has been used extensively as an experimental tool to express and deliver host proteins.

The host will be Salmonella typhimurium as described above. The genetic material is documented below.

The genetic material used in this study will be DNA constructs containing genes for cytokines and mycobacterial antigens. These constructs have been generated for use in DNA vaccination protocols. Initially the cytokines of interest will be GM-CSF and IL-12 and the mycobacterial antigens will be ESAT-6, 65Kda antigen and MPT-83. These constructs have been previous used in other related studies in the laboratory in other protocols and will be used in immunogenicity studies within the laboratory.

Due to its defined mutation, the bacteria pose little risk to humans (due to its limited survival time in the mammalian host) or to the environment.

The mycobacterial antigens cloned into a DNA vaccine construct have no biological activity, are neither enzymes or toxins and do not change the behaviour of the bacteria.

The use of cytokines is assumed to be safe due to the inability of the bacterial to survive in a mammalian host.
The DNA vectors to be used in this study are considered to be non-mobilisable and gene transfer is therefore highly unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 containment will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be disposed of by autoclaving followed by incineration. Validation and control of waste management will be held on file at NIBSC. Hycolin will be used to disinfect surfaces.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The GMSC considered that the risk assessment and the level of containment were appropriate for the work.

Project Ref 251/01.2

Date Ackn'd 19/04/2001
CU2 Project Title REVERSE GENETICS OF MUMPS VIRUS
Class 2, CultureVolClass2 < 1 litre
CultureVolumeClass3-4
Project Additional Information

**Purposes of the contained use**

The main objective of the project is to produce mumps mutant viruses using the rescue virus approach for confirming the structure-function correlation, proposed previously, to understand the mechanisms of virulence, attenuation, persistence and pathogenicity. It is also vital to study mumps mutants so that strict quality control measures can be implemented effectively to some brands of mumps vaccines that otherwise do not have satisfactory safety and efficacy records.

**Recipient or parental organism**

Continuous cell lines of primate sources eg HeLa, Vero, Hep-2, 293 cells, etc.

**Host/vector system**

E. coli K-12 strains, mumps recombinant plasmids, pCITE type, containing genomic or sub-genomic length DNA fragments under T7 RNA polymerase promoter, a disabled vaccinia virus vector (MVA-T7), cell lines of primate sources eg HeLa, Vero, Hep-2, 293 cells, etc.

**Origin & function**

The genetic materials that will be manipulated in the proposed study are originated from the disabled vaccinia virus vector (MVA-T7) and mumps virus vaccine strain. The intend function of MVA-T7 vector system is to supply T7 RNA polymerase enzyme, in vitro, for the transcription of gene inserts encoding for the synthesis of nucleocapsid, phospho and the large proteins of mumps virus and additionally to provide copies of the full length RNA template for in vitro encapsidation and replication. The overall objective of the genetic manipulations that will be carried out under this project is to produce and supply essential components of the virion in vitro for the production of mutant viruses with known genetic finger prints.

**Evaluation of foreseeable effects**

A full risk assessment has been carried out for the proposed project of reverse genetics of mumps virus (copy enclosed). The areas covered under the risk assessment are: human and environmental hazards associated with the recipients micro-organism, hazards arising directly from the insert gene product and the vector system(s), hazards arising from the alteration of existing pathogenic traits including host range, tissue tropism and the likelihood of causing harm to human health in case of accidental exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Class 2 containment applied throughout.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated plastics and culture fluids, etc, will be disinfected overnight in 10% Chloros, the solid waste then will be autoclaved and incinerated while the liquid waste will be discarded in a designated sink. Validation and details of control waste management is held of file at NIBSC.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The GSNC considered that the risk assessment and the proposed containment measures were appropriate for the work.

<td>not applicable</td>
</tr>
</tbody>
</table>

Date Project Ceased

02/03/2022
The aim of this project is to introduce a plasmid for the direct expression of green fluorescence protein (GFP) into Bordetella pertussis that will facilitate the study of phagocytosis and related events particularly relevant to investigate the role of adenylate cyclase toxin (ACT) in pertussis infection and immunogenicity. The labelling of live Bordetella pertussis with GFP permits the bacteria to be easily imaged and quantified and will enable us to measure phagocytosis by techniques such as spectroscopy, microscopy or FACS. Further, GFP expressing B. pertussis can be used to study bacterial colonisation in vivo.

The bacteria to be used in this study will be the wild type challenge strain Bordetella pertussis 18323. Bordetella pertussis is a containment level 2 pathogen. It is an obligate human pathogen that colonises the respiratory tract and therefore is handle in a class II EPC. This strain of Bordetella has been used extensively within the laboratory and related risk assessments for the preparation and handling of B. pertussis are well defined and included in different SOPs.

The host will be the strain Bordetella pertussis 18323 as described above. The genetic material is documented below.

GFP is a well characterised protein from the jellyfish Aequorea Victoria that produces a fluorescent product when expressed in prokaryotic or eukaryotic cells. GFP has been used as a genetic reporter system offering advantages over some other reporters and also as a fluorescent marker with potential use to study bacterial pathogenicity. Different GFP expression vectors have been constructed with such purposes suitable for different bacterial species. The here proposed plasmid constructs for the direct high expression of GFP from a constitutive B pertussis promoter, have been already used in Bordetella pertussis by others for similar studies. Moreover, the genetic modifications proposed have been reported not to mask the activity of adenylate cyclase toxin, or affect bacterial growth or other gene expression, in contrast with other labelling methods. Hence, its interest to study host-parasite interactions. The plasmids also carry an antibiotic resistance marker for easy screening of the colonies.

Neither the protein nor the genes to be expressed have associated specific hazards.

We intend to introduce plasmid constructs for the expression of GFP into B. pertussis to study phagocytosis and related events in pertussis infection and immunogenicity. The GFP is expressed as a cytoplasmatic protein and has no other known function than to emit green fluorescence when irradiated with light of the appropriate wavelength, thus it is very unlikely to change the behaviour and pathogenicity of the bacteria. No increased risk to human health has been described in the large number of publications available to date. Therefore we regard the risk of infection with this modified strain as no greater than the wild-type Bordetella strain.

B. pertussis appears to be adapted exclusively to the human respiratory tract and has no other known environmental or animal reservoirs. The modified GFP expressing B.
pertussis is very unlikely to change this. Thus, neither the parental strain nor the GMO would represent a hazard to the environment. The environment risk can be judged as in the same level as other class 2 biological agents.

The GFP expressing vectors to be used in this study will need to be introduced in B. pertussis challenge strain by electroporation. The very unlikely event of the plasmid transferring between bacteria unintentionally, it is improbable that it would increase the virulence of the recipient micro-organism due to the mentioned characteristics of the GFP vector.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 containment will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be disposed of by autoclaving followed by incineration. Chemical disinfection with chloros-derivates will be used for FACS waste decontamination before disposal. Validation and control of waste management will be held on file at NIBSC. Hycolin will be used to disinfect surfaces.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

02/03/2022
The aim of this project is to use different Bordetella pertussis mutant, which have been genetically modified to block the expression of specific virulence factors, to study the effect of antigenic variation on immunity to B. pertussis. This will permit the study the role of individual antigens in pertussis infection and immunogenicity, through the use of isogenic strains that only differ from each other in their ability to express particular antigens.

The bacteria to be used in this study will be the wild type strains Bordetella pertussis Tohoma and Wellcome 28. These strains are used for studies of B. pertussis infection. B. pertussis is an obligate human pathogen that colonises the respiratory tract. It is a containment level 2 pathogen and is handled in a class II MSC to reduce the risk of laboratory acquired infection from aerosols. These strains of Bordetella has been used extensively within the laboratory and relevant risk assessments for the preparation and handling of B. pertussis are attached. The details of their construction are described in references 5-17 in the Risk Assessment (attached).

The host will be the strain Bordetella pertussis Tohoma and Wellcome 28 as described above.

The Bordetella pertussis strains to be used are deletion mutants that fail to express of one or more of the following virulence factors: pertussis toxin, pertactin, filamentous haemagglutinin, adenylate cyclase, haemolysin, fims virulence gene promoter and LPS. These strains are gifts from other laboratories. They are deletion mutants devoid of one or more of the virulence factors. The genetic modifications carried out lead to reduced expression of the virulence factors. None of the strains have associated specific hazards.
We intend to use these strains to study the role of individual antigen in pertussis infection and immunogenicity. As the strains lack one or more virulence factors, it is very unlikely that they represent an increase risk to human. Therefore we regard the risk of infection with these modified strains as no greater than the wild-type Bordetella strain. B pertussis appears to be adapted exclusively to the human respiratory tract and has no other known environmental or animal reservoirs. There is no reason to expect the modified B. pertussis strains to pose an increased risk to the environment or other animal species.

Evaluation of foreseeable effects

We intend to use these strains to study the role of individual antigen in pertussis infection and immunogenicity. As the strains lack one or more virulence factors, it is very unlikely that they represent an increase risk to human. Therefore we regard the risk of infection with these modified strains as no greater than the wild-type Bordetella strain. B pertussis appears to be adapted exclusively to the human respiratory tract and has no other known environmental or animal reservoirs. There is no reason to expect the modified B. pertussis strains to pose an increased risk to the environment or other animal species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 containment will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be disposed of by autoclaving followed by incineration. Validation and control of waste management will be held on file at NIBSC. Hycolin will be used to disinfect surfaces.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

This project involves the development and use of genetically modified viral vectors based on Retroviruses (MLV), Lentiviruses (HIV-1), Adenoviruses (AdV), Adeno-associated viruses (AAV) and Herpes simplex viruses (HSV). This research is aimed towards the identification of reference reagents and biological assays to standardise viral vectors for proposed use in clinical trials for the gene therapy of human diseases. This work is an important activity that will contribute to the quality, efficacy and safety assessments of gene transfer products.

**Recipient or parental organism**

Cells of primate sources, eg 293, TE671, HUVEC

**Host/vector system**

Attenuated MLV vector (MLV-A), Lentiviral vector (SIN), AdV and AAV vectors containing a reporter gene, eg eGFP, laz or puro under CMV promoter.

**Origin & function**

The genetic materials that will be manipulated in the proposed study are originated from attenuated HIV-1, AdV, AAV, MLV and HSV vectors. All the vectors have been modified considerably from their parent viruses. The intended function of vector system is to supply transient expression of viral proteins and cis element for the delivery and expression of the reporter genes, eg eGFP, Laz and puro. The cytokine genes, eg TNFa, IFNy, VEGF and EGFP, will be used as expression markers for the determination of vector efficiency. The overall objective of the genetic manipulations carried out under this project is to assess the safety and efficacy of the viral vectors.

**Evaluation of foreseeable effects**

A full risk assessment has been carried out for the proposed project of the development and use of viral vectors for gene therapy. The areas covered under the risk
assessment are: human and environmental hazards associated with the recipient's micro-organism, hazards arising directly from the insert gene product and the vector systems, hazards arising from the alteration of existing pathogenic traits including host range, tissue tropism and the likelihood of causing harm to human health in case of accidental exposure. In summary, all the vectors used in this project are disabled and pose no detectable hazard to human. The parental viruses will NOT be used at anytime. The GMM will be manipulated at small scales within the containment level 2 facilities. The GMM would NOT survive and become established in the environment and in any case it would not be a hazard to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Class 2 containment applied throughout.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated plastics and culture fluids etc will be disinfected overnight in 10% Chloros, the solid waste then will be autoclaved and incinerated while the liquid waste will be discarded in a designated sink. Validation and details of control waste management is held on file at NIBSC.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Ref 251/03.1

Date Ackn'd 02/03/2022
Although the GMM will not be cultured at NIBSC, the GMM will be used for immunisation. Risk assessment of the GMM has assigned class 2 containment and hence the immunisation will be carried out in class 2 containment facility.

The parental MVA vaccinia virus has been administered to over 120,000 humans for the purposes of smallpox prophylaxis. It has restricted replication in man.

There are 5 major deletions in the genome of the recombinant MVA virus, rending it replication deficient in humans. No specific receptor is required for infection. The mechanism involves pH-independent fusion with host cell plasma membrane.

The inserted genes are of two types, the first are short DNA fragments derived from the novel translocation between bcr and abi on the philadelphia chromosome, which is only present in people with CML and a T cell epitope from tetanus toxoid. These genes are cloned in open reading frame linked by three amino acid residues. In normal healthy individuals these target antigens are not present and are therefore immunogenic. Active immunity against these targets provides no health risk. The DNA fragments are not oncogenic.

The second type of tene insert is the extracellular domains of a platelet glycoprotein (GPVI). GPVI is expressed on platelets and megakaryocytes in humans and is one of the collagen receptors required for platelet activation. Humans are tolerant to GPVI, and the likelihood of breaking tolerance after exposure is low. A small minority of people when exposed to self antigen in the context of MVA-HumanGPVI could produce symptons of autoimmune thrombocytenia (AI), which is a treatable condition. A high dose antigen is requires in order to break tolerance. The amount of mMVA-human GPVI transferred by accidental needle stick is unlikely to be above this threshold.

Well characterised vaccinia vectors, free from harmful sequences, as in the case of rMVA, will nto increase the stability of the GMM in the environment and will not transfer any resistance amarkers to microorganisms not known to acquire them naturally. rMVA proposed for this project is a highly attenuated strain. It can infect but has restricted...
replication in humans and can only replicate in chicken egg fibroblasts. The characteristics of the recombinant vaccinia in terms of host range and pathogenicity are unlikely to be enhanced compared to the parental virus. The protein products of the inserted genes will not be incorporated into progeny vaccinia virus particles. The infectivity and immune response to rMVA is unaffected from that of the wild type. There is no risk associated with recombination of separate vaccinia viruses. The replication incompetence is confirmed both prior to and following mofigivsyon og yhr bitud. Yhr tômBS id erll vhstsvyrtidfr sfn gtr gtom hstngul drwumvrd snf id trplvsysjon frgivirny in humsn. Rcpodutr yo tômBS yhrtrgtr or podrd rcyrtrmrly loe tidk yo humsn hrrlyh. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The rMVA will be used in containment level 2 laboratories. Transmission, results from exposure of skin, especially damaged skin or via the respiratory route will be minimised by the wearing of gloves and gowns. The amount of waste arising from immunisation will be less than 500 uL per experiment and will be disposed of by incineration. Spillages will be disinfected according to the laboratory rules. This involves soaking of materials and equipment in freshly made 1% (w/v) Virkon or 2.5% chloros overnight. Work surfaces will be wiped with 1% (w/v) Virkon or 70% (v/v) ethanol. These measures will reduce the likelihood of all hazards to negligible levels. The overall risk therefore is minimal with the proposed containment and control measures.

02/03/2022
The aim of this genetic modification work is to introduce plasmids for the direct expression of GFP and or LUC into S. pneumoniae so that S. pneumoniae cells expressing GFP and or LUC can be used in a project to standardise an opsonophagocytic assay used to study the efficacy of pneumococcal vaccines. Bacteria expressing both GFP and LUC will facilitate the study of the process of phagocytosis by differentiated immune cells and the standardisation of the assay. 

The bacterial strains used in this study will be Streptococcus pneumoniae are containment level 2 pathogens. They will therefore be handled according to the containment level 2 code of practice. The strains used will have capsular polysaccharides (serotypes) that are used as vaccine components and will have been genetically characterised by multi locus sequence typing (MLST). Pneumococcal isolates that have been responsible for causing mucosal or invasive infections may be used. Pneumococci can be carried asymptomatically in the nasopharynx.

The host will be the S. pneumoniae strains as described above. The genetic material is detailed below.

The green fluorescent protein originally produced by the jelly fish Aequorea victoria and luciferase originally from the firefly Photius pyralis have both been extensively used to study a) the localisation of bacterial cells and b) gene expression in eukaryotic cells and tissues. Both GFP and LUC genes will be purchased as elements of commercially available plasmid vectors. When excited by the appropriate wavelength of light GFP fluoresces without the need for additional cofactors or substrates whereas LUC requires adenosine tri phosphate (ATP). The gfp and or luc genes will be cloned into a shuttle plasmid vector, either pSET1, pSET2 or pSET3, all of which are capable of replicating in both Escherichia coli and Streptococcus pneumoniae. The host bacterial strain used for the construction of the recombinant plasmid vectors is
Escherichia coli JM101. The pSET GFP and/or LUC constructs will subsequently be transformed into the S. pneumoniae strains detailed above. Once transformed these pneumococcal strains will express GFP and or LUC as well as resistance to spectinomycin. The fluorescence or bioluminescence of S. pneumoniae may be monitored using various techniques (e.g., microscopy, spectroscopy, flow cytometry) during the process of opsonophagocytosis.

**Evaluation of foreseeable effects**

GFP and LUC are both expressed as cytoplasmic proteins and have no other known function other than to fluoresce when irradiated with light of the appropriate wavelength or luminesce respectively. It is very unlikely to change the behaviour, the pathogenicity, or the virulence of the bacteria. No increased risk to human health has been described in the large numbers of publications available to date. Therefore the risk of infection with this modified strain is considered to be no greater than with wild-type Streptococcus pneumoniae strains.

**Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)**

Animal Units  
Large Scale Activities  
Human Clinical Applications
**Project Additional Information**

**Purposes of the contained use**

- Evaluation of efficiency and safety aspects in the use of lentiviral vectors for therapeutic gene delivery
- Lentiviral vectors are potentially infectious for the operator thus containment level 2 is required.

**Recipient or parental organism**

1. E coli K12 derivatives will be used to propagate plasmids containing genes required to produce a lentiviral vector.
2. Eukaryotic cell line 293T will be used as recipient cells in transfection of the plasmids.
3. Hela cells will be used for the transduction of lentiviral vectors.

**Host/vector system**

1. Plasmids have a pBR322 backbone - ie pUC-based vectors. The details of these plasmids have been published and the vectors are widely used in research.
2. The lentiviral vector produced is based on human immunodeficiency virus (HIV-) sequences

**Origin & function**

Four plasmids are involved:

- a. HIV-1 gag, pro, pol and RRE sequences under the control of a cytomegalovirus (CMV) promoter
- b. HIV-1 rev sequence under control of Rous sarcoma virus (RSV) promoter
c. RSV promoter, HIV-1 U5 sequences, HIV-1 packaging signal, partial gag, RRE, transgene under control of non HIV-1 promoter, HIV-1 U5. This is a self inactivating vector as the HIV-1 U3 regions are attenuated.
d. Vesicular stomatitis virus G envelope under control of CMV promoter.

Transient transfection of these plasmids will result in the components being combined to produce a lentiviral vector. Many of the sequences are HIV-1 derived allowing the vector to access mitotically inactive cells. Formation of replication-competent retrovirus is prevented due to the absence of a retroviral envelope. The spread of genes across many plasmids minimises the chance of recombination events, as does the presence of a self-inactivating (SIN) vector limiting the lentiviral vector to a single round of infection. The VSV-G envelope broadens the cell tropism of the vector. All the HIV-1 accessory genes not essential for viral replication have been eliminated.

Evaluation of foreseeable effects

Genetically disabled E. coli K12 variants (such as JM109) are unlikely to survive outside of a laboratory environment due to their auxotrophic requirements for thymidine. Furthermore, recombinant plasmids are derived from poorly mobilizable vectors. The GMMs themselves are not hazardous to the environment. Neither the cloned genes nor their products are hazardous to plants found in the environment. It is unlikely that the GMM will be taken up and the recombinant protein expressed by animal cells unless injected. It is unlikely that the plasmids will produce proteins outside of a cell as the promoters require cellular transcription factors for their activation: each plasmid is designed to be active in mammalian cells thereby producing the protein encoded. The combination of plasmids does not harbour HIV-1 proteins which can result in infectious wild type virus. The transgene, EGFP is not an enzyme nor is it known to be toxic and thus is unlikely to alter the behaviour of recipient cells. The VSV-G envelope gene is capable of mediating endocytosis thereby entering a cell. The Rev protein controls RNA nuclear export in wild type HIV-1. The gag, pro and pol genes encode the capsid, protease and both the reverse transcriptase and integrase enzymes of HIV-1, respectively. These proteins are not reported to cause any adverse effect on their own. Transient expression of the viral and non-viral proteins from the plasmids should they be taken up by cells could theoretically occur. This is an unlikely event through routes other than direct injection. Moreover, the design of each plasmid incorporates safeguards to prevent establishment of viral infection unless all of the packaging vector units are present in a cell.

It is unlikely that the 293T cells sequences will recombine with regions of the vector sequences to produce a novel virus as the lentiviral vector is severely attenuated and limited to one round of replication. The lentiviral vectors themselves are not hazardous to the environment. Neither the cloned genes nor their products are hazardous to plants found in the environment. It is unlikely that the GMM will be taken up by animal cells unless directly injected. Virus production is highly unlikely even in the event that all four plasmids are taken up by a cell: replication pseudotyped envelope will allow entry of the GMM into many cell types the vector is replication deficient and self-inactivating.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be used.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. All equipment and materials associated with bacterial cultures will be disinfected in 10% Microsol3 (Anachem) prior to disposal via autoclaving, or re-use in the laboratory. Using Microsol3 at a 1:50 dilution results in a reduction of bacterial cells of >4.5 log (Gram positive and Gram negative bacteria).
2. All cell culture waste will be disinfected in 2.5% (v/v) Chloros (giving 2,500 ppm available CL) overnight prior to discard via the drain with copious amounts of water. All disposable materials and equipment are disposed of by soaking in 2.5% (v/v) Chloros overnight by autoclaving. The effective use of Chloros as a disinfectant is established against viruses (enveloped, non-enveloped, bacteria, bacterial spores, organic matter, TSE).
The genetic modification safety committee considered that the risk assessment and the proposed containment measures were appropriate for the work.

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee considered that the risk assessment and the proposed containment measures were appropriate for the work.
**Project Additional Information**

**Purposes of the contained use**

Transmissible spongiform encephalopathies are a group of neurodegenerative disease that occur through a change in conformation of the prion protein (PrP). The normal form of the protein, PrPc, is converted from a soluble to an insoluble from that acquires resistance to digestion with proteinase K (PrP Sc).

Currently diagnosis of TSEs relies on post-morten examination of neural tissue. Levels of human TSE agent can only be determined by titration in mice. There is a need to find an alternative methods diagnosing and measuring TSE content, the use of cell lines that are susceptible to infection by human TSEs would provide an invaluable tool for achieving both goals.

Recombinant prion protein (PrP) expressed in bacteria will be used to standardise diagnostic assays. Cell lines over-expressing PrP will be evaluated for their ability to amplify the infectious agent varient Creutzfeldt-Jakob Disease (vCJD) in standard reference materials.

Production of recombinant normal prion protein has been assigned to containment level 2. Generation of a lentivirus vector expressing the normal human prion protein will be carried out in a laboratory approved for work with human TSEs (Containment level 3 with derogation).

**Recipient or parental organism**

1. E coli K12 derivatives will be used to propagate plasmids containing the prion protein open reading frame.
2. E coli BL21 cells will be used for expression of the prion protein in bacteria.
3. Eukaryotic cell lines 293T and RK13 will be used in transient expression experiments.
4. S2 cells will be used for stable expression in insect cells.
5. Human cell lines expressing endogenous retroviral elements (HERVs, eg Tera 1, a teratocarcinoma cell line) will be used for the expression of the prion protein from a lentivirus vector.

**Host/vector system**

1. All plasmids are based on either a pUC or pBR322 backbone and are widely used in research.

**Origin & function**

The plasmids involved in this connected program are as follows:
1. Prion protein (human, bovine, mouse, hamster, ovine and deer from normal tissue or cell lines) under the control of the T7 promoter controlled by the laci operator sequence
2. Normal prion protein under the control of the CMV promoter
3. Normal prion protein under the control of the metallothionein promoter (in insect cells)
4. Lentivirus expression of prion protein is under the control of CMV promoter
5. Normal human or bovine prion protein expressed from endogenous promoters but with multiple integrations, increasing overall levels of expression, in mice.

Prion protein expressed in bacteria will be purified and used as a standard reference material. Purified protein will be refolded to produce the scrapie-associated conformer (PrP Sc), refolding experiments will be carried out in the NIBSC prion laboratory which is containment level 3 with derogation.

Stable cell lines over-expressing PrP will be evaluated for their ability to replicate PrP SC. Tagged versions of PrP will allow the production of nascent PrP SC to be evaluated.

Prion protein expressed in insect cell culture will be affinity purified.

---

02/03/2022
Cell lines expressing human prion protein from a lentivirus cassette will be evaluated for their ability to replicate/amplify PrP Sc from human tissue homogenates (sporadic and variant CJD).

### Evaluation of foreseeable effects

Genetically disabled E. coli K12 variants (DH5a, INVFa, BL21) are unlikely to survive outside a laboratory environment due to their auxotrophic requirements for thymidine. Plasmids used for cloning and expression have only a limited ability to mobilise. The GMMs are not hazardous to the environment. There is no evidence that cloned PrP or recombinant protein is hazardous to the environment. Recombinant protein expression would only be possible after injection. Promoters used for expression of prion protein would not function outside the cell.

Purified protein would only be handled in a containment level 2 setting. Attempts to re-fold recombinant prion protein will be carried out in the prion unit laboratory which has been designated as containment level 3 with derogation. There is no evidence that suggests that recombinant prion protein even when re-folded has any ability to induce disease. However, the re-folded protein will be de-contaminated as if it were potentially infectious.

Cell lines which stably over-express the prion protein will be maintained in containment 2 laboratory and attempts to infect cell lines with PrP SC will be carried out in the prion unit laboratory.

Lentivirus stocks will be produced in the main prion unit laboratory, all viral stocks will be treated as for infectious virus (media will be treated with 2,500 ppm hypochlorite) all plastic ware used during preparation and amplification of stocks will be submersed in chloros prior to disposal as clinical waste (incineration, as per prion unit COP).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be used for over-expression of prion protein in bacterial cultures and for the maintenance of cells (mammalian and insect) stably over-expressing prion protein.

Re-folding of bacterial expressed recombinant proteins will be carried out in the prion unit laboratory which has been assigned as a containment level 3 laboratory with derogation.

Lentivirus vectors overexpressing normal prion proteins will be packaged and amplified in the prion unit laboratory which has been classified as containment level 3 with derogation (not sealable therefore fumigation of laboratory can not be undertaken).

Attempts to infect cells over-expressing prion protein will also be carried out in the prion unit laboratory.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. All equipment and media used for bacteria cultures will be decontaminated using 2% microsol overnight. Flasks etc will be autoclaved before further use in the laboratory. Microsol at a concentration of 2% results in the reduction of bacterial cells of >>>>>>>.5.4log (Gram positive and Gram negative bacteria).

2. Re-folded recombinant proteins will be treated with 2N (NaOH prior to disposal by incineration (in compliance with prion unit code of practice).

3. Cell culture waste will be disinfected in 2.5% (v/v) chloros (giving 2,500 ppm available C1) overnight before discard via the drain with copious amounts of water. All disposable plastics will be disposed of after autoclaving. Plastics used during prion infectivity experiments will be decontaminated overnight in 2N NaOH before disposal by incineration (in compliance with prion unit code of practice). Chloros and 2N NaOH have been approved as suitable agents for decontamination of TSEs.
The GMSC considered that the risk assessment and the proposed containment measures were appropriate for the work.

Project Ref 251/06.1

Date Ackn'd 19/04/2006

Transfer of commercially-produced lentiviral vectors, encoding short hairpin RNAs (ShRNAs) against the calcium-sensing receptor, into mammalian cells to induce knockdown of the gene product by RNA interference (RNAi)

Class 2

Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
Project Additional Information

Purposes of the contained use

The extracellular calcium-sensing receptor (CaR) has been shown to be expressed on the insulin-secreting B-cells within the pancreas, although its function has yet to be described. In an effort to knock down the expression of this receptor in pancreatic B-cells, we will utilise commercially available transduction-ready lentiviral particles (Mission shRNA lentiviral transduction particles) to transduce mammalian cells with specific shRNA constructs and generate cell lines with stable expression of these shRNAs, to facilitate knock down of the CaR gene by RNA interference.

Recipient or parental organism

There is no propagation of lentiviral vectors as the lentiviral particles are commercially available and ready for transduction into mammalian cell lines. The recipient cell lines are well established (MIN6 - mouse insulinoma, HEK293 - human embryo kidney cell line) and are tissue culture adapted so will not survive outside of laboratory culture. They are not considered pathogenic to humans and animals. Once efficient knock down by RNAi has been shown in the HEK293 cells, the human shRNA constructs will be used to transduce primary human islet beta cells, dispersed from human islets of Langerhans (King's College Hospital, Islet transplantation Unit). These islets are screened for HIV and Hapatitis prior to release.

Host/vector system

The lentiviral particles are produced from a pLKO.1 puromycin vector which is a widely used vector in research. The vector contains the 5' long terminal repeat (LTR), SIN/LTR (3' LTR), and Psi Packaging Signal of HIV-1 and these permit viral packaging using a 2-plasmid lentiviral packaging system. Using this multiplasmid approach, resulting viral particles are replication incompetent and cannot be propagated. Also, a deletion in the U3 region of the 3' LTR (SIN/LTR) does not affect generation of the viral genome during packaging, but results in loss of the transcriptional capacity of the viral LTR once transferred to target cells. The vector also contains the puromycin resistance gene for selection in mammalian cells.

Origin & function

s is the aim of this work to utilise commercially available transduction-ready lentiviral particles (Mission shRNA lentiviral transduction particles, Sigma) to transduce mammalian cells with specific shRNA constructs and generate cell lines with stable expression of these shRNAs to facilitate knock down of the CaR gene. Once these cell lines have been established, the role of the CaR in pancreatic B-cells will be evaluated by analysing the function of the cells. These functional tests include measurements of insulin secretion by RIA, measurements of intracellular calcium flux, proliferation and apoptosis assays and analyses of gene expression.

Evaluation of foreseeable effects

Once stably transduced, the cells will express the shRNA which is not toxic and non-mobilisable because of the self-inactivating feature of the lentiviral vector, meaning the target cell cannot produce and release new lentiviral particles. Although possible, the chances of incorporation of the vector into the genome in a position that alters the expression of neighbouring genes such as oncogenes are extremely remote. Although the pseudotyped envelope will allow entry of the GMM into many cell types, the vector is replication deficient and self-inactivating, therefore the chances of the vector entering the human genome and reducing the expression of the CaR are extremely remote. Should this occur, the predicted effect of exposure is difficult to assess but is unlikely to cause harm to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be soaked in 10% (v/v) Chloros (giving 2,5000 ppm available CI) overnight and discarded in a designated sink with copious amounts of water in

02/03/2022
accordance with guidelines for disposal of enveloped virus. As a result of the location of the work all disposable materials and equipment are disposed of by autoclaving and incineration after soaking overnight in 10% (v/v) Chloros (giving 2,5000 ppm available CI). Plastic labware is used. Validation and details of control waste management is held on file at NIBSC.

Any spillages are managed in accordance with the COP for Laboratory 5088. Briefly, liquid spills are decontaminated with absorbent towels soaked with 10% v/v hyrcolin. Contaminated surface areas are wiped with 10 (v/v) Chloros (see above) for 30-60 minutes. Solid waste materials are autoclaved before being disposed.

Cuts, splashes, etc of contaminated material onto exposed skin is washed with copious amounts of soap and water, if appropriate a wound is made to bleed freely. The area is covered, a dressing applied. Eye injuries are washed with copious amounts of water. A copy of emergency procedures for cuts and splashes is displayed in the laboratory.

The GMSC considered that the risk assessment and the proposed containment measures were appropriate for the work.

**Project Additional Information**

**Purposes of the contained use**

We shall receive Human Immunodeficiency Virus and Simian Immunodeficiency Virus from the laboratory (University of Amsterdam) that have been genetically engineered so that replication of these viruses is regulated by the Tet-On regulatory system. We shall propagate these viruses and investigate the impact on cells of infection with these viruses in the presence and absence of the antibiotic doxycycline.

**Recipient or parental organism**

Human Immunodeficiency Virus or Simian Immunodeficiency Virus

**Host/vector system**

The parental micro-organism HIV or SIV will be propagated and handled by infecting cell lines such as Sup T1, C8166 or CEMx174 cells or primary peripheral blood mono nuclear cells.

**Origin & function**

The parental micro-organisms are lab adapted HIV (e.g strain HIV-1 Lai) or SIV (e.g SVmac239) that have been molecularly cloned and so amendable to genetic manipulation.

The Tet-On system is derived from E.coli K12 tet operon for the Tet and the inducible Tet R gene regions and the eukaryotic transactivator derived from the C terminal portion of VP16 derived from Herpes Simplex virus.

The constructs have been prepared and expressed by the group of University of Amsterdam and demonstrated that the expression of the progeny viruses are dependent upon the presence of doxycycline in tissue culture medium.

**Evaluation of foreseeable effects**

The propagation and handling of doxycycline dependent HIV and SIV may result in 3 outcomes:

1) The continued maintenance of genetic information so that the expression of recombinant viruses remain doxycycline dependent.
2) The modification and selection of recombinant viruses that cannot express in the presence or absence of doxycycline (ie replication incompetent viruses)
3) The modification and selection of recombinant viruses for which expression is no longer regulated excessively by the presence of doxycycline (ie revertant viruses)

In no situation is it anticipated that the virus will alter tropism since the genetic changes do not alter the env gene which is the principal determinant of receptor binding and cell entry by the virus.

In all cases recombinant viruses remain an enveloped retrovirus that will remain effectively controlled under bio-containment conditions appropriate for the parental virus.
and susceptible to the same range of disinfectants and inactivation procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

It is possible that the future development of the connected programme will include the genetic manipulation of full length infectious molecular clones of doxycycline dependent HIV or SIV, with the purpose of introducing changes designed to alter the level of dependence of the virus on doxycycline for virus replication. A risk assessment has not been submitted with this application, however, it is likely that such work would be proposed to be performed under the same bio-containment level conditions as those used to handle full length recombinant infectious clones of HIV and SIV inserted in plasmids and propagated in E.coli K12. In principle, this is bio-containment level 2 with additional restrictions on restricted entry to the laboratory and the exclusion of glass and sharps from the laboratory area.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All laboratory waste derived from tissue culture will be soaked in disinfectant (10% v/v Chloros or 10% Microsol3) overnight. Liquid waste will be discarded into the drains and solid waste will be autoclaved prior to disposal. All disinfectants used have proven efficacy against enveloped viruses and the heat labile nature of retroviruses is well documented.

**Project Ref** 251/07.2

The GMSC considered that the risk assessment and the proposed containment measures were appropriate for the work.
Molecular mechanisms of the formation, composition and structure of Neisseria meningitidis outer membrane vesicles (OMV) and the refinement of serological analysis of OMV vaccines.

Nelsseria meningitidis is a class 2 pathogen. It only colonises humans and has no environmental reservoir. It is usually carried asymptomatically in the nasopharynx but occasionally invades the subepithelial tissue when it may proceed to cause septicaemia and/or meningitis.

Recipient or parental organism

Neisseria meningitidis is a class 2 pathogen. It only colonises humans and has no environmental reservoir. It is usually carried asymptomatically in the nasopharynx but occasionally invades the subepithelial tissue when it may proceed to cause septicaemia and/or meningitis.

Host/vector system

The DNA to be transformed into N. meningitidis will utilise a plasmid shuffle vector (pMidg) able to replicate in both N. meningitidis and Escherichia coil. This vector also has the N. meningitidis Ncr strong promoter to drive expression of the cloned insert. In addition the vector also contains the kanamycin resistance gene for the selection of transformed colonies when grown on media containing the antibiotic kanamycin (C.A. O'Dwyer., Infect Immun. 2004 Nov;72(1 I ):651 1-8). In addition the Escherichia coil plasmid vector (pUCI 9) will be used, it is envisaged that this plasmid is solely used for in construction of additional DNA sequences and none of this plasmid will be transformed into N. meningitidis.

Origin & function

The pMidg plasmid will also harbour an operon isolated from the E. coil strain TopI0. In E. Coli these proteins form a complex which spans the peptidoglycan layer and effectively joins the Inner and outer membrane. This has the net effect of stabilising the outer membrane. In addition, sequences of the N. meningitidis porA gene and promoter will be amplified to provide regions for homologous recombination with the wild type sequence. Synthesised oligonucleotides will be annealed and used. A copy of the kanamycin resistance gene for the selection of transformed colonies when grown on media containing the antibiotic kanamycin will also be introduced.

Evaluation of foreseeable effects

It is hoped that after transformation the N. Meningitidis strain will express fully functional genes of the operon from the plasmid vector. The subsequent production of
proteins following their correct formation and localisation would lead to the linking of the inner membrane, peptidoglycan and the outer membrane as seen in E. coli. This protein complex would provide additional stabilisation of the outer membrane and inhibit the formation of naturally produced or detergent induced OMV. The implications of the proposed alterations for meningococcal virulence are unknown; however, it is unlikely that they will increase virulence as the proposed mutants are likely to be less fit for survival in vivo because of alterations to the bacterial cell surface. Neisseria meningitidis is naturally competent and it is highly likely it will have encountered the operon before as it is present in most gram negative bacterial species. The fact that it is not already present in the genome suggests that there is no advantage to the organism from expressing these genes. If the expression of the operon results in reduced vesicle production, one would expect a consequent reduction in the release of lipo-oligosaccharide and hence a reduction in inflammation, which is ultimately responsible for the pathology of meningococcal disease. In addition vesicle production, a known virulence factor in other bacterial species, would also be reduced.

N. meningitidis PorA expression is naturally variable due to the presence of a poly-G track found between the -10 and -35 sequences in the porA promoter. In the wild-type meningococcus this variation occurs through replication slippage as the polymerase crosses the poly-G region. This will be modified to generate spacer sequences of different lengths. It is hoped that after recombination of this sequence into the wild type porA promoter that the different spacers will create a range of gene expression and a set of strains, differing only in the level of the PorA protein in their outer membrane. The pathogenic properties of the bacterium will probably be unaltered in the constructs. The maximum expression of the altered promoters is expected to be no more than that of the wild type promoter, while reduced or lack of expression likely to have a deleterious effect on the growth. All the equivalent variants in promoter spacer length have been isolated from natural populations. Removing the variability in PorA expression, may well eliminate a mechanism by which N. meningitidis evades the human immune response to the highly immunogenic PorA protein.

The likelihood of all GMM's causing harm to human health following exposure is no more than for the wild-type pathogen. Finally, the organism will be resistant to kanamycin, an antibiotic that is not used to treat meningococcal infections but this resistance will only be sustained while selection is maintained.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

no derogation requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Cultures of transformed N. meningitidis are sterilized by autoclaving prior to disposal. Autoclaving is carried out at a minimum of 134°C for a minimum of 30 minutes. Prior to autoclaving additional controls for the safe disposal of cultures are also employed. Petri dish lids are taped to the base to avoid any dispersal of bacteria. Broth cultures are first disinfected by adding Microsol 3 to a final concentration of 10% and left for 30 minutes before being autoclaved. Once autoclaved the liquid waste is deemed harmless disposed of down the sink. All plate cultures and disposable plastic is sent off site for incineration after autoclaving.

#### Project Additional Information

**Purposes of the contained use**

The GMO is being considered for Phase I clinical trial as an investigational medicinal product and so specific dissemination issues arising from the genetic modifications have been identified in preclinical investigations. Specifically, more information on aspects of GMO release from individuals vaccinated with the GMO has been requested with specific information on the potential for shedding of the GMO. There is access to veterinary clinical sample material from cows vaccinated with the rBCG that may assist in clarifying these issues.

**Recipient or parental organism**

The organism (BCG) is the vaccine strain and has been administered to millions of people (neonates, children, young adults, adults and the aged) worldwide for over 80 years. However BCG is Classified as Level II for the purposes of culture and laboratory handling. Laboratory adapted strain of M. bovis originally isolated from bovine origin in late 1800’s.
Another organism used in the project is Escherichia coli (Category I) only for the purpose of cloning and amplification of the plasmid.

**Host/vector system**

The GMO is a recombinant form of BCG. BCG (Prague Strain) was modified to create ureC(KO) hly+ rBCG, which contains the Listeria monocytogenes protein listeriolysin 0 (Hly), which allows escape from the intracellular organelle, the phagosome - and is deficient in urease C, a molecule that has a role in pH neutralization of the phagosome. Deletion of the gene encoding urease C via insertion of a Hygromycin cassette has ensured an acidic pH in the phagosome, thereby promoting the activity of Hly. The strategy is designed to facilitate antigen presentation through phagosome escape and engagement of MHCII antigen presentation. The gene coding for Listeria monocytogenes protein listeriolysin 0 (Hly) has a highly focussed functionality and can act in only very limited circumstances — see (a). It has no local or systemic implications. The urease C knockout is carried out by a gene disruption mechanism using a Hygromycin cassette located with the Hly gene driven by the native mycobacterial promoter for Antigen 85.

**Origin & function**

Hygromycin is not in general use in clinical practice and therefore the HygR characteristic has no significant implications.

**Evaluation of foreseeable effects**

The gene coding for Listeria monocytogenes protein listeriolysin 0 (Hly) has a highly focussed functionality and can act in only very limited circumstances — see (a)- It has no local or systemic implications. The urease C knockout is carried out by a gene disruption mechanism using a Hygromycin cassette located with the Hly gene driven by the native mycobacterial promoter for Antigen 85. Hygromycin is not in general use in clinical practice and therefore the HygR characteristic has no significant implications. Preclinical investigations have demonstrated that the GMO is MORE attenuated (safer) than the parent strain currently used worldwide in human vaccination programmes. (See attached publication — Fig 4 page 2475). The gene coding for Listeria monocytogenes protein listeriolysin 0 (Hly) has a highly focussed functionality and can act in only very limited circumstances — see (a). It has no local or systemic implications. The urease C knockout is carried out by a gene disruption mechanism using a Hygromycin cassette located with the Hly gene driven by the native mycobacterial promoter for Antigen 85. Hygromycin is not in general use in clinical practice and therefore the HygR characteristic has no significant implications.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard disinfection protocols for BCG and E. coli will suffice (these are already in place), autoclave and incineration where specified by laboratory practice.

**Project Ref** 251/09.1

**CU2 Project Title**

Viral based vector delivery systems for efficient transduction and stable gene expression in primary cell lines and adult and human embryonic stem cell lines.

**Class**

Class 2

**CultureVol**

< 1 Litre

**Non-GMM Consent Granted**

Project notified under transitional arrangements

**Historical Significant Changes**

Withdrawn

**Project Additional Information**

**Purposes of the contained use**

Retrovirus and baculovirus based viral vector delivery systems will be used for efficient transduction and stable gene expression in primary cell lines and adult and embryonic stem cell lines.

Banking and characterisation of induced pluripotent stem cells, embryonic stem cell lines, adult stem cell lines and human and mouse feeders created and modified using...
Retrovirus and baculovirus based viral vector delivery systems.

Recipient or parental organism

Viral vectors: There is a pathogenicity associated with the unmodified viruses, for example:
In the case of Murine Moloney Leukaemia Virus, leukaemia in the mouse. This virus has a tropism for mice.
HIV/AIDS in humans in the case of lentivirus, based on the HIV retrovirus.
Baculovirus has a tropism for insect cells and shrimp. It does not pose a hazard to humans since it does not replicate in mammalian cells, and is also inactivated by human complement.

Cell lines: Established cell lines will be used for lentivirus and retrovirus production (e.g. 293FT; Platinum-E cells; ΔΕ cells). 293FT cell line is derived from the 293F cell line and stably expresses the SV40 large T antigen from the plasmid pCMVSPORT6Tag.neo. 293F cell line is a fast growing variant of the transformed human embryonic kidney (293) line. Platinum-E (based on the 293 cell line) and ΔΕ (based on the NIH 3T3 cell line) were generated using constructs for the expression of the retroviral structural proteins (gag, pol and env). A number of cell lines will be transduced with the viral vectors produced in these projects, including, but not limited to, human foetal lung fibroblasts (e.g. MRC5 and IMR90 (ATCC)) and hES cell lines (e.g. SHEF3 (UKSCB)).

Host/vector system

Retrovirus vectors are a traditional delivery system for stable gene expression which will be utilised in this project. Specifically, the pMXs2 and the pBabe vectors will be used in conjunction with Platinum-Ecotropic (Plat-E) packaging cells (pMXs vector, Cell Biolabs Inc.) or ΔΕ packaging cells3 (pBabe vector). These retrovirus vectors are based on the Murine Molony Leukemia Virus (MMLV), and contain the 5’ and 3’ LTR’s plus the ψ packaging signal and a multiple cloning site. The gag genes are disrupted in order to generate vectors free of gag and gag-fusion proteins. Replication-incompetent viruses are produced in the packaging cell lines, which contain packaging constructs for gag, pol and env on two separate plasmids, and can efficiently deliver the gene of interest to the cell to provide stable, long-term expression of the target gene. The system used is a third generation lentiviral system, which includes a number of safety features to enhance its biosafety and minimize its relation to the wild-type HIV-1 virus:
• The pLenti vector contains a deletion in the 3’LTR that results in “self-inactivation” of the lentivirus after transduction of the target cell line.
• Multi-plasmid approach: structural components required for packaging the viral genome are separated onto four plasmids. The plasmids have been engineered so as to not contain any regions of homology with each other to prevent undesirable recombination events that may lead to generation of a replication-competent virus.
• The packaging plasmids allow in trans expression of gag, pol, rev and env proteins for viral progeny to be produced in the 293FT packaging cell line. None of the plasmids contain LTRs or the ψ packaging sequence, therefore none of the HIV-1 structural genes are present in the packaged viral genome, and cannot be expressed in the transduced target cell line. The lentiviral particles produced are replication-incompetent and only carry the gene of interest.
• Gag and pol expression from the pLP1 plasmid has been rendered Rev-dependent by the addition of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.

Baculovirus can infect and replicate in insect cells lines, and has also been shown to effectively transduce (but not replicate in) a variety of both dividing and non-dividing mammalian cells. While expression of viral genes does not take place, baculovirus-based vectors are used for transient expression of genes drive by promoters/enhancers that are normally functional in mammalian cells. Baculovirus vectors will contain the genes required for IPS cell generation (e.g. transcription factors Oct4,uso4, cMyc, Sox2, IN28 and Nanog). In addition to the production of IPS cells, baculoviral vectors may also be engineered to deliver transgenes to both IPS and hES cells for further study into the mechanisms of pluripotency/differentiation and the role of methylation in these processes.
With the exception of one gene, the lentivirus/retrovirus/baculovirus particles will contain non-toxic transgenes (e.g. transcription factors Oct4, Klf4 and Sox2, shRNA or reporter genes) and therefore have no associated pathology, and are not overtly oncogenic in humans, mice or insects. One retrovirus and one baculovirus vector used in this study will contain the oncogene, c-Myc.

Evaluation of foreseeable effects

The inserted genes do not alter pathogenicity or tropism. The lentivirus and retrovirus particles are designed to enter a range of cell types and deliver transgenes for integration into the host cell's genome. The cells will then express these genes, of which the majority are non-toxic, and therefore do not alter pathogenicity or tropism. The viruses are replication incompetent, and therefore extremely unlikely to be able to produce progeny. In addition, the chances of the vector incorporating into the genome in a position that alters the expression of neighbouring genes (such as oncogenes) are extremely remote.

As the engineered lentivirus and retrovirus are replication defective and restricted to a single round of infection in the target cells, it is highly unlikely that the transgenes could be transferred to a related microorganism. Lentivirus vectors can enter a number of cell types, and should this occur the predicted effect of exposure is difficult to assess, although the transgenes are non-toxic, and unlikely to cause harm to human health. The vectors are also replication deficient and viral replication in the host is therefore extremely remote. The retrovirus vectors are ecotropic, and therefore cannot infect human cells.

The baculoviral vectors are replication defective, so it is highly unlikely that the viral particles will be able to transfer the genetically modified sequences to another microorganism. With the exception of one vector that contains c-myc, the majority of vectors will contain non-toxic transgenes. Although the genetic insert is under a mammalian promoter and the predicted effect of exposure is therefore difficult to assess, the vectors are replication deficient, and baculovirus is rapidly inactivated by human complement.

Origin & function

The inserted genes do not alter pathogenicity or tropism. The lentivirus and retrovirus particles are designed to enter a range of cell types and deliver transgenes for integration into the host cell's genome. The cells will then express these genes, of which the majority are non-toxic, and therefore do not alter pathogenicity or tropism. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation from full containment requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be soaked in 10% (v/v) Chloros (giving 2500ppm available Cl) or Microsol 3+ (10% v/v) overnight and discarded in a designated sink (Biotherapeutics laboratory room 5038 or UK Stem Cell Bank) with copious amounts of water in accordance with guidelines for disposal of enveloped virus. All disposable materials and equipment are disposed of by autoclaving and incineration after soaking overnight in 10% v/v Chloros or Microsol 3+ (10% v/v). Plastic labware is used. Validation and details of control waste management is held on file at NIBSC.

All spillages are managed in accordance with the COP for UKSCB, CBI clean room and Biotherapeutics 5038/5030 laboratories. Briefly, liquid spills are decontaminated with absorbent towels soaked with 10% v/v Chloros or Microsol 3+. Contaminated surface areas are wiped with 10% v/v chloros or Microsol 3+ for 30-60 minutes. Solid waste materials are autoclaved before being disposed according to NIBSC safety practices.

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

1. Evaluation immunogenicity of attenuated measles virus vectors.
2. The constructs are potentially infectious for the operator and thus containment level 3 is required.

**Recipient or parental organism**
CD4 T cells harbouring the vector will be handled locally.

**Host/vector system**

The vector will be assembled in a collaborating laboratory and is designed to allow expression of recombinant genes. It can be handled at Containment Level 2.

**Origin & function**

The vector backbone is the measles virus and contains recombinant proteins.

This vector will enable the immunogenicity of this vector to be evaluated.

**Evaluation of foreseeable effects**

Generally, there is no specific guidance for replicative vectors like recombinant measles virus. The closest guidance could come from gene therapy (GT) vectors and relates to quality aspects (cell lines used, seed characterization) and safety aspects (preclinical safety, integration, persistence).

Infection of humans with the cloned sequences to be used is not known to cause disease and the measles vector will not integrate into host DNA.

The GMM is unlikely to present a greater risk to the environment than does the current childhood attenuated measles vaccine, but because the vector may have altered tropism the effects of infection in humans is unknown. Hence, the vector will be used under containment level 3 to minimise release to the environment.

The vector is unlikely to survive outside of a laboratory environment as it does not replicate extracellularly.

The vector and its insert are unlikely to be taken up and the recombinant protein expressed by animal cells unless injected. It is unlikely that the vector will produce proteins outside of a cell. The GMM itself is not hazardous to the environment nor is the cloned gene or its product hazardous to wild animals or plants found in the UK.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the unlikely event that virus be spilled, the spill will be disinfected by soaking in a 2.5% (v/v) Chloros solution (giving 2500 ppm available QAC) overnight prior to discard via the drain with copious amounts of water. All disposable materials and equipment are disposed of by soaking as above and then discarded via autoclaving. The effective use of Chloros as a disinfectant against viruses (enveloped and non-enveloped) and organic matter is established.

Is an emergency plan required according to regulation 20?

Evaluation of immunogenicity of candidate Typhoid conjugate Vaccines

**Recipient or parental organism**

```
02/03/2022 Page 5791 of 15326
```
Host/vector system
The vector will be assembled in a collaborating laboratory and is designed to allow expression of recombinant genes. It will be handled at Containment Level 2.

Origin & function

S. typhimurium C5.507 is a genetically modified strain derived from S. typhimurium C5 and expresses the Vipolsaccharide (ViPS) capsule from S.Typhi. S. typhimurium C5.507 was isolated from Vi-positive S. typhimurium C5 recipients following conjugation experiments with S. typhi at Institut Pasteur (Paris, France). Strain C5.507 harbours the Salmonella Pathogenicity Island (SPI)-7 of S.typhi, which contains the via genes responsible for expression of the Vi capsule and a kanamycin resistance gene (Hale et al., Vaccine 2006;24:4312-20). The vector will be obtained from a collaborator.

Evaluation of foreseeable effects

The pathogenicity island SPI-7 carries a kanamycin resistance gene and consists mainly of genes involved in regulation Vi expression. Toxin genes have not been identified and the plasmid therefore has no intrinsic toxin activity. The capsule does not add to the virulence of the GM: compound to the parent strain C5 the virulence of C5.507 was not increased in Balb/c mice (Hale et al. 2006). As these are hyper susceptible mice it is reasonable to assume that virulence of the GMM has not increased.

The organism is not indicated as a human pathogen and the expression of the Vi PS is unlikely to change its host range.

The pathogenicity island SPI-7 of C5.507 carries a kanamycin resistance gene and the island is believed to be stable despite the presence of characteristics of a potentially mobile element. The gene content of SPI points to an origin as enzymes are present besides genes that regulate the capsular Vi PS expression. Toxin or toxin-like genes have not been identified. SPIs related to SPI-7 have been found in S.enteric serovar Paratyphi C and S. enterica serovar Dublin (both human pathogens). Soil bacteria are thought to be a natural reservoir for SPI-7 or its close relatives (Pickard et al. J Bacteriol 2003; 185:5055-65). Thus transmission of the plasmid/SPI between bacteria may well be occurring in the soil under natural conditions. The transfer of SPI-7 to C5 was successful in the presence of kanamycin. Because kanamycin levels required for a successful transfer are unlikely to occur in the environment, stable introduction of SPI-7 in new transformants is unlikely and hence expression of the genes and establishments of new Vi+ strains or species is bound to be limited under natural circumstances.

The parent strain is not a human pathogen and its virulence in the natural host is also limited. Transmission by the oral route is required and human disease (if any) is associated with food poisoning and only if sufficient numbers will have to be ingested and stomach acidity will have to be by-passed. In addition staff who will work with relative high levels of live organisms have been vaccinated with Vi PS and will thus be immune to infection with the GMM. Aerosol transmission is an unlikely route for Salmonella Infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Methods for disinfecting and dealing with spillages (in accordance with laboratory COP). Benches and equipment will be sprayed with Virkon (DuPont) prior to commencing work and after completion of each piece of work. Virkon is a multi-purpose disinfectant effective in cleaning up hazardous spills, disinfecting surfaces and soaking equipment. It has a wide spectrum of activity against viruses, some fungi, and other bacteria. Virkon will be added to all liquid waste which will be discarded via the laboratory sink with copious amounts of water. If spillages occur, Virkon will be sprayed onto the area and any remaining liquid will be soaked up again with paper towels.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The genetic modification safety committee considered that the risk assessment and the proposed containment measures were appropriate for the work. The Minutes of the committee meeting reflect this decision. A report of this Committee's business is reported to the main Health and Safety Committee, membership of which includes management and scientific representatives from across the Institute and Trade Union representative.

### Project Additional Information

#### Purposes of the contained use

Evaluation of candidate vaccines for tuberculosis. The Connected Programme currently covers two Class 2 activities, both of which are included in this Notification, as well as an overview of the Programme of work.

#### Recipient or parental organism

Candidate vaccines will have been created and safety tested in collaborating laboratories and will be handled at Containment Level 2.

#### Host/vector system

The current licensed vaccines for prevention of tuberculosis (TB) is BCG vaccine. Due to its variability in efficacy in many different developing countries, new vaccines are actively under development. Many vaccine candidates for TB are in clinical studies, including live, attenuated Mycobacterium tuberculosis (Mtb) candidates. They are recombinant Mtb preparations, attenuated by genetically modification; and they are tested (by collaborators) with safety either the same or better than BCG vaccine. Thus they have been classified as ACGM2 organisms. There are many different strategies to attenuate the Mtb by various genetic modifications.

One of the examples is MTBVAC which is recombinant of MT103, which is a clinical isolate of Mtb and is naturally urease deficient and sensitive to the frontline anti-TB drugs used in the clinic. This live, attenuated MTBVAC is constructed to contain two independent non-reverting deletions in the virulence genes phoP and fadD26 [1-3]. It does not contain antibiotic resistance markers, making this strain fully sensitive to front line anti-TB drugs on current market for treatment.

The recombinant BCG preparations are live, attenuated and genetically modified (either by insertion or selection) mycobacteria. There are various strategies for generating rBCG strains in order to improve the safety (e.g. the non-replicating candidates targeting for immunocompromised individuals) and/or enhance protections in M. tuberculosis challenge systems. One of the strategy is designed to facilitate antigen presentation through phagosome escape and engagement of MHC-1 antigen presentation, such as the ureC(KO) hly+ rBCG, which contains the Listeria monocytogenes protein listeriolysin O (Hly), which allows escape from the intracellular organelle (phagosome), and is deficient in urease C, a molecule that has a role in pH neutralization of the phagosome. Another example is the BCG zmp1 mutant showing increased colocalization with late endosomal markers, suppresses inflammasome activation exhibits facilitated antigen presentation and enhanced immunogenicity of mycobacterial antigens in immunized hosts. Alternatively, these rBCGs can also be expressed and secretes the important T-cell antigens, such as ESAT-6 and CFP-10 which are found in Mtb but not in wildtype BCG[4] or proteins related to latent TB.

The proposed project is to evaluate the quality and potency of various attenuated Mtb preparations as vaccine candidates for TB using microbiology, immunology and molecular biology techniques, such as cultural (CFU), flow cytometry, ELISPOT assays and PCR.

#### Evaluation of foreseeable effects

All new TB candidate vaccines are tested for safety (by collaborators) with safety data either the same or better than wildtype BCG: and are classified as ACGM2 organisms prior to shipment to NIBSC. The proposed project is to evaluate the quality and potency of various rBCG and attenuated Mtb preparations as vaccine candidates for TB.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is sought
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The method is identical to that used for BCG vaccine. Diluted alcohol (70%) or Surfanios/Microsol (5%) will be used for spills and for the clean up of areas after use. All waste will be disinfected prior to being autoclaved before disposal.

CU2 Project Title

Study of biology and invasion of Plasmodium falciparum

Class CultureVolClass2 CultureVolumeClass3-4

Class 3 < 1 Litre

Non-GMM Consent Granted

Yes

Project notified under transitional arrangements N

Withdrawn N

Tick if notifying a connected programme of work N

02/03/2022
Project Additional Information

Purposes of the contained use

1. The evaluation of biology and invasion properties of genetically modified P. falciparum
2. There is a low risk of the GM parasites being infectious for the operator, given the absence of the required vector
the only route of infection is via needlestick or similar penetrative injury. However, growth of the parasites to possible
high titres and use alongside wild type parasites directs the work to CL3.

Recipient or parental organism

Plasmodium falciparum (a variety of well characterised laboratory strains and lor recently derived clinical isolates
may be used).
E.coli will be used to construct and screen plasmids, and amplify them to produce quantities required for transfection.
E. coli and Pichia pastoris will also be used to generate recombinant proteins required for in vitro cellular or
biochemical work related to Plasmodium invasion.

Host/vector system

Vectors widely used to transform Plasmodium species may carry either the resistance marker human DHFR mutated
to encode resistance to WR9921 0 or Blasticidin S deaminase gene from Aspergillus terreus to confer resistance to
Blasticidin. These do not affect resistance to anti malarials chloroquine, mefloquine, artemisinin or doxycycline which
can be used (or their derivatives) to treat malarial infections.
Vectors (e.g. pGEX4T, pET28b) for E. coli or (pDUAL, pFASTBACK-HT) S. frugiperda transformation are standard
commerically available vectors encoding resistance to ampicillin or kanamycin for agar plate based selection. They
encode protein tags (such as HIS or GST) for fusion protein expression and purification.
In addition, amplification or synthesis of the genes of interest will be performed for cloning into the appropriate vectors
for propagation.
E.coli will be used to construct and screen plasmids, and amplify them to produce quantities required for transfection.
E. coli and Pichia pastoris will also be used to generate recombinant proteins required for in vitro cellular or
biochemical work related to Plasmodium invasion.

Origin & function
The backbone is P. falciparum

**Evaluation of foreseeable effects**

Parasites may be genetically manipulated in order to:
- i) Alter gene expression,
- ii) Alter translation i.e. protein knockdown,
- iii) Transiently express constructs,
- iv) Enable episomal expression of gene of interest (for complementation or overexpression),
- v) Reporter gene insertion for tagging of gene or protein (eg. fluorescence),
- vi) Gene knockout.

As result of these manipulations the ability to invade and grow in specific red blood cells may be altered. For example, overexpression of genes that are required for invasion could potentially lead to parasites with a better ability to infect selected human red blood cells in vitro. However, it is not expected to significantly increase risk as the proposed genetic modification will not be expected to change the routes of accidental infection (penetrative injury with infected blood) and in conjunction with existing control strategies this remains a very low likelihood event. The modifications are not expected to alter the response to the likely anti-malarial therapy used in the event of a laboratory acquired infection.

Genetic deletion, protein knockdown, and transcriptional inactivation or reduction will most-likely render the parasite less effective at invading host cells and as such will be less pathogenic than the wild type.

The proposed genetic manipulations are not expected to change the susceptibility of the parasite to anti-malaria drugs nor alter parasite biology with exception of the target genes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Inactivation methods currently used for P. falciparum will be applied to genetically modified parasites in accordance with the Code of Practice (B31 & FCS), NIBSC, and HSE regulations. There is no expectation of any change in the efficacy of methods as a result of genetic modification.

Routine inactivation of contaminated materials will be conducted by soaking in a beaker of 10% chloros overnight. The liquid waste can then be disposed of via the sink and the solid waste transferred to autoclave bags for exit via the autoclave route.

**Spillages:**

**Inside the hood**

In the event of a spillage inside the hood, the infectious material must be decontaminated with 70% IMS and mopped up with absorbent material. All absorbent material used to clean up any spillage is disposed of 10% chloros for decontamination overnight. The inside of the safety cabinet must be cleaned thoroughly with 70% Ethanol. Once the spillage is decontaminated a spray cleaner can be used to remove stubborn spots and stains.

**Outside the hood**

All users working in the lab at the time must be immediately made aware of the spillage so that it cannot pose a risk to them. The laboratory manager must be informed immediately. If the spillage is small, it may be diluted with 10% chloros and mopped up with absorbent material and then the area thoroughly cleaned with 70% ethanol. The spillage
must not be left unattended. If a large spillage occurs> 50 mis, the lab must be cleared of users, the laboratory manager informed and sufficient undiluted chloros should be added to inactivate the material. The spillage is contained with absorbent material and left overnight, mopped up and the area cleaned thoroughly with 70% ethanol.

Waste Management:
Routine inactivation of contaminated material is conducted by soaking in a beaker of 10% chlorus overnight. The liquid waste can then be disposed of via the sink and the solid waste transferred to autoclave bags for exit via the autoclave route.
Material for autoclaving is placed in autoclave bags enclosed within autoclave bins; a Browne's tube is placed in a glass universal or bijou in each bin. The bin is autoclaved at 1340 C for 30 minutes on a plastic discard cycle. The autoclave is operated by trained individuals only.
Evidence of effective steam penetration in each autoclave bin is ascertained by checking the Browne's Tube (redgreen colour change). evidence of effective steam penetration the contents of the bin can be disposed of. The autoclaved waste is then be removed and placed into the appropriate bag for disposal (clinical waste is incinerated by third-party contractors).
Laboratory gowns generally do not need to be placed in an autoclave bag within the bin unless known contamination has occurred. If contamination of laboratory gown is known to have occurred then swabbing with absorbent material soaked in 70% IMS will be conducted prior to autoclave.

Please enter comments on the GM safety committee on the risk assessment
The NIBSC Biological Safety sub-Committee reviewed the GM assessment on 19 August 2016. The BSO had made comments prior to this meeting in consultation with the Project Assessor. The Committee was content that the assessment had considered hazards and risks and that the proposed control measures and containment were appropriate for the activity.

Project Additional Information

Purposes of the contained use
To investigate the functions of herpesvirus gene products in virus replication and pathogenesis.

Recipient or parental organism
Adenovirus 5, Amphotropic retrovirus, Vaccinia virus: coding sequences derived from mammalian alpha or beta herpesviruses.

Herpes simplex virus, Human cytomegalovirus: ‘reporter genes’ (eg LacZ, firefly luciferase, green fluorescent protein).

Host/vector system
Eukaryotic viruses (ACDP group 2)/mammalian cell lines (established, commercially available).

Origin & function
Origins: Sequences will be sub-cloned from pre-existing plasmid clones. In some instances herpes virus sequences will be isolated from purified viral DNA.

Functions: The biological properties of herpes virus genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the location and trafficking of herpes virus proteins, or to provide helper functions for disabled herpesviruses. ‘Reporter genes’ will be inserted into herpesvirus genomes to inactivate specific virus genes and to identify the resulting disabled or attenuated viruses.

Evaluation of foreseeable effects
The insertion of ‘reporter genes’ into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

Herpesvirus genes act in concert to achieve virus replication. Some of the gene products are known to be cytotoxic but these are not secreted and only the expressing cell is expected to be affected. Mammalian alpha and beta herpes viruses are not oncogenic and transforming genes have not been identified in these viruses. Herpesvirus gene function is, however not fully understood and some herpesvirus genes are known to evade or modify host immune responses. The eukaryotic vectors used are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing herpesvirus genes is foreseen (see detailed risk assessment).

The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard validated methods will be used:

Liquids: made 2000ppm available chlorine (5% chloros) and disposed via drains after a minimum of 12 hours.

Mixed disposable waste: Validated autoclave, 121 degrees/30 min, then disposed as domestic waste.

Disposable pipettes: Either a) as for mixed disposable waste or b) immerse in solution of 2000ppm available chlorine (5% chloros) for minimum 12 hours, followed by incineration.

Re-usable materials: Autoclave, 121 degrees/30 min.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

I had forgotten to inform you that the local ACGM committee had reviewed and approved the 6 applications.

### Project Additional Information

#### Purposes of the contained use

Adenovirus vectors (Ad5, E1-E3-) encoding Cre recombinase and/or marker genes will be obtained from a commercial source and used to transduce mouse cells in culture in order to delete specific genes.

#### Recipient or parental organism

Primary cells from lab mice: no risk.

#### Host/vector system

Adenovirus vector is itself of no risk as the essential E1 gene is deleted so it cannot replicate. However, homologous recombination in helper cells during production can recreate a low level of replication-competent adenovirus (Ad5, wild-type except for E3 gene deletion; the transgene would be lost), for which the manufacturer can only specify an upper limit of 1 in 10^4 particles. Adenovirus is a mild human respiratory pathogen.
Cre recombinase (for excising genetically tagged genes); Green Fluorescent Protein; beta-Galactosidase (for labelling cells). All non-hazardous.

**Evaluation of foreseeable effects**

The GMOs are not expected to give any effects on human health nor on the environment. The only risk is from possible low levels of replication-competent wild-type adenovirus, which is a mild human respiratory pathogen. The only risk is from the original vector stock as Ad5 cannot replicate in mouse cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Treatment of liquid and plastic waste with 2% Distel or Virkon for 1hr; surface wipe down with 70% ethanol; UV exposure, waste disposal via autoclave. Effectively 100% kill.

**Project Containment**

</tbody>
</table>
The purpose of the project is to understand the movements and interactions of bacteria and immune cells during infection in a zebrafish model.

Recipient or parental organism

Pseudomonas aeruginosa (PAO1, PA14, PAK) and Pseudomonas alcaligenes. This is an opportunistic category 2 human respiratory pathogen. Immunocompromised individuals, individuals with lung disease (e.g. cystic fibrosis) are susceptible to infection. Otherwise healthy individuals come into contact day-to-day with this pathogen without any problem and disease development. Salmonella enterica serovar Typhimurium (ATCC SL1344, NTCC 12023, SL1027). This is an opportunistic category 2 human pathogen and Gram-negative bacterium that is a common source of food poisoning. Staphylococcus aureus (ATCC SL1344, NTCC 12023, SL1027). This is a gram-positive coccal bacterium. S. aureus bacteria are frequently found in the nose, respiratory tract and on the skin. Although S. aureus is not always pathogenic, it is a common cause of skin infections such as abscesses, respiratory infections and food poisoning.

Host/vector system

Plasmids (non-mobilisable PUC or pBR322 derivatives, pGEM-T), phages (P22, Φ11)

Origin & function

We will use mutants that are well characterised and with similar or attenuated virulence and we will use strains in
which a fluorescent protein has been inserted for visualising the bacteria by confocal microscopy. The expression of a fluorescent protein does not increase the virulence of the bacteria.

**Evaluation of foreseeable effects**

The GMOs are not expected to have increased virulence but will carry all the risks associated with the wild type strains which are hazard group 2 pathogens. Therefore appropriate containment measures will be taken, described in detail in the attached risk assessment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste and cultures will be disinfected with 1% Virkon (or equivalent commercial agent) for several hours (according to the manufacturer Virkon is proven to inactivate all these pathogens and many more within a minimum of 10 minutes). Virkon is preferable over bleach due to the fact that it is much less toxic and safe to handle. It also has a built-in dye indicator of biological activity of the target sample. Solid waste will be collected in appropriate collection bins for biological waste and then will be autoclaved and incinerated. Expected degree of killing is 100%

**Is an emergency plan required according to regulation 20?**

N

**Please enter comments on the GM safety committee on the risk assessment**

The risk assessment has been reviewed by a biological safety committee of the PDN Department and a biological safety committee of the Pathology department. Several experts on these pathogens have provided their input and judged that the proposed containment is appropriate for the work. A room has been provided for this type of containment level (CL2) work in the Department of Physiology, Development and Neuroscience. While awaiting establishment of this room, the work will be temporarily carried out in the Department of Pathology in established CL2 rooms with the supervision of experienced staff.

### Project Additional Information

**Purposes of the contained use**

Our laboratory aims to understand the biology of neurodegenerative diseases such as tauopathy and Huntington's disease. To this end we need to be able to study potential modifier genes for these diseases by knockdown and overexpression. To study genetic modifiers, we must introduce DNA or RNA into the mature tissue. In order to get efficient distribution of DNA or RNA into the CNS and retina, we need to use lentivirus to allow the DNA/RNA to be stably expressed within the tissue. The lentiviral vector (carrying the transgene of interest), integrates into the genome of the cell of the host and is therefore stably expressed for the lifetime of that cell. The virus cannot be shed by the cell and therefore cannot spread or be released and therefore there is no transmission risk to other organisms.

**Recipient or parental organism**

Lentivirus particles will be injected into zebrafish (Danio rerio) larvae, therefore zebrafish larvae are the final recipient. Injected larvae will be culled following injection therefore no progeny will be produced and there will not be any germine integration of the integrated DNA/RNA.
In order to generate lentiviral particles, we will work under GM678/12.2. Mammalian 293T cells will be transfected with a three plasmid system where virus replicative, packaging and envelope functions are split over three plasmids and virus particles will be purified for subsequent delivery into the recipient (zebrafish larvae).

**Origin & function**

cDNA or RNA for genes encoding the following will be delivered by lentivirus:

**Health and Safety Executive**

a) cDNA or guide RNA for genes encoding potential modifiers of neurodegenerative disease and related conditions, including forms of tauopathy, Huntington's disease and other dementias to study their affect on disease progression
b) cDNA or guide RNA for genes encoding potential modifiers of autophagy to study their effect on disease progression
c) markers and reporters derived from fluorescent proteins to label intracellular components and monitor them in vivo

**Evaluation of foreseeable effects**

a) Genetic modifiers of neurodegenerative diseases
The expression of genes involved in neurodegenerative diseases may be cytotoxic to the cells which integrate lentivirus (i.e. neuronal cells in the host zebrafish tissue) as these genes are expected to modify (i.e. ameliorate or exacerbate) late onset neurodegenerative diseases (i.e. host may be a wildtype or a genetically modified zebrafish that has a neurodegenerative phenotype). The spread of the virus is limited to the cells in vicinity to the site of injection. It has been shown in rodents that 1 μL injected volume spreads approximately 1-2 mm in brain (Parr-Brownlie et al., 2015), therefore by extrapolation, we would expect that 100 nL volumes used in our study would typically spread 100 - 200 μm in the host tissue. The recipient zebrafish larvae will be culled within 10 days of lentiviral injection for post-mortem analysis.

b) Autophagy modulators and c) reporters
The action of the expressed proteins or guide RNAs which modulate autophagy is unlikely to be cytotoxic in wildtype cells and the fluorescent reporter constructs are expected to be biologically inert. None of the genes to be used are known oncogenes and are therefore extremely unlikely to foster tumour progression. The expression of any of these genes, even in the long term, in a minor population of cells at the likely sites of exposure is unlikely to be harmful and expression would not spread beyond exposed tissues.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The virus cannot replicate and does not spread from the host cell to other cells. It is not possible for the virus to escape into the environment to affect animals or plants. The recipient zebrafish larvae will be culled at the end of the experiment and will be kept in the containment level 2 room in an environmentally controlled incubator for the duration of the experiment. They will not be returned to the animal facility and will not be used to generate offspring. All equipment will be treated with Virkon after use and solid waste material (e.g. disposable plasticware, gloves) will be incinerated.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None applied for

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All disposable labware (e.g. disposable plasticware, gloves) will be autoclaved and incinerated. Liquid waste will be
treated with 1% virkon. Permanent laboratory equipment (e.g. hood, microscope, incubator, bench surfaces) will be wiped with 70% ethanol at the end of experimental work.

This risk assessment has been reviewed and approved by the GM safety committee for the Department of Physiology, Development and Neuroscience and been approved by the Biological Safety Officer of the School of Biological Science. A suitable room available to carry out this work.

The maximum culture volume that could be released at any one time is 10 L.

Waste Disposal

Liquid cultures: 10% hypochlorite is added to give a final concentration of approximately 1% and the solutions are left to stand for a minimum of 2 hrs before disposal. Experiments have shown this is much greater than the time and concentration required to kill the bacteria we use.

Solid waste is placed in sterilin bags and autoclaved. Each bag is numbered and the disposal recorded. Browns tubes in the centre of the autoclave load are used to check for satisfactory autoclave conditions.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
This risk assessment covers a connected programme of work that encompasses the research of the Centre for Reproductive Biology (MRC Human Reproductive Sciences Unit and University of Edinburgh Department of Reproductive and Developmental Sciences).

Introduction

Reproduction encompasses many physiological and molecular processes. These include transcription, mRNA stability, translation and post-translational control. Second messenger signalling utilising G-protein coupled receptors and hormones. Biosynthesis and secretion of hormones or growth factors from highly specialised endocrine regulated tissues or gametes requires regulated synthesis and release and the interplay of numerous factors.

The aim is to manipulate the genetic material of reproductive tissues, organs and relevant cell-lines to create models that will be used to research reproduction and reproductive processes. Genetic material will be obtained from tissues and organs that impact on reproduction these including; testes, ovary, prostate, pituitary, hypothalamus, uterus and breast. Experiments will investigate what impact removing and adding back genetic information will have on the eventual reproductive phenotype. To achieve this, experiments will be conducted in vitro on cultured cell-lines, and in vivo on specified animal models using genetically modified viruses. These will either be self-inactivating non-replicating viruses that integrate into the host DNA, or attenuated adenoviruses that do not integrate. However, the proposed lentivirus...
Vectors carry a woodchuck post-translational response element (WPRE) as part of the vector backbone and this element is thought to be inherently oncogenic due to the presence of a sequence that expresses the WHV X protein. Injection of lentivirus with the WPRE into mice caused liver tumours. This suggests that the vector backbone is inherently oncogenic, before it is manipulated to express genetic material.

The particular focus of Herpes simplex virus type 1 (HSV-1) and human cytomegalovirus (HCMV) will be used to study the mechanisms whereby these viruses interact with the infected host cell with the aim of investigating regulation of translation, which is particularly important in gametes. These studies will focus, in particular, on the regulation of viral messenger RNA translation by the host protein synthesis machinery and the role therein of essential viral regulatory proteins and their interactions with host cell factors. These studies will be carried out by infecting cultured cells with both wild type virus and genetically modified virus in which relevant viral genes have been partially or completely inactivated. Some mutant virus will carry foreign DNA sequences encoding beta-galactosidase and green fluorescent protein (GFP) and its derivatives, either to replace viral genes or as fusions to viral genes as a tool to monitor their expression. Infected cells will subsequently be lysed in detergent, thus inactivating the virus, and processed for biochemical and molecular biological analysis.

### Recipient or parental organism

**Bacteria:** E coli K12 (disabled)

**Primary cells:** derived from humans, mouse, rat and sheep

**Immortalised cell-lines:** HEK293 cells and derivatives BHK, HeLa, Vero cell lines (for HSV-1) HFF2 cell lines (for HCMV)

**Animal models:** Sheep, marmoset, rat, and mice.

### Host/vector system

**Retrovirus:** gag/pol = vector 1; Env = vector 2;

Delivery and cloning vector either VSV-G or MoMLV = vector 3

**Lentivirus:** gag/pol = vector 1 (containing WPRE); Rev = vector 2

Delivery and cloning vector VSV-G = vector 3

**Adenovirus:** shuttle vector containing gene of interest and adenovirus backbone

### Genetic material will either be synthetic (PCR amplification product) or derived by cloning of cDNA or genomic material from a reproductively relevant tissue. Thus these genes will be targeted to specialised endocrine regulated tissues to assume full effect. A wide spectrum of material is being investigated, including known oncogenes e.g. c-myc and growth factors e.g. activin subunits

Some HSV-1 and HCMV modified virus will encode beta-galactosidase and green fluorescent protein as reporter proteins to monitor expression of viral genes in infected cultured cells. These sequences and their products are not associated with any health and safety risk.

### Functions being investigated include; apoptosis, cell growth, cell differentiation, cellular transformation and cell communication focusing on reproductive processes, virus host interaction focusing on viral lytic cycle and post-translational regulation.

### Evaluation of foreseeable effects

E coli K12 and cell-lines are non-harmful and are unable to survive unless held in lab conditions.

Once packaged the virus particles (adeno, lent, HSV and CMV) will be capable of infecting a number of different species, including human. The GM viruses will be less fit than wild type virus, thus production of wild type virus either deliberately (HSV type 1, see below) or by recombination of the E1a gene from the HEK293 cell genome into the adenoviral genome will produce fitter virus. Stocks of adenovirus will not be repeatedly passaged to counteract the production of wild type, which is likely to occur 1 in 1x10e10.

Adverse effects for retroviruses have been reported from gene therapy trials where large numbers of virus (1x10e11) have been specifically infected into cells, selected for genomic integration using antibiotics then the proviral carrying cells injected into the immune compromised recipient. These individuals were initially immune-compromised, so it is unlikely this would happen in healthy individuals even if exposed to high titres (1x10e9/ml) since the virus would have to be injected directly into the blood stream and then viral integration would have to be specifically selected for.

If viral infection does occur then adverse effects are likely to be low. The viruses self-inactivate once integrated into the genome, and cannot re-activate due to deletion of...
the U3 in the 3'LTR. Thus even if infected with wild-type virus, eg an individual was carrying a latent HIV infection then the provirus cannot mobilise and propagate the vector or the inserted genetic material. Although activation of genes adjacent to the integration site is possible as discussed above, this cannot be propagated into a clonal population and instead the infected cells are likely to slough off in the respiratory tract and eye. Percutaneous injection of virus is possible, but this would require injection of large amounts of high titre virus. Since it is anticipated that viral titres will not exceed $1 \times 10^{6}$ per ml then the likelihood of large scale integration and oncogenic activation of cellular genes is low. Insertion of oncogenes into these viral vectors poses an additional risk since expression of these will be driven from constitutively active promoters. Adenovirus infection is most likely to occur by inhalation but again in immune competent individuals this is unlikely to generate a persistent infection, instead cells will be sloughed off.

All activities required for propagation of virus will be done wearing gloves and the production of aerosols will be minimised wherever possible and use of sharps and glassware will be avoided or minimised wherever possible. When producing high titre virus preparations eye protection will be worn. HSV-1 is a common human pathogen for which infection occurs by direct contact with skin or eyes. Worldwide, greater than 40% of the population is seropositive for HSV-1. Accidental infection in the laboratory can occur by splashes of infected material to a mucosal surface or by viral entry through broken skin. Except in immuno-compromised individuals, HSV-1 infection is limited to epithelial cells, in the order of several million, at the infection site, resulting in the appearance of fluid filled vesicles (cold sores) and to the sensory ganglia that innervate the site. Infection of sensory ganglia leads to a life-long latent infection which is asymptomatic. Reactivation, usually triggered by cellular stress, can occur, whereby the virus travels from the ganglia to the site of primary infection and again productively infects several million cells. Herpes infections of the eye are associated with keratoconjunctivitis and repeated recurrences can lead to scarring of the cornea. In very rare cases, approximately one in a million, herpes infection can lead to encephalitis, which if untreated, has a mortality of greater than 70% and most survivors are neurologically impaired. Herpetic whitlow is an infection caused by herpes simplex virus that affects health care workers. The source of infection is generally thought to be damaged cuticle or skin exposed to HSV infected secretions. This results in a short period of symptomatic infection and the establishment of latency. In the laboratory single acute dose exposure by accidental percutaneous injury could result in herpetic whitlow. Antiviral agents for HSV-1 are acyclovir (Zovirax), valacyclovir and famcyclovir.

HCMV is common in the population (in excess of 40% seropositive worldwide). Infection after birth is usually asymptomatic but sometimes a syndrome resembling infectious mononucleosis or glandular fever is caused by the virus. After initial infection the virus establishes a lifelong asymptomatic latent infection primarily in peripheral blood leukocytes. HCMV infection can lead to serious illness or death in immuno-compromised individuals and transplacental transmission during pregnancy can lead to severe neurological damage or death of the foetus. Infection in the laboratory could occur by exposure of cutaneous or mucosal surfaces to infected material or exposure by percutaneous injury. The antiviral agent gancyclovir reduces or interrupts viral replication in vivo. All activities involving viral stocks and infected cell culture will be carried out in a biological safety cabinet whilst wearing gloves and avoiding the use of sharps and glassware. Genetically modified HSV and HCMV viruses, depending on the nature of the modified gene and the severity of the mutation, will have either wild type or reduced infectivity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All GM modified animals are housed in purpose built barrier containment facilities. These facilities are kept locked and are kept secure by restricted digital swipe card access. In addition these key facilities are restricted for general access by non-essential personnel.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM WASTE DISPOSAL

Apart from following the normal waste disposal procedures currently in practice within the building, the following rules must be observed:

(a) All solid and sealed liquid waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] should be placed in a metal autoclave container lined with either a clear or blue plastic bag. The autoclave is regularly tested, and disposal of GM material via autoclaving, in a tested autoclave, meets the requirements of the GMO (2000) legislation. Autoclaving effectively gives 100% degree of kill and is validated annually. Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment, or disinfect with 10,000ppm available chlorine (Presept tablet: sodium dichloroisocyanurate, or Virkon at an equivalent concentration) for a minimum of 30 minutes in line with guidelines previously provided by the manufacturer.
Disinfection - the concentrations and contact times used for disinfection have been shown to result in > 5 log reduction in virus titres (sodium hypochlorite - Croughan and Behbehani 1988 J. Clinical Microbiol 26, 213-215, Virkon - manufacturers data) and a 1% solution of Virkon disinfectant with a contact time of at least 20 mins gives a >99.999% kill of all viruses (data supplied by manufacturer). Discharge any resulting liquids to drains, dispose of solids via clinical waste stream for heat treatment. After autoclaving all waste MUST be placed in an ORANGE bag, and disposed of via the normal clinical waste stream.

(b) Glassware must be decontaminated by soaking in 1% w/v Virkon or 1000ppm Presept [four 0.5g tablets per one liter or four 2.5g tablets per five litres] for 1 hour before being rinsed and placed in the glasswash bucket provided for subsequent incorporation into the general washing process. Uncontaminated broken glassware should be disposed of in the glass waste containers supplied. Empty gas canisters should only be placed in the labeled bin. GM contaminated broken glassware and sharps should be placed in a sharps bin (eg needles, syringes, scalpels etc) and then autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via clinical waste stream for heat treatment.

(c) Large volume, contaminated liquids must be rendered safe by the addition of Presept tablets to a final concentration of [1000ppm], which is 10,000ppm available chlorine (Presept tablet: sodium dichloroisocyanurate, or Virkon at an equivalent concentration) for a minimum of 30 minutes in line with guidelines previously provided by the manufacturer, then discharged to drains. Liquids (eg samples, culture supernatants, tissue culture media etc) can also be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Please enter comments on the GM safety committee on the risk assessment

Staff representative UofE: asked for additional explanation to be inserted into introduction detailing why lentivirus carrying a woodchuck promoter response element (WPRE) is designated as GM level 2.

Staff representative MRC: Wanted clear listing of recipients/hosts especially primary cell-lines. Asked for clarification on containment of aerosols? Agreed to insert clause stating that protective eyeware will be worn at the bench and that all virus to be used at the bench will be aliquoted into screw cap tubes to demarcate them as GM level 2.

UofE Biological Safety Officer: What measures will be put in place to protect pregnant workers and workers with long-term health problems that may also be immuno-compromised? It was agreed that the existing GM competency form will have clauses inserted to state the risks and workers will be asked to sign these before commencing work.

QMRI Safety advisor: Requested that the waste disposal measures included clear statements on use of sharps and the autoclave cycle used.

**Project Additional Information**
Purposes of the contained use

To judge expression of transgenes from constructed viral vectors in primary and established cell lines.

Recipient or parental organism

Human and rodent primary cells.

Host/vector system

replication deficient adenovirus,
replication deficient strain of equine infectious anaemia virus (lentivirus)

Origin & function

Transcriptional factors and similar markers are involved in ontogeny. When expressed in the correct temporal manner during cellular development they direct differentiation.

EGFP (enhanced Green Fluorescent Protein), and improved variant of GFP which was originally isolated from Aequorea victoria, - a jellyfish. This protein has no biological effect other than fluorescing when illuminated.

Evaluation of foreseeable effects

There are no recorded cases of human or rodent infection by equine infectious anaemia virus (EIAV).

EIA vectors are designed to be replication defective. In EIAV vector system the envelope packaging component is the VSV-G protein, derived vesicular stomatitis virus (a rhabdovirus).

The VSV-G sequence has no homology with the vector genome or gag/pol construct, making formation of a replication competent virus by recombination very unlikely.

Since VSV-G pseudo-typing of EIAV retroviral core particles allows their entry into human cells, the EIA vector systems should be classified as class 2.

The adenovirus family (Adenoviridae, genus Mastadenovirus) is divided into specific subgroups. We shall employ proviral DNA from replication deficient Adenovirus (serotype 5, group DE1/DE3), under the control of the cytomegalovirus -1-E promoter/enhancer (CMV). This group (DE1/DE3) of adenovirus is completely non-pathogenic.

In the adenovirus vector system a packaging cell line expressing the E1 protein in trans is required. Since adenovirus vectors retain their ability to enter human cells, the adenovirus vector system should be classified as class 2.

The systems have been designed to permit entry to human cells. The replication deficiency will ensure no systemic infection could occur in an exposed individual however local change cannot be eliminated in the event of direct contact. This will be controlled by use of gloves and good microbiological practice at containment level 2.

The inserts are not harmful.

Primary human and rodent cells and transformed human cells do not survive well in the environment.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

100% kill by autoclave. The autoclave is maintained on contract and each load is monitored by thermocouple. Charts are inspected for deviation from normal. Aberrant behaviour would initiate investigation and re-autoclaving. At monthly intervals the continuing efficacy of the system is checked with thermalog devices within waste sacks.

When cool, autoclaved culture liquid is discharged via the laboratory drain. Solid waste in sacks is removed from the laboratory area and compacted prior to collection by an approved WasteContractor
The committee are informed that full level 2 containment will be required and this is appropriate for culture of primary human cells. The cells are derived from normal healthy individuals and tested for absence of HIV and HepB/C. The GM alterations do not substantially alter the risk of harm from modified cells.

Meeting 5 September
The main element of risk is with the virus (vectors). EIAV, Equine infectious anaemia is not pathogenic to humans but is level 2 on account of environmental hazard. Adenovirus produces non symptomatic infection in human and is also assigned to level 2. Both viruses have been specifically disabled.

There is no risk of oncogenic hazard on local injection. The transcription factors only have effect in suitable target cell populations. General contact, such as with muscle or skin & other epithelial cells, would have no effect for these cells are already differentiated.

The two assessments are linked for HSE notification for which the current fee is 440. The project in future may include other differentiated target cell types.

### Project Additional Information

**Purposes of the contained use**
- To generate replication defective adenoviral vectors.
- To use the adenoviral vectors to transduce target cells.
- To assess the expression of transgenes from the constructed adenoviral vectors in primary and established cell lines.

**Recipient or parental organism**
- Bone marrow stromal cells of human origin.
- Primary cardiomyocytes, neurons, bone marrow cells, hepatocytes, kidney cells and fibroblasts of rodent origin.
- Various laboratory cell lines such as HeLa, CHO, HEK293 etc.

**Host/vector system**
- Replication defective adenovirus.

**Origin & function**
- The transcription factors Nkx2.5 and GATA4 are involved in directing the development of stem cells. When expressed in the correct temporal manner during cellular development they direct differentiation into cardiac cells.
- They would not be expected to exert an effect on adult cells (fully differentiated cells).
- The promoter regions of MHC, ApoA2, and the NFB response elements are DNA sequences. These would not be expected to exert an effect on adult cells.
- GFP (and variants that have been developed to improve fluorescence characteristics) has been isolated from a jellyfish. The protein fluoresces when illuminated with light of an appropriate wavelength. The protein has no known adverse biological effects and is therefore not expected to exert an effect on adult cells.
- MAPKAP is a protein involved in a signal transduction pathway. There is no published data to suggest that overexpression of this protein (eg. as under transcriptional control of the CMV major IE promoter) will exert any adverse effects on adult cells.

**Evaluation of foreseeable effects**
- The adenovirus family (Adenoviridae, genus Mastadenovirus) is divided into specific subgroups. We shall employ proviral DNA from replication deficient Adenovirus (serotype 5, group DE1/DE3), under the control of the cytomegalovirus - 1-E promoter/enhancer (CMV). This group (DE1/DE3) of adenovirus is completely non-pathogenic. In the adenovirus vector system a packaging cell line expressing the E1 protein in trans is required. Since adenovirus vectors retain their ability to enter human cells, the adenovirus vector system should be classified as class 2.
- In generating the recombinant adenovirus vectors there is a remote possibility of generating replication competent adenovirus (RCA). This occurs as a result of...
recombination between the E1 expressed in trans from the packaging cell line and the E1 deleted virus. Continued expansion of the recombinant virus increases the incidence of RCA. To avoid the generation of RCA and to limit the occurrence of RCA, viral stocks will be generated from the first expansion virus.

The replication deficient adenovirus system has been designed to permit entry to human cells. The replication deficiency will ensure no systemic infection could occur in an exposed individual however local change cannot be eliminated in the event of direct contact. This will be controlled by use of gloves and good microbiological practice at containment level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Additional Information

Purposes of the contained use

Re-identification of an assay test system component with object of either:
continuing with use of this component in an assay if it a non-bioactive fragment of E7 (in which case the assessment will revert to class 1, low risk without notification requirement) or
if it is a full length oncogenic E7, to use the component for a limited time while the assay is run in parallel with a substitute to ensure continuity/overlap of the data sets.

Recipient or parental organism

E.coli TG1

A disabled host of the K12 family, unable to survive in the human gut. Requires thiamine to grow.

F' traD36 lacLq(lacZ)M15 proA+B/supE (hsdM-mcrB)5 (rk-mk+McrB-

Host/vector system

E. coli TG1 and pGEX-4T-1, (GenBank Accession No. U13853

Origin & function

Data available indicates the genetic material involved, a GST-E7 fusion, was chosen as a positive control in a QA procedure because it was conveniently at hand during development (in a USA lab) 1993.
It is probable that it is an E7 fragment which would be considered unlikely to cause harm. We currently do not have evidence for this.
An alternative (GST fusion) has already been tried in the assay with poor assay results.

E7 is the oncogenic Human Papillomavirus protein.

Evaluation of foreseeable effects
Delivery of whole E7 is unlikely even if it is present. If it did via inoculation there is low probability of transformation at site of injection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please enter comments on the GM safety committee on the risk assessment
May 02
Project is to grow and establish sequence of this insert. If it is a fragment of E7 then production will continue to use it because it is not harmful to humans or environment. If it is a full E7 then production will use it for a limited time (6 months) while an alternative low risk GST fusion is sourced and proven in the required tests.

/initial comment on circulation to GM Committee
1. As written this assessment should be a containment level 2. Both the Brenner classification and the containment for a potentially oncogenic expressed protein would indicate 2.
2. If the construct is for QC of antiGST antibody, why is this being done on a fusion with a potentially oncogenic protein? Is this just one of a panel of fusion proteins being used? Many other GST fusions with biologically safe proteins must be available. We probably have some being made in one of our current project - let me know if you would like a contact name.

22 July 2002 Committee comments.
The incorporation of the oncogenic papilloma virus E7 protein into the GST fusion (if indeed present - as the purpose of the proposal is to establish whether or not a functional E7 is present) raised the Damage Factor on the Brenner scale, and the GM Class from 1 to 2. This assessment was provisionally approved as GM Class 2 pending a decision as to whether or not to proceed. Alternatives may be acceptable.
Action: MF to advise
Action: CL (Bioassays rep.) to provide budget code for 480 fee to HSE if notification for GM Class 2 process is to proceed.

November 02
Alternative fusion which was tried has given poor results. Notification (to HSE) is now required to enable growth of the original to provide DNA sample for analysis and for use to provide continuity of data.

Project Additional Information

Purposes of the contained use

Research into the discovery of novel antiviral agents with activity against drug resistant strains of HBV.

Recipient or parental organism

HBV DNA will be modified by the introduction of mutations in the pol gene and cloned in E. coli. The mutations introduced will be those known to occur in vivo after treatment of HBV positive patients with nucleoside analogues. The mutated DNA will be transfected into hepatoma cell lines and infectious genetically modified HBV produced.
Host/vector system

(i) HBV DNA will be cloned into pBluescript (Stratagene) and amplified in E. Coli JM109;
(ii) Alternatively pCMVHBV (pBR322) will be used.

Origin & function

HBV DNA will be obtained from either (i) human sera; (ii) virions produced by 2.2.15 cells (HepG2 cells transfected with HBV DNA); or (iii) pCMV HBV (obtained from Dr C Seegers, Fox Chase Cancer Centre, USA), Genetically modified HBV DNA will be used to assess the sensitivity of drug resistant HBV to novel antiviral agents.

Evaluation of foreseeable effects

The only foreseeable effect when hepatoma cells are transfected with the genetically modified HBV DNA will be the secretion of infectious HBV with resistance to various drugs used for the treatment of HBV infected individuals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

I am requesting that the following measures need not be applied under Schedule 8 Part II:

Containment Measure 8 - Autoclave, required in laboratory suite

Justification -
* All waste is chemically disinfected with a chlorine disinfectant prior to it leaving the containment area.
* The autoclave used for sterilising the waste produced from the above project is sited in the same corridor and within 2 metres of the laboratory exit.
* The waste is transported in sealed bags within robust boxes.
* The person/s transporting the waste will be a member of the laboratory staff and have been specifically trained for this task. The person/s concerned will be familiar with the Code of Practice and will have been deemed competent by the Head of Division.
* The waste will always be placed straight into the autoclave and the run commenced straightaway.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

* Liquid wastes will be treated with a solution of 2500 parts per million available chlorine. The resultant solution will be left to stand overnight. This is a well recognised and standard method of disposal and approaching 100% kill is expected.
* Solid waste will be autoclaved using a cycle of 130 degrees C for 15 minutes. Again this is a standard method of disposal and 100% kill is expected.
* Solid waste is sent for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The Committee have reviewed this project and endorse the Classification of 3 and approve it for work at Containment level 3.

**Purposes of the contained use**

To understand how manipulation of the host immune response can be used to regulate viral infection for both therapeutic options and or potentially vaccination.

**Recipient or parental organism**

The recipient strains will be A549 human lung adenocarcinoma cell lines that stably express the IFN promotor fused to GFP, classified as class I containment material by ATCC.
Host/vector system

Recombinant parainfluenza type 5 virus, PIV5 (formerly known as simian virus 5 SV5)), a non-segmented negative strand RNA virus (Paramyxovirus family) whose genome encodes eight viral proteins.

Origin & function

This PIV5 is a recombinant virus that lacks the V protein C-terminal specific domain, referred to as PIV5ΔC (He et al., 2002, Virology. 303: 15-32). It is well documented that the V protein plays an essential role in evasion of the host immune response (specifically by blocking the production and subsequent signalling of type I interferons (IFN-α/β)).

The recombinant PIV5ΔC is therefore unable to disrupt the IFN pathway like its wild type counterpart and is unable to target STAT1 for degradation, or prevent nuclear localisation of the key transcription factor IRF3 and thereby prevent the release of IFNβ.

Evaluation of foreseeable effects

PIV5 is known to infect a range of cell types including primary human cells. Indeed, there has been no report of a cell line that is resistant to PIV5 infection. Importantly, PIV5 causes very little cytopathic effect in infected cells. PIV5 also infects most mammals including humans and is not associated with any clinical disease with the exception of canine kennel cough. The recombinant genetically modified version of this wild type virus, PIV5ΔC as mentioned above, has been disabled in its ability to disrupt the host cell's cellular defence, but it cannot be guaranteed that this will have the same safety profile as the wild type PIV5. Based on the known safety profile of the wild type PIV5, there should be no adverse effects on human health or the environment. The Advisory Committee on Dangerous Pathogens, does not list parainfluenza virus type 5, only parainfluenza virus types 1-4 which are classified as containment 2 microorganisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste arising from conditioned tissue culture medium will be deactivated in freshly prepared Chloros solution, 10000ppm for at least 30 minutes, prior to disposal via the drains. Solid waste such as plastic consumables, dishes etc will be disposed in a dedicated double-bagged bin for the collection of waste from containment 2 work only. This will subsequently be autoclaved prior to disposal. There will be no use of sharps in any of the experimental manipulations.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The Committee were pleased that the applicant was taking an over cautious view. They endorsed the risk assessment and approved the project for work at Containment 2

Project Containment

02/03/2022
The use of lentivirus for transfection of hard-to-transfect mammalian cells

Establishment of transfected cells lines for use in validation assays of therapeutic antibodies.

The production of packaged lentivirus will be carried out in the HEK 293FT cell line from Invitrogen and only differs from the widely used HEK 293T cell line by its fast growth. The T refers to the expression of the SV40 large T antigen, which has shown to be beneficial for generating the lentivirus. The produced virus can infect primary cells, but is not capable of reproduction.

The recipient cell line of recombinant genes will primarily be the human NK cell line NK92 (CRL-2407) available from ATCC but it will also be beneficial to use other hard-to-transfect cell lines used in therapeutic antibody characterisation studies.
NK-92 is an interleukin-2 (IL-2) dependent Natural Killer Cell line derived from peripheral blood mononuclear cells from a 50 year old Caucasian male with rapidly progressive non-Hodgkin's lymphoma. The cell line is dependent on the presence of recombinant IL-2 and a dose as low as 10 U/ml is sufficient to maintain proliferation; cells will die within 72 hours in the absence of IL-2. The cell line is cytotoxic to a wide range of malignant cells; it kills both K562 cells and Daudi cells in chromium release assays.

Host/vector system

pLenti vectors contain the following features:

- Rous Sarcoma Virus (RSV) enhancer/promoter for Tat-independent production of viral mRNA in the producer cell line (Dull et al., 1998)
- Modified HIV-1 5’ and 3’ Long Terminal Repeats (LTR) for viral packaging and reverse transcription of the viral mRNA (Dull et al., 1998; Luciw, 1996) Note: The U3 region of the 3’ LTR is deleted (U3) and facilities self-inactivation of the 5’ LTR after transduction to enhance the biosafety of the vector (Dul et al., 1998)
- HIV-1 psi (Ψ) packaging sequence for viral packaging (Luciw, 1996) HIV Rev response element (RRE) for Rev-dependent nuclear export of unspliced viral mRNA (Kjems et al., 1991; Malim et al., 1989)
- Polypurine Tract from HIV (cPPT) for increased viral titer (Park et al., 2001)
- Human cytomegalovirus (CMV immediate early enhancer/promoter for high-level constitutive expression of the gene of interest in a wide range of mammalian cells (Anderson et al., 1989; Boshart et al., 1985; Nelson et al., 1987)

Origin & function

The genes will be intact or fragments of: human kinases, transcription factors and receptor genes and soluble secreted proteins and plasma membrane proteins that when expressed in mammalian cells will alter cell physiology and signalling pathways; and/or are potential therapeutic targets in human disease. Furthermore, genes can be introduced into mammalian cells to re-establish a function that potentially was lost during cell line formation, but otherwise part of the wildtype cell line's natural repertoire - such as introduction of CD16 expression in the NK92 cell line. This creates a functional cell line for antibody-dependent cellular cytoxicity assays for characterisation of therapeutic antibodies.

None of the genes are oncogenes and this work will not produce toxic agents or oncogenes. These genes will change according to the project needs and new drug targets taken on by MRCT. In the future, other genes are also envisaged to used, however these proteins will be limited to those that have the same safety and risk profile as those outlined above. If the latter does not apply, then a new risk assessment will be made.

Evaluation of foreseeable effects

The most potentially hazardous GMO will be the recombinant lentivirus, which can transduce primary human cells. Transmission can occur by penetration of the skin via puncture or absorption through skin lesions and by mucous membrane exposure of the eyes, nose and the mouth. However, the genetically modified recipient cell lines will not be able to produce replicating lentivirus and neither will primary human cells, so any transmission will be limited to the initial site of infection. The virus will not carry oncogenes or toxic genes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work with the lentivirus will be carried out in containment level 2 laminar flow hood. Sealed centrifuge rotors and/or safety cups will be used for centrifugation of samples to minimise the contamination risk. All liquid waste will be treated with 10% bleach or SuperQ for at least 30 min to inactivate the virus. Solid waste such as disposable plastic consumables will be soaked in 10% bleach before autoclaving and being disposed as other autoclaved waste. Surfaces will be cleaned with Super Q which will also inactivate the lentivirus. There will be no use of sharps in any of the experimental manipulations.
The Biological Safety Committee approved the project at Class 2 for work at Containment 2.

Please enter comments on the GM safety committee on the risk assessment.

Project Additional Information

Purposes of the contained use
The primary aim of the project is to overexpress functionality active mammalian proteins that are required in sufficient quantities for high throughput screening of compound libraries and for monitoring the optimization of chemical inhibitors that have been synthesized for the purposes of drug discovery.

Recipient or parental organism
Replication-disabled adenovirus serotype 5 (ad5).

Host/vector system
Hosts
1. E. coli
2. Human embryonic kidney cell line HEK293
3. Human cervical carcinoma cell line (HeLa cells)

Origin & function
Vector system
pAd/CMV/V5-DEST and pAd/PL DEST (Invitrogen,"ViraPower")

Evaluation of foreseeable effects
PMCA1, PMCA2, PMCA3 and PMCA4: PMCA is a calcium pump located at the plasma membrane. We will use human isoforms of PMCA1, 2, 3 and 4. There is no published data to indicate that PMCAs have any cytotoxic effect. GCaMP2: is a GFP based calcium sensor which will fluoresce when it binds calcium. Luciferase: is an enzyme that emits light originally isolated from firefly Photinus pyralis. It is used as a "reporter" for the activity of any regulatory elements that control its expression. Green fluorescent protein (GFP): is a protein that exhibits bright green fluorescence when exposed to blue light and is originally isolated from the jellyfish Aequorea victoris. It is also used as an "expression reporter". None of the proposed genes are known to be oncogenic. There are no foreseeable effects. With respect to the potential hazard arising from the unlikely accidental transduction of the specific gene of interest to man, the adenovirus does not integrate into the host and cannot replicate. Since the virus is replication-incompetent, the presence of the viral genome and gene of interest is transient and will eventually be diluted out as cell division occurs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
Project Additional Information

Purposes of the contained use

The primary aim of the project is to facilitate the transduction of mammalian cell lines that are very difficult to transfect and obtain stable and high expression with the gene of interest by standard transfection procedures such as lipid-based or electroporation methods. The resulting genetically modified cells lines will be used in functional studies for therapeutic antibody generation.

Recipient or parental organism

The cell line to be used to produce the viral particles is the human HEK293T and the cells to be transduced by them are a variety of immortalized mammalian lines which are not considered hazardous to human health, before or after contact with the virus. OriGene’s overexpression lentiviral vector is a 3rd generation lentiviral vectors with improved biosafety. These safety features are the following:

- The pLenti expression vector is replication deficient as it contains SIN (Self Inactivation), a deletion in the 3’ LTR (6.U3). This SIN deletion does not affect lentiviral packaging, yet results in ~ self-inactivation” after integration into the transduced cell. The integrated lentiviral genome is no longer capable of self-replication.
- The number of genes from HIV-1 that are used in the 3rd generation lenti system has been reduced to three (Le. gag, pol, and rev). TAT, an essential gene for viral replication is eliminated.
- A constitutive promoter (RSV promoter) has been placed upstream of the 5’ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA.
- The packing plasmids (Gag, pol, rev and VSV-G) supporting lentiviral packaging are separated onto three plasmids; none of them contain LTRs or the 4’ packaging sequence.
- Only the lenti vector for gene overexpression contains the packaging signal that can be packaged into viral particles.
- The VSV-G gene from Vesicular Stomatitis Virus is used as the pseudo-envelope, further reducing the chances of recombination with viral genome.

Despite the safety features discussed, the lentiviruses produced with OriGene’s lenti system can still pose some biohazardous risk since it can transduce primary human cells. It is highly recommend that lentiviral stocks are treated and generated using this system as Biosafety Level 2 (BL-2) organisms and strictly follow all published BL-2 guidelines with proper waste decontamination.

Host/vector system

Host: mammalian cell lines (to express the protein of interest), including HEK 293T that will also be used to produce the viral packaging.

Vectors: - pLenti-C-mGFP, allowing the identification of infected cells by fluorescence microscopy.
- Lenti-vpak packaging plasmids mentioned above.

Origin & function

The genetic material to be expressed will include Human and Murine anaplastic lymphoma receptor tyrosine kinase (ALK) genes that were purchased from OriGene. This receptor plays an important role in the development of the brain and exerts its effects on specific neurons in the nervous system. This gene has been found to be rearranged, mutated, or amplified in a series of tumours including anaplastic large cell lymphomas, neuroblastoma, and non-small cell lung cancer. The chromosomal rearrangements are the most common genetic alterations in this gene, which
result in creation of multiple fusion genes in lumourigenesis, including ALK (chromosome 2)/EML4 (chromosome 2), ALKIRANBP2 (chromosome 2), ALKIATIC (chromosome 2), ALKTFFG (chromosome 3), ALKINPM1 (chromosome 5), ALKISQSTM1 (chromosome 5), ALKIKIF5B (chromosome 10), ALKICLTC (chromosome 17), ALKITPM4 (chromosome 19), and ALKIMSN (chromosome X). Wild type ALK and truncated ALK have not been described as oncogenic and only the full length wild type gene truncations thereof will be used to produce viral particles.

Evaluation of foreseeable effects

The mammalian cell lines are established long term lines and can be regarded as Class 1. The final GMO cell lines will contain stably integrated ONA copies of the lentiviral vectors encoding the gene of interest but will not have infectious viruses, therefore posing no hazard to human health or the environment. There is no risk of the infection spreading to the community via human-human contact. The packaged virus is unstable in the general environment and lentiviruses are rendered replication deficient. In lentivirus, the risk of reversion to the wild type is virtually non-existent as the lentivirus lacks four structural genes that reside on non-homologous plasmids in the packaging line. Furthermore, the experimental vectors lack a wild type 3' LTR that is essential for efficient viral replication. The recombinant genes to be expressed from the viral vectors are potential oncogenes, possibly contributing to excess proliferation and prolonging the life of damaged or mutant cells. In addition, lentiviral transduction leads to the stable integration of the virus into the host cell's genome. Therefore there is a very small but identifiable risk to an infected individual of long term alteration of gene expression. However only cells that come in direct contact with the packaged virus could become infected and, as tumourigenesis is recognised to require multiple events (e.g. further mutations in growth pathways), it is unlikely that a single viral infection will result in the formation of a tumour. Viral vectors are engineered to transfer and integrate specific DNA sequences into the genomes of target cells and are designed to be replication-defective to avoid further spread after the initial transfer even.

The route of transmission to deliver lentiviruses is through airways and eyes. The laboratory worker is thus under risk from aerosols and through sharp injury during handling. Exposure to skin, eyes and lungs would be minimal as gloves and protective clothing are used at all times, no sharps are used and all work will be carried out in a Containment Level 2 laboratory and cellular infections in a Class II Microbiological Safety Cabinet or in closed centrifuge systems. The modified viruses should not pose a serious risk as they are inactivated by detergent, UV light and ethanol. The half-life of the virus is 6-9hrs in tissue culture media at 37 °C, it is unknown how long it would survive in the environment. Any residual virus on tissue culture plastics, solid waste and liquid waste is inactivated by use of appropriate disinfectants. MSCs are located in specified rooms designated as Containment Level 2 laboratories and only competent and trained operators would carry out these procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste disposal
All handling of the virus will be carried out in containment level 2. There will be no glassware, blades, needles or sharps used in work involving lentivirus particles. It is advisable to have a container filled with a suitable decontamination liquid in the safety cabinet, with which to
rinse pipettes, pipettes' tips and small plastic containers before disposing of them into the waste container, so to minimize the risk of contamination to the worker when taking them out of the safety cabinet. The method of choice for sterilization is to autoclave the waste material. Used material awaiting sterilization must be stored in a safe and secure manner. Waste must be stored in autoclave bags (blue) and in the robust boxes provided. These boxes must be clearly labelled with the date, room number and Containment 2, and left securely closed on the corridor to be taken to be autoclaved.
Waste for incineration must be placed into either a sharps bin where appropriate, or packed into double yellow bags. Both containers must be labelled with the room number of origin and the date and Containment 2, the bags should be left in an appropriate location where a stores porter can pick them up for incineration. All waste produced must be autoclaved.
Care must be taken to ensure that the bags are not overloaded causing them to split. Similarly care must be taken to ensure that items which are liable protrude through plastic bags e.g. pipettes, are packed properly so that they do not cause a hazard to staff and others.
For general applications the recommended disinfectant is a chlorine based one i.e. Presept. The use of other disinfectants must be justified prior to use.
For routine decontamination.
• Liquid waste inactivated with Chlorine based disinfectant e.g. Presept - 10,000 ppm available changed daily and stock made up weekly.
• Decontamination with Presept 2,500 ppm followed by washing with a suitable detergent.
• For routine washing of benches, MSC, etc., a solution of 1 % Super Q should be used.
Adequate contact time must always be allowed for effective disinfection.
For spillages and accidents
Minor spillages: Presept solution @ 2,500ppm available chlorine

**Project Additional Information**
### Purposes of the contained use

Generation of HIV-1 infectious virus or virus products from plasmids carrying HIV-1 genome sequences. The clones will undergo genetic modification resulting in, for example, the generation of virus resistant to known HIV inhibitors, or the incorporation of markers. The resultant viruses will be used to develop "in vitro" screens for novel anti-HIV compounds. The virus resistant mutations already exist "in vivo" and are not novel mutations.

### Recipient or parental organism

Plasmids containing HIV-1 genome (potentially full sequence)

### Host/vector system

### Origin & function

The HIV clones obtained through the NIH AIDS reagent Programme Repository or equivalent contributors, will be genetically modified using standard molecular biological techniques. The HIV DNA will be transfected into established human cell lines to generate replication competent virus or express virus products.

### Evaluation of foreseeable effects

The GMO will result in products which are of equal hazard status to, or less hazardous than, the wild type and/or its products. Any modifications which confer resistance to licensed anti-HIV therapeutics are identical to those which occur naturally in treated individuals.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Destrict autoclaving (134 degrees C 30 Cat2, 126 degrees C 50 Cat3) of all waste prior to incineration. All liquid waste to be sealed in plastic containers and placed into designated waste bins. Pipettes, tips, culture plates disinfected in chloros (Cat2) or Cidex (prior to autoclaving).

Is an emergency plan required according to regulation 20? **N**

If yes, tick to confirm that it is attached to this form **N**

Tick to confirm that you have attached a risk assessment to this form **Y**

Tick if you are claiming exemption from disclosure for section of the risk assessment **N**

**Other(s)**

For activities involving GMMs, describe the waste management measures which will apply to the activity

Treatment of contaminated waste is by autoclaving at 121 degrees C, 1.2 bar for a minimum of 15 minutes.

The autoclaves are inspected twice yearly, one being a full function test including a twelve point thermocouple test with each of the appropriate disposal loads.

Regarding volumes for disposal: The largest volume of O/N cultures would be in the region of 720 ml (72 x 10 ml).

Generate improved Avian Pneumovirus (APV) vaccines by introducing rational changes using infectious clone technology.

Current commercial vaccines have been created randomly by serial passage of field virus isolates in cell culture. The mutations generated appear to be reversible. These vaccines have been shown to lead to disease in commercial poultry, almost certainly as a result of their reversion back to the parent type virus.

The aim of this project is to introduce attenuating mutations using reverse genetics/infectious clone technology. It is anticipated that stable vaccines, incapable of reversion will be generated. This will be by either:
- incorporation of several attenuating motifs (identified from studying existing vaccines and their progenitors)
- deletion of genes demonstrated to attenuate another similar pneumovirus (Respiratory syncytial virus).

Candidate vaccines will be tested in turkeys in the Leahurst Poultry Isolation Unit.

Avian pneumovirus is in common circulation in commercial poultry, game birds and probably other unidentified avian species. In experimental conditions, APV has been shown to infect only a minority or avian species. Infection of a range of birds (turkeys, chickene, ducks, geese, pheasants, guineafowl and pigeons) resulted in virus only being isolated from the first two (Gough 1988). Experimental infection of the most susceptible avian species known (turkeys) causes mild, non-fatal respiratory disease. Infection in chickens is frequently asymptomatic and game birds infected with APV do not show disease. Wild seagulls have also been found to be seropositive for the virus but disease has not been observed. It is thought likely that other wild birds may be infected but no significant studies have been carried out.

Because of its low pathogenicity, APV is considered to be a category 1 organism (though not yet formally classified). Field strains are treated at this level of containment in UK laboratories (IAH Compton, CVL Weybridge, Intervet Cambs. Vet. Path Liverpool University) and similar laboratories abroad.

With APV infection in commercial turkeys farms, the virus can predispose to secondary pathogens and there can be serious economic losses. With commercial chickens farms disease is rarely seen but reduced weight gain and egg laying statistics suggest that a sub clinical infection probably occurs.

APV is a labile enveloped virus which has a short life in the environment outside of an avian host. Turkeys placed in a room vacated of infected birds did not become infected. It can be demonstrated to transmit to other birds in close contact in experimental conditions. Bird to bird contact has been shown to be the most successful method of virus transfer between birds but aerosol transmission by infected respiratory droplets probably also plays a part. The initial 1980's APV outbreak which spread rapidly from East Anglia to Wales, against the prevailing wind suggests that direct contact with personnel and vehicles to be the main mode of transmission. This is supported by the fact that a key hatchery in southern Scotland which has avoided such contact still remains free of the disease, 15 years later.

The virus itself is being attenuated hence no host is involved.

The virus itself is being attenuated hence no host is involved.

Origin: APV field virus.
Function of modified organism: vaccination of turkeys and chickens against disease caused by APV.
Evaluation of foreseeable effects

The initial work will produce a virus of identical sequence to the field strain and it will therefore have exactly the characteristics of that strain and hence present identical risks.

The modified viruses (the candidate vaccines) would either show reduced pathogenicity or remain unaltered. This has proved the case with similar reverse genetics work with other members of the Paramyxoviridae (e.g. RSV, NDV, Rinderpest). Any viable viruses resulting have all shown reduced or unaltered pathogenicity. Tropism stayed the same or become more restricted.

The risks to the environment would be expected to be the same or less than those encountered when making and testing conventional live attenuated APV vaccines and less than when using field strains (as used routinely in all vaccine challenge models). The changes introduced will either remove virulence factors or introduce attenuating mutations (as identified by sequencing existing conventional live vaccines and their progenitors). In contrast, the conventional live vaccines in general use and produced by random mutations, would be likely to introduce larger unknown changes. However, such changes have never been observed.

APV causes an acute respiratory infection and has never been shown to or suspected of causing persistent infections. In experimental conditions, turkeys remain infected for a short period (approximately 1 week) and it appears likely to be of advantage to the virus to produce maximal disease and virus shedding within that period. Rapid generation of high viral titres and maximum virulence are likely to be the infection characteristics most likely to give the virus a selection advantage. Hence, it is likely that current field strains are close to the maximum potential virulence of the organism. Certainly, viruses randomly mutated during conventional vaccine development have never been found to increase virulence - rather, they have become less virulent or virulence has remained unchanged.

It is likely that vaccines are even less fit to survive in the environment than wild-type strains. Conventional vaccine studies employing molecular biological diagnostics have indicated that live vaccines do not persist in the environment. During long term studies on UK turkeys farms, vaccine was only detected after it has been applied to the actual groups of birds, whereas field strains were found to cycle routinely. It is assumed that this reflects the vaccine's reduced fitness compared to better adapted field strains, in general circulation in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

AVP is labile envelope virus which is not stable in the environment outside of a host. Mild agents such as 70% ethanol readily inactive the virus.

LABORATORY
All manipulations and culture work will be contained within laboratory 1.10. Generated viruses may be moved in sealed containers to en-suite freezer facilities for storage.

Manipulations will be performed in purpose installed class 2 cabinet. Areas within the cabinet will be wiped down routinely with Virkon after use.

All infected materials will be transferred to autoclave bags which will be contained within lock top polyethylene bins. The combination will prevent spillage or penetration in the event collision. The combination will be moved to the en-suite autoclave where bags will be transferred and treated.

ISOLATION UNIT
Birds will be vaccinated with the GMO then 3 weeks later challenged with field virus to test vaccine efficacy.
The unit contains 8 poultry rooms. Entry to the unit is via a locked door into a robing area where full overalls, head covering and gloves are put on. Boots are dipped in FAM disinfectant. After robing a central corridor is entered and from here there is access to each poultry room via its own anti room. Exhaust air is from each poultry room is HEPA filtered. Footbaths containing FAM disinfectant for boot dipping are in the corridor and inside the entrance of each anti room. Overalls, head coverings and gloves are discarded into FAM disinfectant after use, while still within the outer secure area.

Rooms and anti rooms will be disinfected by Virkon spay before and after each experiment.

Poultry and litter will be bagged and incinerated after each experiment. Both are almost certainly NOT infectious by the experiment finish but, in any event, persisting virus would be wild type field virus (not the GMO).

Drains within poultry areas are sealed for the duration of the experiment and until disinfection has occurred.

Is an emergency plan required according to regulation 20?

Project Additional Information

**Purposes of the contained use**
To investigate putative virulence homologues of FHV with a view to improve the safety and efficacy of vaccines

**Recipient or parental organism**
FHV is a respiratory pathogen of cats not known to infect non-felids.
FHV in which putative virulence homologues have been deleted is expected to show an attenuated phenotype.

**Host/vector system**
FHV/gfp

**Origin & function**
The gfp expression cassette to be inserted has been obtained by PCR from the commercially available vector pEGFP-N1 (Clontech UK Ltd).
GFP is a marker protein that fluoresces green and is being used to allow the identification and selection of recombinant FHVs.

**Evaluation of foreseeable effects**
Recipient micro-organism FHV is not listed in ACDP hazard groups 2, 3, or 4. Any recombination (unlikely) would only result in reversion to wild type phenotype. There are no known hazards associated with the inserted gene product and its expression (personal communication, Clontech, attached). GFP has been widely used as a marker in many infectious systems and no harmful effect has ever been demonstrated following insertion of this gene. Deletions of putative virulence homologues or other alpha-herpesviruses have resulted in attenuation of the virus and as FHV is not infective for humans it is highly unlikely that the GMM would be infective for humans.
No aspect of the proposed work require specific control measures to safeguard human health. FHV only survives up to 24 hours in the environment and is highly susceptible to standard disinfectants. FHV with specific deletions in putative virulence homologues would be expected to be attenuated relative to wild type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
none applied for
All laboratory waste is placed in autoclave bags and transported to the autoclave in lidded buckets. Waste is autoclaved at a temperature of 121°C for 20 minutes. The autoclave is routinely monitored and maintained according to the guidelines laid down by the insurers. After autoclaving, the waste bags are secured in yellow clinical waste sacks and placed in the refrigerated container designated for such waste awaiting collection by the University contractor, for ultimate incineration.

Non-GMM  

Consent Granted  

Date Project Ceased 02/03/2022  

Page 5896 of 1532
**Project Additional Information**

**Purposes of the contained use**
To study cellular immune responses in individuals infected with HIV.

**Recipient or parental organism**
Vaccinia virus containing one of the following genes: HIV-1, gag, env, pol, nef; influenza; nucleoprotein, matrix protein, pol; papilloma virus (HPV16 and 18) E6 and E7 fusion protein -- the E6 and E7 proteins have oncogenic properties. Transformation requires E7 to bind to retinoblastoma protein. To remove oncogenic potential the E7 protein is mutated at two amino acid residues to abolish binding to retinoblastoma protein. There is no evidence in the literature that modification of the vaccinia increases its pathogenicity.

**Host/vector system**
Vector: vaccina virus
Host cell: TK 143, a thymidine kinase negative cell line.

**Origin & function**
Inserted genes: HIV-1 gag, env, pol, nef, influenza matrix, nucleoprotein, pol Papilloma virus types 16 and 18 E6 fused to a mutated E7 protein.

The genes will be transfected into human dendritic cells to facilitate antigen presentation to stimulate virus specific cytotoxic T cells.

**Evaluation of foreseeable effects**
Accidental exposure to the vaccinia modified vector may result in the generation of an immune response to the product of the inserted gene. No other clinical outcome would be expected as a result of the modification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (plastics): 2% Virkon overnight. The manufacturer specifies that this will give 100% kill. The decontaminated waste will be then autoclaved prior to disposal via the Chelsea and Westminster Hospital waste disposal services.

Liquid waste: via autoclave, 134 degrees centigrade applied including air extraction, heating and steaming for 30 minutes. The manufacturer specifies that this will give 100% kill. Indicator strips to be used to monitor every autoclave run. Regular six monthly servicing and testing of the autoclave by the manufacturer.

The principal investigator to monitor staff to ensure correct disposal routine is followed.

Is an emergency plan required according to regulation 20?

Project Ref 275/04.1

Date Ackn’d 11/06/2004  
CU2 Project Title Immunity to Kaposis Sarcoma Herpes Virus (KSHV)

Class 2  
CultureVolClass2 < 1 Litre  
Consent Granted  
Non-GMM Not Applicable
**Project Additional Information**

**Purposes of the contained use**

To study cellular immune responses to KSHV in healthy immunocompetent individuals and in individuals infected with HIV.

**Recipient or parental organism**

KSHV containing a Green Fluorescence protein (GFP) insert. The modified KSHV genome contains an insert of GFP (expressed by the elongation 1-alpha promoter) and the neo gene (expressed by the RSV promoter). This construct was inserted through homologous recombination between ORF 57 and ORF 59 of the KSHV genome (Gao et al, J. Virol 2001.75: 1378-1386). The recombinant KSHV has been designated as rKSHV:152. There is no evidence that the modification of the KSHV increases virulence or pathogenicity.

**Host/vector system**

Vector: KSHV
Host cells: BCBL-1, a human primary effusion lymphoma cell line containing wild type KSHV.

**Origin & function**

Inserted gene: GFP derived from Jellyfish.

GFP will be used to detect recombinant KSHV infection in a range of mammalian cell types including endothelial cells, fibroblasts, lymphocytes and myeloid cells.

Infected cells will be used as targets for KSHV specific NK cell and T-cell responses.

**Evaluation of foreseeable effects**

KSHV infection does not result in pathogenic effects in healthy individuals. This virus can lead to the establishment of tumors in HIV-1 patients.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Maximum volume produced at any one time - 500 ml bacterial culture, dozen or so petri dishes containing transformed plant material.

Disposal methods: Liquid culture through autoclaving on cycle designed for decontaminating liquid loads (130 degrees C, 20 minutes), plant material in petri dishes through autoclaving on cycle designed for decontaminating agar plates (130 degrees C, 30 minutes).

Liquid load (sealed glass) discard. Air is removed from the chamber by progressive dilution with steam in a series of negative pulses, followed by a pre-sterilising stage (steam admission) to achieve load temperature of 130 degrees C. The sterilising stage is 130 degrees C for 20 minutes.

Agar plate (plastic) discard. Air is removed from chamber by progressive dilution with steam in a series of negative and positive pulsing, followed by pre-sterilising stage (steam admission) to achieve load temperature of 130 degrees C. The sterilising stage is 130 degrees C for 30 minutes.

In both cycles the timer starts when the temperature controller fed by the load probe senses the sterilising temperature.

Monitoring: Each load is recorded (chart recorder) via a temperature probe.

Validation: Annual testing and certification of the cycles using thermocouples (performed by external service engineers).

Project Ref 277/08.1

Generation and use of lentiviral vectors to investigate the role of proteins associated with various psychiatric and neurological disorders such as Schizophrenia, Alzheimer's Disease and Depression.

Date Ackn'd 12/06/2008

Date Project Ceased 24/08/2020

Withdrawn N

Tick if notifying a connected programme of work N

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 1-50 Litres

Consent Granted Not Applicable

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

The purpose of the study is to use a lentiviral vector system to express reporter genes or overexpress/knockdown specific genes or proteins thought to play a role in psychiatric and neurological disorders, in rodent primary neuronal cultures, cultured cell lines or rodent brain slice preparations.

Recipient or parental organism

HEK 293T cells will be used to propagate the virus
Target cells to be infected include:
Neuronal (e.g. SH-SY5Y, NG1 08-1 5) or non-neuronal (e.g. CHO) Hazard Group 1 cell lines
Rodent primary neuronal cultures and rodent brain slice preparations
Primary human cells will not be used

Host/vector system

Only lentiviral delivery systems that are replication deficient with a history of safe laboratory use will be used. Most commercially available lentiviral packaging system are at least 3rd generation versions and utilise split-genes to separate structural and other components required for packaging onto several plasmids. This reduces the risk of generating replication-competent lentivirus because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Some examples of these plasmids are shown below.

Vectors for packaging genes:
pVSVG, pLPNSVG, pDelta8.9, pLP1 and pLP2, ViraPower packaging mix (Invitrogen), Lenti-X HT Packaging Mix (Clontech)
Vector for inserting genes/shRNA of interest:
pLKO.1 (Sigma), pLenti (Invitrogen), Lenti-XTM Tel-On Advanced and Lenti-X Tet-Off Advanced (Clontech)

Origin & function

Human and rodent cDNAs encoding full-length or partial protein sequences known to be associated with psychiatric and neurological disorders or shRNA to knock down genes of interest associated with these disorders.
For example:
Phosphodiesterases — enzymes that hydrolyse the second messengers cAMP and cGMP thereby regulating the transcription of many genes
Tau I Tau kinases — Tau is a neuronal microtubule-associated protein that stabilises axonal microtubules. Phosphorylation of tau by kinases such as cdk5 and GSK-3f has been associated with Alzheimer’s disease.
The cDNAs may be tagged with reporter genes (e.g. EGFP).
Evaluation of foreseeable effects

The generation of lentivirus containing the gene of interest is the most hazardous part of the process with potential routes of exposure being through broken skin, self-inoculation and mucus membranes. The use of sharps, such as needles, will be prohibited whilst the use of a Class II biological safety cabinet will guard against exposure to aerosols.

The effect of any one of the genetic inserts mentioned above is likely to be minimal and would be confined to the local area of infection due to the replication deficiencies of the virus. However, there would be an increased risk of a recombination event if the individual were to be already infected with a wild-type lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (e.g. pipettes, flasks): Will be soaked overnight in disinfectant. Excess liquids will then be discharged to drain. The remaining solids will be transported from the laboratory area to the autoclave in sealed metal boxes on a trolley. Following autoclaving, residual waste will be placed in a sealed bin for incineration by external contractors. Liquids (e.g. medium wash-off): Will be treated with disinfectant overnight then disposed of to drain with running water.

Safety cabinets Will be wiped down with 70% ethanol! 1% SDS. The cabinets are serviced and containment checked every 6 months.

Degree of kill:
- Autoclave — effectively 100% kill. Autoclave is serviced and validated every 3 months
- Incineration — effectively 100% kill
- Chemical disinfection will be with 1% Virkon or 10% MicroSol 3Plus following the manufacturers’ instructions — from the manufacturers’ data sheets kill will be effectively 100%. This will be verified experimentally once Class 2 work commences.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was reviewed by the Erl Wood genetic modification safety committee on 8th May 2008. Appropriate amendments were made and the assessment was subsequently approved for submission to the HSE.

Laboratories.
1. Disabled bacteria
2. Recombinant viruses
3. Transfected cell lines - Disinfected by immersion, in Presept (hypochlorite) solution overnight or by autoclaving.
   Authentication of disinfection efficacy has been established or is under investigation by attempting to culture GMMs or similar preparations from disinfected material.

Maximum culture volumes of any culture a), b) or c) at any given time would be 5000 ml, but usually less than 2000 ml.

Animal waste:
1. Animals infected with GMMs are double-bagged and placed in sealed plastic containers for incineration.
2. Waste - solid faecal matter is scraped into sealable, leakproof container. The outside is sprayed with disinfectant. Disposal of by incineration as above.
4. Animal rooms - after removal of waste material - see point 2 above - rooms steamed as point 3 above and fumigated with formaldehyde after disinfectant wash.

Isolators
Waste to sealable, leakproof containers or via sealed drums to sealed pit then treated with sodium hypochlorite. Thoroughly cleaned/disinfected then formaldehyde fumigation.

Checks.
1. 5 temperature probes in steam steriliser, record temperatures reached during the process.
2. Regular validation checks.
3. Periodic checks to recover microorganisms (pre and post sterilisation process).
4. Tests to ascertain minimum temperature and time necessary to kill 100% of microorganisms under study.

Clinical Waste
1. Annual inspection of facilities of clinical waste disposal contractor.
2. Full records kept of all materials disposed of in this way.

**Project Ref** 291/03.1

- **Date Ackn'd**: 07/07/2003
- **CU2 Project Title**: USE OF RECOMBINANT VACCINIA VIRUSES AS VECTORS TO EXPRESS T CELL ANTIGENS AND OTHER VIRAL PROTEINS
- **Date Project Ceased**: 26/04/2005

**Project notified under transitional arrangements**

- **Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

- Project transferred to GM130 on 26/04/2005

---

**Project Additional Information**

---
Purposes of the contained use

Recombinant vaccinia viruses will be used for several purposes:
1. To immunise mice with recombinant antigens
2. To measure immunity against recombinant antigens.
3. To infect cells in vitro for the purpose of screening immune responses.
The antigens to be used represent non-functional proteins either of viral or mammalian origin.

Laboratory work involving recombinant vaccinia viruses will be carried out at ACGM Containment Level 2 with the use of a microbiological safety cabinet. In laboratory situations, sharps will not be used and workers will wear gloves at all times. In the case where animals will be inoculated with recombinant vaccinia viruses, virus will be delivered via the intraperitoneal, intravenous or subcutaneous routes. In all cases needles will be used. Workers involved in inoculation of animals will be trained to a high level to minimise the risk of needle-stick injuries. The highest inoculum used will be 10 million plaque forming units per mouse. Vaccinia virus infection does not spread within mouse or human communities. The virus does not cause persistent infection since it lyases cells upon infection. Infection with recombinant vaccinia virus may however lead to some blistering or scabbing during the acute phase of infection. Tissues recovered from infected animals will be manipulated within microbiological safety cabinets and animal carcasses will frozen and later disposed of by incineration.

Recipient or parental organism

The recombinant vaccinia viruses to be used have already been constructed through homologous recombination of plasmid DNA (pSC11) into the thymidine kinase gene of vaccinia virus (Western Reserve, WR). Inserted genomes encode for: 1) mouse melanocyte antigens; 2) the glycoprotein of murine leukaemia virus; 3) influenza antigens; 4) antigens from lymphocytic choriomeningitis virus and 5) non-functional murine proteins. A complete list is shown in Appendix 1. These inserted tenes pose no risk.
Indeed, insertion of these genes into vaccinia virus WR, reduces the virulence of the virus 10,000 x (Buller et al. 1985. Nature 317: 813).

Host/vector system

The recombinant vaccinia viruses to be used have already been constructed through homologous recombination of plasmid DNA (pSC11) into the thymidine kinase gene of vaccinia virus (Western Reserve, WR).

Origin & function

Inserted genes encode for: 1) mouse melanocyte antigens; 2) the glycoprotein of murine leukaemia virus; 3) influenza antigens; 4) antigens from lymphocytic choriomeningitis virus and 5) non-functional murine proteins. A complete list is shown in Appendix 1. These inserted tenes pose no risk. Indeed, insertion of these genes into vaccinia virus WR, reduces the virulence of the virus 10,000 x (Buller et al. 1985. Nature 317: 813).

Evaluation of foreseeable effects

Use of recombinant vaccinia viruses within the laboratory will be confined to a class II microbiological safety cabinet. In some situations it will be necessary to infect mice and therefore to transport viruses from the laboratory to the animal house. Vials containing vaccinia viruses will be transported from the laboratory to the animal house within sealed containers. The possibility of spillage from sealed containers is very unlikely. In the event that a spillage does occur, the spillage will be dealt with according to local rules at the University of Wales College of Medicine.

With regards to environmental risks, it is known that there was no colonisation of domestic or wild animals in the UK following widespread administration of vaccinia virus to humans in the smallpox eradication campaign, nor has the recombinant vaccinia virus that has been used to control rabies in part of Belgium and France led to colonisation of wild-species. There is no reason to believe that recombinant vaccinia viruses produced in this work are any more likely to survive and become established in the environment than the wild-type virus. Thus, taking into account the control measures assigned above, the overall risks to the environment from the modified organisms produced in this work are effectively zero. Therefore no additional containment or control measures are considered necessary to protect the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables including plasticware and pipettes will be autoclaved for at least 15 minutes at 121-130 degrees C. Subsequently autoclaved waste will be disposed of by incineration with other clinical waste. Liquid waste will be treated with Hycolin for 30 minutes prior to discharge to drains.

Animal bedding will be autoclaved and animal carcasses will be destroyed by incineration.

Degree of Kill:
Autooclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Additional detail required in environmental assessment - now added. Advice should be sought regarding avoidance of handling virus by persons with sensitive skin conditions, eg eczema. Agree with assessment as Class 2 activity requiring Containment Level 2 facilities.

**Project Additional Information**

**Purposes of the contained use**

Prion protein is a normal component of many of our cells (especially neurons) that has the unusual ability to change its conformation, either spontaneously or in response to genetic mutation or to prion infectious agent, to an amyloidogenic form that resists proteolysis, accumulates in the brain and appears to be capable by itself of propagating infection. While recent studies have been increasingly successful in replicating elements of this conformational conversion using recombinant prion protein modified in the test tube, no one has produced an infectious agent except within a living cell, suggesting that the full conversion from normal to infectious protein requires the action of some cellular process. The trafficking of prion protein from the cell surface into endosomes is a candidate for such a cellular process since the acidification that occurs in endosomes is used by other proteins (eg diphteria toxin) and viruses (eg 'flu) to change their conformation, enabling the latter types of agent to fuse with the membrane and enter the cell.

Curiously, there is not a strong correlation between the accumulation of this infectious form of protease-resistant prion protein, and neural degeneration. Recently it has...
become apparent that prion protein is capable, during its biosynthesis, of being incorporated into the membrane, not only by its major mechanism (linkage to the luminal surface of the endoplasmic reticulum by a glycosylphosphatidylinositol (GPI) anchor), but also by utilisation of an internal cryptic transmembrane sequence. The proportion of prion protein that is incorporated via this alternative route, which is increased by some mutations that in man predispose to familial CJD, has been found to correlate better with neurotoxicity than has the accumulation of amyloidogenic prion protein in fibrils.

The underlying cause of neurophathology and toxicity in each case is aberrant trafficking of prion protein. Similar faults in protein trafficking are increasingly becoming to be seen to cause other amyloid diseases such as Alzheimer's.

The purpose of the contained use is to enable us to mutate residues (or groups of residues) within normal mouse prion protein to enable us to study particular aspects of the trafficking of this protein, and in particular its translocation into the endoplasmic reticulum and its recycling between the cell surface and endosomal compartments. The mutations will be assessed firstly for their effect on the trafficking of the protein, either in transfected cell lines (N2a cells) or in simplified cell-free systems (microsomal or endosomal preparations); mutations that change trafficking characteristics will then be evaluated for their interaction with delivered mouse scrapie agent (from non-BSE derived strains).

Recipient or parental organism

The parental organism (original source of inserted cDNA was normal (non-infected) mouse brain.

The recipient organisms are:
1. XL2-Blue, derived from XL1-Blue, multiple auxotroph, classified as disabled or non-colonising (ACGM Compendium of Guidance, Part 2A, Annex II, Section 11).
2. N2a mouse neural cell line, maintained without harm or escape in many labs since its derivation in 1969.

Host/vector system

XL2 Blue/pCDNA for construction of expression vectors with mutated PrP
Mouse N2a neural cell line/pCDNA3/4 for expression of above in mammalian cells.

Origin & function

Mouse cDNA encoding normal mouse prion protein was derived originally from mouse brain library. Fragments of it will be subjected to PCR-based directed mutagenesis, which when confirmed by sequence will be incorporated into expression vectors (CDNA 3/4) along with an epitope or fluorescent protein tag (normally inserted after the signal sequence (amino acids 1-22), either immediately before aa 23; Lee et al (2001) J. Neurochem. 79: 79-87) or slightly more distally (after aa 42; Negro et al (2001) Mol. Cell. Neurosci. 17:521-38) where it appears not to perturb prion protein trafficking), for the following purposes:

1. Translocation of prion protein: individual amino acids will be altered to one with an expected functionally neutral character primarily within the signal sequence (amino acids 1-22), or the surrogate transmembrane sequence (aa's 100-136) or the GPI anchor (aa 231 ff). These alterations very the proportion of prion protein that is incorporated into the membrane via its standard means (GPI anchor) compared to its minor variations, as a type 1 or type II transmembrane protein (Kim et al, (2001) J. Biol. Chem 276: 26132-40; Stewart, R. S. et al (2001) Mol Biol. Cell 12: 881-9). These constructs incorporated as cDNA into expression vectors will primarily be transfected into N2a cell lines to allow cell fractionation followed by immunoaffinity purification to determine the chaperone associations of the proteins (Graham, C H Anderton, B A & Morris, R J (2001) submitted for publication) as they traffic between the biosynthetic compartments of the cells. Studies may also be done where these constructs are introduced into primary cultured neurons by microinjection or by chemically-assisted transfection (Ca 2+, Liptofectine etc), to allow comparison with real neurons. In addition, sense RNA may be transcribed using an RNA polymerase, capped and polyadenylated before being used in in vitro translation studies with microsomes (Kim et al (2001) J. Biol Chem 276: 26132-40).

2. Interaction of externally applied prion infectious agent with translocation of mutant prion protein at the endoplasmic reticulum. To determine whether and how exogenously applied prion infectious agent could alter the routing of prion protein as it is made on the ER, mouse scrapie-associated fibrils or whole homogenate of mouse scrapie-infected brain or cells will be added to cells expressing normal or mutant forms of prion protein (from step 1), and the proportion of protein translocated in the
transmembrane forms (and its subsequent fate) determined, with particular attention paid to any change in the chaperone proteins associated. It should be noted that here and in 4 below, long studied mouse strains of scrapie derived originally from sheep (ME7, Chandler) and not from bovine or human sources will be used.

3. Endocytic trafficking of mutant forms or prion protein. We have an existing CL2 approved project (GM295/01.2) for investigating the effect of mutations in the N-terminus (aa's 23-108) of prion protein upon the trafficking of prion protein from the cell surface to intracellular compartments; this application will extend this by using mutations within the C-terminal domain, primarily with the surrogate transmembrane domain and GPI anchor (as in 1 above).

4. Interaction of externally applied prion infectious agent with mutant prion protein. We have an existing CL2 approved project (GM295/01.3) for investigating the interaction of mouse scrapie agent with cells; this application will extend this by studying the interaction with cells bearing mutations in prion protein that affect the endocytic trafficking of this protein (as in 3 above).

**Evaluation of foreseeable effects**

It must be assumed that at least some of the mutations we produce will predispose the mouse prion protein to adopt an infectious or neurotoxic conformation. Regarding the infectious form, the amounts produced will be small, contained, and rigorously denatured by oxidants before disposal for incineration. Moreover, the point mutations involved will in no way break down the species barriers for transmission of the infection to either man or to cattle, so that any escape of the mutation should affect no more than any local mouse populations. Regarding the potential neurotoxicity of the transmembrane forms of prion protein, these are not protease resistant and will be broken down normally by our usual physiological barriers in the gut and skin (and by our containment and denaturation procedures). There is no reason to think there is any species barrier to the neurotoxicity, but equally the barriers to a foreign protein reaching a nerve in our body are formidable.

At the genetic level, in the regions that will be mutated the mouse sequence is either identical or very similar to the human sequence. CL3 level of containment, with accompanying SOPs (minimisation of aerosols, use of sharps etc) will ensure that escape of mutated sequences does not occur, but should, despite these precautions, cDNA encoding a mutant form of prion protein be injected into eg the finger of a researcher, and become translated into mutant protein, all the other prion protein in the body would remain human and non-mutated, so that any production of infectious prion should be restricted to the site of injection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Given the work involves mutant prion protein, all work will be done under containment level 3 conditions with the additional safeguards appropriate for working with mouse scrapie itself. Of these the most important are those for waste disposal, outlined below.

Liquid waste will be disinfected in 20,000 ppm active chlorine (as sodium hypochlorite) overnight before being washed down the drains with copious water. Solid waste will be double bagged for autoclaving (135 1 degree C, 18 min) prior to incineration.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid wastes: Double bag and autoclave at high vacuum, 135 1 degree C for 18 min (or, if not possible inactivate overnight with 20,000 ppm active chlorine then double bag), dispose by incineration as clinical waste.

Liquid waste: Inactivate with 20,000 ppm active chlorine in the form of sodium hypochlorite overnight, wash down drains with copious water.

For treatment of liquid wastes 20,000 ppm active chlorine is considered to be a completely effective procedure for inactivation of TSE agent; for solid waste, incineration is completely effective, the autoclaving will substantially reduce the titre of any agent (should it be produced) adding an extra level of security during the transport to the incinerator.

Monitoring is only applicable to the autoclave step, where we use Brown tubes within a load, and have a printed readout of each cycle; the autoclave is serviced annually. The ultimate form of the prion protein will be fragmented and highly oxidised carbon derivatives with no biological activity.
The Genetic Modifications Safety Committee of the MRC Centre for Developmental Neurobiology reviewed this application at its meeting of 13 December 2001. The Committee were satisfied that the steps taken to contain and dispose of the mutant mouse prion proteins and the constructs encoding it were sufficient and conformed fully to national guidelines and local needs. The staff involved have been fully consulted in drafting the Risk Assessment, and effective Standard Operating Procedures are in place. The Committee therefore accepted this application.

Historical Significant Changes: Transferred to GM386 on 08/09/2003
**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to enable us to pursue studies of primate lentiviral replication (that is, HIV-1, -2, and SIV) and of murine leukemia virus (MLV) without exposure of personnel or of the external environment to these pathogens. In addition, contained use will enable proper decontamination of the laboratory space and large equipment used for these studies.

HIV is the causative agent of Acquired Immunodeficiency Syndrome (AIDS). HIV-2 and SIV are related viruses that cause less severe disease in human being. MLV is a retrovirus with a tropism for a variety of mammalian cells.

**Recipient or parental organism**

A variety of immortalized cell lines will be utilised for these studies including:

- Human T lymphoid (Jurkat, CEM, SupT1, C8166, HUT78, H9)
- Human fibroblast (HeLa, 293T)
- African green monkey fibroblast (COS)
- Murine fibroblast (3T3, L)
- Murine Lymphoid (EL4, Timi)
- Quail fibroblast (QT6)

**Host/vector system**

HIV-1, -2, SIV or MLV viruses will be passaged in the immortalised cell lines mentioned above.

**Origin & function**

All immortalised cell lines and wildtype viral isolates are obtainable from the AIDS repository at the US National Institute of Health.

The genetic material involved is intended to aid in the investigation of viral protein function and the molecular mechanisms of viral assembly and infection. Generally, by removing regions of the viral genome, we can examine in what ways the virus life cycle is altered and thereby determine the role of the deleted region.

**Evaluation of foreseeable effects**

In comparison to wild type virus, all modified HIVs will have reduced pathogenicity as a consequence of disruption of essential viral sequences. Importantly, all such viruses will be maintained and used under category 3 conditions. All necessary precautions are being undertaken to prevent infection of workers or release from the containment 3 laboratory. Special attention has been paid to minimisation of aerosols and sharps. In the unlikely event of exposure of a worker to the virus, prophylactics and emergency procedures are on hand.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Given the work involves primate lentiviruses, all work will be done under containment level 3 conditions. Of these the most important are those for waste disposal, outlined below.

Liquid waste will be disinfected in 10% active chlorine (as sodium hypochlorite) overnight before being washed down the drains with copious water. Solid waste will be...
double bagged for autoclaving (135 1 degree C, 18 min) prior to incineration

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid wastes: Double bag and autoclave at high vacuum, 135 1 degree C for a minimum of 18 minutes. After autoclaving, waste is bagged in designated yellow bags, offloaded from the site as clinical waste and, ultimately, incinerated.

Liquid waste: Inactivate with 10% active chlorine in the form of sodium hypochlorite overnight, wash down drains with copious amounts of water.

For treatment of liquid wastes 10% active chlorine is considered to be a completely effective procedure for inactivation of retroviruses. For solid waste, autoclaving is completely effective.

Monitoring is only applicable to the autoclave step, where we use Brown tubes within a load, and have a printed readout of each cycle; the autoclave is serviced biannually.

**Project Additional Information**

**Purposes of the contained use**

The purpose of this activity is to study the intracellular signalling mechanisms that mediate the response of cells to growth factors and extracellular matrix molecules, including proliferation and migration, and thus play a role in the development of human cancers and in cellular differentiation.

**Recipient or parental organism**

(i) E. coli

(ii) murine cells (NIH3T3, and the NIH3T3 variants 293T, GP+E86, GP+EnvAm12)

(iii) human primary keratinocytes and carcinoma cell lines

(iv) monkey cells (COS-7)

**Host/vector system**

(i) Host: E. coli DH5a; Vector: pCEV27, pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr, pRcCMV, pC1, pGET-T, pPCR-Script

(ii) Host: GP+E86 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid

(iii) Host: GP+envAm12 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid

(iv) Host: Murine and human mesenchymal cells (osteoblasts, chondrocytes, fibroblasts, and adipocytes) either as established cell lines or primary cultures, as well as osteoclasts, osteoclast precursors, haematopoetic stem cells, and embryonic stem cells. Vector: pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr virus

(v) Host: NIH3T3 murine fibroblasts; Vector: pBABEneo/puro plasmid

(vi) Host: HNEK, H357, A431, HN12, HN4 & MCF7 human keratinocytes; Vector: pBABEneo/puro virus

(vii) Host: 293T cells; Vector: PINCO (modified from plasmid LZRSpBMN-Z).
Mouse and human cDNAs encoding signalling intermediates, cell cycle control genes, and AP-1 transcription factors, as well as novel cloned target genes, will be obtained by PCR, or excised from existing plasmid vectors, subcloned into viral plasmids, and used to produce amphotropic/ecotropic viruses as a means of expressing them in the target cells (see above). The intended function is to investigate growth factor and extracellular matrix-dependent signalling pathways that regulate cellular differentiation, proliferation and motility, all of which are key aspects of cancer development.

Evaluation of foreseeable effects

The vectors to be used in these studies are replication-defective recombinant retroviruses, and have been well characterised and extensively used (Morgenstern & Land, Nucl Acids Res 18: 3587, 1990; Gasperi et al., Journal of Leukocyte Biology 66: 263-267, 1999). They are non-mobilisable in mammalian cells, and are rapidly inactivated by serum. The cell lines (GP+E86 and GP+envAm12 are third generation packaging cell lines, and have been specifically constructed to prevent recombination events between introduced constructs and endogenous viral structural sequences. Investigators using this system have not observed production of any replication-competent virus (RCV) (Markowitz et al., Virology 167: 400, 1988). The recipient cell lines are free of helper virus, and transduction of these lines with replication-defective viruses will not generate RCV. In spite of these findings, assays to detect RCV will be carried out as a matter of course. Thus, although the vectors will be packaged with ecotropic and amphotropic envelopes, and could conceivably infect rodent (ecotropic) and human cells (amphotropic), such viruses would be incapable of replication. Furthermore, these viruses are unstable at ambient temperatures, with a half-life of around 2 hours. Some of the gene products encoded by cDNAs cloned into these vectors have oncogenic potential. Therefore, the assessment is that work with both ecotropic and amphotropic viruses will be carried out at level 2. The containment level and procedures proposed for the study, together with the inherent safety of the packaging systems, will make the environmental risk effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach (Haztabs; 1 tablet per litre = 2,500 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines which are extremely liable. In addition, the retroviruses and cell lines have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed, and placed within and autoclaved in a closed metal container. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136 degrees C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services, the use of autoclave indicator tape (which measures a temperature of 134 degrees C for 3 minutes) during every run. Autoclaved waste will then be incinerated by White Rose.
The GMSC accepted the risk assessments for these projects.

### Project Additional Information

The purpose of this activity is to characterise the molecular function of regulatory molecules during craniofacial and limb development; how aberrations of these mechanisms may result in malformations and disease; and to understand how we might prevent and/or treat these conditions.

Recipient or parental organism
1. **Host/vector system**

| 2. Host: chick and quail fibroblasts; Vector: RCAS(BP), RCAN retroviruses |
| 3. Host: COS-7 cells; Vector: pcDNA3 |
| 4. Host: murine cartilage (ATDC5) and myogenic cells (sol8 and C2C12); Vector: pJMF2 |
| 5. Host: NIH3T3 murine fibroblasts; Vector: pJMF267. Host: D17 canine fibroblasts; Vector: pCXL |
| 6. Host: Rat B1 Fibroblasts; Vector: LNCX murine retrovirus |

**Origin & function**

Human, chick, zebrafish, Monodelphis, Xenopus and mouse cDNAs for this project have been isolated from cDNA libraries and cloned into the vectors listed above. The intended function is to investigate signalling pathways involved in muscle development and in the development of sensory structures, and to uncover the signalling mechanisms underlying human diseases and syndromes.

**Evaluation of foreseeable effects**

The vectors to be used in these studies are, with the exception of the RCAS(BP) virus, incapable of replication/transmission outside the laboratory.

The vector, RCAS(BP) is an avian specific retrovirus based on Rous sarcoma, from which the host derived oncogene src has been removed. This virus has been characterised and used extensively (see Morgan and Fekete, 1996. Methods in Cell Biol. 51, 185). The retrovirus is unable to infect cells other than avian cells and is only transmitted by direct injection/transfection of avian cells. For infection and growing viral stocks, O line cells which are free of any known ASLV endogenous viruses, eliminates the possibility of recombination between exogenous and cryptic endogenous virus. The retrovirus, pCXL vector, can infect avian, primate and rodent cells. This vector is replication defective. Thus, the infective virus can only be produced in a specialised packaging cell line. Thus once injected or introduced into the host avian cells there is minimal possibility of viral spread within the tissue or outside the laboratory. The expression plasmids are not released from the host tissue culture cells and are used within dedicated containment 2 laboratories. They, therefore, pose no risk to the outside environment.

Exposure and risk to health of the researcher is reduced to negligible levels by (a) performing culture work in a class 2 MSC and (b) injecting the retrovirus or using retrovirally infected cells in a dedicated area of containment 2 laboratory where other workers do not have free access. In addition, before carrying out these procedures all personnel are fully trained. This will reduce risk of accidental injection of either the RCAS(BP) or pCXL virus to the absolute minimum.

For all these cell/retroviral studies, infected cells will be contained within dedicated incubators. All GM manipulated material described above will be destroyed on site. Together with the instability of the viruses at ambient temperature this generates effectively zero risk to the environment.

Cells containing the retroviruses and cell lines transfected with plasmid expression constructs/retroviruses will be cultured in dedicated incubators in a containment level 2 tissue-culture laboratory. The retroviruses, RCAS(BP) and pCXL will also be used within a dedicated area of a level 2 molecular laboratory, again infected cells will be cultured in dedicated incubators. All material will be destroyed on site immediately after use. Liquid waste will be bleached and therefore, the GM material will be destroyed, within the contained tissue culture laboratory. Solid waste will be autoclaved. Transport to the autoclave from the tissue culture and molecular laboratories, will be in double bags within contained metal boxes. The waste will be autoclaved in these boxes to prevent any possible accidental spillage/release. Autoclaved waste will then be placed in yellow bags for incineration by White Rose.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach ( Haztabs; 1 tablet per litre = 2,5000 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines which are extremely liable. In addition, the retroviruses and cell lines have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed, and placed within and autoclaved in a closed metal container. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136 degrees C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services, the use of autoclave indicator tape (which measures a temperature of 134 degrees C for 3 minutes) during every run. Autoclaved waste will then be incinerated by White Rose.

Project Ref 295/03.1

Date Ackn'd 10/02/2003

CU2 Project Title ANTIBODY MODULATION OF TB INFECTION

Class 3

CultureVolClass2 75 ml

CultureVolumeClass3-4 75 ml
**Purposes of the contained use**

Mycobacterium tuberculosis (MTb) is a class 3 human pathogen and requires level 3 containment facilities for use. The recombinant MTb expressing luciferase gene would be used to significantly decrease the experimental times for bacterial determination in infected cultures and BCG expressing either luciferase or green fluorescent protein (GFP) would allow additional flexibility in substituting pathogenic MTb in certain types of assays. Luciferase and GFP are biologically harmless genes but as the recipient strain is pathogenic the containment level 3 would be required for the use of recombinant strains as for the wild type MTb. The same applies to Mycobacterium bovis (MB) expressing luciferase gene which would be used to uncover differences in pathogenesis between these two closely related species.

**Recipient or parental organism**

The recipient organism is bacterium Mycobacterium tuberculosis (MTb) or the attenuated strain of Mycobacterium bovis (MB) known as BCG (Bacilliys of Calmette and Guerin). MTb and MB are class 3 organisms and BCG is Class 2

**Host/vector system**

pSMT1 and pSMT3, both non-mobilisable vectors.

**Origin & function**

Luciferase gene is of bacterial origin and its function in the intended recombinant strains of Mycobacteria is to serve as reporter gene for quantitative determination of bacteria. The green fluorescent protein (GFP) is derived from jellyfish and is a fluorescent marker for tracking down the recombinant bacteria during infection of cells.

**Evaluation of foreseeable effects**

The recombinant Mycobacterium tuberculosis and Mycobacterium bovis expressing luciferase and BCG expressing luciferase or GFP are generated several years ago in the laboratory of Douglas Young at Imperial College London (Lab GM77). They have been used since then worldwide and several publications have quoted the use of these strains. Both genes are reporter constructs. Luciferase is an enzyme that converts certain type substrates in to chemiluminescent products and GFP is a fluorescent protein that can be easily identified by fluorimetric techniques such as flow cytometry (FACS). These two genes have been used in numerous experimental systems with no biologically harmful effects every being reported. The use of these two genes would normally require level 1 containment measures but as the recipient strains are class 3 (MTb and Mb) or class 2 (BCG) organisms, it is necessary to apply the class 3 or respectively, class 2 containment measures. There is no indication from the originator or from the others who have used these strains that they are in any way different in terms of virulence from the corresponding wild type strains.
Therefore, the environmental or personal risk from using these strains is no different from that of wild type strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Re: APPLICATION FOR DEROGATION FOR AUTOCLAVE FACILITY FOR CONTAINMENT LEVEL 3 LABORATORY

During a recent inspection by HSE, it was pointed out to us that there had been a change in the regulations defining what constitutes a laboratory suite, and as a result our containment level 3 facility (room 311, floor 28 Guy’s Tower) contravened the new interpretation under the Genetically Modified Organism (Contained Use) Regulations 2000 (CU2000). I therefore am applying for derogation from Schedule 8 of CU2000.

The relevant features, following the guidance attached to Newsletter 30 are:

a) Both the autoclave and the containment facility are located at the far end of the building remote from the main access to the floor. They are joined by a short corridor that is not used by students, non-scientific staff or members of the general public. There are no offices at this end of the building, only laboratories.

b) The infection with Mycobacterium tuberculosis and mycobacterium bovis occurs through respiratory route. The infectious dose has not been firmly established but it is thought that the size of aerosol-born droplets containing bacteria is critically important (i.e. several droplets containing 3-5 bacteria each, if inhaled by an immuno-susceptible person may establish an infection). Only 5% of infected individuals develop the disease.

c) The highest concentration of bacteria ever present in the waste is 10^7/ml which is the remaining stock solution from the experiment (the stock solution is 1 ml, thus the amount of this waste is always less than 1 ml). The unused stock solution is routinely treated with hycolin for several hours prior to disposal. Typical concentration of bacteria in the experimental liquid waste is 10^5/ml or less.

d) The waste is in loosely tied autoclave bags contained in metal autoclave bins.

e) Following the inspection we have purchased autoclave tins with clip-on lids to replace the identical ones without clip-on lids.

f) as in (e) above.

g) The container will be placed on a trolley following an agreed procedure that has been in place for the last 2 years.

h) the removal of waste from the Containment Laboratory does not take place unless it is clear that the autoclave is available for use. After this waste has been loaded into the autoclave low level waste may also be added, but only by the staff loading the level 3 waste.

i) As in (h) above.

j) The container is placed directly in the autoclave and the tray that sits on the trolley is then also placed in the autoclave.

k) The only personnel that move the waste are trained for work at containment level 3.

l) The SOP (revised to include the use of clip-on lids) for use of the Containment facility is attached. This contains an emergency procedure to be followed in the event of a spillage during waste transport.
1. All glassware and plastics must be autoclaved on a cycle to reach 126 degrees C before removal from the laboratory suite. Autoclave bins with properly fitting clip on lids containing the waste in loosely tied autoclave bags must be taken from the CL3 laboratory to the autoclave immediately prior to autoclaving. The following procedures will be follows:
   i) at least two trained staff must be available to carry out these procedures
   ii) the autoclave is room 3245 must be available for use
   iii) one member of staff will act to open doors; one will move the autoclave bins from the CL3 facility onto the transport trolley
   iv) the autoclave bins will be removed from the CL3 facility and placed on a tray on a trolley outside the CL3 laboratory
   v) autoclave bins from the CL3 laboratory will be taken directly to the autoclave and placed in the autoclave
   vi) when all autoclave bins have been loaded into the autoclave, the tray will also be placed in the autoclave and the autoclave cycle will be started.

2. If a spillage of CL3 infectious material occurs during transport of waste, the area will be disinfected by treatment with Presept, and/or by swabbing with disinfectant.
   i) Any contaminated clothing must be removed and any affected skin should be washed with soap and water. In the event of cuts, the First Aid Officer should be contacted.
   ii) Notification of the Biological Safety Officer and the relevant Line Manager must then take place. They will decide if any further action is required.

The waste consisting of disposable plastics and liquid waste in volumes of 100 ml or less in plastic containers will be placed in plastic bags, sealed and transferred to metal bins with clip-on lids. The standard internal operating procedure for removal and autoclaving of waste will then be applied (for details please see above application for derogation of autoclave facility for CL3 room).

The autoclave will operate the cycle at 126 degrees C for 80 min at 2.5 bar. The waste will then be placed in bags and disposed to designated bins.

This procedure is effective for complete killing of Mycobacterium tuberculosis wild type as determined by re-plating of the autoclaved material on microbiological plates. Similar test will be conducted for GM strains of MTb and MB (ie following completion of the cycle the metal been containing the waste will be returned to CL3 room in a reverse of the removal of waste procedure and the waste placed in Microbiological Safety Cabinet. An aliquot of the liquid waste and a swab from the solid waste will be tested for the presence of live bacteria by microbiological methods. Only following the negative result of the test will the remaining waste be removed from the room in a repeat of standard procedure and autoclaved prior disposal. This test-procedure will be repeated each time when the nature or the quantity of the waste significantly differs from the routine waste.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim of this study is to investigate the role of candidate intracellular proteins involved in exocytosis, endocytosis and membrane recycling by expressing them acutely using recombinant Semliki Forest Virus.

**Recipient or parental organism**
The virus to be used is the replication deficient, recombinant Semliki Forest Virus (SFV) as this offers the only viable means for acutely expressing exogenous proteins in populations of post-mitotic cells and established cell lines. SFV is an enveloped positive-strand RNA virus in the alphavirus genus of the Togaviridae family and has been extensively studied in cell biology and virology laboratories. Replication deficiency is achieved by deleting the codons encoding the structural proteins necessary for packaging the RNA from the viral genome (Liljestrom, P. and Garoff, H. (1991) "A new generation of an imal cell expression vectors based on the Semliki Forest virus replicon" Biotechnology 9, 1356-1361 Knight D E (1999) "Secretion from bovine chromaffin cells acutely expressing exogenous proteins using a recombinant Semliki Forest Virus containing an EGFP reporter". Molecular and Cellular Neuroscience 14: 486-505). Certain features of SFV make it unique for use as an expression system. As an RNA virus, it has a broad host range and rapidly synthesize exogenous proteins encoded in its genome. It effectively takes over the host protein synthesis.

Host/vector system

The virus will be used to infect bovine adrenal medullary cells (maintained in culture for about one week after isolation from the adrenal gland) and into established cell lines, such as BHK, HEK, HEP2 and PC12 cells. DH5a bacteria will be used to grow up plasmids necessary for the production of the RNA viral genome. The plasmids to be used are pSFVEGFPsubX, pSFVXiresEGFP to construct the viral genome, pSFV-help1, pSFV-help2 to construct the structural proteins necessary to generate the recombinant virus, and pRK5, pEGFP, pEYFP as subcloning vectors and to construct fusion proteins (Knight D E (1999) "Secretion from bovine chromaffin cells acutely expressing exogenous proteins using a recombinant Semliki Forest Virus containing an EGFP reporter". Molecular and Cellular Neuroscience 14: 486-505). None of the DNA vectors alone are pathogenic or oncogenic. The RNA viral genome derived from pSFVEGFPsubX and pSFVXires EGFP will eventually kill the infected cells as the viral RNA will replicate and take over the cell's endogenous protein synthesis machinery.

Origin & function

The proteins to be expressed are all proteins that are thought to be involved in membrane traffic or are used to detect membrane traffic. They fall into four groups.

a) Well characterised membrane proteins that are used as models for membrane traffic, and include various subunits of ligand gated ion channels (Serotonin and glutamate receptors) and also secretory products (chromogranin and human growth hormone)

c) Small GTP binding proteins including rab 3 and rab 5, and the subunits of the heterotrimeric GTP binding protein.

d) Putative calcium sensors (or fragments thereof) including synaptotagmins, freqeulin and calmodulin.

Evaluation of foreseeable effects

The recombinant Semliki Forest Virus is replication incompetent. The efficiency of viral RNA replication and the rapid exogenous protein synthesis effectively starves an infected cell of its own protein synthesis. The lifetime of an infected cell ranges from less than 1 day for BHK cells to about 3 days for post mitotic chromaffin cells. The proteins to be expressed by the recombinant virus are all proteins that are thought to be involved in membrane traffic or are used to detect membrane traffic. When expressed in isolated bovine adrenal medullary cells, which have been maintained in culture, they might affect the rate and extent of catecholamine secretion and the subsequent uptake and recycling of vesicular membrane.

Expression of secretory markers will allow regulated secretion to be monitored in nominally constitutively secreting cells. There are no foreseeable effects on the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved at 121 degrees C for 20 minutes before being disposed of as clinical waste.
All fluid waste will be incubated in 3% Virkon overnight before being disposed of in the sink.

Is an emergency plan required according to regulation 20?

PROJECT TRANSFERRED ON MERGER OF GM295 WITH GM386  

Tick if notifying a connected programme of work  

Y
The key objective is to bridge the gap between Imaging, Cancer Cell Biology and Medicine, particularly in the field of translational cancer research. The aims are summarised as follows:

1. Development of cancer cell imaging facilities which can measure biochemical changes in cancer patient-derived tumour samples, including fresh primary tumour cells.
2. Investigation of the function of specific gene products/protein in a range of mammalian cell lines and primary cells, by gene expression or knockdown.
3. The cells for these gene expression or knockdown studies will include primary tumour cells, primary human T cells, human T-cell leukaemia cells, monocytes and endothelial cells, and primary cells derived from mouse tissues. For these studies, we use plasmid-based expression vectors, retroviruses, adenoviruses and lentiviruses.

Recipient or parental organism

E. coli strains: E.coli JM101, JM109, DH5alpha, DH1OB, DB 3.i, InvcuF+, JS4, XL1-Blue, BL2i(DES), TOPIO. TNV1 10, Kl2 strains DHSu, BL21(DE3) and TOP10

Cells:
- Human breast — MCF7, MDA-MB-231, MDA-MB-435, MDA-MB-361, MDA-MB-468
- Human T-cell — Jurkat, NKL, CCRF-CEM
- Human embryonic kidney — 293T, 293A, 2930P0
- Mouse Fibroblast — PT67
- Rat Breast Carcinoma — MTLn3, MTLn3e
- Human hepatocyte — HepG2
- Human B-cell — 721.221, Raji
- Human NK cell — YT, NK92
- Human Myelogenous Leukaemia — K562
- Primary human tumour cells, T-cell leukaemia cells, primary human T cells and endothelial cells, and primary cells derived from mouse tissues.

Host/vector system

Host:
- B. coli strains: Ecofl JM101, JM109, DH5alpha, DH1OB, DB 3.i, InvcuF+, JS4, XL1-Blue, BL2i(DES), TOPIO, INVI 10, Kl2 strains DHSu, BL21(DE3) and TOP10

Vector names:
- For expression in mammalian cells: pEGEP C 1/2/3 and Ni pECFP-C1. pEYFP-C1 are members of the Clontech "Living Colours" family of vectors pcDNA 3.1+ and pcDNA3J MycHis vectors (Jnvitrogen)
- For expression in E.coli:
  - pGEX vectors (Aniersham)
  - pLPCX, pLHCX (Clontech)
- Lentiviral vectors
  - pLL4.4 (CAG promoter EGFP-MCS)
- Lentiviral packaging plasmids (3rd generation tour plasmid based system)
pCMV-VSVG, pRS V-REV, pMDLg/pRRE, pAR 8.91 (encodes accessory proteins for replication including Gag-Pol from WV-i), pMD.G (encodes VSV-G), pLKOJ-puro (Mission vector), p'HRsincptSkW-eGFP

Adenoviral vectors: pCR220 (Serotype 5 backbone with E1 and E3 regions deleted)

Host:
Human T-cell line — .Turkati-luman embryonic kidney ccl line —2931, 293A, 293GPG
Mouse Fibroblast cell line — P167
Rat Breast Carcinoma cell line — MTLn3, MTLn3e
Human hepatocyte cell line — HepG2
Human B-cell line—72121I, Raji
Human NK cell line — Yl, NK92, NKL
Human Myelogenous Leukaemia cell line — K562
Primai-y human rumour cells, primary human 1 cells and endothelial cells, and primary cells derived from mouse tissues.

Origin & function

Human, mouse, rat cDNA5 are obtained from existing eDNA libraries.

Lentiviral vectors encoding shRNAs targeting human proteins, obtained from Sigma (Mission library)

The intended function is to investigate the regulation of cancer cell and leukocyte motility

Evaluation of foreseeable effects

Lentivirus:
The pLentilox lentiviral vector system is a so-called 3 generation lentiviral vector that has been extensively
modified to prevent viral replication outside the packaging cells:
- pLentilox has a self-inactivating 3'LTR (TATA box deletion) and large deletions result in absence of env, tat, rev, vpr, vpu, v(f and nef. Therefore, there are no viral gene
products expressed from pLentiox.
- the gag, pot, and coy genes are supplied in trans from separate plasmids only in the packaging cell line.

References for packaging vectors:

References for self-inactivating LTR:

Adenovirus:
- The pCR220 (adenovirus serotype 5 backbone) is a plasmid containing most of the human adenovinis serotype 5 (Ad5) genome, with deletions in the genes E1 and E3. This vector has been developed to infect but not replicate in non-permissive target cells. The E1 gene is provided in the packaging cell line (HEK293 cell line) in trans. Exposure and risk to health of the researchers is reduced to negligible levels by performing the class 2 work in a class 2 microbiological safety cabinet in a dedicated area of a containment 2 laboratory. All personnel are fully trained to reduce the risk of accidental spill of virus to a minimum. For all these cell/retroviral studies, infected cells will be contained within dedicated incubators. All GM manipulated material will be destroyed on site.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach (Haztabs; 1 tablet per litre 2,500 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to the manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines. In addition the cell lines and retroviruses have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed and autoclaved. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136°C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services and the use of autoclave tape (which measures a temperature of 134°C for 3 minutes) in every autoclave run. Autoclaved waste will then be incinerated by White Rose.

Date Project Ceased 04/03/2014

Withdrawn N Tick if notifying a connected programme of work N
The overarching goal of this study is to gain greater functional insight into the physiological and pathophysiological regulation of the female reproductive tract during pregnancy. Our work focuses on
i) The control of uterine smooth muscle growth and excitability and ii) the response of reproductive tract to infection and inflammation.
i) Ion channels and related proteins play a major role in regulating uterine excitability and rhythmic contraction.

We are interested in the contribution of potassium channels (alpha and beta subunits) which are hypothesised to promote uterine quiescence in early-mid pregnancy (Aaronson et al., 2006; McCallum et al., 2009; Ohya et al., 2009) and calcium channels (e.g. TrpCs; Dalrymple et al., 2004; 2007) and related proteins (e.g. Stim and Orai, caveolin and flotillin) which can control cell growth, excitability and responses to agonists.

ii) Toll-like receptors and related signaling pathway (e.g. MAPkinases, cytokines etc) on reproductive tract (e.g. cervical and vaginal cells and human myometrium) responses to infection.

In order to investigate their functional roles in regulation of parturition/contraction we intend to introduce a range of molecular tools which include:
1) Over expression and assessment of gene promoter regulation in well known model cell systems (eg HEKs) which may help to assess the role and significance of genes taking part in human pregnancy and parturition
2) Stable shRNA delivery (using commercially available plasmids and viral vector systems) which is a highly effective strategy for permanently disrupting the function of individual genes in order to study their role in signaling pathways in myometrial cells (primary cultures and hTERT HM cell line) and epithelial cells of the reproductive tract (VK2/E6E7cell line)

Recipient or parental organism
- Primary cultured and passage 1-6 pregnant human myometrial smooth muscle cells (HMSM)
- Human myometrial cells immortalised with retroviral hTERT vector (HTER-HM)
- Vaginal epithelial cell line (ATCC CRL-2616 ) (VK2/E6/E7)

Host/vector system
- Lenti-X 293T cells
- HEK 293
The viral vectors which will be used in the study are listed below however we might use other vectors with similar properties without changing the containment level:

Lenti-X pLVX-shRNA1, SMARTvector® 2.0 Lentiviral shRNA Particles, GIPZ Lentiviral shRNAmir

All lentiviral constructs contain all the viral processing elements necessary for the production of replication-incompetent lentivirus and elements responsible for improved viral titer and overall vector function.

Genes encoding the structural and other components required for packaging the viral genome are separated onto mix of plasmids minimizing the threat of recombinant replication competent virus production. Lack of homology between the packaging mix of plasmids and Lenti-vectors also prevents transfer via homologous recombination.

After transduction viruses cannot replicate autonomously in target cells (SIN vectors).

Non-mobilisable (Bom-, Mob-, Tra-) plasmid vectors which may be used in the study:

- pIRES2-EGFP: Expression vector which contains bacterial and mammalian promoter and internal ribosome entry site (IRES) that allows the co-expression of a marker gene and another gene from a single transcript

- pKD: siRNA expression plasmid H1 promoter, Fl ori, , PuC ori, Amp

- pGL3: Basic plasmid which lacks a resident promoter. Encodes firefly luciferase which expression depends on insertion of the promoter sequence. SV40 promoter, Amp, ori, Luc+)

**Origin & function**

Inserts are all human based sequences

Stim (1-2): Stim proteins have emerged as potential candidates underlying store-operated channels (SOCs). STIM1 is a calcium sensor integrated within endoplasmic reticulum. It has been shown to relocate to the plasma membrane on store depletion and activate store-operated calcium entry (SOCE). STIM2 may be a negative regulator of STIM1-induced SOCE and is thought to be involved in the regulation of basal/cytosolic and endoplasmic reticulum Ca2+.

Orai: Orai proteins are thought to form the plasma membrane channel regulated by STIM. There is compelling evidence that Orai1 encodes the Ca2+ selective SOC channel/ICRAC current in a range of non excitable cells, but as SOC currents display distinctly different characteristics in excitable cells, it has yet to be fully established whether Orai channels or STIM can also mediate this more non-selective cation current alone.

KCNQs: KCNQ (Kv7) genes encode a family of K+ channel α-subunits most extensively investigated in cardiomyocytes and the CNS where they contribute to action potential repolarisation and subthreshold excitability respectively. More recently a role for Kv7 channels in smooth muscle has emerged, with functional roles being seen in the vasculature, the GI tract and the uterus.

KCNE(1-5): KCNE subunits modulate KCNQs and other voltage-gated channels in vitro and in vivo

Caveolin(1-2): Caveolins serve a structural role, inducing and maintaining caveolae invaginations and can act as a scaffold proteins to sequester and modulate the activity of many signalling effector and receptor proteins.

Flotillin(1-2): Flotillins are integral membrane proteins and constituents of lipid rafts. Flotillin-1 and -2 were originally discovered in neuronal cells as Reggie-2 and -1, respectively, and they are thought to be involved in signalling transduction and modulation.

Toll-like receptors (2,4): Toll-like receptors (TLRs) are pattern recognition receptors and serve as the first line of defense in host immunity. Current data suggests that TLR2 and TLR4 may play a protective and/or regulatory role in an effort to limit a lethal inflammatory response.
TrpC: Transient receptor 'canonical' channel proteins are proposed to form store-operated (SOCE) and receptor operated (ROCE) calcium channel entry in a variety of tissues. We have shown that several TrpC proteins are gestationally regulated in myometrial tissue and that pregnancy associated stimuli (stretch, cytokines) induce differential expression of TrpC proteins in human myometrial smooth muscle cells.

None of above mentioned genes and their products are potentially hazardous, infectious or oncogenic. Their overexpression will not have any influence on the environment.

**Evaluation of foreseeable effects**

The ability of retroviruses to integrate into the host cell chromosome raises the possibility of insertional mutagenesis and oncogene activation. Both these phenomena are well known in the interactions of certain types of wild-type retroviruses with their hosts.

In order to improve the risk-benefit ratio associated with retroviral-mediated techniques several approaches are currently developed, like the design of self-inactivating (SIN) vectors containing an internal promoter to drive transgene expression instead of the long terminal repeat-containing enhancer of standard retroviral and lentiviral vectors, reduced homology between retroviral vector and packaging components and split-genome conditional packaging systems.

Probability of survival of host cells or viruses in environment is very unlikely and disable genomes of these vectors prevent events of replication and creating new strains of wild type viruses.

Contact with viral particles and infection of cells at the contact site could resist in transient immune response with local swelling and inflammation. This is unlikely to be more than a minor effect. Moreover 3rd and 4th generation lentiviral constructs cannot replicate after infection so no virus could be passed on to other people.

Low to none if experimental work is done with all safety procedures maintained:

1. Personal protective clothing (gloves, lab coats)
2. MSC class 2, mechanical pipetting devices, safety centrifuge caps and rotors, autoclave, sharp containers, clinical waste yellow bags
3. All laboratories have lockable doors and sinks for hand washing and can be easily cleaned and decontaminated

Each researcher completes an individual risk assessment for their work and are aware of potential hazards.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste contaminated with GMOs will be inactivated so as to ensure that any contact between the GMOs and humans or the environment is limited to an extent commensurate with the risks identified in the risk assessment and to provide a high level of protection for humans and the environment.

Historical Significant Changes:
Project transferred to GM386 on 8/9/2003

Project Additional Information

Purposes of the contained use:
(i) Propogation of small stocks and recombinant Vaccinia Virus (rVV) and recombinant Adeno Virus (rAd) .
Infection of simian and murine antigen presenting cells in vitro with rVV and rAd which will be used to restimulate in vivo primed cytotoxic T lymphocytes.

51Cr labelling of rVV or rAd infected cells (see (ii)).

Inoculation of rhesus macaques

Recipient or parental organism

(i) Thymidine Kinase deficient vector WR strain vaccinia virus.
(ii) Adenovirus -5. (1.88kb E3 deletion).

Vaccinia virus deleted in the thymidine kinase (TK) gene from Strain WR Adenovirus 5 (1.88kb deletion in early region 3 (E3)).

Host/vector system

The hosts used in propagating recombinant vaccinia virus (or recombinant Adenovirus) are mammalian cell lines which cannot survive in the environment and this can be considered safe. The vector (WR strain of vaccinia virus) is Thymidine Kinase negative and thus attenuated in replication of virulence. Adenovirus 5 is replication competent in mammalian cells, but cannot survive outside the host used in its propagation.

Origin & function

rrVV SIVgag, rVV EBVgpH wild-type Vaccinia (WR strain) small scale propagation, infection of cell lines in vitro for immunological assays.
rrVV SIVgag-pol, rVV SIVgag, rVV SIVenv, rVV SIVnef*, rVV SIVrev, small scale propagation, infection of cell lines in vitro for immunological assays.
raD-5-Luciferase, raD-5-B-galactosidase, small scale propagation, infection of cell lines in vitro for immunological assays.
rrVV SIVgag, rVV SIVenv, rVV SIVnef*, in vivo immunisation of rhesus macaques via the mucosal, Intra-dermal and Intra-muscular routes.

Evaluation of foreseeable effects

Although recombinant vaccinia and recombinant Adeno-5 viruses can persist in a non-replicating form (outside their host) for an unknown length of time, at Containment Level 2 where the material is handled in a Class 2 exhaust ducted Hepa filtered safety cabinet (MAT design), the risk of release to the environment is effectively zero. The products of genes expressed by the vectors used are not known to be toxic, oncogenic or mediate pharmacologic effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid waste inactivated overnight in 10% chloros (14,000 ppm available chlorine). Hypochlorite level checked with starch iodine strips. Solid waste subsequently drained from chloros, autoclaved 121oC x 20 mins (in leakproof containers).
Solid animal waste collected for incineration.
Inactivated liquid waste to mains drainage. Inactivated solid waste for incineration.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form
The committee have reviewed and approved this risk assessment and the facilities where this work will be conducted. The committee is satisfied that the personnel involved with work at Containment Level 2 have received the appropriate training.

**Date Ackn'd** 21/09/2007

**CU2 Project Title**

The use of RNA inhibition to assess gene function in primary cultured human myometrial cells. Myometrial cells will be transfected with plasmid vectors containing gene specific antisense gene fragments to inhibit gene translation.

**Class** Class 2

**CultureVolClass2** < 1 Litre

**CultureVolumeClass3-4**

Non-GMM Consent Granted

- Not Applicable

**Project notified under transitional arrangements** N

**Withdrawn** N

**Historical Significant Changes**

TRANSFERRED FROM GM 386 - 21/9/07 PROJECT TRANSFERRED BA

**Date of Significant Change**

21/09/2007

**Project Additional Information**

**Purposes of the contained use**

The plasmid vectors and inserts to be used require containment level 1 conditions. The host cells to be transfected will be primary cultured human myometrial smooth
muscle cells and passaged human myometrial smooth muscle cells. Primary cultured cells require containment level 2, thus all work will be performed at containment level 2.

Recipient or parental organism

The recipient cells will be primary cultured human myometrial smooth muscle cells and also passaged human myometrial smooth muscle cells.

Host/vector system

The host cells will be primary cultured human myometrial smooth muscle cells and also passaged human myometrial smooth muscle cells. The vectors we plan to use are non-mobilisable plasmid vectors.

Origin & function

The non-mobilisable plasmid vectors will contain small gene fragments that will generate RNAs that will be processed to 23 mers. Inserts will be chemically synthesised and will be homologous to human genes. Transfection of the plasmid will inhibit gene translation and will enable physiological functions to be determined.

Evaluation of foreseeable effects

We plan to transfected myometrial cells with plasmid vectors containing short gene fragments, which will functionally knock out specific genes rather than add genes. Transfected and untransfected human myometrial cells are unable to survive outwith tissue culture facilities, so they will have minimal effect to the environment. Prior to disposal, cells will be inactivated using 50% Virkon. Cells and all culture materials will be incinerated with hospital waste. Cells are unable to colonize laboratory workers. The non-mobilisable plasmid vectors that we plan to use are unable to enter cells without mechanical or chemical manipulation and plasmids are unable to transcribe the inserted gene fragment out with the host cell, there will be minimal risk to the laboratory staff or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Transfected cells and culture medium will be treated with 50% Virkon which will cause cell inactivation. In addition, cells will be unable to remain viable out of tissue culture facilities. Cells and tissue culture materials will be autoclaved in a vacuum cycle at 135 degrees C for 5 minutes and then incinerated with hospital clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The assessment was approved by the local GMSC committee on 23 June 2004 with some minor amendments. The class of activity is 2.

The safety audit of the laboratory where the work will be carried out has also been done.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|---|---|---|---
Level 1 (GMMs) | | | | |
Level 2 (GMMs) | | | | |
This will consist of autoclaving or in the case of anything designated clinical waste, incineration.

Local departmental rules cover annual servicing of autoclaves and sterility testing either by chemical indicators, B. stearothermophilus spore survival or both.

No untreated waste is allowed to leave the University.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick if confidential

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
Purposes of the contained use

The infection of mammalian cells with adenovirus carrying genes which will, in the majority of cases, selectively block the NFkB signalling pathway through the transient expression of dominant negative genes. The use of recombinant adenovirus will allow an investigation of the regulation of inflammatory signalling in mammalian cells that is not possible using other transfection methods because of their low efficiency: normal lipid-based transfection strategies give a 10-40% transfection efficiency in rat aortic smooth muscle cells, adenovirus facilitates a transfection efficiency of 90% or greater.

Recipient or parental organism

Human adenovirus is a double-stranded DNA virus of which there are more than 40 serotypes. These wild-type viruses are all category II biological agents. The adenoviral genome which forms the basis of the constructs here is Ad5 which is responsible for mild respiratory infections in children. The normal route of infection is believed to be through aerosols and the majority of adults are likely to have antibodies to the virus.

The Ad5 adenoviral genome is well characterised, the commercially available Ad5 genome (Adeno-Xtm) used in this study has had large sections of the Early Regions 1 and 3 deleted to make it replication-incompetent. Such replication-incompetent Ad5 viruses are generally considered a category I biological agent (dependent on the inserted genes). The 293 cell line has been transformed to stably express the Ad5 E1 genes essential for virus replication and therefore acts as a packaging cell line for the growth of the virus. Other mammalian cells which are susceptible to infection by the virus are transiently and non-cytopathically infected (cell lysis does not take place). The replication-incompetent adenoviral vector cannot be maintained in tissue (it persists for less than eight weeks in respiratory epithelium). The adenoviral DNA is not incorporated into the host genome, the adenoviral genes are not transcribed and the DNA is not replicated. Adenovirus is not known to naturally infect any other species. These adenoviral constructs are therefore "unlikely to cause human disease" or be a particular hazard in the environment.

Each new recombinant adenovirus is screened for the ability to replicate outside of the permissive cell line eg by looking for plaque development after infection of a non-permissive cell line. If an adenoviral construct is found to be replication-competent it will be destroyed. Humans are the natural reservoir for wild-type adenovirus and there is a possibility of a recombination event occurring between the wild-type adenovirus and the recombinant virus to produce a replication-competent recombinant adenovirus. However there is a very low probability of the recombination event occurring and a negligible risk of a viable virus resulting.
A number of cultured cell types will be infected with adenovirus: eg 293 cells (human embryonic kidney cells); human aortic smooth muscle cells; rat aortic smooth muscle cells; human umbilical vein endothelial cells; human keratinocytes (primary cultures, HaCaT, NCTC 2544); RAW 264.7 macrophages (Murine). It is possible that a primary cell culture may harbour a virus (eg Epstein-Barr) which could trans-complement the E1 deletion in the replication-incompetent, however this is very easily detected, as previously described, by the development of plaques and the rounding up and detaching of cells. Under these circumstances the infected cells would be destroyed by the methods detailed in part 12.

**Host/vector system**

The gene of interest is inserted into pShuttle, a high copy number 4.1 kb shuttle vector containing a multiple cloning site, the human immediate early cytomegalovirus promoter (CMVIE), the bovine growth hormone polyadenylation signal, a kanamycin resistance gene and pUC origin. Plasmids are propagated in standard disabled E.coli (XL1 blue). The gene expression cassette is excised from pShuttle and introduced into the adenoiral genome by an in vitro ligation reaction. The adenosiral genome into which the expression cassette containing the gene of interest is introduced contains an ampicillin resistance gene and pUC origin. The adenosiral genome must be linearised by the Pac I restriction enzyme and transfected, eg by Lipofectamine TM, into 293 cells before infectious (but replication-deficient) virus is produced. A number of flasks of 293 cells are then infected with this virus to produce stocks quantities of the virus. The adenosiral genome is used in the commercially available Adeno-X TM genome (Clontech). No manipulation of wild-type adenovirus is carried out in the lab.

**Origin & function**

Adenoviral constructs containing a human gene will be made in the laboratory, these will include: Inhibitory kappa B (IκB)-a (dominant negative); IκB- (dominant negative); IκB Kinase (IKK)-A (dominant negative); IKK- (dominant negative); IKK-y (dominant negative); NFκB- inducing Kinase (dominant negative); MEKK1/2/3/4 (dominant negative); MKP-2; Green Fluorescent Protein; -galactosidase. These genes are either innocuous markers such as GFP or -galactosidase or genes which would be expected to negatively regulate inflammation or growth of cells. As such the risk to health associated with expression of the genes themselves is low.

**Evaluation of foreseeable effects**

The adenoviral constructs will be expected to inhibit the NFκB signalling pathway at several levels blocking the inflammatory signalling stimulated by compounds such as the bacterial endotoxin component, lipopolysaccharide, and tumour necrosis factor-α. NFκB activation is implicated in a range of diseases such as, atherosclerosis, asthma, arthritis, cachexia, cancer, diabetes, euthyroid sick syndrome, AIDS, inflammatory bowel disease and stroke. Particular emphasis has been placed on inhibition of NFκB signalling as a cancer therapy. NFκB is required for oncogenesis at multiple levels and inhibition of NFκB strongly enhances the apoptotic potential of many forms of chemotherapy. A range of anti-apoptotic genes are activated by NFκB eg c-IAP-1, c-IAP2, XIAP, TRAF1, TRAF2, A1/Bfl-1 and IEX-IL (for review see: Baldwin, A.A. (2000)). The inhibition of NFκB signalling is believed to be responsible for the condition incontinentia pigmenti (a defect in an upstream kinase (IKK-y) has been identified in humans (Smahi et al., 2000)). In mice, knock-outs of NFκB subunits p50 or p52 had no effect but the double-knockout displayed osteopetrosis (Iotsova et al., 1997) and a block in osteoclast differentiation (Franzoso et al., 1997). Mice in which the p65/Re1A subunit was knocked out died at day 16 of development as a result of extensive liver apoptosis (Bel et al., 1995). However the consequences to health of an individual being infected with adenovirus carrying a gene which will inhibit the NFκB pathway is unlikely to be severe since non-steroidal anti-inflammatory drugs and glucocorticoids which both block NFκB activation are used for long term treatment of disease and can be tolerable with minor side-effects. Expression of the genes would also be transient (as described in the first part of section 7) and since adenovirus is not known to naturally infect any other species no negative effects on human health or the environment are foreseen. It is possible that the virus itself will elicit an immune response in an infected individual. The deletion of the E3 region of the Ad5 genome means that there is increased MHC translocation to the cell surface this could mean that an infected individual might have an increased inflammatory response but should also mean that the virus would be cleared more rapidly from the tissue. since the genes involved in this study are selected to inhibit the inflammatory response any influence of the E3 deletion may be countered.

Franzoso, G. et al. (1997) Requirement for NF-kB in osteoclast and B-cell development.. Genes Dev. 11, pp. 3482-3496.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste whenever possible is disinfected by immersion in a 2,500 ppm sodium hypochlorite solution overnight. A 30 minute soak is sufficient to kill 100% of the virus. The waste along with gloves and similar items is then bagged for autoclaving (121°C, 15 minutes free steam) before disposal. The autoclave is situated close to the laboratories where the work will take place, it is overhauled and tested annually by a specialist engineer, a chart recorder will allow monitoring of the time and temperature of the autoclave during the programme run. Samples of adenovirus will be autoclaved and then tested for the ability to infect 293 cells as a means of validating the autoclaving process. The liquid waste is also disinfected in a 10,000 ppm sodium hypochlorite solution (final concentration) overnight, before being disposed of down a designated sink. Hypochlorite-treated adenovirus samples will be dialysed to remove the sodium hypochlorite and then tested for the ability to infect 293 cells as a means of validating this disinfection process.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The local GM Safety Committee (GMSC) has considered this risk assessment in an iterative process, based on the procedures outlined in the ‘Compendium’. Comments were obtained from every member of the Committee and a revised version (‘round 2’) of the risk assessment prepared. It was the unanimous view of the Committee that the work proposed fell clearly into Class 2, as defined by the Regulations.

The local GMSC acts as a subcommittee of the overall ‘Statutory Advisory Committee on Safety’, that is the forum of communication between employer and all employees of the University of Strathclyde.

Project Additional Information

Purposes of the contained use

The research programme aims to improve the knowledge and understanding of the biochemistry, molecular biology and immunology of the parasitic protozoa, Toxoplasma gondii, Acanthamoeba castellani and Leishmania spp (L. major, L. Mexicana, L. donovani and L. infantum). Genetic manipulation of these organisms allows us to investigate parasite molecules involved in metabolism, growth regulation and virulence. Genetically modified micro-organisms may have the potential to be developed as attenuated live vaccines. Genetic modification of the organisms allows us to validate potential drug targets. It is envisaged that the genetic modification would make the organisms less able to survive in vivo.

Recipient or parental organism

Organisms to be used in this study

(a) Toxoplasma gondii is capable of infecting a range of mammals, including man, cattle and rodents. Transmission is through ingestion. Symptoms are normally mild to asymptomatic although congenital transmission can be serious. Infection with the RH strain (virulent) may be serious if left untreated.

(b) Leishmania spp. are capable of infecting a range of mammals including man, dogs and rodents. The predominant Leishmania species used in this study is Leishmania Mexicana, the causative agent of cutaneous leishmaniasis. L. Infantum, and L. donovani which can cause visceral disease) and L. major may also be used on an occasional basis. Transmission is through the bite of a sand fly. Cutaneous leishmaniasis can leave unsightly scars while visceral leishmaniasis can be fatal if left untreated.

(c) Acanthamoeba castellanii are normally free-living protozoa, but have recently been identified opportunistic parasites of humans. They are responsible for Acanthamoeba keratitis most commonly in contact lens wearers and for Granulomatous Amoebic Encephalitis a condition that can develop in the immunocompromised patients (including those with HIV and AIDS).
Toxoplasma, Leishmania mexicana and Leishmania major and Acanthamoeba are classed as ACDP hazard group 2. Both non-genetically modified parasites and
generally modified parasites are handled in accordance with ACDP guidelines. It is considered unlikely that genetically modified T.gondii, Acanthamoeba or Leishmania will
cause harm to humans or the environment above that inherent in the pathogenicity of the wild type parasites themselves.

L. donovani and L. infantum are ACDP hazard group 3. Since transmission requires a bite from an infected female sand fly, handling of L. donovani and L. infantum will be
carried out without all the conditions of Hazard Group 3 organisms as described in the HSE document ‘Biological agents: managing the risks in laboratories and healthcare
premises’ 05/05 Appendix 3.2. Thus the laboratory does not need to be maintained at an air pressure negative to the atmosphere as the agents are not transmissible
through the airborne route, the laboratory does not need to have exhaust air extracted through HEPA filters (although any work carried out that could result in aerosols will
be carried out in Class II microbiological safety cabinet). The laboratory does not need to be resealable as the organisms cannot survive or multiply in the environment and
are extremely easily broken down.

However, although the HG3 organisms in use are derogated and do not need full CL3 containment laboratory facilities it does require certain CL3 management and
procedural measures as specified in Appendix 3.2 of the ACDP guidance document ‘Biological Agents – Managing the Risks in Laboratories and Healthcare Premises’
which will be employed. This document can be viewed at http://www.hse.gov.uk/biosafety/biologicalagents.pdf
Specifically, (1) Segregation of work from any other going on in that particular laboratory where this is shared or there are different projects being undertaken. (2) Need for
records of those working with HG3 organisms. (3) Observation window to view occupants or a means of checking on workers.
The work will be separated from the other work by performing it in a separate room within the containment level 2. Importantly, none of the proposed genetic modifications
are envisaged to be capable of altering the organisms to change this assessment.

Host/vector system

The hosts for the genetic manipulations will be T.gondii, Acanthamoeba and Leishmania major, Leishmania donovani, Leishmania infantum and Leishmania Mexicana.
T.gondii can be propagated in tissue culture using a variety of mammalian cell lines as host cells. The leishmania species and Acanthamoeba can be grown axenically in
tissue culture prior to and following genetic manipulation.
Drug resistance genes of prokaryotic origin, such as neo, hyg, pur, ble, bla, CAT or sat will be used as positive selectable markers in T.gondii, Acanthamoeba and
Leishmania. These drug resistance genes do not confer resistance to drugs commonly used to treat Toxoplasma or Leishmania infections in man or animals. Green
fluorescent protein from jellyfish may also be used as a positive selectable marker.
Negative selectable markers will be (i) Herpes simplex virus thymidine kinase in combination with the drug ganciclovir (ii) Trichomonas vaginalis methionine-gamma-lyase
in combination with the compound trifluromethionine.
In addition, the availability of T.gondii lacking HXGPRT (hypoxanthine-xanthine-guanine phosphoribosyl transferase) allows T.gondii HXGPRT to be used as positive
selectable marker in the presence of mycophenolic acid and as a negative selectable marker in the presence of 6-thioxanthine Donald and Roos (1998) Molec. Biochem.
Parasitol. 91, 295-305. This system has the benefit of not introducing any resistance genes into the T.gondii.

Origin & function

Selection methods for gene knockout and episomal gene expression in T.gondii, Acanthamoeba and Leishmania require plasmid vectors containing prokaryotic antibiotic
selectable markers (eg.neomycin phosphotransferase conferring resistance to the antibiotic G418) or the green fluorescent protein (GFP) from the jelly fish Aequorea
Victoria (including colour shifted mutants) or fire fly luciferase (including enhanced mutants). Intended functions are to either delete or episomally over-express a particular
genome to understand (a ) its function and or location in a cell. (b) its role as a cysteine proteinase. (c) its role in metabolism and potential as a drug target and (d) its role in
infectivity.
DNA encoding genes from the parasites (included mutated versions of these) and in some instances DNA from other organisms (e.g. human, yeast) may be expressed in
the parasites in order to test whether this heterologous DNA is functional in the parasite. (genetic cross species complementation)

Evaluation of foreseeable effects

The overall aim of this work is to gain an understanding of the molecular genetics, biochemistry and immunology of the parasitic protozoa Toxoplasma gondii,
Acanthamoeba and Leishmania spp. and their interaction with the host. This should facilitate drug target identification, validation and design.

Organisms to be genetically modified (1) Toxoplasma gondii (2) Acanthamoeba castellanii (3) Leishmania Mexicana, Leishmania donovani, Leishmania Mexicana and L.major.

There are four major research themes to this project. The foreseeable effects are identical for the 4 species of Leishmania and are thus discussed together. The particular parental strain of Leishmania is probably the most significant factor in determining which of the proposed GMMs are most hazardous (see below).

(a) Understanding how Toxoplasma and Leishmania regulate their cell cycle.
We have isolated a number of genes from Toxoplasma and Leishmania that have homology with genes known to regulate the cell cycle in yeast and higher eukaryotes (eg cyclin-dependent kinases and cyclins). We wish to manipulate these genes in the parasites in order to define their function and in particular to determine if the genes are essential for parasite survival. Essential genes are likely to encode proteins with value as novel drug targets. As these genes are crucial to cell cycle progression in other eukaryotes, it is likely that disruption or modification of them will be detrimental to the parasite, which will therefore be less virulent than wild type. It is also of significant value to test if similar genes from very divergent organisms (such as humans or yeast) are able to function in the same capacity in the parasites (a standard test to determine functional homology between genes of different species). Thus, we wish to express the human and yeast cdc2 genes in Leishmania mutants lacking crk3 gene to test if they are functional homologues. Similar studies will be performed in Toxoplasma gondii. This will provide information on gene function between highly divergent species. The heterologous DNAs to be used for transfection of the parasites do not encode a toxin, oncogenic protein, allergen or other protein with a potentially harmful biological activity.

(b) Cysteine proteinases of Toxoplasma gondii and Leishmania
We have isolated a number of cysteine proteinase genes from Leishmania. We wish to use genetic modification to elucidate their function in the parasites. We have shown that cysteine proteinase deficient mutants of Leishmania (lacking 1 to 19 cysteine proteinase genes) have reduced virulence (Mottrom et al., (1996) PNAS 93,6008-6013). These mutants have potential as attenuated live vaccines. Cysteine proteinase genes, altered by site-directed mutagenesis, will be expressed in Leishmania mutants lacking cysteine proteinase genes, in order to study proteinase expression and processing. The resulting mutants are likely to be less virulent than wild type Leishmania. There is no reason to believe that expressing cysteine proteinase genes in Leishmania will increase the virulence of the mutants or alter their pathogenic characteristics.

Genes to be analysed (Im, Leishmania Mexicana); Cathepsin L/B-like cysteine proteinases: Imcpa. Imcpb, Imcpc, thcp. (2) GPI:protein transamidase Imgpi8, tbgpi8.

(c) Metabolically important enzymes and other potential drug targets in T.gondii, Leishmania and Acanthamoeba castellanii
We have recently isolated a number of genes encoding metabolically important enzymes of T.gondii and Acanthamoeba castellanii. These include enzymes of the shikimate pathway and of type –II fatty acid biosynthesis such as chorismate synthase and FabI. We have shown that inhibitors of certain enzymes are able to restrict the growth of T.gondii and Acanthamoeba in vitro (Roberts et al., (1998) Nature 393:801-805; McLeod et al., (2001) International Journal of Parasitology 31:109-13; Roberts et al., unpublished). Mutant parasites lacking these functional enzymes are likely to be attenuated (as has been noted for a number of bacterial pathogens lacking shikimate pathway enzymes). Genes to be analysed from T.gondii include those encoding all the shikimate pathway enzymes and potential branches from the shikimate pathway; and all enzymes involved in Type II fatty acid biosynthesis. Genes to be analysed from Acanthamoeba include those encoding all the shikimate pathway enzymes and potential branches from the shikimate pathway and the alternative oxidase. Similar studies will be performed in Leishmania.

(d) Establishment of T.gondii in the host cell
T.gondii is an obligate intracellular parasite and as such uses a number of parasite derived molecules to invade and modify the host cell in which it resides. In particular proteins released from the dense granules (GRA), rhoptries (ROP) and micronemes (MIC) assist in this process.
Mutant parasites lacking these proteins are likely to be unaffected, (due to multiple redundancies) or to be adversely affected (attenuated). Genes to be analysed from *T. gondii* include the GRA, ROP and MIC genes.

*Toxoplasma gondii*, *Acanthamoeba* and *Leishmania* major and *Leishmania* Mexicana are classed as ACDP hazard group 2. *Leishmania donvani* and *Leishmania* infantum are hazard Group 3, but can be derogated to handling under containment level 2. The work to be undertaken is a small scale activity. Both non-genetically modified parasites and genetically modified parasites will be handled in accordance with ACDP guidelines. Genetically modified parasites will be tested in in vivo models (mice, guinea pigs, rabbits and cotton rats, occasionally parasites will be tested in mutant or genetically modified mice such as RAG-/- or IFN-gamma-/-). Procedures for maintenance of animals infected with genetically modified parasites are covered by the Home Office Inspectorate; Animals (Scientific Procedures) Act 1986

**Part 1 INHERENT BIOLOGICAL PROPERTIES OF GENETICALLY MODIFIED MICRO-ORGANISM**

For properties of micro-organisms to be used in this study, see above for recipient or parental organisms.

(i) Considerations relating to whether the product of the inserted gene has a biological activity which can act directly to cause harmful effects.

Three types of genetic modification for *T. gondii*, *Acanthamoeba* and *Leishmania* are envisaged.

(a) Gene disruption.

Generation of mutant parasites by insertional mutagensis (Insertion of selectable markers by homologous recombination). It is considered likely that gene disruptions will be detrimental to parasite survival or will have no phenotype difference from wild type cells.

Two types of positive selectable markers will be used. (i) Drug resistance genes of prokaryotic origin, such as neo, hyg, pur, ble, bla, CAT or sat. These drug resistance genes do not confer resistance to drugs commonly used to treat *Toxoplasma* or *Leishmania* infections in man or animals. (ii) Green fluorescent protein from jellyfish.

Two types of negative selectable marker will be used (i) Herpes simplex virus thymidine kinase in combination with the drug ganciclovir (ii) Trichomonas vaginalis methionine-gamma-lyase in combination with the compound trifluoromethionine.

In addition the availability of *T. gondii* lacking HXGPRT (hypoxanthine-xanthine-guanine phosphoribosyl transferase) allows *T. gondii* HXGPRT to be used as a positive selectable marker in the presence of mycophenolic acid as a negative selectable marker in the presence of 6-thioxanthine (Donald and Roos (1998) Molec. Biochem. Parasitol. 91. 295-305). This system has the benefit of not introducing any resistance genes into the *T. gondii*.

(b) Homologous gene expression

The expression of homologous genes in *T. gondii*, *Acanthamoeba* or *Leishmania* will be achieved from episomal expression vectors or via integration into the genome. These vectors have low to medium levels of expression.

(c) Heterologous gene expression

The expression of heterologous genes in *T. gondii*, *Acanthamoeba* or *Leishmania* will be achieved from episomal expression vectors or via integration into the genome. These vectors have low to medium levels of expression. These experiments are designed to test for cross species complementation. It is also of significant value to test if similar genes from very divergent organisms (such as humans or yeast) are able to function in the same capacity in the parasites. Thus, we wish to express the human and yeast cdc2 genes in leishmania mutants lacking the crk3 gene to test if they are functional homologues. This will provide information on gene function between highly divergent species.

Other heterologous genes include reporter genes such as green fluorescent protein (GFP) from the jelly fish *Aequorea victoria* (including mutants of this protein engineered to give greater fluorescence or a different colour of light emission) and luciferase from the firefly *Photinus pyralis* (or mutant versions of this gene from this or other organisms).

The heterologous DNAs to be used for transfection of the parasites do not encode a toxin oncogenic protein, allergen or other protein with a potentially harmful biological activity.

*Leishmania*, *Acanthamoeba* and *T. gondii* risk assessment. As access will be restricted to contained handling in a containment level 2 laboratory and expression will be low to medium levels of non-toxic and modified host genes, risk levels are kept to a minimum.

(ii) Consideration relating to whether the inserted gene encodes a product that might act alongside the existing characteristics of the recipient micro-organism, so as to
endow the GMM with altered pathogenic properties.

It is possible that disruption of T.gondii, Acanthamoeba or Leishmania genes will alter the pathogenicity of the parasites. It is envisaged that genes modified in this project will lead to either no change in virulence or a loss of virulence (hence the desire to create gene-specific deletion mutants for use as attenuated live vaccines). None of the genes to be modified in this project are thought to encode proteins that would be sufficient to alter the pathogenic properties of the organism with respect to tissue tropism or host range. Cysteine proteinases of Leishmania have been identified as virulence factors. We wish to express modified cysteine proteinase genes in Leishmania to investigate the function of the protein in the parasite. Our extensive work (and that of others) suggest that expression of modified cysteine proteinases will not alter the pathogenic properties of the parasites above that of the wild type cell line.

Drug resistance genes of prokaryotic origin, such as neo, hyg, pur, ble, bla, CAT or sat, will be used. These drug resistance genes do not confer resistance to drugs commonly used to treat T.gondii, Acanthamoeba or Leishmania infections in man or animals (the preferred drugs of choice being pyrimethamine and sulphadiazine (for T.gondii), antimonials (for Leishmniaisis) and polyhexamethylene biguanide [PHMB] and chlorhexidine (for Acanthamoeba)). Neomycin has been used in various combinations with other antimicrobials in the treatment of Acanthamoeba keratitis, but is not a first line choice. Consequently, Acanthamoeba genetically modified to carry the Neo selectable marker should be susceptible to standard treatment. Furthermore, in the ubiquitous nature of Acanthamoeba in the environment, the incidence of Acanthamoebiasis is extremely rare and has been documented in those individuals who perform poor contact lens care and in the immunocompromised. Immunocompetent people are at very low risk to infection and this risk can almost, if not completely eliminated by use of safety goggles (rather than safety glasses).

(iii) Consideration of the most hazardous GMM to be created

The most hazardous GMM generated is likely to be Leishmania donovani as these are inherently more infective than Acanthamoeba and less amendable to treatment than Acanthamoeba or Toxoplasma. Most of the proposed genetic modifications are expected to produce attenuated organisms lacking one or more genes. Therefore, the most hazardous is likely to be a GM Leishmania expressing a reporter construct such as GFP that does not decrease the fitness of the organism.

(iv) Considerations relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient micro-organism, could give rise to harm as a result of natural gene transfer to another, possibly related organism.

Leishmania and Acanthamoeba are essentially asexual organisms. Sexual exchange has not been reported for Leishmania or Acanthamoeba. T.gondii can reproduce sexually but this only happens in the domestic cat. Genetic exchange with other organisms has not been reported for T.gondii, Leishmania or Acanthamoeba.

The genetically modified parasites will be contained with ACDP containment level 2 facilities. The chance of escape into the environment is negligible. The details of the appropriate systems of work are held within the appropriate COSHH risk assessments and standard operating procedures.

Part 2 Animal Work

Genetically modified T.gondii and Leishmania will be grown in animals (mice, rats, guinea pigs, rabbits). The University of Strathclyde has an animal facility with ACDP containment level 2 classification. It is not envisaged that genetically modified T.gondii and Leishmania will present any additional environmental hazard than wild type parasites with respect to animal infection. There is no increased risk envisaged in using the genetically modified micro-organisms rather than the parental micro-organisms in genetically modified animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM modified T.gondii or Leishmania may be inoculated into wild type or KO mice (of various backgrounds eg BALB/c) to analyse their virulence for example RAG deficient and IFN-gamma deficient etc. Guinea pigs, rabbits or rats may also be used to grow parasites. These animals will be housed in a security monitored home office licensed facility in appropriate surroundings at containment level 2. The risk of these reaching the external environment is negligible. All animal tissue will be incinerated (by the University appointed contractors) and spillage of body fluids and surfaces that have been in contact with tissue will be treated with Virkon. All animal handling will involve the use of gloves. All workers should have tetanus vaccination up to date. Bites and scratches with an antiseptic plaster. Toxoplasma and Leishmania cannot be transmitted by bites or scratches.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
We apply for derogation of the handling of *L.*donovani and *L.*infantum to be carried out without all the conditions of hazard group 3 (HG3) organisms as described in the HSE document 'Biological agents: managing the risks in laboratories and healthcare premises' 05/05 Appendix 3.2 Thus the laboratory does not need to be maintained at an air pressure negative to the atmosphere as the agents are not transmissible through the airbourne route, the laboratory does not need to have exhaust air extracted through HEPA filters (although any work carried out that could result in aerosols will be carried out in Class II microbiological safety cabinets). The laboratory does not need to be sealable as the organisms cannot survive or multiply in the environment and are extremely easily broken down. Outside the laboratory the parasites can only be transmitted by the bite of a female sandfly. The work will be separated from the other work by performing it in a separate room within the containment level 2 facility. Importantly, none of the proposed genetic modifications are envisaged to be capable of altering the organisms to change this assessment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All parasite manipulation will be conducted in accordance with ACDP guidelines. Acanthamoeba, *T.*gondii and *Leishmania* promastigotes and amastigotes are handled under containment level 2.

1) Are any of the work procedures likely to generate aerosols? An important feature of safe handling of *Leishmania*, is that there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. The consequence of this is that the safety measures required are relatively straightforward. *T.*gondii and Acanthamoeba can be transmitted by aerosols and work should be carried out in class II microbiological safety cabinets in containment level 2 conditions.

2) How will you dispose of waste material?

Animal waste will be disposed of through an authorised waste disposal company, provided through the Clinical Waste Service.

Solid waste is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. When the liners are no more than 3/4 full, they are removed from the bin, loosely sealed with autoclave tape (to allow steam penetration during autoclaving), labeled with lab number, operator and date and then transported to the autoclave room on a trolley. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM' which results in their inclusion on a run on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. The record is kept on file by the autoclave room staff. The autoclave material is disposed of in solid waste by an authorised waste disposal company, provided through the Clinical Waste Service. The routine autoclave regime will be 126 °C for 30 min, which has previously been established to produce a 100% kill (British Pharmacopeia 2005, Vol IV, Appendix XVIII A385-A388).

Liquid waste (e.g cultures in flasks or 'spent broth' wherein the cells have been separated from the culture both by centrifugation) will be sterilised in the culture flasks the same day by addition of Virkon ® to a final concentration of 1% w/v (10% w/v for Acanthamoeba), and left overnight. Virkon-disinfected solutions will be disposed of into the waste water supply. Virkon solutions are stable for up to 7 days ( manufacturer’s data), and thereafter disinfectant solutions will be discarded (the pink colouration fades). Virkon is a peroxygen compound and disinfection requires a contact period of at least 10 min for 1% w/v solution: see http://www.antechh.com/framehet.html.

Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v (10% w/v for Acanthamoeba), Virkon® overnight (polypropylene and polystyrene centrifugation buckets, steel and glass are not corroded by 1% w/v Virkon). Glassware and buckets will then be rinsed in tap-water and dried.

Small volume spills (up to 100ml) on hard surfaces (floors, work benches, trolleys) will be disinfected by mopping up the spill with absorbent tissue paper and spraying the surface with a 1% w/v (10% w/v for Acanthamoeba) Virkon solution or sprinkling the area with powder Virkon and leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towels will then be bagged for disposal as solid waste (above).

Large volume spills (100ml to 0.5l) on hard surfaces (floors, work benches, trolleys): Absorbent granules will be used to cover the spill, if necessary, contained using absorbent booms. Granules and booms will be bagged for disposal as solid waste (above). The contaminated area will then be disinfected by wiping or spraying the surface with a 1% Virkon solution or sprinkling the area with powder Virkon and leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towels will then be bagged for disposal as solid waste.
3) Does your laboratory avoid sharps?
Yes, where possible. However, where it is necessary to use sharps, the laboratory provides Sharps containers and has guidance for the use and safe disposal after use.

4) Has the disinfectant been validated?
Yes, Virkon kill has been validated in house to kill 100% of the Leishmania and Toxoplasma when used as per manufacturer’s instructions (1% weight/volume). For Acanthamoeba a 10% w/v has been found to be necessary to kill 100% of organisms. The autoclave has also been validated. When genetically modified organisms are created these will also be tested. This is done by incubation in Virkon at different concentrations for different lengths of time and examination by microscopy.

5) Does the nature of the work preclude it being undertaken by any workers who have a serious skin condition?
No. All workers must wear adequate protective clothing, including laboratory coats and disposable gloves, safety glasses or safety goggles (in the case of Acanthamoeba handling)

6) Will workers receive any vaccination?
No vaccinations are currently available for Leishmania, human toxoplasmosis or Acanthamoeba.

7) Is the recipient micro-organism controlled by DEFRA?
No

Assignment of control measures

It is believed that the genetically modified T.gondii, Acanthamoeba and Leishmania provide no significant additional risk over and above the wild type parasites. Non-gentically modified T.gondii, Acanthamoeba and Leishmania are currently handled at Containment Level 2. All genetically modified T.gondii, Acanthamoeba and Leishmania will also be handled in Containment Level 2 facilities only.

Conclusions from risk assessment
1. The work will be undertaken at containment level 2.
2. The work is classified as being Class II under the Contained Use Regulations, 2000.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [ ]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment
Work with Toxoplasma, Leishmania and Acanthamoeba has been performed at Strathclyde University for a number of years. This notification of intention to conduct individual contained use activities will enable the extension of these existing studies to the use of genetically modified forms of these organisms. The University Genetic Modification Safety Committee has reviewed this application in detail, together with a relevant COSHH risk assessment form and a local Genetic Modification risk assessment form. The committee is in agreement that the assessment of risk has been appropriately performed and that the work can proceed at Strathclyde University. Strathclyde University is already registered with HSE as a Class 2 site.

### Project Additional Information

#### Purposes of the contained use

The work involves the investigation of metabolism of T. vaginalis in order to identify novel biochemical pathways that might be suitable for therapeutic intervention. The
essentiality of potential drug targets will be analysed by gene knockout (either by gene deletion or RNAi). The cellular localisation and expression of proteins will also be determined using epitope-tagged constructs.

Recipient or parental organism

The parental organism is Trichomonas vaginalis, which is listed in ADCP hazard group 2. The parasite infects the human urogenital tract and is sexually transmitted — there are no other known routes of transmission.

Host/vector system

Vectors for genetic modification of T. vaginalis will be derived from the non-mobilisable E. coli vectors (Bom-/(Nic-), Mob- and Tra-). They will contain well characterized T. vaginalis promoters such as the ap65-1 or SCS promoters to direct expression of homologous and heterologous genes. Vectors for gene deletion will contain a selectable marker gene flanked by sequences homologous to the 5’ and 3’ flanking sequences of the target gene. RNAi methods will use a tetracycline inducible system (Ortizt and Johnson, 2003. Mol. Biochem. Parasitoli. 128, 43-49.

Origin & function

Inserted material: the majority of material cloned and expressed on the plasmids is derived from T. vaginalis. Typically these are genes that will have been deleted in order to study function. The fact that the genes are from the genome strain of the parasite (for which draft genome sequence is available) allows excellent bioinformatic based analyses, which informs the researcher of the likely function of the target gene. Two key areas of interest involve (i) the study of, vaginalis genes involved in central metabolism of the parasite, including cysteine synthase (Westrop et al., 2006. J.Biol Chem. 281, 25062-75) mercaptopyruvate sulfurtransferase and thioredoxin reductase (Coombs et al. 2004. J.Biol Chem. 279, 5249-56) (ii) the study of T. vaginalis genes involved in the biosynthesis of surface molecules (these do not include surface virulence factors). The heterologous genes expressed include the drug resistance genes from prokaryotes used as positive selectable markers for construction of over-expressing cell lines and gene-deletion mutants. The markers used in this study include puromycin resistance (pac), G418 resistance (neo), hygromycin resistance (hyg), bleomycin resistance (ble), ampicillin resistance (bla). Promoter fusions drive known and well characterised reporter genes and epitope tags of synthetic origin. The reporter genes include green fluorescent protein (GFP) from the jelly fish Aequorea victoria and mCherry fluorescent protein, chloramphenicol acetyl transferase (CAT) and b-galactosidase. Development of inducible expression systems for RNAi will require heterologous expression of the Tet-repressor from E. coli and the bacteriophage 17 RNA polymerase. None of the heterologous genes expressed encode a toxin, oncogenic protein, allergen or other protein with a potentially harmful biological activity. The markers used for selection in T. vaginalis or in E. coli do not confer resistance to an antibiotic used in the treatment of T. vaginalis infections.

Evaluation of foreseeable effects

Trichomonas vaginalis is listed in ADCP hazard group 2. The parasite infects the human urogenital tract and is sexually transmitted — there are no other known routes of transmission. Infections are asymptomatic to mild (vaginitis. or urithritis) and are successfully treated with the nitroimidazole drugs, metronidazole and tinidazole. The parasite has no cyst stage and the organism has no capacity for survival in the environment. Humans are its only natural host. The genetic manipulations in this study are not envisioned to lead to over-expression of proteins or other metabolites that are harmful to humans. None of the genes in this study are thought to encode proteins that are sufficient to alter the pathogenic properties of T. vaginalis with respect to host range or tissue tropism. The genetic manipulations planned in this study are intended to lead to either no change in virulence or a loss of virulence. The drug resistance genes used as positive selection markers (such as puromycin acetyl transferase in combination with puromycin) do not confer resistance to drugs used in the treatment of T. vaginalis infections (metronidazole or tinidazole). Genetically modified T. vaginalis strains will be propagated in-vitro as trophozoites in complex defined medium. They are not able to survive in the environment. Sexual exchange of genetic information has not been reported for this ‘organism. Genetic exchange between T. vaginalis and other microorganisms has not been reported. It is envisioned that the genetically modified T. vaginalis strains will be either less hazardous or about the same as the parental organism (ACOP Hazard group 2). The containment level required is ACDP laboratory containment level 2. No additional measures above ACDP laboratory containment level 2 are required.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Conclusion from risk assessment:
(1) The work is classified as GM class 2 under the Contained Use Regulations, 2000.
(2) The work will be carried out under ACDP containment level 2 conditions.

Waste management.
(1) Liquids containing the GM organism will be exposed to an appropriate disinfectant at a known effective concentration. After disinfection the liquid waste is disposed of to the drain. The disinfectant Virkon (http://www.antechh.com/frameset.html) has been validated in house to kill 100% of T.vaginalis following 30 mm incubation at room temperature, at the manufacturer’s recommended concentration (1 % weight/volume). Disinfection procedures will be validated for new GM T.vaginalis strains by incubation of growing cultures of the organism with different concentrations of Virkon for different times and examination by microscopy to determine viability. (2) Solid waste including disposable culture flasks will be autoclaved in a validated autoclave under conditions established to produce 100% kill. The autoclaved waste is disposed of by an authorised waste disposal company, provided by the University’s clinical waste service. (3) Contaminated glassware and centrifugation buckets will be disinfected by complete submersion in 1% (weight/volume) Virkon overnight. Glassware and buckets are then rinsed in tap-water and dried. Small volume spills (up to 100 ml) on hard surfaces (floors, work benches and trolleys) will be disinfected by mopping up the spills with absorbent paper towels and spraying with 1% (weight/volume) Virkon. Paper towels are then bagged for disposal as solid waste (see above). Large volume spills (100 ml to 1000 ml) on hard surfaces: Absorbant granules will be used to cover the spill and bagged for disposal as solid waste. The contaminated surface will be cleaned by sprinkling the contaminated area with Virkon powder, leaving for 20 minutes and drying with a paper towel to remove any remaining white deposit. Paper towels are then bagged for disposal as solid waste.

Project Containment

Laboratory Activities  Glass Houses  Growth Rooms

02/03/2022
Project Additional Information

Purposes of the contained use

PARS are G-protein coupled receptors whose upregulation is observed in a number of disease states including rheumatoid arthritis and multiple sclerosis. The goal of this project is to characterise the organisation and interaction among intracellular Ca2 stores in smooth muscle using novel genetic technique. The lentiviral gene delivery system will be used to transduce the cells with fluorescent5 protein-tagged PARs in various rodent (rat & mouse) and immortalised (human and rodent in origin) cell types including neurones, astrocytes, smooth muscle cells and fibroblasts. The lentiviral gene delivery sytem will be used to transduce the cells with fluorescent protein-tagged PARs (green fluorescent protein).

Recipient or parental organism

E Coli strain
The host is disabled. Ecoli. K12 Auxotrophic strain is non-pathogenic to humans. coli are used only to amplify the viral transfer and packaging plasmids. Genes in these plasmids are not under the control of bacterial promoters and are thus not expressed in the bacteria. Each bacterial strain contains only one plasmid, to prevent recombination of viral genes between plasmids in the bacteria. STSL3 E coli will be used to amplify the packaging and transfer ’ectors (a standard plasmid DNA extraction). The scale of the activity is small, that of any standard lab plasmid amplification. The STBL3
E. coli are recombinase deficient, reducing the risk of unwanted homologous recombinations of long terminal repeats (LTRs). As previously stated, the gene products of the packaging and transfer vectors are not expressed in E. coli due to the absence of bacterial promoters. Human embryonic kidney cell line (HEK293 or HEK293 FT cells)
The host is disabled. HEK29S FT cells (InVitrogen) are a Human Embryonic Kidney cell line optimised for viral transfection. These cells are unable to survive outside tissue culture conditions and are antigenically incompatible if accidentally introduced to humans. These cells will be grown under containment level 2 conditions. The cells are used for the generation of the pseudoviruses and preparations are validated not to contain replication competent particles. Any preparations transduced with the harvested pseudovirus should not make virus since the transducing particles are replication incompetent and self-inactivating. Thus, the appearance of any capsid protein in supernatants from such preparations is indicative of replication competent retrovirus (RCR) and must be discarded. RCR testing is done with an ELISA kit to detect the p24 gag capsid protein in cells transduced with the virus. If the virus is functioning correctly, the gag gene is excluded from the virus, thus transduced cells cannot make new viruses, and consequently the culture medium assay will be negative.

Guinea-pig colonic myocytes
Guinea-pig portal vein myocytes
SO-i0Op1 of concentrated viral stock will be added directly to the culture medium of the myocytes under containment level 2 conditions. From this point on, the myocytes, medium and all cultureware associated shall be treated with level 2 containment and disposed of according to stated procedures (all media changes will be carried out in a class II microbiological safety cabinet, following this, all waste will be disposed of as per virus instructions). Cells will be safely transported to the microscope. Dishes will be sealed with parafilm and placed inside a larger culture dish inside a polystyrene box labelled clearly as virus containing. Virkon solution and blue roll will be made available in case of spillage and the microscope will be decontaminated after use with Virkon.

The myocytes are transduced with the pseudoviral particles. Pyhazards are unchanged. The virus only delivers GEP or plN-KDEL genes and these are self-inactivating and so incapable of being incorporated into new viruses. However, in the unlikely event that myocytes contained the lentivirus, these transgenes could not recombine into new viruses, and even if they possibly could, they would merely deliver an additional GFP or plN-KDEL gene with them which would make no difference to the hazard posed by the virus.

Host/vector system

Packaging Vectors — pRSV-Rev, pMDLg/pRRE and MD2.VSVG
Transfer Vector — pCCL.sin.PPTprom[Insert]*.Wpre
[Insert] refers to EGFP or plN-KDEL (an ER/SR targeting GFP) All the vectors are based on a pUC19 backbone, are defective in transfer to other hosts, are Bom, Tr&Mob and non-mobilisable (see SACGM ‘Compendium of Guidance’ 2007).

Packaging vectors:
pMDLg/pRRE - Genes = gag and pol. Encodes structural proteins (gag) and enzymes (reverse transcriptase, integrase & protease) for viral replication
These are also a rev response element in the encoded RNA (RRE, see later) - CMV promoter
pMD2.VSVG - Gene = VSV-G. Encodes envelope glycoprotein from the vesicular stomatitis virus - CMV promoter
pRSV-Rev - Gene = Rev. Rev interacts with transcribed viral RNAs (via the RRE) to facilitate nuclear export such that translation may take place. Rev is therefore beneficial for the expression of structural proteins to make daughter virions - RSV promoter

Transfer vectors:
pCCL.sinPPTprom.EGFP.Wpre - Gene = EGFP. Expresses EGFP - CMV promoter.

Origin & function

The lentiviral gene delivery system we plan to use is a 4 generation system, specifically designed for gene therapy applications. The origins of the lentiviral delivery system lie in attempts by Naldini and colleagues to engineer replication-defective HIV-1
Since the generation of this 1 generation system successive modifications have been made which enhance its safety and efficacy. This system is in use and is being further developed.

02/03/2022
developed in laboratory at the University of Leicester.
The advantages of the above lentiviral system are multi-fold and include:
1) Sustained expression of transgenes following stable integration into the host genome
2) Transgene expression in non-dividing cells (of special significance to muscle biologists).
3) Packaging and expression of large inserts (at least T5kbp).
4) Broad target cell range.
5) Low inflammatory potential due to lack of replication activity.
The goal of this project is to characterise the organisation of the intracellular Ca2 store, the sarcoplasmic reticulum, in smooth muscle, using a novel genetic technique. The lentiviral gene delivery system will be used to transduce the cells with a store located green fluorescent protein (c3FP). The GFP or p1N-KDEL (an ER/SR targeted enhanced GEP) will be used to target the sarcoplasmic reticulum. The use of the lentiviral gene delivery system is required because of the known difficulties in transfecting differentiated smooth muscle cells.

Evaluation of foreseeable effects
The lentiviral gene delivery system has been developed for gene therapeutic applications and, being replication deficient and self-inactivating has low toxicity. The system, first developed by Naldini and colleagues, has undergone numerous modifications to enhance biosafety and improve transduction efficiency. Therefore, there are no foreseeable difficulties.
In the event of replication competent retrovirus (RCR) generation, all viral stocks will be immediately disposed of with virkon (approved method). However, risk of generating RCRs is minimal. The only way RCRs could be generated is by multiple recombination events which have caused all packaging genes to end up on one plasmid, with packaging signals flanking them. Packaging and transfer vectors will be kept in separate bacterial cultures, so no cross-recombination can occur, and we will only transiently transfect the FT cells. The transfer vector is also self-inactivating; any genes transferred by the virus cannot be incorporated into new viruses as they will lack viral promoters. Therefore, the probability of RCR generation is virtually zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All handling of the host bacterium will take place within a containment level 1 laboratory, using standard microbiological practice which will be sufficient to keep contact with humans and the environment to negligibly low levels.
Solid waste (e.g. agar plates containing bacteria, pipette tips, used gloves etc) is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. After every use and/or when the liners are 3/4 full, they are removed from the bin, and placed inside a second autoclave bag to minimize the risk of spillage from a torn autoclave bag. The outer bag will then be loosely sealed with autoclave tape (to allow steam penetration during autoclaving), labeled with lab number, operator and date and then transported to an autoclave room on a trolley. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM', which results in their inclusion on a 'run' on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. On that basis the autoclaved material is disposed of in solid waste; removed by authorised waste-disposal specialist companies. The record is kept on file by the autoclave room staff. The routine autoclave regime will be 126°C for 30 mm, which has previously been established to produce a 100% kill (see waste inactivation guidelines regarding autoclaving and chemical disinfection (http://www.mis.strathacuklSecretariat/Publications/local/gmsc/gms-com.html)).
Liquid waste (e.g cultures in flasks or ‘spent media’ wherein the cells have been separated from the culture media by centrifugation) will be sterilised in the culture flasks the same day by addition of Virkon® to a concentration of 1% w/v, and left overnight Virkon-disinfected solutions will be disposed of into the wastewater supply. Virkon 1% solutions are stable for up to 7 days, and thereafter disinfectant solutions will be discarded (the pink colouration fades). (Virkon is a peroxygen compound and disinfection requires a contact period of at least 10 mm for 1% w/v solution: see http://www.relyon.dupont.com/index2.asp) Virkon will be used under the conditions set out by the manufacturer to ensure suitable inactivation. Please see www.relyon.dupont.com
Virally-treated (HEK293 cells, myocytes) and packaging cells (HEK293-ET) will be disposed of following disposal of culture medium by addition of 1% w/v Virkon to the culture vesSEL. The culture media will be drained and disinfected as previously detailed and the empty flask will be disinfected with 1% w/v Virkon. After leaving overnight, liquid waste will be disposed to the wastewater supply. Cultureware will subsequently be disposed as per solid waste.

Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v Virkon overnight (polypropylene and polystyrene centrifugation buckets, steel and glass are not corroded by 1% w/v Virkon). Glassware and buckets will then be rinsed in tap-water and dried.

The designated Class II Microbiological Safety cabinet and centrifuge will be disinfected by thoroughly wiping down with 1% w/v Virkon solution after every use. Wiping materials (e.g. blue roll) shall be disposed of as per solid waste. The Class II Microbiological Safety cabinet shall also be irradiated for 5 minutes with UV light. This is carried out as an extra precaution.

Virkon is sufficient to inactivate the virus.

Glass microinjector pipettes will be disinfected by complete submersion in 1% w/v Virkon overnight, washed and disposed of in safety bins.

**Project Ref** 298/08.3
PARs are G-protein coupled receptors whose upregulation is observed in a number of disease states including rheumatoid arthritis and multiple sclerosis. The goal of this project is to determine the physiological and pathophysiological role of PARs in various rodent (rat & mouse) and immortalised (human and rodent in origin) cell types including neurons, astrocytes, smooth muscle cells and fibroblasts. The lentiviral gene delivery system will be used to transduce the cells with fluorescent protein-tagged PARs (green fluorescent protein-PAR-1 (PAR1-GFP), enhanced yellow fluorescent protein (EYFP)-PAR-2 (PAR2-YFP) and enhanced cyan fluorescent protein (ECFP)-PAR-4 (PAR4-CFP) to investigate the consequences of receptor overexpression, EYFP alone as a control or with PAR RNAi to investigate receptor knockdown.

The host is disabled. E.coli K12 Auxotrophic strain is non-pathogenic to humans. E.coli are only used to amplify the viral transfer and packaging plasmids. Genes in these plasmids are not under the control of bacterial promoters and are thus not expressed in the bacteria. Each bacterial strain contains only one plasmid, to prevent recombination of viral genes between plasmids in the bacteria. STBL3 Ecoli will be used to amplify the packaging and transfer vectors (a standard plasmid DNA extraction). The scale of the activity is small, that of any standard lab plasmid amplification. The STBL3 E coli are recombinase deficient, reducing the risk of unwanted homologous recombinations of long terminal repeats (LTRs). As previously stated, the gene products of the packaging and transfer vectors are not expressed in the E.Coli due to the absence of bacterial promoters.

Human embryonic kidney cell line (HEK293 or HEK293 FT cells).

The host is disabled. HEK293 FT cells (Invitrogen) are a Human Embryonic Kidney cell line optimised for viral transfection. These cells are unable to survive outside tissue culture conditions and are antigenically incompatible if accidentally introduced to humans. These cells will be grown under containment level 2 conditions. The cells are used for the generation of the psuedoviral particles and preparations are validated not to contain replication competent particles. Any preparations transduced with the harvested pseudovirus should not make virus since the transducing particles are replication incompetent and self-inactivating. Thus, the appearance of any capsid protein in supernatants from such preparations is indicative of replication competent retrovirus (RCR) and must be discarded. RCR testing is done with an ELISA kit to detect the p24 gag capsid protein in cells transduced with the virus. If the virus is functioning correctly, the gag gene is excluded from the virus, thus transduced cells cannot make new viruses, and consequently the culture medium assay will be negative.
Lentivirus preparation and characterization will be carried out by Dr Kumlesh Dev at University College Cork. Viral replication incompetence/deficiency will be confirmed prior to transfer to the University of Strathclyde.

Primary cell culture: small quantities of 0.5-20.0 ul of concentrated pseudoviral particles (1x 10 (6) - 1x 10(10) muscle cells or fibroblasts) under containment level 2 conditions. The cells are transduced with pseudoviral particles, which are self-inactivating and so incapable of being incorporated into new viruses. The cells, medium and all culture shall be treated with level 2 containment and disposed after Virkon (1%w/v) and/or autoclave decontamination (all media changes will be carried out in a class II Microbiological Safety Cabinet). Prior to any movement of transduced cells from the Containment Level 2 laboratory, the bathing medium will be changed twice in order to reduce the risk to Containment level 1 activity/material. Cells will then be transported in sealed containers to microscopes (SIBS419, SIBS421, SIBS565, SIBS66, Centre for Biophotonics Rm 1&3). Microscopes to be used will be labelled for viral use. Dishes will be sealed with parafilm and placed inside a larger culture dish inside a polystyrene box labelled clearly as virus containing. Virkon solution (1% w/v) and blue roll will be made available in case of spillage and the microscope will be decontaminated after use with 1% w/v Virkon.

Organotypic Slice Culture: Small quantities of 0.5-20.0 ul of concentrated pseudoviral particles (1 x 10 (6) - 1 x 10 (10) TU/ml) will be added directly to the culture medium of organotypic slice cultures under containment level 2 conditions. Alternatively, 0.5 - 20.0 ul concentrated viral stock will be injected into the region of interest of an organotypic slice culture, for example CA1, CA3 or dentate gyrus region of a hippocampal slice culture or molecular or Purkinje cell layer of cerebellar slice culture using an electronically controlled glass microinjector pipette. This injection will require a dissection microscope and will be performed under containment level 2 conditions. Care should be taken when using glass pipettes and appropriate training will be taken prior to use. Should an injury be sustained, e.g. skin puncture, take appropriate action to encourage some bleeding, wash with running water and use antiseptic wipes to clean the injury and report the accident immediately to the Departmental Safety Convenor or the Biological Safety Officer. The organotypic slices are transduced with the pseudoviral particles which are self-inactivating and so incapable of being incorporated into new viruses. From this point on, the cells, medium and all culture shall be treated with level 2 containment and disposed after Virkon and/or autoclave decontamination (all media changes will be carried out in a class II Microbiological Safety Cabinet). Prior to any movement of transduced organotypic cultures from the Containment Level 2 laboratory, the bathing medium will be changed twice in order to reduce the risk to Containment Level 1 activity/material. Organotypic slices will then be transported in sealed containers to microscopes. Microscopes to be used will be labelled for viral use. Dishes will be sealed with parafilm and placed inside a larger culture dish inside a polystyrene box labelled clearly as virus containing. Virkon solution and blue roll will be made available in case of spillage and the microscope will be decontaminated after use with Virkon.

The vector

The system will use the cloning vector pLL4.0 as described by Osinde et al (2008) and the packaging vector from Invitrogen. A list of the individual vectors and references are given below. Also refer to Fig 1 which shows the vectors to be used.

Packaging vectors

ViraPower Packaging Mix: This mix contains an optimized mixture of the three packaging plasmids, pLP1, pLP2 and pLP/VSVG. These plasmids supply the helper functions as well as structural and replication proteins in trans required to produce the lentivirus. For further details please see http://tools.invitrogen.com/contents/sfs/manuals/virapower lentiviral systems man.pdf

Cloning vector:

pLL4.0: the EGFP will be replaced with EYFP, fluorescently tagged PARs or PAR RNAi and the CMV promoter replaced by cell type specific promoters including Phosphoglycerate Kinase (PGK) or synapsin. Please see Rubinson et al (2003) and Osinde et al (2008).

Origin & function

The lentiviral gene delivery system we plan to use is based on that described by Rubinson et al (2003) and Osinde et al (2008).

The advantages of the above lentiviral system are multi-fold and include:
1) Sustained expression of transgenes following stable integration into the host genome
2) Transgene expression in non-dividing cells.
3) Packaging and expression of large inserts (at least 7.5kbp)
4) Broad target cell range.
5) Low inflammatory potential due to lack of replication activity.

The origins of the lentiviral delivery system lie in attempts by Naldini and colleagues to engineer replication-defective HIV-1. Since the generation system successive modifications have been made which enhance its safety and efficacy.

The goal of this project is to determine the physiological and pathophysiological role of PARs in various cell types including neurons, astrocytes, smooth muscle cells and fibroblasts. The lentiviral gene delivery system will be used to transduce the cells with either fluoresceinently tagged PARs, EYFP as a control or RNAi. The use of the lentiviral gene delivery system is required because of the known difficulties in transfecting differentiated cells.

Evaluation of foreseeable effects

The lentiviral gene delivery system has been developed for gene therapeutic applications and, being replication deficient and self-inactivating has low toxicity. The system, first developed by Naldini and colleagues, has undergone numerous modifications to enhance biological safety and improve transduction efficiency. Therefore, there are no foreseeable difficulties.

In these systems the provirus are deleted from all regulatory and accessory genes (tat, rev, vif, gene W and gene Y), most gag/pol sequences, most of the envelope gene and most of the U3 region. Lentiviral vectors can mediate efficient delivery, integration and stable expression of transgenes in dividing as well as non-dividing human cells. Hence the use of a Class 2 facility for the production and purification of the viral particles is of multi-use to our experimental approaches. All materials and equipment will be disinfected after use and biological wastes will be autoclaved.

In the event of replication competent retrovirus (RCR) generation, all viral stocks will be immediately disposed of with Virkon. However, risk of generating RCRs is virtually zero. The only way RCRs could be generated is by multiple recombination events which have caused ALL packaging genes to end up on one plasmid, with packaging signals flanking them, which is highly improbable. Packaging and transfer vectors will be kept in separate bacterial cultures, so no cross-recombination can occur, and we will only transiently transfect the FT cells. The transfer vector is also self-inactivating; any genes transferred by the virus cannot be incorporated into new viruses as they will lack viral promoters. Therefore, the probability of RCR generation is virtually zero.

Direct Lenti virus contact
Counselling may be required when considering the potential hazard of protein X. This will be sought from Occupational Health, University of Strathclyde and/or the NHS.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All handling of the host bacterium will take place within a containment level 1 laboratory, using standard microbiological practice which will be sufficient to keep contact with
Humans and the environment to negligibly low levels.

Solid waste (e.g. agar plates containing bacteria, pipette tips, used gloves etc) is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. After every use and/or when the liners are 3/4 full, they are removed from the bin, and placed inside a second autoclave bag to minimise the risk of spillage from a torn autoclave bag. The outer bag will then be sealed with autoclave tape labelled with lab number, logged into the room. Prior to autoclaving, the seals are loosened (to allow steam penetration during autoclaving) and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them GM which results in their inclusion on a 'run' on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. All GM waste is autoclaved as above and removed as Clinical Waste by the University's authorised Waste Contractor. The record is kept on file by the autoclave room staff. The routine autoclave regime will be 126°C for 30 min, which has previously been established to produce a 100% kill.

Liquid waste (eg cultures in flasks or 'spent media' wherein the cells have been separated form the culture media by centrifugation) will be inactivated in the culture flasks the same day by addition of Virkon to a concentration of 1% w/v and left overnight. Virkon-disinfected solutions will be disposed of into the wastewater supply. Virkon 1% w/v solutions are stated to be stable for up to 7 days, and thereafter disinfectant solutions will be discarded (the pink colouration fades). However if discolouration occurs prior to 7 days, new stocks will be prepared (Virkon is a peroxygen compound and disinfection requires a contact period of at least 10 min for 1% w/v solution: see http://www.relyon.dupont.com/index2.asp and part vii below). Virkon will be used under the conditions set out by the manufacturer to ensure suitable inactivation. Please see www.relyon.dupont.com (please note Virkon is also known as ReplyOn MSD).

Virtually-treatment cells, including organotypic slice cultures and HEK293-FT cells, will be disposed of following disposal of culture medium by addition, to a final concentration of 1% w/v, of Virkon to the culture vessel. The culture media will be drained and disinfected as previously detailed and the empty flask will be disinfected with 1% w/v Virkon. After leaving overnight, liquid waste will be disposed to the wastewater supply. Cultureware will subsequently be disposed as per solid waste.

Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v Virkon overnight (polypropylene and polystyrene centrifugation buckets, steel and glass are not corroded by 1% w/v Virkon). Glassware and buckets will then be rinsed in tap-water and dried.

The designated Class II Microbiological Safety Cabinet and centrifugation will be disinfected by thoroughly wiping down with 1% w/v Virkon solution. Wiping materials (e.g. blue roll) shall be disposed as per solid waste. The Class II Microbiological Safety Cabinet shall also be irradiated for 5 minutes with UV light. This is carried out as an extra precaution. Virkon is sufficient to inactivate the virus.

Glass microinjector pipettes will be disinfected by complete submersion in 1% w/v Virkon overnight, washed and disposed of in glass safety bins.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University Genetic Modification Safety Committee has reviewed this application in detail, together with the local Genetic Modification risk assessment for (attached). The Committee is in agreement that the assessment of risk has been appropriately performed and that work can proceed at Strathclyde University, which is already registered with HSE as a Class 2 site.
# Project Additional Information

**Purposes of the contained use**

To assess the over-expression or knockdown of genes associated with cognition and their signalling partners, in the rat brain. The viral vectors (pseudotyped lentiviral and rAAV) contain modified genomes into which genes/shRNAs of interest have been inserted. The viral vectors will be injected into specific regions of the rat brain. Transduced regions of the rat brain will be analysed by in situ hybridisation, immunofluorescence and western blotting. The rats will also be assessed in behavioural tasks of cognitive performance.

**Recipient or parental organism**

Hooded Lister male rats.
Host/vector system

VSV-G pseudotyped lentiviral particles consist of a vesicular stomatis virus G glycoprotein (VSV-G glycoprotein) envelope, HIV-1 Gag-encoded capsid proteins, HIV-1 Pol-encoded reverse transcriptase and integrase enzymes and two RNA copies of the expression constructs. RAAV particles consist of a capsid of AAV serotype 5/7/8/9, two ITR sequences of AAV serotype 2 and one single stranded DNA copy of the expression constructs.

Origin & function

The genomes of the viral particles do not contain any viral genes but only viral sequences to facilitate nuclear export and packaging of the expression construct into virions (5’ and 3’ LTRs, Psi packaging signal and WPRE for the lentiviral particles or AAV2 ITR and WPRE for the rAAV particles). There have been a few reports of some forms of this element expressing truncated forms of the WHV x protein, which has oncogenic properties. Studies into the association of WPRE and oncogenicity are ongoing. Rat cDNAs and synthetic shRNA sequences will be cloned into the viral vector genome. In addition cDNAs for fluorescent markers, including GFP and eGFP will be included. Upon infection/transduction of host cells, the RNA genome of the lentivirus is reverse transcribed into double stranded DNA which is randomly integrated into the genome of the host cell and the single stranded DNA of the rAAV is used as a template to generate double stranded DNA. This primarily remains episomal but in a small percentage of infections it integrates into the genome of the host cell.

Tranduced cells will therefore express the viral DNA. The cDNA transgenes in the viral genome will result in over-expression of genes associated with cognition, whilst the shRNAs will result in gene expression knockdown of genes associated with cognition. Transduced cells will be observed fluorescently. As the viral genomes do not contain any viral genes there will be no over-expression of viral genes in infected cells and consequently no production of new viral progeny.

Evaluation of foreseeable effects

These viral particles are replication deficient. They therefore perform a "one hit" infection without viral progeny being formed. For this reason, animals which have been injected with this agent should not excrete the viral particles in any form. Thus no special measures need to be adopted for the housing of these animals. The genetic modification is localised to the infected cells (small brain regions). The viral vectors do not carry any viral genes and therefore cannot make new viral progeny in infected cells. Therefore no virus can be shed from infected rats. Upon injection, the virus infects brain cells within 1-2mm of the injection site. These cells will contain the transgenes encoded in the viral genome. There will be no viable virus circulating in the rats and no new viral progeny produced. There is no germline transmission of the genetic modification and so the genetic modification to the brain cannot be inherited.

The routes by which exposure to the viral particles present a risk to health, if control measures are not adopted are as follows: Penetration or absorption through skin or cut in skin, oral self inoculation and accidental parenteral inoculation via needle stab. This may result in an immune response such as transient swelling and inflammation localised to the site of injection or penetration. There may be overexpression of genes in a small number of cells around the injection site. Overexpression of EGFP containing pseudoviral particles is not a biological hazard. Psychosis-related PsyRING genes are not predicted to cause a risk to health of the individual involved.

The viral vectors do not contain the WPRE (Woodchuck Hepatitis Virus Post-transcriptional regulatory element) to facilitate nuclear export of viral mRNA. There have been a few reports of some forms of this element expressing truncated forms of the WHV X protein, which is though to have ongogenic properties. Only the cells infected by the original virus will contain this sequence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals will be housed individually following surgical procedures. The room where these animals will be kept will be labelled, as will the individual cages to indicate that viral work has taken place. Animals do not require to be housed in a separate room since the likelihood of animals, other than those who have been injected, coming into contact with viral particles is minimal. Animal house staff will be fully informed of animals that have undergone the procedure.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All plasticware and experimental reagents that come into contact with the viral particles and transduced cells will be soaked in 3% Virkon (final concentration) for 24 hours in a designated category II hood, prior to sealing in two autoclave bags. The waste will then be autoclaved and disposed of via the University's authorised waste disposal contractor. Genetically modified brains will be dissected form the rats and transported from Strathclyde University on dry ice, in sealed containers and taken to the PsyRING laboratories at the University of Glasgow by taxi/public transport by the research scientists involved in this project. Rat carcasses will be stored within the animal facility at Strathclyde University at -20°C and disposed as clinical waste via the University's authorised waste disposal contractor for incineration. The genetically modified rat brains will be sectioned onto glass slides for immunohistochemistry at the University of Glasgow. These sections will be autoclaved and disposed as routine glass waste at the University of Glasgow. Unused brain material will be stored at -20° and disposed as clinical waste via the University's authorised waste disposal contractor for incineration. Disposal of transduced material is covered by Glasgow University GM committee ref:GM37/n.08.2/A001.

The University Genetic Modification Safety Committee has reviewed this application in detail, together with the local Genetic Modification risk assessment form (attached). The Committee is in agreement that the assessment of risk has been appropriately performed and that work can proceed at Strathclyde University, which is already registered with HSE as a Class 2 site.

Non-GMM | Consent Granted
The work will involve disrupting genes that encode for the virulence determinants of selected ACDP category 2 pathogenic bacteria in order to attenuate virulence. As such, we intend to generate GMM's that are actually less virulent than the parent strains in order to study the mechanism of disease by mutagenesis of virulence factors. We will also test the attenuation of virulence using a variety of tissue culture based assays as well as using non mammalian hosts such as Caenorhabditis elegans and Acanthamoeba spp. To assess alterations in host-pathogen interactions without the use of whole animal models. Strains to be examined include:

- Salmonella enterica (non-typhoidal serovars and the attenuated vaccine strain Ty21a) (PH, NT, JY)
- Escherichia coli (including lineage of Shigella sonnie; non-vero/shiga-toxin-producing) (PH, NT, JY)
- Campylobacter jejuni (PH)
- Corynebacterium diphtheriae, Corynebacterium spp (PH)
- Staphylococcus aureus and coagulase-negative staphylococci (PH,NT)
- Mycobacterium marinum, Mycobacterium smefmatis (PH, NT)
- Nocardia farcinica and related Nocardia spp. (PH)
- Burkholderia cepacia (NT)
- Pseudomonas aeruginosa syringae (NT)
- Vibrio vulnificus and related category 2 Vibrio spp., excluding Vibrio cholerae (NT)

A. Cloning of DNA fragments from pathogenic bacteria is non-mobilisable vectors into laboratory strains of E. coli such as DH10B, DH5a, JM110, JM109, MC1000 etc. with a view to sequencing or mutating the fragments.
B. Generating mutants in wild type strains by random transposon mutagenesis using eg. mud-lac and resulting in insertional inactivation, linked in some cases with the creation of transcriptional fusions to reporter genes.
C. Creation of mutants of pathogens by allele replacement using a suicide vector (or insertion duplication vector) e.g pK18mob.
D. Allele replacement using a gene that expresses a marker protein which is highly unlikely to have any biological effect (such as beta-galactosidase, luciferase, green-fluorescent protein, red-fluorescent protein) into a pathogen to monitor gene expression under different environmental conditions.
E. Expression of proteins at a high level in a disabled host bacterium (eg. E. coliBL21 to enable further chemical/biochemical characterisation of the protein.) Proteins will also be expressed in the original pathogenic host organism in order to complement mutations.
F. Expressing in the originating strain of a gene from a pathogenic bacterium running off its own promoter on a shuttle vector (eg pNV19), in order to complement a mutant phenotype, thus confirming the function of that gene.
G. Expression and disruption of natural antibiotic resistance determinants in a host bacterium to enable further characterisation of the resistance mechanism.
### Hosts for activities A-G as listed above.

Activity A - Disabled laboratory strains of *E. coli* and pathogenic bacteria as described above including *Salmonella enterica* (non-typhoidal serovars and the attenuated vaccine strain Ty21a), *Escherichia coli* (including lineage of *Shigella sonnie*; non-vero/shiga-toxin-producing), *Campylobacter jejuni*, *Corynebacterium diphtheriae*, *Corynebacterium smegmatis*, *Nocardia farcinica* and related *nocardia* spp., *Burkholderia cepacia*, *Pseudomonas aeruginosa*, *Pseudomonas syringae*, *Vibrio vulnificus* and related category 2 *Vibrio* spp.

Activities B, C and D - Wild type pathogenic bacteria as described above in section 6.

Activity E - Lab strains of *E. coli* and pathogenic bacteria as described above.

Activity F - Lab strains of *E. coli* and pathogenic bacteria as described above.

Activity G - Lab strains of *E. coli* and pathogenic bacteria as described above.

### Host/vector system

Hosts for activities A-G as listed above.

Activity A - Disabled laboratory strains of *E. coli* including DH5a, DH10B, MC1000, BL21, JM109 and pathogenic bacteria as described above, including *Salmonella enterica* (non-typhoidal serovars and the attenuated vaccine strain Ty21a), *Escherichia coli* (including lineage of *Shigella sonnie*; non-vero/shiga-toxin-producing), *Campylobacter jejuni*, *Corynebacterium diphtheriae*, *Corynebacterium* spp, *Staphylococcus aureus* and coagulase-negative *staphylococci*, *Mycobacterium marinum*, *Mycobacterium smegmatis*, *Nocardia farcinia* and related *nocardia* spp., *Burkholderia cepacia*, *Pseudomonas aeruginosa*, *Pseudomonas syringae*, *Vibrio vulnificus* and related category 2 *Vibrio* spp.

Activities B, C and D - Wild type pathogenic bacteria as described above in section 6.

Activity E - Lab strains of *E. coli* and pathogenic bacteria as described above.

Activity F - Lab strains of *E. coli* and pathogenic bacteria as described above.

Activity G - Lab strains of *E. coli* and pathogenic bacteria as described above.

### Vecotrs for activities A-G as listed above.

Activity A - Any non-mobilisable or mobilisation-defective vector.

Vectors include:

Activities B, C and D - Non-mobilisable or mobilisation defective vectors that can be propagated in safe laboratory strains of *E. coli* strains but not in target species, eg. pUC replicates in safe laboratory strains of *E. coli* but not in *C. jejuni*. Or *Corynebacterium, Nocardia, or mycobacteria*; show temperature sensitive replication in *E. coli* eg pNIL and pGOAL series; recombine with the target gene on the chromosome to cause insertional duplication of the plasmid in *S. pneumoniae*, eg p326(cat)pDL278(spc),pCR2(erm).

pSUP102 and derivatives: Tn5-B10 (KanR0, B11 and B12 (GentR), B13 (tetr), B20 (KanR) Transposon mutagenesis vector (Hobbs et al. PiiS and PiIR, a two component transcriptional regulatory system controlling expression of type 4 fimbriae in Pseudomonas aeruginosa. Molecular Microbiology (1993) vol. 7 (5) pp. 669-82).

pML1 (GmR) and pLR27 (KmR), and pALMAR3 for Tn5 delivery to the chromosome (Runyen Janecky et al. The virulence plasmid-encoded impCAB operon enhances survival and induced mutagenesis in Shigella flexneri after exposure to UV radiation. Infection and Immunity (1999) vol. 67 (3) pp. 1415-23).

pKNG101 and pEX100 and derivatives, host restricted to the attenuated E. coli strain CC118 (Bordi et al. Regulatory RNAs and the HptB/RetS signalling pathways fine-tune Pseudomonas aeruginosa pathogenesis). Molecular Microbiology (2010).

Activity E - Non mobilisable vectors, eg pGEX series, the pET and pCAL vectors, that express the protein, either from strong promoters or from the gene's native promoter in its native form or as part of a his-tagged, calmodulin-binding peptide-tagged or similar fusion to an innocuous protein. pET family vectors include pET21a and pET28, pQE30X (for generating his tagged proteins, Qiagen), pEGFP and derivatives for engineering GFP fusions. pAC or pAN and derivatives: aviTag. AmpR. pBAD vectors and derivatives for use as arabinose inducible expression vectors. GATEWAY plasmids (Invitrogen) for recloning and expressing tagged genes. pT7 and derivatives for overexpression of tagged proteins.

(Kelin et al.; Expression cloning of a cDNA encoding a retinoblastoma-binding protein with E2F-like properties. Cell (1992) vol. 70 (2) pp. 351-64

Studier et al. Use of T7 RNA polymerase to direct expression of cloned genes. Meth Enzymol (1990) vol. 185 pp. 60-89

Activities F and G - Non-mobilisable or mobilisation defective shuttle vectors which carry origins of replication that work in both E. coli and a given other pathogen (eg Corynebacteria, Mycobacteria and Nocardia - pNV18, pK18, pEPR1 and pMP220 in P. aeruginosa and B. cepacia). The vectors used in activities F and G include vectors already listed above associated with activities A-E.

Origin & function

The GMM's generated in this work will be defective in selected virulence determinants such as:
1) Protein secretion systems e.g. PA1663 and PA2359 from P. aeruginosa, that regulate a novel secretion system
2) Metabolic pathways that allow colonisation of other organisms e.g. nitric oxide reductase
3) Stress response systems e.g. nitrosative stress response genes
4) Transcriptional regulators of the above systems e.g. sigma factors such as rpoN. As such, the resulting strains will be less virulent than the wild-type parent strain. We
will also utilise common selective markers from existing systems such as widely used antibiotic resistance markers. Promoter sequences from parent strains will be fused
to genes encoding commonly used enzymatic and fluorescent markers such as GFP and beta-galactosidase. Disease causing ability of wild type and mutated strains will
be assessed using cell based tissue culture assays and non-mammalian infection models such as C. elegans and Acanthamoeba spp.

Well charcterised transposable elements, eg for Salmonella - Mud-lac: For pseudomonas - mini-Tn5, mini-ctx and its derivatives mini-Tn5-luxCDABE, mini-Tn5-gfp,
mini-Tn5-lac: Beta galactosidase, firefly or luminescent vibrios for luciferase, jellyfish for GFP and other fluorescent marker proteins; for Mycobacteria, Corynebacteria and
Nocardia - Tn5 derivatives EZ-Tn (Epicentre), pNV18, pK18 and their derivatives.

Genes overexpressed in E. coli will include transcriptional regulators that control the expression of virulence determinants in the pathogenic strains (e.g. enhancer binding
proteins from P. aeruginosa, that regulate a novel secretion system), although the targets of regulation are not present in E. coli

**Evaluation of foreseeable effects**

Disease causing ability of wild type and mutated strains will be assessed using cell based tissue culture assays and non-mammalian infection models such as C. elegans
and Acanthamoeba spp.

Effects of mutating transcriptional regulators will be assessed using promoter fusion assays by measuring the activity of fused beta-galactosidase, green fluorescent protein
(or its derivatives) or luciferase.

For specific activities:
- Activity A - No risk to human health, this part of the work falls into containment level 1.
- Activities B, C and D - The disruption of putative virulence genes anf their fusion to reporter genes will produce a GMM which will be no more hazardous than the wild type
  (likely to be less hazardous) and which can therefore be handled at the ACDP category relevant to the wild type - i.e. level 2.
- Activity - The disruption of putative virulence genes and their fusion to reporter genes will produce a GMM which will be no more hazardous than the wild type and which
can therefore be handled at the ACDP category relevant to the wild type - i.e. level 2.
- Activity D - The introduction of the gene for the marker protein and disruption of the resident gene will produce a GMM which will be no more hazardous than wild type and
can therefore be handled at the ACDP category relevant to the wild type - ie level 2.
- Activity E - Proteins that will be over-expressed and purified in E. coli will include transcriptional regulators that will be out of their genomic context (ie. They will have no
regulatory target in E. coli).
- Activity F - The shuttle vector simply re-introduces a characteristic that was already present in the wild type and had then been removed by mutagenesis. The procedure will
therefore produce a GMM which will be no more hazardous than the wild type.
- Activity G - No risk to human health

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All workers on level 6 of the SIPBS Hamnett Wing (Class 2 area), including those who are not directly involved, will be informed that GM work involving the organisms listed
above is ongoing.

Contaminated disposable plasticware are collected in autoclave bags for sterilisation after experiments. Other disposable plastics and non-disposable glassware are
soaked in 5% (W/V) fresh (< 48 hours old and still pink in colour) virkon overnight prior to disposal or washing and re-use to autoclave bags for sterilisation. Always clean
the work bench surface after work.
Solid-Solid waste for disposal will be bagged in approved autoclave bags and loosely sealed with autoclave temperature indicator tape and placed in the waste boxes provided by SIPBS and autoclaved at 121°C before disposal. Waste boxes will be labelled with the laboratory of origin and a contact name and telephone number. Waste will be disposed of via the University's approved contractor. Kill level for these procedures is effectively 100%. The autoclave is validated annually.

Liquid - Liquid waste will also be chemically treated with Virkon to a final concentration of 5%, and autoclaved prior to disposal in designated sinks. Virkon solution should be fresh (no more than 48 hours old). Again, the kill level for these procedures is effectively 100%

Small spillage (less than 25 ml), will be dealt as follows. A) on even surface (eg bench top): paper towels are to be used to absorb the spillage and then 5% (W/V) of fresh Virkon solution. Paper towels are collected to autoclave bags for sterilisation prior to disposal. B) Broken culture tubes in a centrifuge: collect broken tubes to autoclave bags, absorb the bacterial culture with paper towels from the rotor and collect paper towels to autoclave bag. Spills in the centrifuge will be cleaned by removal of the rotor, immersion in 1% Virkon for 10 min followed by its washing with soapy water, rinsing and drying. The centrifuge bowl will be cleaned by wiping with Virkon solution soaked paper towels which will be collected to autoclave bags for subsequent sterilisation by autoclaving. Spill granules are available for large spillages (e.g. >50ml). Spill granules should be collected and disposed of by autoclaving in the manner described above. The area should then be cleaned with fresh 5% Virkon solution as described above. Culture volumes are less than 1 litre.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University Genetic Modification Safety Committee has reviewed this application in detail, together with the local Genetic Modification risk assessment forms. The committee is in agreement that the assessment of risk has been appropriately performed and that the work can proceed at Strathclyde University. Stathclyde University is already registered with HSE as a Class 2 site.

The brain is a complex network, where billions of neurons are highly interconnected. We know very little about how diverse neurons work collectively to process incoming sensory signals and to make appropriate actions with correct decisions. Traditionally, neurophysiological investigations with in vivo electrophysiology have revealed neural correlates of such processes. However, "optogenetic" approaches now allow us to elucidate "casual" relationships between neural activity in the specific circuit and behaviours. The channelrhodopsin-2 (ChR2) and halorhodopsin are such optogenetic actuator proteins, which allow us to manipulate neuronal activity with high temporal resolution. Given this context, this activity aims to investigate the neural mechanisms of information processing at the neural circuit level. By manipulating neural activity with optogenetic tools, effects of manipulated activity on neural transmission and behaviours will be assessed.

Recipient organism is rats.

The AAV vector will be stereotaxically injected in the brain. The virions will infect/transduce nerve cells in the close vicinity (approx 1mm radius of the injection site and will not replicate outwith this site.

Following infection, double stranded DNA is synthesised from the viral single stranded DNA which can either remain in the nucleus (episomal) or in a small number of instances may integrate into the host genome. Due to the injection site in the brain, minimal tropism and lack of viral replication, no germ cells will be infected by the virus.
AAV vectors contain recombinant transgene sequences (see below) flanked by the AAV inverted terminal repeats (ITRs) which consist of only 6% of the wild type AAV genome. The removal of the viral structural genes renders the vector replication-incompetent. Therefore they are unable to establish a productive infection and thus amplify in infected cells. It is a "1 hit" infection in brain cells.

The following plasmids are used to produce the viral particles:

- CaMKlla.ChaR2(H134R)-EYFP
- CaMKlla.ChR2(H134R)-mCherry
- CaMKlla.eNpHR3.0-EYFP
- CaMKlla.ChR2-EYFP
- CAG.ChR2(H134R)-mCherry
- Syn.eNpHR3.0-EYFP
- Syn.ChR2(H134R0-EYFP
- Syn.ChR2(H134R)-mCherry

These plasmids and viral particles are commercially available from the Penn Vector Core at the University of Pennsylvania or the University of North Carolina. The maps of these plasmids are available online at www.addgene.org or www.optogenetics.org

Origin & function

The vector is AAV where one of the following plasmids will be inserted:

- CaMKlla.ChR2(H134R)-EYFP.WPRE
- CaMKlla.ChR2(H134R)-mCherry.WPRE
- CaMKlla.eNpHR3.0-EYFP.WPRE
- CaMKlla.ChR2-EYFP
- CAG.ChR2(H134R)-mCherry.WPRE
- Syn.eNpHR3.0-EYFP.WPRE
- Syn.ChR2(H134R0-EYFP.WPRE
- Syn.ChR2(H134R)-mCherry.WPRE

All AAV vectors are commercially available.

All AAV vectors contain recombinant transgene sequences flanked by the AAV converted terminal repeats (ITRs) which consist of only 6% of the wild type AAV genome. The removal of the viral structural genes renders the vector replication-defective and dependent on adenovirus helper functions. Thus, the viral particles are replication incompetence/deficiency will be performed by the Penn Vector Core at University of Pennsylvania or the University of North Carolina before transfer to University of Strathclyde.

<Promoters>

- CaMKlla promoter: a promoter of alpha CaMKII. Expression under control of this element tends toward to the forebrain, in particular excitatory neurons.
- CAG promoter: a combination of the cytomegalovirus (CMV) early enhancer element and chicken beta-actin promoter. The CAG promoter is frequently used to drive high levels of gene expression in mammalian expression vectors.
- Syn promoter: a promoter of human synapsin 1. Expression under control of this element tends toward to neurons.

<Transgenes>

- ChR2 and ChR2(H134R): Channelrhodopsins are a subfamily of opsins proteins that function as light-gated ion channels. They serve as sensory photoreceptors in unicellular green algae, controlling phototaxis. Expressed in cells of other organisms, they enable the use of light to control intracellular acidity, calcium influx, electric excitability, and other cellular processes. Three channelrhodopsins are currently known and ChR2 is one of them. ChR2 is nonspecification channels. ChR2(H134R) is
introduced the mutation of Histidine 134 to Arginine in order to optimize its performance.

eNpHR3.0 Halorhodopsin (NpHR) is a light-driven ion pump, specific for chloride ions, and found in phylogenetically ancient archaea, halobacteria. Just as ChR2 opens up to the ability to activate excitable cells (such as neurons) with blue light, NpHR opens up the ability to silence excitable cells with brief pulses of yellow light. Enhanced NpHR3.0 is the latest version of engineered NpHR, where the C-terminal trafficking signal from the potassium ion channel Kir2.1 is added to improve the localization to the plasma membrane and inhibitory capacity.

<Reporter>
EYFP: One of derivatives of GFP (green fluorescent protein), which is protein composed of 238 amino acid residues that exhibits bright green fluorescence when exposed to blue light. This enhanced yellow fluorescent protein is a colour mutant GFP.

mCherry: One of the Fruit Fluorescent Proteins, which are mutants derived from mRFP1, monomeric mutant of DsRed, by directed mutagenesis. It has been demonstrated stable expression, perform successfully in numerous fusion applications, and are already well characterised and recognised in the literature.

<Other element>
WPRE: Woodchuck Hepatitis Virus Post-transcription Regulatory Element. The WPRE contains an enhancer element We1, a promoter for the woodchuck hepatitis virus (WHV) X protein, and the sequence for the first 60 amino acids of the X protein. The WPRE therefore has potential promoter activity and the potential to express a 60 amino-acid X protein-derived peptide. It has been suggested that the X protein is pivotal to the generation of liver cancers. It has been suggested that the X protein truncated at the C-terminal may have oncogenic properties if expressed (Tu et al 2001) Cancer Research 61, 7803-7810). However, many studies have suggested that the X promoter is non-functional in the absence of a second enhancer, We2, which is not present in the WPRE, and this has been confirmed in the context of at least a lentiviral vector (Nash et al 2004 J Gene Med 6, 974-983). At present there is no direct evidence that the N-terminal fragment used as a cis element in vectors is oncogenic (Kingsman et al 2005 Gene Therapy 12, 3-4). Thus, although there still remains the possibility that the WPRE might present a negligible risk when handling transfected tissue thereafter if expressed, it is unlikely that the X promoter becomes functional without We2, and that X proteins truncated at the N-terminal have oncogenic properties.

Evaluation of foreseeable effects

In the unlikely event that these GMOs were to escape, they may be able to survive for an unknown period of time and may survive long enough to breed. However, there would be no germline transmission of the genetic modification and thus the genetic modification would not be transmitted to the offspring.

Thus, the GM does not increase the level of risk to the health of the human population and to the environment above that of non-GMO if animals were to escape.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Rats are indigenous to the UK and therefore in the unlikely event that these GMOs were to escape they would probably be able to survive and breed in the environment outside the containment. However, the genetic modification will only be in the brain and not in the germ cells and therefore cannot be transmitted.

Additionally, ChR2 or NpHR expression does not increase the capacity for environmental survival or give the GMO a competitive advantage. The genetic modification to these animals will exist solely in the small number of region specific transduced cells in the brain.

Thus, the GMO does not represent an increased hazard to the environment compared to the parental organisms and consequently presents minimal risk to the environment. Therefore, control measures will be secured animal unit with rodent barriers.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A the right viral dilution stage, wate and plastic-ware will be exposed to Virkon® to a concentration of 3% w/v, and left overnight. Virkon-disinfected solutions will be
disposed of into the waste water supply. Virkon 3% solutions are stable for up to 7 days, and thereafter disinfectant solutions will be discarded (the pink colouration fades). (Virkon is a peroxigen compound and disinfecton requires a contact period of at least 10 min for 1% w/v solution: see www.anachem.co.uk and part vii below).

Non liquid waste will then be placed into designated autoclave bags. This waste will be double bagged. When the bags are no more than 3/4 full, they are loosely sealed with autoclave tape (to allow steam penetration during autoclaving), labelled with lab number, operator and date and then transported to the autoclave room (BPU RW538) on a trolley. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM', which results in their inclusion on a 'run' on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. All GM waste is autoclaved as above and removed as Clinical waste by the University's authorized Waste Contractor. The record is kept on file by the autoclave room staff. The routine autoclave regime will be 126°C for 30 min, which has previously been established to produce a 100% kill.

At the injection stage, in the unlikely event of a spillage these areas will be disinfected by wiping the surface with a 23% w/v Virkon solution, leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towel will then be bagged for disposal as solid waste. Any plastic-ware will then be disposed of as described above.

Since the viral particles are replication deficient and will not be shed from the animals, it will not be necessary to dispose of bedding separately and no specific disposal procedure is required.

Cadavers will initially be frozen before being disposed of via the University's Clinical Waste Service to an authorised waste contractor.

**Historical Date of Additional Info**

02/03/2022
E. coli O157:H7 is a toxigenic strain of E. coli and ingestion of the organism may occasionally lead to severe illness including life threatening hemolytic-uremic syndrome. E. coli O157:H7 is a class 3 organism according to the ACDP classification and as such requires level 3 containment for safe use, a requirement that can limit studies on this organism due to the expense of constructing and maintaining such facilities. A naturally occurring strain of E. coli O157:H7, retaining the O157 and H7 phenotypes but which is non-toxigenic, since it lacked the toxin genes stx1 and stx2, was previously chromosomally marked with the lux CDABE cassette using transposon mutagenesis to provide a low-risk substitute to verocytotoxin producing E. coli O157:H7 in environmental survival studies (Ritchie et al 2003). A strain of S. enterica serovar typhimurium containing a plasmid borne lux gene fusion is also available enabling safer and more accurate detection and quantification of this organism (Lewis et al. 2006). The purpose of this project is to use a luminescence assay to determine how a range of environmental parameters effect the survival and activity of the bacteria. This project will not involve the creation of any new GMOs.

The recipient E. coli strain was a naturally occurring isolate of E. coli O157:H7 which was shown via PCR to lack the genes stx1 and stx2 which encode cytotoxins. The recipient Salmonella strain was S. enterica serovar typhimurium DT104 which is a well characterised and common pathogen in humans.

The recipient E. coli strain was mated with with E. coli s17 lambda pir which contained a suicide plasmid harbouring a transposon Tn5 derivative with a luxCDABE cassette. The absence of the suicide plasmid in the transposon mutated E. coli O157:H7 strain was confirmed by an inability to grow on ampicillin (the plasmid conferred ampicillin resistance) and via small scale plasmid DNA preparations.

The recipient S. enterica strain was transformed, via electroporation, with the broad host range plasmid pBBR1MCS-5 in which the lux CDABE genes from Photorhabdus luminescens had been cloned. Gentamycin selection was used to confirm transormation since the plasmid encodes gentamycin resistance.

The genetic material transferred to the E. coli O157:H7 strain included a gene for kanamycin resistance enabling antibiotic selection for successful transposon mutagenesis together with the lux CDABE cassette from Photorhabdus luminescens encoding the ability to produce bioluminescence.

The genetic material transferred to the S. enterica strain included a gene for gentamycin resistance enabling antibiotic selection for successful transformation together with the lux CDABE cassette from Photorhabdus luminescens encoding the ability to produce bioluminescence.

There are no hazards arising directly from the inserted DNA since the genes do not encode the production of any toxins or other virulence factors or extend the host range of the bacteria. In the case of the genetically modified strain of E. coli, the likelihood of the inserted DNA being transferred to related organisms is small and in any case they would not increase the pathogenicity of the recipient organisms. The naturally occurring non-toxigenic strain of E. coli O157:H7 does not pose a risk to the environment and the genetic modification performed has not resulted in any increased potential for environmental damage.

The likelihood of the inserted material in the modified strain of S. enterica being transferred to other organisms is greater since the plasmid containing the cloned DNA has a broad host range and is mobilisable if the RK2 transfer function is provided in trans (Kovach et al 1995). However, even if transfer did occur it would not increase the pathogenicity of the recipient organisms or their ability to cause environmental damage.

It is well-established that the toxin genes stx1 and stx2 play a key role in virulence of entero-hemorrhagic strains of E. coli O157:H7. The lack of stx genes in the naturally occurring non-toxigenic strain of E. coli O157:H7 means that it is a low risk to human health. However, if this bacteria were to acquire the ability to produce toxins via plasmid
Transfer from another organism it has the potential to cause disease since it retains the intimin phenotype and can colonise human guts (Ritchie et al. 2003). In such circumstances the genetic modification of the strain increases the risk to humans marginally since kanamycin would no longer be an effective antibiotic with which to treat any disease. It should be noted, however, that kanamycin is actually very rarely used as a treatment for E. coli O157:H7 infections in any case.

S. enterica serovar Typhimurium DT104 is recognised as a major cause of food poisoning worldwide and is assigned to Hazard Group 2. The wild type strain is characterised by multiple drug resistance and hence the genetic modification does increase marginally the risk to human health since gentamycin would no longer be an effective treatment in case of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This work will produce a variety of wastes including contaminated pipette tips, agar plates and liquid cultures. Contaminated pipette tips are immediately placed in a solution of sodium hypochlorite (12-14% v/v aqueous solution) and subsequently autoclaved using a cycle including an initial steam purge and kill step of 121 °C, 15 psi for 20 minutes. All petri dishes and liquid wastes are killed via autoclaving as described above. Autoclave tape is routinely used and the efficacy of the kill cycle regularly checked by autoclaving a thick culture (approx 1 E9 colony forming units per ml) and subsequently plating on non selective agar and checking for growth at 37 °C over a 4 day period. All autoclave use is documented and autoclaves are subject to regular inspections and maintenance.

### Project Additional Information

**Purposes of the contained use**

To minimise the risk of infection from class II cell lines, in accordance with good microbiological practice and the protection of both work and worker. Work carried out at the premises will be limited to research activities.

**Recipient or parental organism**
The cell lines used may include adenovirally transformed lines (e.g., HEK-293) or cells classed as Biosafety level 1 that have been transfected with mammalian expression vectors or via adenovirus. The cell lines themselves are not infectious.

### Host/vector system

The GM cell lines may be virally transformed, adenovirally transfected or stably transfected using expression vectors. Adenovirus has been identified by the ACDP as a Level 2 Biosafety Hazard. However, the risk of transmission to humans in this activity is considered negligible. In some cases the inserted product may be expressed as a membrane bound protein. The antigens under study are not in themselves pathogenic but should be handled according to good microbiological practice.

### Origin & function

Adenovirus has been used to transform some commercially available cell lines, in order to render them immortal for long-term culture. Adenovirus is also as a means of introducing a gene of interest for over-expression, usually at the cell surface, for use as a selection target. The product may occasionally be released into the medium as a soluble protein, or purified from the cell, but will then be captured for use as a selection target or for in vitro characterisation and testing of the antibodies under development.

### Evaluation of foreseeable effects

Biosafety level 2 hazard is introduced to the proposed work by use of adenovirally transformed or transfected cell lines. Other cell lines or products are currently evaluated at level 1. The risk of transmission of adenoviruses from these systems to humans is negligible and the cell and genetic material will not survive in the external environment. Standard level 2 decontamination and containment facilities are in operation. Overall, the foreseeable effects are considered negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cell lines will be cultivated in disposable plasticware at a scale from 50ul to 500ml under aseptic conditions and harvested by centrifugation. All waste resulting from these procedures will be either chemically inactivated or autoclaved prior to disposal. All equipment and materials used within the procedures will also be sterilised by autoclaving for 20 minutes at a temperature of 121 degrees C or chemically disinfected (e.g., Virkon, TriGene, or Proceine40) prior to disposal or re-use. All operations will be performed in laboratory facilities in which spillages can be effectively disinfected so the wider environment is unlikely to become contaminated.

Project Ref 302/01.3

Date Ackn'd 02/05/2001  CU2 Project Title ADENO VIRAL INFECTION OF CELLS FROM DISEASED TISSUE AS A TOOL TO

Class 2  CultureVolClass2 < 1 litre  CultureVolumeClass3-4

02/03/2022  Page 6035 of 15326
This project aims to use replication deficient adenoviral vectors to investigate intracellular signalling in cell lines and in human cells from diseased synovial tissue. These replication deficient adenoviruses can still infect cells but not replicate within them. Thus, if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, would ensue. Many people have immunity due to previous exposure, however, as this is a common pathogen. The project will not involve the production of new recombinant adenoviruses on site using vector DNA, but will involve growup of adenoviruses from imported stock using the 293 cell line, and infection of cells.

Host/vector system

This project aims to use replication deficient adenoviral vectors to investigate intracellular signalling in cell lines and in human cells from diseased synovial tissue. These replication deficient adenoviruses can still infect cells but not replicate within them. Thus, if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, might ensue. There could be no other complications unless a massive dose of virus was deliberately injected intravenously. The project will not involve the production of new recombinant adenoviruses on site using vector DNA, but will involve growup of adenoviruses from imported stock using the 293 cell line, and infection of cells. These imported stocks are all from the Kennedy Institute of Rheumatology and have been carefully monitored to exclude contamination with wild-type adenovirus.

Origin & function

It is primarily planned to use

1) A replication deficient adenovirus with no insert (as a control).
2) A replication deficient adenovirus transferring the beta-galactosidase gene. This is a non-harmful molecule that is useful for determining viral infectibility.
3) A replication deficient adenovirus transferring the green fluorescent protein gene. This is a non-harmful molecule that is useful for determining viral infectibility.
4) A replication deficient adenovirus transferring the gene for I-kappa-B the natural inhibitor of NF-kappaB, an anti-inflammatory molecule.
5) A replication deficient adenovirus transferring the dominant negative form of the I-kappa-B kinase-2, a modification that would also be expected to have an anti-inflammatory effect.
6) A replication deficient adenovirus transferring the dominant negative form of the p38 MAP kinase, a modification that would also be expected to have an anti-inflammatory effect.

All of these have been constructed from plasmids at the Kennedy Institute, London. These molecules are all anti-inflammatory rather than pro-inflammatory, as would be expected if they would be any use as treatment for inflammatory diseases. No adenoviruses with oncogenic genes or sequences will be used. No animal work is planned. The adenoviral work will take place in a category II facility with a class II vented hood designated for adenoviral work. A locked, designated -70 degree virus freezer will be used for virus storage. There is a designated incubator for infected cells.

**Evaluation of foreseeable effects**

All vectors used will be based on adenovirus serotype 5, and will be replication deficient due to disabled in the E1 region by an insert that prevents the packaging of viable particles. The E1 region is replaced with inserted foreign DNA. These replication deficient adenoviruses can still infect cells but not replicate within them. Thus if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitis (harmless eye inflammation), lasting a few days at most, might ensue, in case the person infected did not, like the majority of the population, already possess antibodies to the wild type virus. All inserted gene products will be anti-inflammatory rather than the opposite. None will have mutagenic or oncogenic effects. They should not cause any excess risk. There will be no alteration of existing pathogenic tracts, except for the replication deficiency mentioned above, which will not cause any hazard but rather the opposite. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an adenovirus without an insert. There is thus a risk of very slight and time limited harm should a non-immune person be exposed to these adenoviral vectors.

It is known that recombinant adenovirus reverts to wild type at a low frequency (10^-7). To monitor this and exclude any risk, cytopathic assays are regularly used every 2-3 months to check for replication-competent virus. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an adenovirus without an insert.

The parental virus is ACDP Hazard Group 2. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an replication deficient adenovirus without an insert. Therefore the provisional containment level is 2.

It is not thought that these replication incompetent adenoviruses would pose a risk to animals or plants in the environment, particularly as good care is taken to protect human health. Nor would there, as these viruses will be kept in a locked freezer, be any risk of exposure in a fire, landslide or flooding.

Since the decision was made to apply containment level 2, the activity class is confirmed as Class 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation is made.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved prior to incineration. The laboratory is separated from the rest of the building by means of a lockable door. Culture medium and liquid waste should be disinfected using 10% Microsol, with exposure at least 1h prior to disposal in the sink.
The committee was in principle satisfied with the risk assessment for this project and that the work requires Containment level 2 facilities and is class 2.

### Project Additional Information

#### Purposes of the contained use

Generation of defined deletions in the human cytomegalovirus (HCMV) and human herpesvirus-6 (HHV-6) genomes will be performed to investigate gene function. To further analyse betaherpesvirus gene function sub-genomic or cDNA fragments will be subcloned and expressed using a range of prokaryotic and eukaryotic expression vectors.

#### Recipient or parental organism

HCMV and HHV-6 are both ACDP category 2 pathogens that are both predicted to encode a large number of open reading frames (in the order of 200). Currently functional information is available for a relatively small number of their genes. Both viruses are associated with mild disease in healthy individuals but occasionally HCMV causes severe disease in immunocompromised individuals. There is no compelling evidence to link either virus with cancer. Both virus are species-specific with productive replication being effectively restricted to human cells. Deletion of genes would usually be expected to reduce virus pathogenicity. Both viruses are expected or known to encode genes that modify cellular physiology and others that modulate the immune response.

The cloning of such genes in a replication-deficient Ad vector will generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals. Adenovirus is a ADCP category 2 pathogens although the deletion of the E1 gene region will make both unable to replicate or promote efficient early phase gene expression. Being replication-deficient the recombinant viruses have limited potential for lateral spread, although this could be facilitated by a co-infection with a wt Ad. Wild type Ad type 5 is capable of productive replication in very few species and is associated with mild upper respiratory tract infection in childhood.

#### Host/vector system

E.coli JM109, TOP10 or XL1-blue. Prokaryotic vectors include pcDNA3.1/ct-GFP-Topo, pBLUETOPO, pUC-based vectors containing the HCMV major IE promoter (pMV100), adenovirus transfer vectors pAL200 (and variants with alternative cloning sites), pJM17 (contains the complete Ad5dl 309 genome), episomal vectors containing the EBV origin of replication and the EBNA1 gene (p220.2).

The recombinant adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo for the generation of antibodies.

For the generation the HCMV genome will be used in the first instance. The HCMV strain AD169 and Toledo genomes will be used in preference. Deletion of the HHV-6 genome is planned in future but will be dependent on the development of better systems for growing the virus.

#### Origin & function

HCMV strains AD169 and Toledo are characterised laboratory isolates. The Strain AD169 genome is sequenced and published and there is extensive sequence data available for strain Toledo.

HHV-6 strain Z29 and U1102 have been fully sequenced. We intend also to investigate sequence variation in a range of fresh clinical isolates.

#### Evaluation of foreseeable effects

The expression of individual HCMV or HHV-6 genes in cells transiently or in established lines is of low potential hazard. Both viruses are expected or known to encode genes that modify cellular physiology and others that modulate the immune response. The cloning of such genes in a replication-deficient Ad vector will generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals. HCMV encodes 6 gene that modulate class I presentation, two functions that modulate resistance to NK cells and both viruses encode chemokine and chemokine receptor homologues.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichloroisocyanurate (Actichlor), after 4h solution can be discarded to mains drainage. Pipettes immersed in 2500 ppm Sodium Dichloroisocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the high concentration overcomes high organic content of media. Animals may be inoculated in a contained isolator or if Class I or Class II microbiological safety cabinet. All animal waste is incinerated.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Approved.

Project Ref 302/01.5

Date Ackn'd CU2 Project Title
01/06/2001 DEVELOPMENT OF ADENOVIRUS VECTOR SYSTEMS

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 1-50 litres
This notification covers the development of adenovirus vectors designed to facilitate the induction/modulation of specific immune responses by transgenes expression of. Host immune responses to vector components can be proinflammatory and often over-ride or subvert potential biological effects associated with the transgene. Specific mutations in the E2, E3, E4, L5 genes will be incorporated into adenovirus type vectors to limit breakthrough expression from replication-deficient adenovirus vectors. Ad5 vectors utilise CAR as a primary receptor for virus infection. We intend to deliver transgenes to cells that do not express detectable levels of CAR (notably lymphocytes). Using established technology, we intend to modify the fibre gene so that the expressed protein will no longer recognise its native CAR receptor and so that it will recognise specific receptors present on target cells. The modified fibre will not be inserted into an adenovirus genome but expressed as a complementing function in a helper cell line. Many individuals have been exposed to adenovirus type 5 and will also generate strong immune responses on exposure to this vector. Adenovirus type 4 has been used as a live viral vaccine. Fewer individuals have seroconverted to adenovirus type 4 and it can potentially also be used in combination with Ad 5 vectors in prime:boost vaccination protocols. We wish therefore to develop replication-competent and replication-deficient adenovirus type 4 vectors. A range of tumour-associated and virus antigens will be expressed in these vectors.

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E.coli K12 strains specifically developed for application in recombinant DNA cloning experiments will used. These strains have limited potential to colonise the gut or survive in the environment. Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Adenovirus type 4 infection is also associated primarily with mild, debilitating respiratory tract infections but can occasionally cause an acute respiratory disease (ARD), acute haemorrhagic conjunctivitis or rarely a fatal non-bacterial pneumonia. To protect against infection, a non-attenuated live Ad4 vaccine has been administered to military recruits in North America. This live viral vaccine consists of an enteric-coated tablet containing live, non-attenuated, tissue culture grown Ad4 virus. The enteric coating prevents infection of the respiratory tract and when swallowed virus is only released from the tablet in the stomach where it infects the gut inducing protective immunity but not disease. Over half a million doses of this vaccine has been administered without complication and it has proved to be effective in preventing ARD. It has been proposed that this vaccine and method of administration might be used as a vector to generate an immune response against both Ad4 and the heterologous immunogens. Ad4 recombinants expressing a range of viral genes have been generated and tested in animals and humans with promising results. The Ad4 virus strain used in the vaccine virus will be used as the basis for all Ad4 vectors and recombinants constructed. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad4 vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus. Both wild type Ad4 and Ad7 exhibit a severe host restriction and are capable of productive replication in very few species other than man.
E. coli strains JM109, TOP10 and XL1-blue will be used. Prokaryotic vectors include pcDNA3.1/ct-GFP-Topo, pBLUETOPO, pUC-based vectors containing the HCMV major IE promoter (pMV100), adenovirus transfer vectors pAL200 (and variants with alternative cloning sites). Commercial Ad5 vector systems will be used as the basis for vector development. From Microbix (Canada) pJM17 (contains the complete Ad5d/309 genome) and the Admax TM vector system will be used. From Qbiogene (Hareford, Middx) the Ad5 based AdEasy TM vector system, which involves all recombination events be performed in E.coli, will be used.

Ad4 vectors will be generated de novo from the vaccine strain.

Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo. A 293 cell line expressing E4 will be obtained from a commercial source (Microbix). Additional helper cell lines will be constructed in 293 or 911 cells.

### Host/vector system

A number of human and murine tumour-associated antigens will be cloned.

- **gp100** cloned cDNA normal human and mouse melanocytes [Bakker et al, J Exp Med 179:1005, 1994]
- **Melan A** cloned cDNA normal human and mouse melanocytes [Coulie et al, Immunity 2:167, 1995]
- **BAGE** cloned cDNA melanoma and normal testis [Boel et al, 178:489, 1993]
- **Mage 1** cloned cDNA melanoma and normal testis [Castelli et al, J Cell Physiol 182: 323, 2000]
- **Mage 2** cloned cDNA melanoma and normal testis [Castelli et al, J Cell Physiol 182: 323, 2000]
- **Mage 3** cloned cDNA melanoma and normal testis [Castelli et al, J Cell Physiol 182: 323, 2000]
- **Mage4** cloned cDNA melanoma and normal testis [Castelli et al, J Cell Physiol 182: 323, 2000]
- **NY-ESO-1** cloned cDNA melanoma and normal testis [Chen et al, PNAS 94: 1914, 1997]
- **CT10** cloned cDNA melanoma and normal testis [Gure et al, Int J Cancer 85:726, 2000]
- **SOX** cloned cDNA colon carcinoma and normal testis [Tureci et al, Int J Cancer 77:19, 1998]
- **ZIC** cloned cDNA colon carcinoma and normal testis [Tureci et al, Int J Cancer 77:19, 1998]

Human cytomegalovirus and Human herpes virus 6 are closely related human herpesviruses capable inducing disease in immunocompromised individuals but with no recognised association with cancer. Genes from both these viruses will be cloned into adenovirus vectors for the purpose of generating and measuring immune responses. Venezuelan Equine Encephalitis virus (VEEV) is an Alphavirus that replicates in the cytoplasm of infected cells. The virus particle contains genomic RNA packaged in a capsid consisting of core proteins and an envelope containing the glycoproteins Env1 and Env2. Two other proteins Env3 and 6k may also be found in the virus particle. These two small proteins contain the translocation signal sequence for Env1 and Env2. Being an Alphavirus, the structural proteins are translated from a subgenomic RND as a single polyprotein that is then cleaved by cellular proteases. Env2 contains a major protective epitope. Replication-competent and replication-deficient adenovirus recombinants encoding VEEVEnv3Env2/6K will be generated.

### Origin & function

Some of the tumour-specific antigens are expressed in melanocytes and are involved in the melanin biosynthetic pathway. All such proteins are expressed either in normal testis or in melanocytes. None of these proteins in isolation have any toxic, oncogenic, carcinogenic or allergenic properties since they are all expressed in normal cells. The risk of any autoimmune disorder triggered by an overexpression of these proteins is negligible because no autoimmune effect has been reported in healthy volunteers and melanoma patients with high frequencies of cytotoxic T lymphocyte specific for these proteins. (Van Pel et al., Immunological Review. 145:229, 1995; Coullie et al., J Cancer 50:289, 1992). The immune response specific to colon carcinoma antigens is still ill defined, and very few proteins have been shown to be specifically expressed by colon cancer cells. One of the most promising family of newly characterised colon cancer proteins are the SSX proteins, which are expressed in a high proportion of colon.

The expression of individual HCMV or HHV-6 genes in cells transiently or in established lines is of low potential hazard. Both viruses are expected or known to encode
genes that modify cellular physiology and others that modulate the immune response. The gene product of VEEV E3, E2 and 6k sequences are not known to be toxic, allogenic or oncogenic although E2 is associated with a strong humoral immune response. The cloning of such genes is a replication-deficient Ad vector will not generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals.

This work involves standard laboratory protocols and there are no unusual procedures that require additional containment measures. A more detailed risk assessment was performed for the local ACGM safety committee.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichloroisocyanurate (Actichlor), after 4h solution can be discarded to mains drainage, Pipettes immersed in 2500 ppm Sodium Dichloroisocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the high concentration overcomes high organis content of media.

Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste (max culture volume 500ml) will be chemically treated with an appropriate disinfectant (Hycolin, Chloros or Virkon) used at the manufacturers specified concentration for the appropriate length of time. Solid waste will be autoclaved.

Project Additional Information

Purposes of the contained use

Recombinant seV will be used to transfer reporter and therapeutic genes to different cell types (in vitro and in vivo) and compared to currently available gene transfer vectors.

Recipient or parental organism

Sendai virus (SeV) is an enveloped virus with a nonsegmented negative-strand RNA genome of 15384 nucleotides and is a member of the family Paramyxoviridae. The SeV genome contains six major genes: nucleoprotein (NP), phosphoprotein (P) and large protein (L) form a ribonucleoprotein (RPN) with the SeV genomic RNA. The matrix protein (M) engages in the assembly of viral particles. Two envelope glycoproteins, hemagglutinin-neuraminidase (HN) and fusion protein (F) mediate the attachment of virions and penetration of RNPs into infected cells. SeV replication is independent of nuclear functions and does not have a DNA phase. Therefore, it does not transform cells by integrating its genetic information into the cellular genome. SeV has been reported to naturally infect rodents (causing upper respiratory tract infections) and has never been reported to infect humans.

Host/vector system
Transgenes are normally inserted immediately before the ORF of the viral 3'-proximal nucleocapsid (NP) protein gene in a full-length SeV CDNA copy. The inserted gene is flanked by "gene start signal" and polyadenilation/stop sequences and recognised by the viral RNA polymerase.

### Origin & function

The Sendai genome derives from the Z-strain. The recombinant virus has been developed by a Japanese biotech company, DNAVEC. The recombinant SeV will carry different transgenes:

1. bacterial transgenes, such as beta-galactosidase or CAT;
2. Eukaryotic tran genes such as luciferase (from Photinus pyralis) and GFP (from jellyfish);
3. Therapeutic genes

### Evaluation of foreseeable effects

1. Recombinant SeV does not have an altered tropism compared to wild type virus. However, insertion of a transgene reduces the replication speed as well as the final virus titre in a way, that is proportional to the size of the transgene, carried. In vivo a remarkable attenuated replication and pathogenicity were generally seen (Sakai et al., FEBS Lett 1999; 456: 221-226).
2. Virus replication and transmission to neighbouring cells has been demonstrated in the host species (rodents). SeV has never been reported to infect humans.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Recombinant Sendai virus is stored at-80C in 1-2 ml vials separately from the biological samples. All experiments are carried out in class II cabinets. After use, cabinets are UV irradiated for at least 30 minutes, Single-use plasticware is used. The solid waste produced is double-bagged and autoclaved (121C/1 atm). For the liquid waste, Hypachlor for > 10 min with chlorine (2500 ppm final concentration) is used. Personnel will wear labcoats, gloves, masks and overshoes.

Please enter comments on the GM safety committee on the risk assessment

The Generic Modification Safety Committee has reviewed the application in great detail. The committee is satisfied that the virus poses no risk to humans and that adequate measures have been taken to ensure that the virus will be wholly contained within the dedicated unit set up specifically for this work.

### Project Containment

02/03/2022
The aim of this project is characterise pseudotyped SIV-based gene transfer agents in the lung. Proof-of-principle for gene therapy for cystic fibrosis (CF) has been established in several clinical trials (1). However, gene transfer is generally inefficient and of short duration. Our group has a long standing interest in CF gene therapy and we have evaluated several non-viral and viral gene transfer agents in pre-clinical studies (2). However, most gene transfer agents are inefficient and express the transgene only very transiently (less than one week). This includes commonly used liposomes, adenoviral vectors and Sendai virus (SeV). Lentiviral vectors, such as SIV have recently been suggested for airway gene transfer, as they transduce non-dividing cells (3). Lentiviral vectors are retroviruses, that have to integrate into the host genome and therefore offer the potential for long lasting gene expression. We have previously assessed generation 3 SIV, pseudotyped with the traditional pleiotropic envelope coat protein, VSV-G airway gene transfer and shown that transfection efficiency is very poor (unpublished data). Here, we want to evaluate an SIV vectors pseudotyped with the F and HN envelope protein from parainfluenza viruses (3). Parainfluenza viruses such as Sendai virus have been shown to transduce airway epithelial cells efficiently. In addition, VSVG-pseudotype lentiviral vectors will be used as controls. The main difference between 2 and 3 generations SIV is that the viral genes gag-pol and rev are on one plasmid for production of 2 generation viruses, but are separated onto two plasmids for the production of 3rd generation viruses, which
further reduced the chance of recombination and production of replication competent viruses.

References:

Recipient or parental organism

The Simian immuno deficiency virus isolated from Africa green monkey (SiVagm) has to the best of our knowledge not been associated with pathology in its natural host or animal models (1). The vector used is described by Nakajima etal, and is a self-inactivating (SIN) vector, because the U3 region of the 3’ long terminal repeat is deleted (2). This region contains viral promoter and enhancer elements. Deletion of the U3 region will prevent mobilisation by replication-competent viruses. SiV vectors pseudotyped with F and HN protein or VSV-G envelope proteins will be produced by DNAVEC, Inc (Japan).

A four plasmid system will be used for production 2nd generation SiV:
Plasmid 1: CMV prom-F protein or (VSVG-protein)
Plasmid 2: CMV prom-HN protein
Plasmid 3: CMV prom-gag-pol-rev
Plasmid 4: Modified LTR-CMV prom-R-U5-Y-cPPT-prom-transfene-WPRE-Du3-R-U5 (as described by Dull T 1998)

F/HN or VSV-G pseudotyped SiV vectors will be used to transduce transformed cells such as C127 and 293T cells. The recombinant virus will carry reporter genes such as B-galactosidase or functional genes, such as the cystic fibrosis transmembrane conductance regulator (CFTR). Some viral constructs may contain the cPPT (central poly purine tract) and the woodchuck hepatitis virus post-transcriptional regulatory element (WPRE) to enhance transgene expression.

Using to above construct replication competent SiV vectors have never been generated (DNAVEC Inc, personal communication).

Host/vector system

The SiV vector is derived from a Simian immunodeficiency virus, which is not pathogenic in its natural host. The vector is not replicating and has been further inactivated by removing the 3’ LTR (SIN) vector. There are several reports in the literature stating that people working with primates have been exposed to SiV, but have not developed an immunodeficiency.

Origin & function

The pseudotyped SiV vector is produced by DNAVEC, Inc (Japan).

Evaluation of foreseeable effects

SiV, as all Lentiviruses integrate randomly into the genome of transduced cells, which may be associated with pathogenicity, if integration occurs into an oncogene or tumor suppressor gene. However, this is considered a very unlikely event as only about 3% of the human genome encode genes and only a very small proportion of these are putative oncogenes or tumor suppressors. Most recently a clinical trial using retrovirus-mediated gene transfer into hematopoetic cells of SCID children has reported two cases of Leukemia. However, a large number of humans has been treated with retroviruses and apart from these two cases, no adverse side-effects have been reported and may in the French Scid children be linked to using the gamma c-chain cDNA.

Recombination of SiV (SIN) vectors or other lentiviral vectors hgas, to the best of our knowledge, never occurred in preclinical studies or clinical studies. The risk is effectively zero as the vectors are replication defective and many viral genes have been deleted.
If transduction into the gonads of animals outside the laboratory would occur, the virus would be maintained outside the laboratory. However, careful safety precautions will be in place to prevent this. In addition the virus has a short half-life and is non-replicating.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection (Hypachlor for >10 min with final chlorine concentration of 2500 ppm, killing capacity: effectively 100%) will be used for all solid GM waste. Solid waste will include plastic labware including pipette tips and tissue culture plates are likely to contain live virus particles. In addition to chemical disinfection all GM waste will also be autoclaved and subsequently be disposed of using clinical waste procedures.

Liquid tissue culture medium will be treated with 1% Virkon, according to manufacturers recommendations, leading to effectively 100% killing.

Is an emergency plan required according to regulation 20?  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment

The Imperial College genetic modification committee’s comments included:
1. Clarify containers used for transportation of GMM (Section 10.2)
2. State that lab coats and gloves are worn at all times for any laboratory work (Section 7.1)
3. Discuss health surveillance with occupational health.

All comments were considered and included in the risk assessment.

Project Containment
Purposes of the contained use

Chronic obstructive pulmonary disease (COPO) is an inflammatory disease that results in poorly reversible airflow limitation, with symptoms including chronic cough, shortness of breath and sputum production. Macrophages are inflammatory cells that are essential in the maintenance of lung homeostasis. These cells are highly phagocytic, and are crucial in the clearance of bacterial and cellular debris. Macrophage phagocytosis is impaired in COPO, resulting in bacterial colonisation and increased risk of infection, and there has been increasing incidences of patients with COPO being infected with Aspergillus. Aspergillus Fumigatus may affect macropahge phenotype and function, as this has also been affiliated with worsening symptoms at exacerbation. We plan to investigate uptake of Aspergillus Fumigatus by macrophages derived from human blood and lung samples.

Recipient or parental organism

Aspergillus Fumigatus strain ATCC46645 (ACOP classification 2).

Host/vector system

Aspergillus Fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments.  
1. The eGFP gene (Clontech, Heidelberg, Germany) and the gpdA promoter from A fumigatus were amplified by high fidelity PCR (Roche, Mannheim, Germany) using oligonucleotides GFP-For, GFP-Rev, gpdA Prom-For and gpdAProm-
Rev. The amplification products were cloned into the pOrive cloning vector (Qiagen, Hilden, Germany) and sequenced using external plasmid-derived primers. The fragments were subsequently cloned into the EcoRV site of pBluescript KS+ (Stratagene, Amsterdam, the Netherlands). The hygromycin resistance cassette containing the hygromycin B phosphotransferase gene of E. coli under the control of the gpdA promoter was isolated from plasmid pUCGH pyrG and inserted into the Kpnl site of pBluescript KS+. Both fragments were cloned into pBluescript KS+ in opposite orientation resulting in plasmid pMAF1, that was transformed into A fumigatus protoplasts using a method described previously (Langfelder et al., 1998).

**Origins & function**

GFP label in Aspergillus is fluorescent on the FITC channel.

**Evaluation of foreseeable effects**

Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments. The addition of the GFP gene allows the microbe to become fluorescent. There are no further functional changes to the microbe, and therefore it poses no greater threat to human health compared to the unmodified strain.

To create this GFP labelled strain, a hygromycin resistance cassette was inserted into the plasmid. The strain would therefore be resistant to this antibiotic. This should be noted in case of accidental infection to a human user.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

A Class II Microbiological safety cabinet (MSC) will be used when handling/processing samples. After use, the safety cabinet will be decontaminated using 2% Distel or 2% Virkon. All buckets used in centrifuges will be fitted with lids when spinning samples, and the centrifuge and buckets will be decontaminated post use using 2% Distel.

In case of spillage within the centrifuge, the centrifuge lid will remain closed for 1 hour to allow any aerosol to settle. After 1 hour, the spilled material will be wiped up, area will be sprayed with 2% Distel or 2% Virkon. Distel bottle will be kept near the centrifuge.

Solid Waste: Solid waste will be collected in a biohazard bag inside the Biosafety Cabinet. Pipette tips will be collected in a small Biobin, and the bin closed and deposited into the biohazard bag (in the Biosafety Cabinet) at the end of the work session. Solid waste exposed to A Fumigatus are first disinfected with 2% virkon, prior to disposal in Biobins or biohazard bags. At the end of the work session, the biohazard bag will be closed, sprayed with 70% EtOH, and deposited into a biohazardous waste container. These will be autoclaved, and taken off-site to be incinerated.

Liquid Waste is normally aspirated into a vacuum flask containing 1/10 volume Virkon. The vacuum flask must have a final concentration of at least 10% virkon, for a minimum time of 30 minutes prior to drain disposal. Liquid waste that is not aspirated must be treated with virkon, to a final concentration of 2%, in the hood, allowing a minimum time of 30 minutes to inactivate fungus.
Many thanks for the attached and I note that all changes noted in e-mails below and in the form C have been made to the 8101. However I do have some additional comments for both the CU2 and 8i01. Hope this makes sense. Please send the completed forms back to Biosafety@imperial.ac.uk and we will fill in our bits. Many thanks

CU2 - The must read the same as the Bi01 and vice versa. I have the following comments
Section 5 - This should be the Title of the activity from the Bi01. Lentiviral transfection for overexpression studies to correct defective phagocytosis in human MOM in COP. O. If this title no longer fits the activity please change it in the Bi01 and the Cu2
Section 6 - The highlighted text does not appear to be in the Bi01. Please put this explanation in the Bi01. 1.1 is probably the best place for it.
*and there has been increasing incidences of patients with COP being infected with Aspergillus. Aspergillus Fumigatus may affect macrophage phenotype and function, as this has also been affiliated with worsening symptoms at exacerbation. We plan to investigate uptake of Aspergillus Fumigatus by macrophages derived from human blood and lung samples*
Section 7 -
Recipient - This is different to the text for the recipient strain in 2.15 of the Bi01. Please make it the same. Le. Aspergillus Fumigatus strain ATCC46645 (ACOP classification 2).
Vector - This is different to the text for the recipient strain in 2.16 of the Bi01. Please make it the same. i.e. Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments.
1. The eGFP gene (Clontech, Heidelberg, Germany) and the gpdA promoter from A. fumigatus were amplified by high fidelity PCR (Roche, Mannheim, Germany) using oligonucleotides GFP-For, GFP-Rev, gpdA-Prom-For and gpdAProm-Rev. The amplification products were cloned into the pDrive cloning vector (Qiagen, Hilden, Germany) and sequenced using external plasmid-derived primers. The fragments were subsequence quently cloned into the EcoRV site of pBluescript KS+ (Stratagene, Amsterdam, the Netherlands). The hygromycin resistance cassette containing the hygromycin B phosphotransferase gene of E. coli under the control of the gpdA promoter was isolated from plasmid pUCGH-pyrG and inserted into the KpnI site of pBluescript KS+. Both fragments were cloned into pBluescript KS+ in opposite orientation resulting in plasmid pMAF1, that was transformed into A. fumigatus protoplasts using a method described previously (Langfelder et al., 1998).
Origins and intended functions of the genetic material - This is different to the text for the recipient strain in 2.17 of the Bi01. Please make it the same. Le. GFP label in Aspergillus is fluorescent on the FITC channel.
7. Please add the following text which is in the CU2 to the Bi01 sections 2.18 and 4.20
*Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes,
FACS and phagocytosis experiments. The addition of the GFP gene allows the microbe to become fluorescent. There are no further functional changes to the microbe, and therefore it poses no greater threat to human health compared to the unmodified strain.

To create this GFP labelled strain, a hygromycin resistance cassette was inserted into the plasmid. The strain would therefore be resistant to this antibiotic. This should be noted in case of accidental infection to a human user.

Section 9.1 This answer is different to the 8i01 section 4.4 please make sure that the volumes are the same.

Section 12 is different to the waste section 7 in the 8i01. Please take the text from the CU2 which is nicely detailed and add it to the 8i01. Please do not refer to an MSC as a "hood" you can use the phrase Microbiological Safety Cabinet or MSC.

Section 15 I will add this once you have modified the above.

Section 16 this is usually the PI.

Section 18 we will complete this.

GM Safety Committee 4th Dec 2015

Dear Professor

Following the discussion of your proposal entitled "Lentiviral transfection for overexpression studies to correct defective phagocytosis in human MOM in COPO" (GMIC-4695), the committee request that the following amendments are made to the proposal prior to approval:

Reviewer 1

Section 2.15; This section asks for recipient species and strains with their ACDP classification, add Aspergillus fumigatus here.

Section 2.16 List the vector that has been used for aspergillus here, what resistance cassette is used? What type of GFP?

The added GM Aspergillus fumigatus (GFP labelled) is a class 2 GMO because the host is HG2. This project was originally a Class 1. This will mean that the project will now require notification to the HSE.

Section 2.17 GFP has a functional property; it's fluorescent ... otherwise it would be pointless expressing it

Section 4.16 GFP is not completely non-functional, you use it because it expresses fluorescent protein

Section 4.17, does the GFP vector have a selective resistance cassette? This might have an impact on treatment if somebody gets exposed to Aspergillus

Section 5.5, Who grows the Aspergillus? In which Jab? under which risk assessment? Is it just being donated or are people from RB campus going to SK campus 10 grow this up? Or just to collect?

Section 5.13 Tick the box for using FACS analysis or Sorting and mention SOP

Section 14+15 Aspergillus work is not mentioned here. GM Aspergillus fumigatus (GFP labelled) is Class 2

Reviewer 2

All looks ok in principle. I believe the room that the work will be taking place in is B148 not B146 at Guy Scadding. Also there is a discrepancy between centrifuge spillage procedures, in the form it correctly states that it will be left for 1 hour to allow aerosols to settle, but in all the SOPs it says 15mins - this is needs to be amended.

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE CU2 form (attached to this email), and copy of the Purchase Order (for BACs Payment) made payable to the HSE should be sent to me, I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.

For further information, please see http://www3.imperial.ac.uk/safety/subjectsbiosafety/gmprocedures

Please note that th is work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.

**Project Additional Information**
Purposes of the contained use

I wish to study the molecules involved in lymphocyte growth. This will take place in B and T-lymphocyte cell lines as well as primary human cells. The molecules chosen include ras, P13K, Jak, and STATs, all of which are activated in response to T-cell receptor or cytokines, the molecules that result in T-cell growth. Human primary lymphocytes are not easily transfected and infection remains the best way to modulate their genotype.

Recipient or parental organism

The GMO that will be generated are retroviruses based on the murine (MuLV) system containing molecules involved in lymphocyte growth and signalling.

Host/vector system

A retroviral vector system has been chosen. DNA corresponding to molecules involved in lymphocyte signalling will be introduced in the pinco retroviral plasmid. This plasmid will be introduced into the Phoenix AM cell line that allows the production of amphotropic retroviruses. Phoenix is a second-generation retrovirus producer line for the generation of helper free ecotropic and amphotropic retroviruses based on the murine (MuLV) system. The lines are based on the 293T cell line. The Phoenix cell line was chosen because it is a well established cell line that has been extensively tested for helper virus production and established as been helper-virus free. The cell line contains two separate plasmids for the generation of the env protein and the gag-pol protein. Both the gag-pol and envelope constructs with non-moloney promoters were used to minimise recombination potential. Different retrovirus cannot be produced from these cells.

Origin & function

The genetic material for the retroviruses are derived from the murine (MuLV) system. The genes that will be introduced into these vectors are mammalian in origin. Each of these have been chosen because of their role in the manipulation of the immune system. While all of these molecules play an important role in growth and/or survival, none have been shown to induce lymphocyte malignancy alone. Wild type, active and inhibitory forms of the molecules will be studied.

Evaluation of foreseeable effects

The retroviruses by themselves do not constitute a risk. DNA corresponding to many different proteins have been described on the attached sheet. Details from each of these gene products have been given. Whenn considering the possible hazard to human health it is appropriate to consider the gene product that has the most potential to cause harm. The virus with the most potential to cause harm is the V12-ras retrovirus. However, this has been used safely in other Departments within the University of Wales College of Medicine. This retrovirus could result in the expression of V12 in human cells. However this would only cause harm if administered in large doess or were to become infectious. However, the amounts of virus generated will be low and there are many features of the retroviral system that proscribe the ability of the retrovirus to become infectious.

Three other important factors:
(1) While V12 is an oncogene, it is unable to transform primary human cells alone. The short half life of the virus minimises the duration of any exposures. None of the other inserts are oncogenic.
(2) The pathogenicity of the retrovirus is unaffected by any of the inserts and there is unlikely to be any transfer of harmful sequences to related viruses.
(3) The viruses generated cannot cause a productive infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste contaminated with GMMs will be treated with freshly prepared 2500 ppm sodium dichloroisocyanurate. This completely destroys the retrovirus.
The Genetic Modification Safety sub-committee found the risk assessment to be suitable and sufficient and agreed that the work was Class 2, requiring Containment Level 2 facilities.

**Historical Significant Changes**

Project transferred to GM130 on 26/04/2005
The immune system is controlled by a complex balance between the innate and the adaptive immune responses. IL-10 is associated with shifting the balance of the immune response away from a TH1 and towards a TH2 response. Work in other centres has demonstrated that adenovirus (Ad) vectors encoding the Epstein-Barr virus (EBV) interleukin 10 (IL-10) homologue is effective in suppressing inflammation in animal gene therapy models of autoimmune disease (Apparailly et al 1998 J Immunol. 160, 5213). Recently, a functional human cytomegalovirus IL-10 homologue has also been identified (Kotenko et al 2000 PNAS 97, 1695). We wish to use Ad recombinants encoding human, rat, EBV and HCMV IL-10 in both in vitro and in vivo assays. An Ad vector is required for efficient expression of these molecules. We intend to test the relative efficiency of the various versions of IL-10 on dendritic cell (differentiation and maturation), CD8+ cytotoxic T cells (CTL) and NK cell function in vitro. Major histocompatibility class I molecules play a key role in functional interactions of all these three cell types and are regulated by IL-10. As part of this programme of work, we will use permission to express both classical (HLA-A,C) and non-classical (HLA-E and HLA-G) molecules in replication-deficient Ad vectors. HLA-A,C are highly polymorphic and a number of variant genes may be expressed. In contrast HLA-E and HLA-G are highly conserved but subtle variants do exist and may be expressed.

The capacity of NKX2.5 to modulate myeloid cell function in vitro will be examined in a pilot study. LIR-1 is an inhibitory receptor found on cells of the myeloid lineage, T cells and NK cells that interacts with classical MHC-1 molecules and HCMV MHC-1 homologue gpUL18. We intend examining functional interaction between HCMV gpUL18 and LIR01. This notification covers the limited use of Ad recombinants designed to modulate immunological responses by transgene expression. In particular, we intend testing replication-deficient adenovirus recombinants encoding the EBV and HCMV IL-10 homologues in an established in vivo experimental model of rheumatoid arthritis.

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E. coli K12 strains specifically developed for application in recombinant DNA cloning experiments will be used. These strains have limited potential to colonize the gut or survive in the environment.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or gene rescue from the helper cell line.

Commercial Ad5 vector systems will be used as the basis for vector development.

For the construction of replication-deficient adenovirus recombinants:

- The Admax vector system from Microbix, Canada (pDC511, pDC512, pDC515 and pDC516, PBHGfrtDE1,3FLP,pXCXL-based transfer vectors, pJM17) will be used.
- From Qiagen (Hareford, Middx) the Ad5 based AdEasytm vector system (pAdEasy-1, pShuttle, pShuttle-CMV, pShuttleCMV-LacZ) will be used.

Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (e.g. 293 or 911 cells) and then used to infect target cells in vitro or in vivo.

Human, rat, EBV and HCMV IL-10 genes will be used to evaluate their relative capacity to modulate a range of immune responses in vitro and in vivo assays. NKX2.5 is a transcription factor associated with maturation of cardiomyocytes, its effect on myeloid cell maturation will be evaluated.

- HLA-A, HLA-B, HLA-C, HLA-E, HLA-5 and the human cytomegalovirus MHC-1 homologue UL18 as test ligands of LIR-1 and to examine function of IL-10.
LIR-1 is an inhibitory receptor originally identified by high-affinity binding to synthetic gpUL18 and subsequently shown to bind a broad range of MHC-1 molecules.

All DNA are cDNA clones obtained commercially or gifts from collaborators. DNA sequences are known and will be confirmed in adenovirus transfer vectors prior to generation of recombinant virus.

Evaluation of foreseeable effects

It is recognised that there is a potential hazard associated with using Ad recombinants encoding transgenes capable of modulating the immune response IL-10 is a 17-18kDa homodimer that can be secreted by T cells, macrophages and EBV- transformed B cell lines. IL10 functions by binding the IL-10 receptor. IL-10 was first recognized for its ability to inhibit activation and effector function of T cells, monocytes, and macrophages, and is a multifunctional cytokine with diverse effects on most haemopoietic cell types. The principal routine function of IL-10 appears to be to limit and ultimately terminate inflammatory responses. In addition to these activities, IL-10 regulates growth and/or differentiation of B cells, NK cells, cytotoxic and helper T cells, mast cells, granulocytes, dendritic cells, keratinocytes, and endothelial cells. hIL-10 is active on both mouse and human cells, whereas mIL-10 is effective only on mouse cells. The mature hIL-10 and EBV viral IL-10 (vIL-10) amino acid sequences are 84% identical, and most differences occur in the N-terminal 20 amino acids. We are primarily interested in utilizing and evaluating the EBV IL-10 vireme as a positive control (standard) in a rat model of rheumatoid arthritis. This is a widely used system. to date, there are at least 20 publications by other laboratories describing results of experiments using Ad EBV IL-10 recombinants including demonstration that they are effective in inhibiting the induction of arthritis in experimental animal models. Human and rat IL-10 are expected to have similar or lower efficacy. The cmvIL-10 has only low homology to hIL-10. It is only 27% identical to hIL-10, yet nonetheless binds to and signals via the IL-10R complex. The CMV IL-10 homologue is expected to be less potent than either human or EBV IL-10.

This construct is thus expected to have a biological function following in vivo delivery. There is evidence in mice and humans that elevated IL-10 production usually imposes some limits on the effectiveness of antipathogen immun responses, especially innate immunity and adaptive Th1 responses. This cost if often outweighed by the ability of IL-10 to protect the host from collateral damage by antimicrobial cytokines and effector molecules. IL-10 has been considered an attractive candidate for therapeutic use based on its potent in vitro immunomodulating activities and proven effects in animal models of acute and chronic inflammation, autoimmunity, cancer and infectious disease. Phase I and II clinical trials investigating safety, tolerance, pharmacokinetics, pharmacodynamics, immunological and hematological effects of single or multiple doses of IL-10 administered by intravenous (iv) or subcutaneous (sc) route. IL-10 has been tested in specific patient populations including those with Crohn's disease, RA, psoriasis, and patients suffering from chronic hepatitis C infections. Administration of IL-10 (7 days iv) reduced the Crohn's disease activity index score in patients with steroid-refractory Crohn's disease and showed some clinical benefit in a larger 28-day sc safety and efficacy study in patients with chronic active Crohn's disease. Similarly, a trend towards efficacy and a good safety profile was observed when IL-10 was administered for 28 days to RA patients. Single intravenous (iv) or subcutaneous (sc) doses of IL-10 resulted in transient dose-dependent changes in white blood cell populations, including increases in total white blood cells and neutrophils.

There are a number of theoretical hazards associated with this experiment. Firstly, as the recombinant virus is intended for in vivo use, there is the potential that the virus could spread from animal to animal and hence get into the natural population. However any in vivo injections will be local and given the fact the virus cannot penetrate more than a few layers of cells, the systemic spread of the virus should be negligible. Even in the highly unlikely event of the spread of the virus systemically, the recombinant virus is replication deficient, is not maintained in dividing cells and as such is incapable of horizontal spread throughout a population. Additionally wild-type Ad type 5 is able to undergo productive virus replication in very few non-human cells.

A second potential hazard is the exposure of humans to the recombinant virus. All manipulations of the virus will be performed in a class II biological safety cabinet in the laboratory. In vivo injections of Ad recombinants encoding recombinant genes into animal models will be carried out in an animal isolator, a negative pressure facility (i.e in a class I cabinet) or a class II cabinet. A potential human infection will be a needle stick injury. Use of sharps will be kept to a minimum but are required for animal inoculations. In this event, gene expression from the Ad recombinant should be localised and the potential inhibition of complement localised and transient. In the unlikely scenario that the recombinant inhibitor becomes systemic, for the reasons stated above (inability to replicate without E1 complementation and the loss of the virus in dividing cells) the effect of the complement inhibitor should be transient. Also the effect of the complement inhibitor in humans should be minimal as the dose will have been designed for a rate and should therefore be at too low a level for a significant effect in humans. Horizontal spread of the recombinant virus through the human population is not likely for the same reasons as it is not likely in the rat population.
Classical and non-classical MHC molecules are widely expressed on human cells. The over-expression on non-classical HLA A-C molecules could promote antigen specific or allospecific immune responses and expression of any of the classical or non-classical HLA molecules could suppress NK recognition but should this occur the risk is minimal. LIR-1 (also known as ILT-2) is an inhibitory receptor thus its over-expression in lymphocytes or myeloid cells could suppress the function of that the target cell. The Ad5 vector infects lymphoid and myeloid cells relatively inefficiently. It is extremely unlikely that with the natural biological containment that the gene could be delivered with sufficient efficiency to exert a biological effect in man or animals. NKX2.5 transcription factor (a cell specific expression marker in cardiomyocytes) that will be subcloned into a replication-deficient Ad vector. There is no known transforming activity or toxicity associated with this gene. Use of this construct has been independently approved at ACGM 2 level elsewhere.

These recombinant viruses will be contained using ACGM level 2 procedures as stipulated in the risk assessment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichloroisocyanurate (Actichlor), after 4h solution can be discarded to mains drainage. Pipettes immersed in 2500 ppm Sodium Dichloroisocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the high concentration overcomes high organic content of media.

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

## Project Additional Information

### Purposes of the contained use

The proposed project involves the construction of adenoviral recombinants for the expression of complementary inhibitory molecules in cell lines in vitro and eventually in animal models of disease.

### Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E-coli K12 strains JM109 and XL1-blue specifically developed for application in recombinant DNA cloning experiments will be used. These strains have limited potential to colonise the gut or survive in the environment.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or recombination with the E1 gene in the helper cell line.

### Host/vector system

E-coli strains JM109 and XL1-blue will be used. Prokaryotic vectors include pUC-based vectors including the Ad transfer vector pAL119. A commercial Ad5 vector...
systems provided by Prof Frank Graham will be used as the basis for the vector (Microbix, Canada). pJM17 contains the complete Ad5dl309 genome vector system cloned into the pBR322-based vector pBRX. Recombinant viruses will generated following recombination in 193 cells. Prokaryotic cloning experiments are required to manipulate the complement inhibitory genes prior to recombination into the Ad genome. Expression will not be sought in E. coli and no specific hazard has been identified for prokaryotic manipulation. Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo.

**Origin & function**

The molecules of interest include human CD59, DAF (Decay Accelerating Factor), MCP (Membrane Cofactor Protein) and CR1, the rat analogues of DAF, CD59 and MCP and the rat complement inhibitor Crry. It is intended to clone these molecules in two forms: a) the natural form which includes the sequence necessary to anchor the protein to the cell surface and b) with a deletion of the sequence responsible for anchoring the protein to the membrane so that it is secreted from cells in a soluble form. Secreted forms of complement inhibitors do occur naturally. We also intend to perform mutagenesis on the predicted active sites of the complement inhibitors to examine function. Such constructs can be expected to have reduced hazard potential under most circumstances, although a dominant mutation could possibly reduce the efficiency with which complement action is inhibited.

DAF and CR1 have decay accelerating activity of the bimolecular enzyme complexes which constitute the convertase in both the classical and alternative complement activation pathways. They dissociate the C2a or the Bb subunits from the formed convertases and may also prevent the subsequent association of their procatelititic precursors C2 and B with membrane bound C4b or C3b molecules. Hence by accelerating the decay of preformed convertases and inhibiting the formation of new ones, DAF and CR1 can prevent amplification of the C3 activation on the host cell surface. Cr1 also acts as a cofactor for the cleavage of iC3b to C3c and C3d.g (iC3b can bind and activate neutrophils via CR3). CR1 also acts in vivo to mediate phagocytic binding of particles opsonized with C3b and participates in the transport of immune complexes on erythrocytes.

Like CR1, MCP acts as a cofactor for the factor-I cleavages of C3b and C4b and hence prevents the formation of active C3/C5 convertases. Although this inhibits both the classical and alternative pathways of the complement system, MCP is thought to act preferentially on the convertase of the alternative pathway.

CD59 works at the end of the complement pathway by inhibiting the assembly of the MAC (Membrane Attack Complex). It does so by incorporating into the partially formed MAC by binding to C5b8 and interfering with the subsequent binding and polymerization of C9.

The specific mechanism for Crry function is still unclear although it is thought to be a functional homologue for human MCP and/or DAF.

The main function of the complement system is its role in both the adaptive and humoral immune system in killing foreign microorganisms. Other biologically important functions mediated by the complement system include:

1) Low molecular weight anaphylotoxins C3a, C4a, and C5a which promote smooth muscle contraction and increase vascular permeability.

2) Large C4b and C4b fragments involved in the binding to the complement activator and therefore interact with specific receptors to allow efficient clearance of the activating cell of particle including virus.

3) Degradation of the fragments of C3b to iC3b, C4d.g and C3d which are also important in the clearance of the immune aggregates and the triggering of the receptor mediated activities including the regulation of the immune response.

Hence expression of the human (only) complement inhibitory proteins could result in a reduction/inhibition of systemic complement in man and potentially inhibit to varying degrees one, some or all of the above activities leading to an increased susceptibility to infection and the accumulation of immune complex precipitates.

The recombinant virus will be based on an Ad5 dl309 background with an additional deletion in the E1 gene at which site the insert will be inserted. The deletion of the E1
gene make the Ad recombinant replication-deficient and thus replication of the virus requires complementation by a helper function. 293 or 911 cells both carry an integrated copy of the Ad5 E1 gene and hence will be used for the construction and propagation of new recombinant virus. The complement inhibitory genes will be inserted at the site of the E1 deletion.

**Evaluation of foreseeable effects**

Activation of complement is known to be an important factor in numerous diseases including the development and propagation of inflammation of the rheumatoid joint. Efficient inhibition of complement could therefore ameliorate disease. This has been shown previously in the case of rheumatoid arthritis, by systemic and local inhibition of complement using complement inhibitory proteins. This project is an extension of this work but is intended to avoid repeated protein injections by assessing the viability of in situ expression of complement inhibitors using adenoviral vectors.

There are a number of theoretical hazards associated with this experiment. Firstly, as the recombinant virus is intended for in vivo use, there is the potential that the virus could spread from animal to animal and hence get into the natural population. Complement inhibitors exhibit host specificity and can be considered as a significant hazard only in the homologous species. However any in vivo injections will be local and given the fact the virus cannot penetrate more than a few layers of cells, the systemic spread of the virus should be negligible. Even in the highly unlikely event of the spread of the virus systemically, the recombinant virus is replication deficient, is not maintained in dividing cells and as such is incapable of horizontal spread throughout a population. Additionally wildtype Ad type 5 is able to undergo productive virus replication in very few non-human cells.

A second potential hazard is the exposure of humans to the recombinant virus. All manipulations of the virus will be performed in a class 11 biological safety cabinet in the laboratory. In vivo injections of Ad recombinants containing human complement inhibitory proteins into animal models will be carried out in an animal isolator, a negative pressure facility (ie in a class 1 cabinet) or a class 11 cabinet. A potential human infection will be a needle stick injury. Use of sharps will be kept to a minimum but are required for animal inoculations. In this event, gene expression from the Ad recombinant should be localised and the potential inhibition of complement localised and transient. In the unlikely scenario that the recombinant inhibitor becomes systemic, for the reasons stated above (inability to replicate without E1 complementation and the loss of the virus in dividing cells) the effect of the complement inhibitor should be transient. Also the effect of the complement inhibitor in humans should be minimal as the dose will have been designed for a rat and should therefore be at too low a level for a significant effect in humans. Moreover there are a total of 10 known complement regulatory molecules and the transient increase of one or two of these molecules should not significantly imbalance the immune system. Horizontal spread of the recombinant virus through the human population is not likely for the same reasons as it is not likely in the rat population.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichloroisocyanurate (Actichlor), after 4h solution can be discarded to mains drainage. Pipettes immersed in 2500 ppm Sodium Dichloroisocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the high concentration overcomes high organic content of media.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Please enter comments on the GM safety committee on the risk assessment

Assessment suitable and sufficient. Concern expressed re use of sharps. Questioned - no alternative for inoculating animals.

Project Ref 312/02.4

Date Ackn'd
26/1/2002

CU2 Project Title
MODULATION OF LYMPHOCYTE FUNCTION WITH ADENOVIRAL VECTORS

Class
Class 2

Consent Granted
not applicable

Project notified under transitional arrangements N

Historical Date of Additional Info
Project transferred to GM130 on 26/04/2005

Project Additional Information

Purposes of the contained use
I wish to study the molecules involved in lymphocyte growth. This will take place in B and T-lymphocyte cell lines as well as primary human cells. The molecules chosen include P13K, Jak, and STATs and other molecules that modulate cell growth and gene expression. Human primary lymphocytes are not easily transfected and infection
remains the best way to modulate their genotype.

Recipient or parental organism

The GMO that will be generated are adenoviral system containing molecules involved in lymphocyte growth and signalling.

Host/vector system

The adenoviral host vector systems are commonly used and well-characterised. All adenovirus vectors will be replication deficient due to deletion in the E1 gene region; this is a recognised safety feature. Repair of the deletion in the E1 gene region may occur due to homologous recombination with the E1 gene in the helper cell line (an extremely unlikely event) or following co-infection of a cell with a wild type Ad. In the unlikely event of such a recombination, it is likely to result in concomitant deletion of the transgene.

Origin & function

The genetic material for the adenoviral system are derived from the human Ad5 system. The genes that will be introduced into these vectors are mammalian in origin. More information is shown on the attached sheet. Each of these have been chosen because of their role in the manipulation of the immune system and gene expression. While all of these molecules play an important role in growth and/or survival, none have been shown to induce lymphocyte malignancy alone. Wild type, active and inhibitory forms of the molecules will be studied.

Evaluation of foreseeable effects

The adenoviruses by themselves do not constitute a risk. When considering the possible hazard to human health it is appropriate to consider the gene product that has the most potential to cause harm. The virus with the most potential to cause would be the active PKB or dominant negative PML. Both of these proteins have the capacity to enhance cell survival and proliferation. However neither alone is sufficient to cause malignant transformation. Cells of the haematopoetic system are most at risk from these proteins. However, these cells are poorly infectible by adenovirus. Furthermore, the transient nature of expression following adenoviral infection makes the expression unlikely to affect human health.

As the Ad is replication deficient, ie cannot replicate in host cells unless E1 sequences are provided in trans (eg in HEK 293 cells for virus propagation). It is considered highly unlikely that this will happen spontaneously. Furthermore efficient delivery of large number of virus particles would be required to infect cells. Expression using the Ad vector is only transient and is quickly lost in dividing cells as it only integrates DNA at a low frequency. The Ad vector is unlikely to cause any permanent change in cells it infected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste contaminated with GMMs will be treated with freshly prepared 2500ppm sodium dichloroisocyanurate. This completely destroys the adenovirus.

**Historical Significant Changes**

Project transferred to GM130 on 26/04/2005

**Project Additional Information**

**Purposes of the contained use**

The dominant negative and wild-type protein kinase C constructs will be transfected into cells in order to determine the role of isoforms of this enzyme in cell signalling leading to volume regulation, cell proliferation and drug resistance.
Recipient or parental organism

Recipient myocytic cells are only capable of proliferating to a couple of generations before they terminally differentiate, transfection of these cells is therefore unlikely to pose a hazard, however all work with the transfected cells will be conducted in a class 2 laminar flow cabinet and all media and labware treated with Virkon solution.

Breast cancer cell lines such as MCF-7 and our Tamoxifen resistant derivative thereof are able to grow in culture for significant periods of time. Transfection with the virus however would only be transient and the biological hazard therefore negligible. These cell lines do not contain other viral particule which might recombine with the vector beginning introduced, such as has been found in cell such as Hela cells. Again all work will be conducted in a class 2 laminar flow cabinet and all media and labware treated with Virkon before disposal.

Host/vector system

The host vector system is well characterised and available commercially. All adenovirus vectors used will be replication deficient due to deletion in the E1 gene region; This is a recognised safety feature. Repair of the deletion in the E1 gene region may occur due to homologous recombination with the E1 gene in the helper cell line (an extremely unlikely event) following co-infection of a cell with a wild-type adenovirus. Such a recombination event is likely to result in concomitant deletion of the transgene, is extremely unlikely but not impossible. Such recombinations also only usually occur within a subgenus not between subgenus. Adenovirus vectors are associated with extremely efficient in vivo delivery and can be spread by aerosol. This hazard will be contained by restricting manipulation with the virus to biological safety caninets and sealed centrifuge rotors. Adenovirus have no mechanism for cytolysis so in culture most viral particles remain cell-associated, although they can spread to neighbouring cells, leading to plaque formation.

Origin & function

PKC- 'Gutless' tetracycline - regulated binary adenoviral vectors will be supplied  (Harding et al., 1997, J. Neurochem 69 2620-3 and Harding et al., 1998, Nature Biotech 16: 553-5) (Hussain S, Assender JW, Bond M, Wong LF, Murphy D, Newby AC 2002; "Activation of protein kinase-C is essential for cytokine-induced metalloproteinase-1, -3 and 9 secretion from rabbit smooth muscle cells and inhibits proliferation." J. Biol Chem.: 277; 30: p27345-52). The original kinase defective (point mutation within the AT binding site 275 Lys> Trp) dominantnegative mutant was obtained from Dr Moscat, Universidad Autonoma de Madrid.

PKC-a and : Wild-type and kinase defective (point mutations within the AT binding site) dominant negative mutants of PKC-a and PKC- have been obtained from Dr Ohba, Instit of Mol. Oncology, Showa University, Tokyo (Nature 325: 161-66, 1987; Mol Cell Biol 18: 5199-5207, 1998; EMBO 13: 2331-2340, 1994). Rabbit PKC-a cDNA (-4~+2647), mouse PKC- cDNA (-13+2525/genbank:X60304), Dom neg PKC-1 cDNA (-42647 with 1 nucleotide mutation, AAGATCC>ACGATCC: 368 k>r), Dom neg PKC- cDNA (-13+2525 with 4 nucleotide mutation AAGTGTC>GCATGCC: 376 k>a). These will be used to determine the effect of over or non-expression of these signalling molecules on cell proliferation and Tamoxifen resistance in breast cancer and regulatory volume decrease in myocytes.

Evaluation of foreseeable effects

There is a potential hazard associated with using adenovirus recombinants to express transgenes that are overtly transforming or have a strong capacity to primate host cell proliferation. Protein kinase C is a signal transduction molecule associated with cell proliferation in a number of cellular systems. Although not thought to be the driving force behind cell replication, it does appear to act as a reostat, enhancing proliferation/apoptotic responses. The inserted gene product could therefore potentially be harmful, however due to the transient nature of the infection (see below), this risk is thought to be minimal. Dominant negative mutants of protein kinase C have previously been widely used in other laboratories and by the co-applicant. "Activation of protein kinase-C is essential for cytokine-induced metalloproteinase-1, -3 and 9 secretion from rabbit smooth muscle cells and inhibits proliferation". J Biol Chem.: 277 (30): p27345-52).

As the adenovirus is replication-deficient due to E1 and E3 deletions, they can not replicate in host cells unless E1 sequences are provided in trans (eg in HEK 293 cells for virus propogation). It is considered highly unlikely that this will happen spontaneously. Furthermore efficient delivery of large numbers of virus particles will be required to infect target cells, which is unlikely to ahppen, in vivo. Furthermore, since the adenovirus is replication deficient, no persistant long term effects are likely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solutions (such as tissue culture media or buffers such as PBS) will be inactivated by addition of more than an equal volume of sodium Dichloroisocyanate (Actichlor, 25000 ppm). After 4h, the solution will be discharged to main drains. Pipettes will be totally immersed in 2500 ppm sodium dichloroisocyanurate for 4h before transferring to plastic containers for autoclaving. All plasticware will be autoclaved after exposure to the virus. Acticlor is a broad spectrum and rapid acting biocide, effective against all viruses. The high concentrations used here will ensure that the high organic content of the media is overcome and 100% killing should be achieved.

<td>MANIPULATION OF ACTIVITY OF THE INTERFERON SIGNALLING PATHWAY IN CULTURED HUMAN CELLS</td>
<td>Class 2</td>
<td>&lt; 1 litre</td>
<td></td>
<td>not applicable</td>
<td></td>
</tr>
</tbody>
</table>
the aim of the project is to manipulate the levels of activity of the interferon signalling pathways in cultured human cells, both normal and immortalised, and potentially in combination with infection with other human retroviral vectors, already covered by HSE notifications in our laboratory, such as that encoding Ras. We have identified the interferon pathway as an important area of investigation due to our previous study of the effect of activated Ras in thyroid cells. Ras confers a limited proliferative potential to thyrocytes. However the cells eventually cease to divide. We have analysed gene expression in this arrested state using DNA microarrays and it appears that the interferon pathway is involved. This project will involve manipulating the interferon response pathways in a background where mutant Ras has already been introduced. Interferons play key roles in mediating antiviral and antigrowth responses and modulating the immune response, particularly in response to viral infection. Interferons are proteins naturally produced by many cells in the body. The interferons are pleiotropic cytokines that are induced in response to virus infection and act in a paracrine fashion to elicit an antiviral state in nearby cells. Binding of interferons to their cell-surface receptors induces a tyrosine kinase signalling cascade that leads to the activation of latent cytoplasmic signal-transducer-and-activator-of-transcription (STAT) factors. Activated STATs then translocate into the nucleus, where they are targeted to conserved promoter-enhancer sites to induce the transcription of interferon-responsive genes, that encode for protein with potent antiviral, growth-inhibitory, anti-tumour and immunomodulatory properties. There are 3 classes of interferon: interferon alpha, beta and gamma. Interferon alpha and beta signal through the Type 1 pathway, and interferon gamma uses the closely-related Type II pathway. We are interested in altering the levels of various members of the interferon signalling pathways, to attempt to modulate signalling of each pathway. We intend to do this by over-expression of various components of the pathways, the use of inhibitory genes, either naturally occurring (e.g. IRF2) or known dominant negative mutant alleles (e.g. of STAT 1). Cells will be studied in culture (e.g. phase contrast microscopy, the response to drug or other treatments), or killed and then subjected to cellular and molecular biology assays, such as immunocytochemistry, Western blotting, and extraction of RNA and DNA for subsequent analysis. We may also during the course of this work generate dominant negative and loss-of-function versions of the genes specified on accompanying risk assessments and below. These will be tested in the same manner as the wild type genes, as described above.
Cytokines: Interferons alpha, beta and gamma
Interferon alpha/beta receptor: Cell-surface receptor for interferon alpha and beta
Interferon gamma receptor: Cell-surface receptor for interferon gamma
Components of interferon signalling pathway: Interferon Regulatory Protein 1 (IRF1); Interferon Regulatory Protein 2 (IRF2); Interferon Regulatory Protein 3 (IRF3); Interferon Regulatory Protein 5 (IRF5); Interferon Regulatory Protein 6 (IRF6); Interferon Regulatory Protein 7 (IRF7); Interferon Regulatory Protein 8 (IRF8, ICSBP); Interferon Regulatory Protein 9 (IRF9, p48); Janus Kinase 1 (JAK1); Janus Kinase 2 (JAK2); TYK2; SHP-2 (tyrosine phosphatase); Cytosolic phospholipase A2 (CPLA2).
Components of interferon signalling pathway and transcription factors: Signal Transducer and Activator of Transcription 1 (STAT1); Signal Transducer and Activator of Transcription 2 (STAT2); Signal Transducer and Activator of Transcription 3 (STAT3); CREB-binding protein (CBP/p300)
Inhibitor of IRF-1: Nucleophosmin (NPM)

Evaluation of foreseeable effects
With regard to the hazards associated with the host/recipient the following have been considered including the pathogenicity of host strain, virulence infectivity and toxin production. In this case recipients and hosts are non pathogenic.
With regard to the hazards rising directly from the inserted gene these are non oncogenic and are downstream members of signalling pathways.
With regard to the hazards arising from the alternation of existing pathogenic tracts there is no increase in infectivity or pathogenicity and no disabling mutation within the recipient can be overcome due to the insertion of the foreign gene. Foreign genes do not encode pathogenicity determinants from a related organism.
Considering whether an inserted sequence, that does not give rise to harmful phenotype in the recipient micro-organism could give rise to harm as a result of natural gene transfer to another possibly related organism this is extremely unlikely to have a harmful effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All retroviral work will take place in a dedicated Class II facility. All liquid waste is sterilised at point of use by sodium hypochlorite. All solid waste is sterilised in adjacent autoclave facility. Use of glass and needles will be avoided to reduce the risk of sharps injury.
Autoclave thermocouple tested annually, also daily monitoring of efficacy of autoclave. Discussed determining efficacy of disinfectants with HSE inspector on recent visit. Relying on manufacturer's quality control and the very unstable nature of GMOs involved.

Purposes of the contained use
We intend to perform a systematic investigation of Human cytomegalovirus (HCMV) gene function by the cloning and expression of HCMV genes in cell lines, baculovirus vectors and replication-deficient adenovirus vectors. The vast majority of assays will be performed using cultured cells in vitro. Occasionally, animals will be inoculated with As recombinants primarily to generate antibody specific for the expressed transgene.

Recipient or parental organism
Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E. coli K12 strains specifically developed for application in recombinant DNA cloning experiments will be used. These strains have limited potential to colonise the gut or survive in the environment. Continuous cell lines expressing HCMV gene is also envisaged Prokaryotic cloning experiments, transient and continuous cell lines will be at ACGM category 1 level.
Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Vectors will also contain defined deletions in the non-essential E3 gene region. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or gene rescue from the helper cell line. The use of more disable Ad vectors, specifically gutless vectors, is envisaged when feasible.

Baculovirus vectors are replication competent in insect cells but replication-deficient in mammalian cells. The vectors lack the non-essential polyhedrin gene.

**Host/vector system**

- E. coli strains DH5α, JM109, BJ583 and XL1-blue will be used. Details of vectors for ACGM1 work is given in the risk assessment.
- Commercial Ad5 vector systems will be used as the basis for vector development.
- For the construction of replication-deficient adenovirus recombinants:
  - The Admax vector system from Microbix, Canada (pDC511, pDC512, pDC515 and pDC516, pBHGFrtDE1,3FLP, pXCXL-based transfer vectors, pJM17) from Qbiogene (Hareford, Middx) the AdEasy vector system (pAdEasy-1, pShuttle, pShuttle-CMV, pShuttle-CMV-LacZ) and a gutted Ad vector as described by Schneider et al (J. Virol. 2002, 76 1600).
- Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo.
- Baculovirus Vectors: Introgen Insect Select and Novagen BacVector System. SF9 cells for virus growth of baculovirus vectors. HCMV genes may be placed under the control of the baculovirus polyhedrin promoter to provide for high level expression in SF9 cells. Genes may also be inserted into the baculovirus vector under the control of a constitutive promoter namely the HCMV major IE promoter. Baculovirus can infect (inefficiently) but not replicate in mammalian cells. Baculovirus vectors thus can thus be used as a replication-deficient gene delivery system in mammalian cells as an alternative to adenovirus vectors.
- Tissue culture cells including primary fibroblasts, U373, THP-1, primary myeloid cells.
- Animals may be inoculated with Ad recombinants, primarily with the intention of generating polyclonal or monoclonal antibodies for the further characterisation of gene products.

**Origin & function**

- Genes will be cloned from any human cytomegalovirus isolate including the laboratory strains AD169, Towne and Toledo. Sequences will also be cloned from clinical isolates. HCMV is a ubiquitous herpesvirus with the largest genome of any characterised human virus (approx 235Kb). It is designated as an ACDP 2 agent. The virus is extremely well-adapted to its host with the vast majority of infections passing unnoticed. Between 50-100% of adults are seropositive depending socio-economic conditions. In healthy individuals primary infection is normally asymptomatic or associated with a mild febrile infection, followed by lifelong persistence (clinically silent) in its host. The virus is thought to establish ‘latency’ in a subset CD34+ myeloid progenitors with reactivation accompanying cellular differentiation. However, HCMV is an occasional cause of heterophile-negative infectious mononucleosis and a major viral vane of congenital malformation. In severely immunocompromised individuals (notably late stage AIDS patients and bone marrow recipients), HCMV disease is associated with morbidity and mortality. HCMV is not believed to cause cancer nor to encode oncogenes. ‘Transforming regions’ of the genome have been defined but have extremely low potency (Macarski and Courcelle, 2001; In Fields Viology, ed; DM Knipe & PM Howley pp2675-2705. Lippencott William & Wilkins, Philadelphia). Although HCMV is known to encodes a number of immunomodulatory genes, there is no compelling evidence that HCMV infections are immunosuppressive.

- The complete sequence of the laboratory-adapted HCMV strain AD169 was determined by Chee et al (1990) and was predicted to encode 208 non-overlapping ORFs of greater than 80 amino acids. However, strain AD169 is known to harbour a number of defects, most spectacularly a 15 kb deletion that has since been sequenced in strain Toledo. Mocarski and Courcelle (2001) have recently updated the analysis of the HCMV genetic content and this was used as a basis for the risk assessment (attached). The complete sequencing of the HCMV clinical isolate Merlin is now being undertaken in the University of Glasgow (A. Davison, personal communication). The HCMV isolate Merlin will be used in the majority of our studies to avoid issues of genetic instability associated with laboratory-adapted strains. However, we also envisage a need to clone DNA fragments and genes from other HCMV laboratory strains and primary isolates to analyse sequence variation. The definition of HCMV ORFs by Mocarski...
and Courcelle (2001) is known not to be definitive. More detailed analysis will identify additional functional ORF and delete spurious ones. HCMV also encodes untranslated transcripts (eg the B2.7 gene). We seek to cover the expression of all HCMV genes including untranslated transcripts. The herpesviruses encode a core set of genes associated with nucleic acid metabolism, DNA replication, capsid assembly and the production of infectious viruses that can be readily predicted from their sequence. A number of functions associated with transcriptional regulation and immune function have been identified, some by homology to cellular proteins. However, clearly a large proportion of the HCMV genome awaits detailed analysis.

There are few antibodies available to HCMV proteins. HCMV ORFs will therefore also be expressed as fusion proteins with GFP/RFP or YFP variants, a 6xHis tag, a streptavidin-binding peptide tag, a tetracysteine peptide tag or an Fc fusion protein to monitor expression, facilitate purification or identify binding ligands.

**Evaluation of foreseeable effects**

Most HCMV genes either have no known biological functions or encode functions that have no predictable detrimental effect when expressed in the proposed vectors. A risk analysis is performed on HCMV gene product with known functions that have the highest potential to cause harm. The virus does not encode any known oncogenes or toxins. HCMV gB is involved in virion attachment to a currently unknown cellular receptor. Recently, microarray experiments and other systems indicated that the binding of gB to its receptor modulates the transcription of a large number of cellular genes including the induction of an interferon-like response (Simmen et al, PNAS 2001; 98; 7140). Recombinant gB thus has the potential to induce transcriptional effects when expressed. Although normally a membrane protein, secreted forms of gB would have the potential to effect cells in trans. An Ad5 recombinant expressing HCMV gB is capable inducing a neutralising immune response (Marshall et al, J. Infect. Dis, 162, 1177). Ad is not enveloped so expression of gB does not have the potential to effect Ad5 tropism. Ad5 recombinants encoding cell-associated or soluble versions of gB have the capacity to transiently modulate expression in trans following in vitro or in vivo administration. There is a potential hazard with Ad-gB recombinant viruses that should gB released from cells it has the potential to modulate transcription in adjacent cells. This effect may be similar to an interferon response, is liable to be detrimental to the cell but should be transient.

IE2 is the predominant regulatory protein in the virus. It is a promiscuous transactivator that interacts with a wide range of cellular factors (including p53 and Rb), may inhibit apoptosis, promotes cell cycle progression and cell cycle arrest in G1/S. By itself IE2 is not transforming, indeed expression of this protein in mammalian vectors has proved problematical as it appears incompatible with long term cell survival, probably due to the block in cell cycle progression. IE2 has some capacity to rescue an Ad E1a deletion but does not rescue a complete E1 deletion. An ADIE2 recombinant has been shown in microarray analysis to increase the levels of RNA molecules that promote cell cycle progression (Song and Stinski, PNAS 99, 2836). Infection with an Ad5 1E2 construct is liable to be inconsistent with the long term survival of the cell (as is a wt Ad5 infection) but would not be expected to result in the release of virus nor cell transformation. HCMV encodes a series of additional regulators of cellular gene expression that appear to be significantly less potent than IE2; including IE1 (weak transactivator; disperses PML-bodies), pUL36 (IE) the virion proteins ppUL82 (pp71), ppUL69, pIRS1 and pTRS1. There is no clear potential for hazard associated with the expression of these molecules. HCMV has become a paradigm for investigating virus modulation of cellular immune systems. A number of immunomodulatory genes have been characterised and it is anticipated that a significant number of uncharacterised HCMV genes will be found to interact with immune systems. The expression of genes capable of modulating immunological r esponses in Ad5 vector systems constitute a potential hazard.

HCMV UL111a is a functional IL-10 homologue. IL-10 used therapeutically to suppress immunological responses yet is well tolerated and in high doses could predispose to infection. Ad recombinant encoding cellular and EBV vIL-10 have been used in animal models to suppress immunopathologies. The CMV homologue is believed to be of lower potency. As a secreted virokine Ad recombinants have a theoretical potential to induce transient, localised suppression of Th1 immune responses. There is a low level potential hazard with Ad-UL111a recombinant viruses that has recently been approved at ACGM2 level in a separate notification from this laboratory. HCMV encodes a number of putative secreted immunomolecules that may be considered to represent a comparable hazard level to the UL111a gene product and a substantial number of additional secreted glycoproteins is predicted by analysis of ORFs and preliminary expression studies. Preliminary data indicates the hypervariable UL146 gene product (vCXC-1) to be an IL-8-like chemokine that induces chemotaxis of neutrophils. UL147 also exhibits cysteine spacing and weak homology to CXC chemokines. Additional uncharacterised chemokine-like ORFs are expected to be functional.

US2, US3, US6 and US11 encode glycoproteins that act on infected cells to downregulated cell surface expression of MHC-1, and thus they can be expected to promote evasion of CD8+ CTLs. The leader sequence from UL40 acts to upregulate cellular HLA-E expression and thus promote protection against attack by CD94/NKG2A+ NK cells. gpUL16 promotes the intracellular retention of ligands for the NK activating ligand NKG2D and this may also impede NK recognition. GpUL18 is expressed on the cell surface where it binds the inhibitory ligand Lir-1 that is present of NK subsets, T cell subsets anad myeloid cells. The functional role of gpUL18 is controversial, it may...
inhibit NK and T cell subsets. Four HCMV genes (UL33, UL78, US27, US28) are predicted to encode 7TM receptors. US28 encodes a functional C-C chemokine G-protein-coupled receptor (GCR) which binds both CC and CX3C chemokines and signals in response to some. Experiment by others using an AdUS28 recombinant infecting vascular smooth muscles cells indicate that US28 expression can direct cells movement (Sgtrebnow et al, Cell 1999; 99, 511). HCMV is predicted to encode additional NK inhibitory mechanisms and additional glycoproteins that may be expected modulate the expression of existing surface glycoproteins, to promote intracellular signalling and/or promote interaction with other cells. All these genes would normally only be expected to functions only in the transgene-expressing cell and thus are of lower potential hazard. The hazard with cell surface inhibitory receptors (eg UL18) may be increased if expressed as soluble forms to a hazard level similar to that of cmvIL-10 (UL111a). There is a potential hazard associated with the expression of biologically active molecules in native and modified (soluble or epitope tagged) forms. The hazard is reduced by the vector being replication-deficient. Although, the Ad vector has the potential to provide for relatively efficient in vivo delivery of these agents, in both animal models and in clinical trials it has been difficult (although possible) to deliver transgenes with Ad vectors efficiently enough to induce therapeutic effects with immunomodulatory cytokines such as IL-2 and IL-10. Hazards associated with using replication-deficient Ad recombinants encoding HCMV immunomodulatory genes are similar to those with human cytokines. This hazard should be controlled by providing ACGM-2 containment.

Baculovirus recombinants have the potential for environmental harm due their capacity to kill insects. Enhanced baculovirus pathogenesis/virulence as a consequence of expressing a novel transgene is therefore to be avoided or controlled. Baculovirus is an enveloped virus and HCMV protein expressed in a baculovirus recombinant have the potential to be incorporated into baculovirus virions. HCMV has an extreme restricted tropism productively infection only certain human cell types. HCMV infection also requires a complex series events involving a number of HCMV glycoproteins acting together (gB, gH, gL, GO). While the HCMV receptor has not been characterised, the complex nature of the HCMV infectious process make it extremely unlikely that the expression of an HCMV gene product would be capable of modifying the tropism of the baculovirus vector. The immune system of insects and humans have diverged. The HCMV immune modulators have evolved to have very precise effects on the human immune system. It is extremely unlikely that an HCMV-encoded immune modulator would be able to mediate a significant function in insects. Soluble chemokines and virokines depend on interactions with a matched receptors. Genes involved in MHC-1 downregulation and NK evasion also depend on highly specific interaction with molecules such as the MHC-1 proteins, TAP or NK ligands that are not likely to have survived evolutionary divergence. Baculoviruses-expressing HCMV genes have an extremely low likelihood of having enhanced virulence in insects. In certain cases HCMV genes may also be inserted into baculovirus under the control of a constitutive promoter for transgene expression to mammalian cells. Specific baculovirus recombinants would then have the potential to express HCMV immune modulators in human cells as with replication-deficient Ad vectors. The potential hazard is lower because Baculoviruses infect human cells relatively inefficiently and following infection there is an absolute barrier to replication. There is extremely low likelihood of enhanced environmental hazard with these constructs, for the same reasons as given above.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Animals are inoculated in a Class 2 safety cabinet. The site of inoculation is disinfected according to agreed protocols before the animals are placed in filter-top cages. It is not anticipated that the virus will remain viable in the animal nor be secreted from the animal. Nethertheless, both the animal and waste are incinerated according to standard procedures in Biomedical Services approved by the Health and Safety Unit.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The committee queried 'whether or not the environmental Risk Assessment was sufficient for the use of baculovirus'. One has now been appended to the Risk Assessment.

The committee was happy that the containment level and classification of work assigned was appropriate. Class 1 Containment Level 1 for prokaryotic organism and cell lines. Containment level 2 for adenovirus and baculovirus.

### Purposes of the contained use

We intend to perform a systematic investigation of human Epstein-Barr virus (EBV) gene functions by the cloning and expression of EBV genes in cell lines using baculovirus, vaccinia virus and replication-deficient adenovirus vectors. Previous work by our group has focussed mainly on the limited number of 'latent' viral genes expressed in B lymphoblastoid cell lines growth-transformed by EBV. However, the virus contains about 80-90 genes in total. Most of these are expressed only in cells entering the lytic virus productive cycle. The functions of some lytic cycle genes are quite well characterised (eg the BZLF1 immediate-early gene, encoding a transcriptional activator which initiates a cascade of viral gene expression) while the products and functions of many other genes are uncharacterised. The broad aims of this project are to investigate the mechanisms regulating induction and progress through EBV lytic cycle, and to screen for novel functions of EBV genes, particularly those which modulate immune responses. Experiments involving the use of replication-deficient recombinant adenoviruses may also include the use of a plasmid expression vector for the adenovirus receptor (CAR) to render specific cell lines susceptible to infection. Other components of the work designed to elucidate the mechanisms of EBV immunomodulating genes may also involve expression of components of the antigen processing pathway (eg HLA and TAPs). The vast majority of experiments will be performed on cell lines, but animals may occasionally be inoculated with Ad-recombinants primarily to generate antibodies specific for the transgene.

### Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant viruses. Genetically disabled E.coli K12 strains specifically developed for application in recombinant DNA cloning will be used. These strains have limited potential to colonise the gut or survive in the environment. Prokaryotic cloning experiments will be at ACGM category 1 level.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region renders the adenovirus vectors replication-deficient, which limited the potential for lateral spread. Theoretically, lateral spread could be facilitated by co-infection and a wt adenovirus or by gene-rescue from the helper line.

Vaccinia virus is an ACDP category 2 pathogen. Recombinant viruses may retain the pathogenic potential of wild-type vaccinia. The WR strain is a replication-competent lytic virus which has the potential to cause lesions, whereas the MVA strain is non-lytic and has to be generated in chicken embryo fibroblast (CEF) or BHK-21 cells. However, neither WR nor MVA recombinants are compatible with cell survival. Insertion of foreign genes into the thymidine kinase (TK) locus results in a TK phenotype which is attenuated relative to wild-type virus. The MVA strain is already highly attenuated.

Baculovirus vectors are replication competent in some insect cells but are replication-incompetent in mammalian cells. The vectors lack the non-essential polyhedrin gene.

### Host/vector system

- **Prokaryotic hosts:** E. coli strains DH5a, JM109, BJ583 and XL-blue will be used.
- **Adenovirus recombinants:** Commercial Ad5 vector systems will be used. The Admax vector system from Microbix, Canada; the AdEasy vector system from Qbiogene, Hareford, Middx. Additionally, the gutted Ad vector as described by Schneider et al (J. Virol. 2002, 76:1600). Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo.
- **Vaccinia virus recombinubabts:** These will be made in the Western Reserve (WR) or in the Modified Virus Anraka (MVA) vaccinia strains. WR virus will be reaped in TK 143 cells, while MVA will be prepared in CEF or BHK-21 cells.
- **Baculovirus recombinants:** Commercial Insect Select (Invitrogen) and BacVector (Novagen) systems. Sf9 insect cells for growth of baculovirus vectors.
- **Target cells:** Tissue culture cells, including human tumour lymphoid (eg Burkitt's lymphoma B cell lines, and Jurkat T cell line) and epithelial cell lines (eg Hele, 293). Primary lymphoid and fibroblast cells.
- **Animals:** Animals may be inoculated with Ad recombinants, primarily to generate polyclonal or monoclonal antibodies.
### Origin & function

Genes will be cloned from Epstein-Barr virus isolates, including B95.8 and Raji which have been used to generate a complete 'wild-type' sequence (EBV-wt; accession number AJ507799) of 171,823 basepairs with approximately 80-90 known or postulated genes. Epstein-Barr virus is a category 2 ACDP pathogen. It is a lymphotropic/epitheliotropic gamma-herpesvirus that is carried as a life-long persistent infection by more than 90% of adults. Despite the asymptomatic nature of EBV infection, the virus has the potential to transform one of its principal target cells, B lymphocytes, and experimental infection of B cells in vitro leads to the establishment of lymphoblastoid cell line (LCL). These LCL carry EBV predominantly as a 'latent' (ie non-productive) infection. In healthy EBV-positive individuals, the persistent virus infection is effectively controlled by immune mechanisms, particularly cytotoxic T cells (CTLs). Since EBV is a virus with transforming potential, one potential hazard of the vectors to be generated is the possibility that the expressed genes may be oncogenic. The role of EBV genes in cellular transformation is well studied. At least five of the 'latent' genes are known to be absolutely essential for the ability of EBV to transform human B cells. The main function of the EBNA1 protein is maintenance of the EBV episome during cell replication. EBNA2, EBNA3A and 3C are nuclear proteins that activate and/or repress transcription of EBV and cellular genes. LMP1 is a membrane protein that mimics a constitutively active receptor of the CD40/TNF superfamily. Both LMP1 and EBNA3C have been defined as having oncogenic or immortalizing properties in rodent fibroblast assays. However, all attempts to demonstrate conversion of non-malignant human cells to a full malignant phenotype with any single EBV gene have been unsuccessful. While some of this work will necessitate using EBV 'latent' genes in recombinant adenovirus or vaccinia virus expression vectors, the main objective of this project is to identify functions of the lytic cycle genes, most of which are poorly characterised, if at all. The original impetus for this work derived from a wish to identify those genes responsible for down-regulating expression of components of the antigen processing pathway in cells harbouring EBV as a productive, lytic infection. Therefore, it can be deduced that we expect some EBV genes to have immunomodulatory functions. Indeed, one well-characterised gene (BCLF1) is known to encode an IL10 homologue. However, there is no compelling evidence to suggest that EBV infection is immunosuppressive; on the contrary, it elicits potent immune-responses.

In addition to vectors expressing wild type EBV genes and mutated genes, other constructs will be required for this project. The use of adenovirus vectors on B lymphocytes, a natural host for EBV, is hampered by the fact that these cells often express only low levels of adenovirus receptor (CAR). Therefore, a human or porcine CAR-expression plasmid will be used to make stable transfectants of established cell lines to generate lymphocytes that can be efficiently infected with replication-deficient adenovirus vectors. The potential risk of the CAR expression plasmids in this context is minimal.

Some experiments, designed to establish the mechanisms by which EBV genes modulate antigen presentation, will also require the use of expression plasmids or recombinant viruses for components of the immune recognition process (eg human MHC, TAP, NK receptors).

Other experiments will use a number of reporter plasmids with specific transcription factor binding motifs to characterise signalling functions or to indicate activation of lytic cycle. Furthermore, reagents generated from related notified projects (“modulation of lymphocyte function with adenoviral vectors” - Dr Brennan; and “Analysis of Epstein-Barr virus latent gene functions” - Prof Rowe) will be used to assist elements of this project. For generation of new expression plasmids, we will use well characterised constructs, some of which are designed to incorporate 'tags' to allow detection and/or isolation of the expressed proteins. These tag sequences are unlikely to pose any significant additional hazard.

### Evaluation of foreseeable effects

Most EBV genes have no known biological functions or functions that have no predictable detrimental effect when expressed in the proposed vectors. The 'latent' genes associated with the growth-transforming functions of EBV may be considered to constitute the greatest potential hazard when expressed in the proposed vectors. Both LMP1 and EBNA3C have been defined as having oncogenic or immortalising properties in rodent fibroblast assays. However, it is clear that EBV requires the co-operative action of at least 5 genes (EBNA1, EBNA2, EBNA3A, EBNA3C, and LMP1) to immortalize human B cells. Therefore, the hazard posed by accidental expression of these genes is substantially reduced. Furthermore, the adenovirus and vaccinia virus vectors should give only transient expression whereas the potentially pathogenic effects of the latent genes require persistent expression. Finally, all EBV latent genes (with the possible exception of EBNA1) are effectively targeted by cytotoxic T cell immune response. Thus, the potential hazard with regards possible transformation of human cells infected with Ad virus recombinants expressing EBV latent genes is acceptably low. This view is supported by the fact that similar work has already been approved at Birmingham (Rickinson Group) and Liverpool (Blaake group) and is being performed under category 2 containment.

The effects of most EBV lytic cycle genes on cellular gene expression and phenotype is unknown - which is the very reason for undertaking this project. However, none of the lytic cycle associated EBV genes studies have been reported to show oncogenic properties. Indeed two of the immediate-early genes (BZLF1 and BRLF1) have been
expressed by others in Ad virus vectors and have been shown to selectively inhibit growth of EBV-positive tumours (J. Virol., 2002. 76:10951). Unlike many other members
of the herpesvirus family, EBV encodes relatively few genes that are obvious homologues of immunomodulatory molecules. The notable exception is BCRF1 which is
highly homologous to IL-10 and shares functional properties with the human cytokine. IL-10 is used therapeutically to suppress immunological responses, and is well
tolerated in high doses although it may predispose to infection. Ad recombinants encoding cellular and EBV vIL-10 have been used in animal models to suppress
immunopathologies. As a secreted virokine, vIL-10 Ad recombinants have a theoretical potential to induce transient and localised suppression of Th1 immune r
esponses. Therefore, there is a low level potential hazard with Ad-BCRF1 recombinant viruses.

Adenoviruses are ACDP level 2 agents that are naturally infectious to the respiratory tract as aerosols. If accidental inoculation were to occur, the viral DNA would be
introduced into a number of cells giving transient expression of the transgene over a period of a few days to weeks. However, all Ad vectors used will be
replication-deficient due to deletion of the E1 and E3 gene regions; this is a recognised safety feature. Therefore, following accidental inoculation, further spread would not
occur. With time, the genome will be lost from the infected cells, this process being more rapid in proliferating cells. Chromosomal integration of Ad virus sequences is a
rare event (in the region of one integration in 10(4) exponentially growing cells). It is generally agreed that most cells of the respiratory tract epithelium are post-mitotic and
on the differentiation pathway. Therefore, it is our opinion that a considerable intake of virus, much greater than 10(5) pfu, would be required to produce a single integration
event. Working practices are designed to minimise the risk of any human contamination, and the likelihood of accidental infection followed by viral integration is almost
negligible. Repair of the E1 deletion of the Ad vectors could potentially occur in vitro due to homologous recombination with the E1 gene in the helper cell line, or in vivo
following the unlikely event of coinfection of a single cell with recombinant Ad virus and a natural wild-type Ad virus. Such recombination events are likely to result in
concomitant deletion of the transgene in the E1 locus. Generation of a replication-competent Ad carrying the whole or part of the transgene is not impossible, but extremely
unlikely. It is notable that attempts to detect such complementation by dual infection in the cotton rat model gave negative results. The potential hazard of the recombinant
adenoviruses should be adequately controlled by adhering to ACGM-2 containment.

Vaccinia viruses are ACDP category 2 agents which have the ability to a wide range of cells in human and non-human hosts. Vaccinia may cause puustular lesions at the
site of infection, and can cause severe disease in individuals with active skin disorders such as eczema or psoriasis. Acute conjunctivitis may occur after inoculation into
the eye but permanent eye damage is rare. Disseminated vaccinia necrosum can occur in immunosuppressed or immunodeficient individuals. Recombinant viruses may
retain the pathogenic potential of wild-type vaccinia. The WR strain is a replication-competent lytic virus which has the potential to cause lesions, whereas the MVA styrian
is non-lytic and has to be generated in chicken embryo fibroblast (CEF or BHK-21 cells. However, neither WR nor MVA recombinants will be compatible with cell survival.
Therefore only transient expression of the inserted genes will be obtained, and the additional risk posed by the inserted genes will be low. It is not clear whether EBV
glycoproteins would be expressed in the vaccinia virus envelope, but it is not expected that this would alter the tropism of the virus. The potential hazards of the r
ecombinant vaccinia viruses should normally be adequately controlled by adhering to ACGM-2 containment. However, individuals with skin disorders are at greater than
normal risk for working with vaccinia viruses and should seek additional advice.

Genetically modified baculoviruses retain the ability to infect cells of the insect host species but do not efficiently infect human cells. During infection of insect cells,
expression of the gene insert will occur under the control of the Polyhedrin or P10 promoters, but these promoters are not expected to be functional in human cells. It is not
clear whether EBV glycoproteins would be expressed in the baculovirus envelope, but the complexity of the EBV infection process makes it extremely unlikely that insertion
of a single EBV protein would alter the tropism of a recombinant baculovirus. Therefore the nature of the EBV gene insert in recombinant baculovirus itself is not expected
to pose any additional risk to human health or to the environment. A case could be made for using the recombinant baculoviruses at ACGM level 1, but taking a more
cautious view we propose to adhere to ACGM-2 containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Virus in solution (tissue culture medium or buffers such as PBS) will be inactivated by adding at least an equal volume of 2500 ppm sodium dichloroisocyanurate (Antichlor). After 4 hr, the solution can be discarded to mains drainage and flushed with excess water. Contaminated pipettes are immersed in 2500 ppm sodium dichloroisocyanurate (Antichlor) for 4 hr prior to transferring to a containing for autoclaving. All plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the chosen concentration overcomes the high organic content of tissue culture media.

Animals may be inoculated with recombinant adenoviruses in a Class 2 microbiological safety cabinet. The site of inoculation is disinfected according to agreed protocols before the animals are placed in filter-top cages. It is not anticipated that the virus will remain viable in the animal nor be secreted from the animal. Nevertheless, both the animal and all animal waste is incinerated according to standard procedures in Biomedical Services approved by the Health and Safety Unit.

<tr>
<td><strong>Host/vector system</strong></td>
<td>Balb-c's were cross-bred at NIBSC onto ICR mice already transgenic for Trangene 21 polio virus receptor (Tg 21 PVR).</td>
</tr>
</tbody>
</table>
Intended function (at NIBSC, not RVC): to screen human polio vaccines for neurovirulence. |
| **Evaluation of foreseeable effects** | A worst case scenario is that the mice escape, breed with wild mice to give a population of mice with this Mendelian dominant Tg 21 PVR gene and thereby set up a new animal reservoir for polio virus after it has been eradicated in man. However experiments have shown viral transmission between TgPVR mice is poor (WHO Bulletin OMS, Vol 71, 1993 - pages 497-502). Balb-c mice are albino, docile and used to ad-lib water and pelleted food in a controlled temperature cages and so would be unlikely to survive and interbreed to set up a sustainable mouse colony in central London. |
| **Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)** | The mice are kept in metal cages in a positive-pressure isolator whose plastic film mice cannot gnaw. The isolator is in a secure room with swipe card in a secure building with computer-controlled entry by encoded swipe card and also card holder's code. There are no drains and the one in the adjacent preparation room has an in-built rodent trap. The animals are attended to by qualified technicians with three or more years experience of isolators. Sick animals are reported to the named veterinary surgeon. Live mice never leave the isolator. |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

---

The waste from the isolator and any culled animals are bagged in the isolator, double bagged in the exit port of the isolator and then autoclaved on site before being tertiary bagged for incineration at Cambridge pet crematorium.

This was passed without comment in 1998.
Hepatitis C virus (HCV) is a major human pathogen worldwide causing persistent infection, chronic disease and is associated with a high risk of development of hepatocellular carcinoma. Although complete genome sequence and cDNA clones are available for HCV, the testing of potential anti-viral therapies is constrained by the lack of efficient in vitro virus culture systems and the in vivo challenge systems (humans and chimpanzees). These limitations do not apply to the closely related veterinary pestivirus, bovine viral diarrhoea virus (BVDV), for which infectious cDNA clones, in vitro culture systems and large animal challenge systems are well established. To facilitate the in vivo assessment of potential anti-viral therapies for HCV, we propose to investigate the use of BVDV as a model for HCV and further develop a small animal challenge model (neonatal rabbits) for BVDV infection. The challenge of rabbits with BVDV is an issue not within the remit of this application (BVDV is an ACDP category 1 pathogen).

However, to exploit the potential of this system we will also construct recombinant viruses where key components of the HCV genome are substituted into a BVDV infectious cDNA. This will generate chimeric viruses capable of replication in the bovine cell culture system but which are dependent on HCV functions to direct protein expression or replication. These chimeras will eventually be targets for the development of HCV-specific anti-viral therapies. The recombinant plasmids containing these
clones are not infectious (BVDV is an RNA virus, the plasmid clones are DNA). The infectious RNAs for recombinant (chimeric) viruses will either be generated in vitro (in a microfuge tube) using a bacteriophage T7 polymerase promoter or following transfection of the plasmid DNA into a mammalian cell line engineered to express the T7 RNA polymerase. The RNA produced in this way is chemically fragile but is capable of replication if introduced into a suitable host cell and may produce infectious virus.

As this proposal intends to deliberately create novel chimeras between an endemic veterinary virus and a human pathogen, issues of safety and containment need to be carefully addressed, particularly with respect to potential changes in the host range of virulence of any chimeric viruses.

To avoid these hazards the project will introduce only HCV sequences which will not affect the tropism of the recombinant virus, including the 5'-untranslated region (which has no protein coding capacity but directs the initiation of viral protein synthesis) or sequences encoding virus non-structural proteins such as NS3 (serine protease and NS5B (RNA polymerase)). Passive markers for gene expression such as the green fluorescent protein may also be used.

Recipient or parental organism

Bovine viral diarrhoea virus (BVDV) is a worldwide pathogen of artiodacyla (even toed ungulates), primarily cattle, sheep and to a lesser extent, goats and pigs. This pestivirus is endemic in the UK and usually associated with a mild or inapparent clinical illness which results in reduced milk yield and reproductive performance. Natural immunity to BVDV is high (70-90% of animals) and effective vaccines are available.

All work will be based on the highly lab-adapted, cytopathogenic NADL strain of BVDV which is licensed as a live virus vaccine in the USA. Cytopathogenic strains of BVDV are unable to establish persistent in utero infections in cattle.

BVDV is not known to infect humans. At no stage will infectious HCV be used.

Host/vector system

Infectious cDNA clones of the NADL strain of BVDV will be modified to include additional sequences or to replace normal viral sequences. These include: firstly, the HCV 5'-untranslated region (the internal ribosome entry site or IRES initiates protein expression) and later, green fluorescent protein (marker protein) or the HCV non-structural proteins NS5 (RNA polymerase) or NS3 (serine protease). These sequences are not toxic. It is unlikely that these components will have any effect on host range. The basis for this statement is the observation that both virus protein expression and RNA replication occur in non-permissive (BHK) cells transfected with pestivirus RNA; substituting the BVDV sequences with the HCV homologues is unlikely to change this situation. Host range is determined by the interaction of the virus structural proteins with a host specific, cell surface receptor molecule: virus structural proteins limit the susceptible host range. NO ATTEMPT WILL BE MADE TO CHANGE THE VIRAL STRUCTURAL PROTEINS in this project. Infectious cDNA clones or RNA derived from them will be transfected into mammalian cells in culture and the properties of the chimeric viruses generated will be compared with those of the parental BVDV strain. At no stage will infectious HCV be used.

Origin & function

Sequences encoding the green fluorescent protein (GFP) or regions of the hepatitis C virus (HCV) genome will be cloned into the BVDV infectious cDNA clone. The function of GFP will be to provide a passive marker for viral gene expression, facilitating the quick and simple detection of virus growth within cells. The HCV derived sequences will be noncoding genome sequences (the 5'-untranslated region containing the internal ribosome entry site). This non-coding RNA sequence controls the expression of viral protein synthesis or regions encoding viral non-structural proteins such as NS3 (serine protease) and N35B (RNA polymerase). These proteins assist the replication of the viral genome within an infected cell. They do not play a role in virus entry into an uninfected cell. None of these changes are likely to affect the pathogenicity, host range or tropism of the chimeric viruses. Previously published work describes similar viruses (see Frolov, McBride and Rice (1998) RNA 4:1418-1435 and lai VC, Zhong W, Skelton A, Ingravallo P, Vassilev V, Donis, Hong and Lau (2000) J Virol 74:6339-47) and there is no evidence that these chimeric viruses have modified growth characteristics in cell culture (except that some recombinants replicate poorly in vitro).

The eventual aim would be to use the chimeric viruses to test the efficacy of anti-HCV specific anti-viral therapies. This would be done by growth of the virus in cells cultured in vitro and, if these studies were successful, later application may be made to assess the viruses in a laboratory rabbit challenge model.

Evaluation of foreseeable effects

The cDNA plasmid clones present no foreseeable risk (both BVDV and HCV are RNA viruses, the cDNA clones are DNA) as potentially infectious RNA can only be produced under the control of T7 RNA polymerase promoter, either in vitro or in a specially engineered cell line expressing this protein. T7 RNA polymerase is not normally
produced by the E. coli strains that contain these plasmids or the host species potentially susceptible to infection with BVDV.

Previously published data confirms that RNA from cDNA clones of BVDV and CSFV, can be transfected into cells in culture. During transfection the viral RNA is complexed with agents that mediate the transfer of nucleic acid directly into the cell cytoplasm and bypass the normal mechanisms of receptor-mediated cell infection. When cells permissive for normal virus infection were used for transfection of infectious RNA, both viral RNA and proteins were produced and assembled into virus particles capable of extensive cell to cell spread within the culture dish. When cells non-permissive for virus infection were used for transfection of infectious RNA eg BHK cells, viral RNA and proteins were produced. This confirms that these cells are not susceptible to virus infection but can support intracellular replication of the virus (Behrens et al, J Virol 72:2364-2372, 1998). This indicates that host range is limited by the interaction of the virus structural proteins with a host specific, cell surface receptor molecule and that virus structural proteins limit the susceptible host range. NO ATTEMPT WILL BE MADE TO CHANGE THE VIRAL STRUCTURAL PROTEINS in this project. This means that the host range and tissue tropism of the chimeric viruses should be the same as the parental virus - primarily infecting cattle or sheep but not humans.

Infectious virus will be produced either in vitro or in vivo following transcription by T7 RNA polymerase. The RNA produced in this way is chemically fragile but is capable of replication in a suitable host cell (if RNA produced in vitro it is very difficult for it to get into a cell) but if introduced, it may produce infectious virus. This virus will be capable of infecting susceptible bovine cells. However, the parental BVDV strain is the lab-adapted NADL strain which will infect cattle but is not considered to be pathogenic or virulent. The previously published literature on this subject suggests that the modifications proposed are likely to have a neutral effect or to decrease the replicative fitness of the chimeric viruses (Frolov, McBride and Rice RNA 4:1418-1435, 1998). This means that chimeras are unlikely compete efficiently with wild type virus.

The risk of infection in human cells by the BVDV chimeras is unchanged compared to the parental BVDV which is unable to infect human cells, a property that is determined by the virus structural proteins which will be entirely derived from BVDV. The risk of infection of cattle by the BVDV chimeras is unchanged and the available published data suggests that these changes will have a neutral or a detrimental effect on the ability of the virus to replicate in bovine cells (see Frolov, McBride and Rice (1998) RNA 4:1418-1435 and Lai VC, Zhong W, Skelton A, Ingravallo P, Vassilev V, Donis, Hong and Lau (2000) J Virol 74:6339-47). I anticipate that the virulence and pathogenicity of the recombinant virus will not be increased compared to the parental NADL strain and the virus will be unlikely to replicate to high titres in cattle.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sealed in plastic bags, stored within a robust container before transfer to the autoclave for inactivation prior to disposal by offsite incineration. All liquid waste will be mixed with Virkon to give a final concentration of 1% and stored overnight before the residue is flushed away with excess water. Plastic pipettes/pippette tips will be immersed in Virkon overnight before the liquid is drained off, the plastic put into bags for autoclaving and disposal.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
At a special meeting on July 22 2002 the assessment of this project as class 2 was considered to be correct because BVDV is an animal pathogen and the HCV genes being introduced are non-structural, do not encode toxic proteins or enable BVDV to infect man.

The committee asked Dr Collins to expand on whether the inserted genes enhance the pathogenicity of BVDV. She commented this is a complex issue. The parent virus that is to be modified is the NADL isolate which is a cytopathic BVDV isolate and is used as a live vaccine in the USA. It does not normally establish a persistent or virulent infection. The reason why GM-NADL is being treated as an animal pathogen is that, if it recombined in vivo with another BVDV genome in a cow, it could become capable of infecting calves in-utero and inducing a life-long viraemia in them. The additional inserts will not alter the BVDV vector's ability to cause life-long infections or its tissue tropism because these are determined by the structural genes: the serine proteases, RNA polymerase and ribosomal entry sites are not known to control tissue tropism of BVDV. She commented how the HVC serine protease uses a different substrate to the equivalent protease in BVDV but inserting this gene into BVDV would not alter its growth properties in cell culture (see Lai VC, Zhong W, Skelton A, Ingravallo P, Vassilev V, Donis, Hong and Lau (2000) J Virol 74:6339-47). Similarly adding the ribosomal entry site of HCV to BVDV will have a neutral or detrimental effect as evidenced by the growth in-vitro being 10-1000-fold less than wild type BVDV (see Frolov, McBride and Rice (1998) RNA 4:1418-1435).

**Project Additional Information**

**Purposes of the contained use**

To prepare and characterise both defined and random transposon mutants of the pig pathogen Actinobacillus pleuropneumoniae in the laboratory.

To prepare and characterise both defined and random transposon mutants of the pig pathogen *Streptococcus suis* in the laboratory.

The project is intended to construct random transposon mutants in order to select those genes which contribute to survival using transposon screen by microarray (TSM) and signature-tagged mutagenesis (STM). Defined mutants of *A. pleuropneumoniae* and *Streptococcus suis* will also be constructed to test the effect of particular mutations.

The purpose of this contained use is to allow ongoing work, already covered by CU2 (Imperial College - *A. pleuropneumoniae* [Ref GM77/02.4; research conducted University of Cambridge - *S. suis* [Ref GM407/97.2] to be taken forward.

**Recipient or parental organism**

*Actinobacillus pleuropneumoniae* is a Gram-negative bacterial pathogen. It is naturally present in pigs throughout the UK in which it causes pig respiratory disease (contagious porcine pleuropneumonia). It is host specific and does not survive for long in the environment outside the respiratory tract of the pig (Nicolet, 1992; Rycroft & Assavacheep - unpublished). Transmission is via direct or close aerosol contact between pigs (Velthuis, 2002). *A. pleuropneumoniae* is harmless to humans. There is no hazards to human health.

*Streptococcus suis* is a Gram-positive bacterial pathogen. It causes meningitis and septicaemia in the pig and is a rare zoonosis with the capability of causing meningitis in humans when introduced through wounds. It is widespread among farm pigs in the UK and is thought to be carried in the upper respiratory tract (Sanford & Higgins, 1992). It survives poorly in the environment, especially in dry conditions (Clifton-Hadley & Enright, 1984).

The GMMs will be mutants of *A. pleuropneumoniae* or *Streptococcus suis*, derived by either insertion of a transposon, or by allelic exchange to replace a specific gene with a mutant form of the gene. Some mutants will be restored to normal function by complementation using the functional gene expressed on a plasmid. Apart from the introduction of marker genes such as Kanamycin resistance, the experiments will be self-cloning, ie inserted DNA will be otherwise derived from the host organism.

Hazards to the environment could only arise if the organisms were able to gain access to the pig population outside the containment facility. This could only happen through carriage outside the facility by humans. Such a possibility will be prevented by the measures outline below.

Such hazard would be very unlikely to lead to disease or harm to pigs which would be materially different from that caused by the natural parental organisms and GM *A. pleuropneumoniae* or *S. suis* would be expected to die out naturally and not harm the environment. GMMs which carry a mutation, or additional genetic load due to a plasmid complementing that mutation, would be less (or not more) fit to survive in the competitive environment of the pig than the wild type.

Actinobacillus pleuropneumoniae 4074 and other strains carrying part or all of one of the following plasmids:

For introduction of mutations:
pUC18 series cloning vectors carrying mutant A. pleuropneumoniae gene. For introduction of mutant A. pleuropneumoniae genes or transposon mini-Tn10 by conjugation (pUC18 carrying mobRP4) from E. coli to A. pleuropneumoniae. Since colE1-based plasmids will not replicate in A. pleuropneumoniae, these are suicide vectors when transferred to this organism.

PBKM1 conjugative plasmid based on pBluescript SK (with mobRP4), multiple cloning site, Kan® and transcriptional fusion of the omA promoter with the sacB gene for sucrose sensitivity [Oswald et al., 1999]. For introduction of mutant A. pleuropneumoniae genes. The plasmid will be lost from the desired mutant organisms by its conferring sensitivity to sucrose.

For introduction of A. pleuropneumoniae genes for complementation:
pMIDG plasmid capable of replication a A. pleuropneumoniae with the sodC promoter of A. pleuropneumoniae for expression of foreign genes. For complementation experiments to express A. pleuropneumoniae genes previously mutated on the chromosome. [Web et al., 2001]

pYG53-series plasmids. These are closely related to the natural Mannheimia haemolytica plasmid pMHSCS1 (accession: NC 002637) which replicates in A. pleuropneumoniae. Confers chloramphenicol resistance. For complementation experiments to express A. pleuropneumoniae genes previously mutated on the chromosome.

Streptococcus suis P1/7 (serotype 2) carrying transposon Tn917 and Tn917-tag.
A bank of Streptococcus suis mutants carrying transposon mutations previously introduced on the vector plasmid pTV408 by electroporation. This is a temperature-sensitive plasmid carrying mutant at the non-permissive temperature (37-42 degrees C). pTV408-tag also carries signature tags in the transposon (unique sequences of DNA that allow the identification of individual mutants amongst mixed pools of mutant bacteria). These have been introduced into the strain to make a mutant bank in earlier work at University of Cambridge.

References

Origin & function

1. Self-cloning: Actinobacillus pleuropneumoniae chromosomal DNA mutated by deletion or insertion and re-introduced by allelic exchange.

3. Transposon mini-Tn10 or similar (for random mutagenesis) in A. pleuropneumoniae.

4. Transposon Tn917 carrying erythromycin resistance in Streptococcus suis.

The aims of the project are to generate mutants of A. pleuropneumoniae and Streptococcus suis by transposon mutagenesis and by defined, site-directed mutagenesis,
using allelic exchange. A selectable marker will be used in most cases: either Kanamycin resistance from mini-Tn10 or from pUC4K. A counter-selectable marker, such as sacB conferring sucrose sensitivity to recognise those mutants which have lost the plasmid vector, will also be used.

Genes of A. pleuropneumoniae or S. suis will also be cloned and transferred to the mutant parent to restore the mutant function. The genes will be transferred using replication-competent vector plasmid such as pYG53 (Lalonde & O'Hanley, 1989), pJFF224 (Frey, 1992) or pMIDG (Webb et al., 2001). This is necessary to demonstrate that lost phenotype can be restored by reintroduction of the gene alone.

References:

Evaluation of foreseeable effects

Actinobacillus pleuropneumoniae is a respiratory pathogen of the pig, causing the widespread disease contagious pleuropneumonia. There are no other known natural hosts and humans are not affected by this organism. The wild-type organism is present on the large majority of normal pig farms throughout the world.

Genetic modification will be the introduction of random or genetically defined mutations. The effect of knocking-out a gene is very unlikely to make this organism more pathogenic than it already is and is extremely unlikely to alter the host range of the pathogen to infect other species. In other cases the strain will be as virulent as the parent. Genetic modification is not expected to alter the survival in the environment, which is already very poor, and mutations will tend to make the organism less fit to survive in a pig host than the wild-type. Introduction of erythromycin, kanamycin or chloramphenicol resistance markers will not confer selective advantage in relation to natural A. pleuropneumoniae since erythromycin, kanamycin or chloramphenicol are not used in therapeutically in the treatment of pigs.

Experiments will also be conducted to complement the mutations by expression of the gene, from a plasmid within the mutant, using a promoter known to be effective in A. pleuropneumoniae. Reversal of the mutation in this way is needed to unequivocally demonstrate the effects of the mutation are due to the mutation alone.

There is relatively small risk through the accidental release of genetically modified S. suis or A. pleuropneumoniae, reaching and surviving in the environment. However, because these organisms are inherently very delicate and are unable to survive outside the body of an animal for very long, we consider survival or spread of the organisms (and their mutants) from the laboratory to be a very unlikely event and therefore of extremely low risk.

Genetic modification will be the introduction of random or genetically defined mutations. The effect of knocking-out a gene is very unlikely to make this organism more pathogenic than it already is and is extremely unlikely to alter the host range of the pathogen to infect other species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Incineration off-site.

For activities involving GMMs, you will normally need to apply all the measures specified as requirements for the relevant containment level. If, however, your risk assessment indicates that any of those measures are unnecessary, you may ask for permission to omit them. Indicate any such measures with a brief justification that includes reference to the relevant parts of the risk assessment. You CANNOT claim confidentiality for the actual containment measures (unless your intellectual property rights might be affected) BUT the justification may be claimed as confidential. If any claim is made for confidentiality, the confidential information must be included in section 17 together with justification.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste, including plate cultures, will be sealed in plastic bags, stored within a robust container before transfer to the autoclave for inactivation prior to disposal by offsite incineration. All liquid waste will be mixed with Virkon to give a final minimum concentration of 1% and stored overnight, or alternatively boiled before the residue is flushed away with excess water. Plastic pipettes/pipette tips will be immersed in 1% Virkon overnight before the liquid is drained off, the plastic put into bags for autoclaving and disposal.

Is an emergency plan required according to regulation 20?  
N

If yes, tick to confirm that it is attached to this form
Y

Tick to confirm that you have attached a risk assessment to this form
Y

Tick if you are claiming exemption from disclosure for section of the risk assessment
N

Please enter comments on the GM safety committee on the risk assessment

1. The use of conjugative instead of non-mobilisable plasmids is noted as necessary.
2. The purchase of solid robust containers for carriage of class 2 GMOs from lab to autoclave is necessary.
3. The forms question on safety cabinets is worded badly and their class should be omitted. (All have been addressed and advice acted upon where required).

## Project Additional Information

**Purposes of the contained use**

To characterise function of regulatory molecules during development of skeletal tissues. Various strategies will be used to achieve 'gain-of and 'loss-of-function' of distinct genes and their effects on regulation of cell behaviour described. Modification in expression will be verified. RCAS(BP) vectors harbouring specific genes will be used to deliver proposed modifiers of cell behaviour and signalling.

**Recipient or parental organism**

i) E. Coli XL1-Blue. H) RCASBP (A and B) retrovirus (helper genes are in 2 separate blocks of DNA to eliminate chances of reversion to replication competence by a single recombination. Although RCAS(BP) has sic oncogene removed, it retains minimal oncogenic potential in chicks, but not mammalian species cram et al 2002; J Virol. 76(9), 4275-4286; Du et al., 2007 PLos Biology, 5(10), e276). These reports provoke the Class 2 categorisation of RCAS (BP) retroviral use in avian cells and tissues in our studies.

**Host/vector system**

i) E. Coli XL1-Blue. This is effectively a pro-virus as it provides only a DNA copy of the viral genome and includes an origin for replication allowing it to act as a plasmid, and ii) Avian cell line (DF1) and avian cells/tissues. DF1 cells will be used to ‘grow-up’ RCAS(BP) viruses containing genes of interest and these will be used to transfect avian cells and tissues in vitro and in ovo. Unlike other viral delivery systems, the RCAS(BP) system does not require the use of a packaging cell as these viruses are replication competent.

**Origin & function**

cDNAs for this project have been isolated and cloned into the vectors listed. The intended function is to investigate signalling pathways involved in development of musculo-skeletal system and to uncover the signalling mechanisms underlying human diseases and syndromes. Vectors will contain genes in either native1 constitutively-active or dominant-negative configuration, and will initially include representatives of: i) Glycosaminoglycan synthesis enzymes and regulatory proteins (uridine diphospho-glucose dehydrogenase, UDPGD); ii) Wingless (Wnt) family members (eg. Wnt-4, and 5a), Wnt-antagonists (eg. Noggin, DKK); iii) Signalling molecules and their receptors (eg. mitogen-activated protein kinase (MAPK and p38) and protein kinase (PKC and family members); iv) Fibroblast Growth Factors (FGF5); v) Bone Morphogenetic Protein (BMP) family members; vi) cyclooxygenases (COX5); vi) Markers of skeletal cell differentiation (eg. connective tissue growth factor (CTGF), growth differentiation-5 (GDF5) and BMP-receptors). The intended function of such vector gene insertion and the purpose of this activity is to characterise the molecular function of regulatory molecules during the development of skeletal cells; and to understand how such ‘gain-of and ‘loss-of-function’ strategies applied in vitro effects the regulation of skeletal cell behaviour described. The RCAS(BP) system is ideal for the delivery of genes of interest to avian cells and tissues and the choice of genes to be delivered is based upon their likely and proposed involvement in the regulation of skeletal cell behaviour. We will examine the effects of these genes, where possible, in their native, constitutively-active or dominant-negative configuration. It is unlikely that these genes present any known risk in their native configuration, and although the risks associated with their constitutively-active or dominant-negative configuration is not known, it is unlikely that they represent any significant oncogenic, cross-species, tissue tropic, toxic and transmission risk.
Chick retroviruses (RCAS(BP)A or B) infect avian but not mammalian (human) cells. With the exception of RCAS(BP) virus, vectors used are incapable of replication/ transmission outside the laboratory. Exposure and health risk to the researcher is negligible by performing all work as Class 2 procedures, where other workers do not have free access. None of the genes we intend to use are known oncogenes and furthermore they will only be manipulated using the RCAS(BP) system that fails to infect mammalian cells. All of the work will be carried out in accordance with Safety Policy and Local rules, and performed in level 2 flow cabinets. All these procedures are in agreement with Local Rules preparation of viruses will take place in appropriately designated area within the lab at the RVC. Excess virus will also be disposed of by decontamination as outlined (Form B, section iv) and all solid matter disposed of by incineration. Although the RCAS(BP) retrovirus has had the src oncogene removed, it appears to retain minimal oncogenic potential in chicks as demonstrated by the studies of Tam et al (2002; J Virol. 76(9), 4275-4286). These authors have shown that a untranslated RNA, bic, in RCAS(BP) is capable of cooperating with c-myc to support infrequent and restricted tissue-specific oncogenicity; 2% of very late stage (l8day old) embryonic chicks receiving 0.1 ml of virus suspension containing 1 Omillion infectious units of virus per ml, injected directly into the chorioallantoic vein, developed lymphoma, but not erythroblastosis, myelocytomatosis, sarcoma or adenocarcinoma. This indicates a very low risk of complications in our studies when using avian cells and tissues. There is also a report indicating limited scope for somatic gene transfer using the RCAS(BP) retrovirus into mice with no obvious deleterious effects apparent due to the inability of RCAS(BP) to proliferate in mammals (Duet al., 2007 PLos Biology, 5(10), e276). There is therefore no risk to mammalian species. Nevertheless, despite the very small insignificant risk associated with RCAS(BP) retroviral use in avian cells and tissues in our studies all work using these viruses will be categorised as Class 2. The work will all be done in a laboratory without any contact with the animal house where non-breeding chickens are only kept on an occasional basis Any disease risk to birds from this project is therefore very small

Evaluation of foreseeable effects

No viable GMO will be produced — see attached Risk Assessment

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

RCAS(BP) retroviral-mediated gene transfer will be carried out in accordance with Safety Policy and Local rules, and performed in level 2 flow cabinets. Separate lab coats and double gloves will be worn. Liquid waste from bacterial and vertebrate cell cultures will be treated using standard, approved disinfection procedures; with freshly prepared VirkonTM in accord with the Manufacturer's instructions for more than 24 hours, and disposed of appropriately. This will result in at least 99.99% kill of bacteria and 100% kill of viral GMMs and cell lines. In addition, the retroviruses and cell lines have a very short half-life at room temperature. All solid waste, including plastics and waste chick materials will be placed in double autoclave bags and placed within an outer robust stainless steel container, sealed with clips. This will be transported by dedicated, trained staff from designated areas to a new autoclave in the same building, autoclaved at 136 degrees centigrade and then treated as clinical waste. and removed from the RVC by a professional transport company for incineration at an off-site crematorium (Cambridge Pet Crematorium). Autoclave function will be monitored by annual services, the use of autoclave indicator tape (which measures a temperature of 134 degrees centigrade for 3 minutes) and checked using ComplyTM ThermologTM Steam Chemical integrator indicator sticks (3M no.2134) during every run. This will result in complete inactivation of GMMs. Preparation of viruses will take place in appropriately designated area within the lab at the RVC. Excess virus will also be disposed of by decontamination as outlined (above). These designated areas all within a single building that is different from that in which any viable, hatched avian species will be kept For this reason as well as those outlined above, the risk to avian health is insignificant.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
To review ass 2 project # 189 with on Effects of gain-of-function and loss-of-function genetic manipulation of cells and tissues. This was an update of a project started in 2003 to include a replication competent avian leukosis virus vector (RCAS) from which the original src gene has been removed. This virus does not replicate in mammals is termed class 2 because of advice on low oncogenicity of every transmissible avian leucosis virus participated in discussion of his project which centered on 3 issues. Firstly, how reasonable is the case for RCAS pathogenicity to animals. The evidence is based on a paper in which intravenous injection of one million infectious units of virus into 18-day-old embryos caused 2% lymphomas within 4 months (Tam et al, J Virol, 76:4275). In the RVC class 2 project most avian embryos will be killed before day 10 of embryonation and none will be allowed to hatch. The work will all be done in a laboratory without any contact with the animal house where non-breeding chickens are only kept occasionally. Disease risk to birds is therefore very small. Secondly, was insertion of the wingless (wnt) gene into RCAS able to increase RCAS oncogenicity for chickens or self-injected humans. The wnt genes being used are known not to be potentially oncogenic, unlike wnt 1 and 3, and so this was not considered to add to tumour risk. Anecdotal evidence was that several cases of RCAS self injection did not result in any lesion, confirming the inability of RCAS to grow in mammalian cells. A third issue, unrelated to RCAS, concerned why waste from zebra fish in which harmless genes were being expressed by disabled virus, needed to be disinfected by Virkon. The committee concluded disinfection was unnecessary as no infectious 0MM could enter the water.
Project Additional Information

Purposes of the contained use

The purpose of the contained use in this project is to make defined deletion mutants of R. equi and to characterise the effects of these mutations on the ability to cause disease in mouse models of infection.

Recipient or parental organism

Both Escherichia coli and Rhodococcus equi will be used in this project. E. coli will be used as a cloning host for the manipulation of R. equi DNA. The strains that will be used are (crippled) laboratory E.coli K12 derived strains DH5alpha and TOP10. These strains are ACDP hazard group 1 and have a history of safe use in molecular biology (Sambrook & Russell, 2001)

R. equi is a Gram positive opportunistic bacterial pathogen that causes bronchopneumonia in foals. It is an ACDP hazard group 2 organism. The route of infection in foals is through the inhalation or ingestion of contaminated soil (Muscatello et al., 2009; Takai, 1997). R. equi infections have been described in humans however, such instances are often associated with an immuno-compromised status and are rare (Esteves et al., 2007). Transmission in humans is thought to be by inhalation or ingestion of R. equi in the environment (Verville et al., 1994). The strain used in this project is a virulent foal isolate and has been widely used for studies of the type proposed here. (De La Pena-Moctezuma et al., 1996; Hondalus & Mosser, 1994; Kelly et al., 2002; Navas et al., 2001; Pei et al., 2006 Pei et al., 2007; Wall et al., 2005). This strain contains a conjugative plasmid (VapA) that codes for a number of virulence factors (Takai et al., 2000).

The GMMs will be E.coli containing R. equi DNA cloned in a non-integrative, self-replicating extra-chromosomal plasmid. This is non-self cloning ie. the inserted DNA is not derived from the host organism. Mutants of R. equi will be derived by allelic exchange to replace a specific gene with a deleted version. Also, complementation of these mutations will be achieved by expressing the wild-type R. equi gene on a self-replicating extra-chromosomal plasmid. These manipulations are self cloning ie. the inserted DNA is derived from the host organism.

References

Host/vector system

pUC18/19 - These are widely used for the cloning and manipulation of genes in E. coli. They are ampicillin resistant and non-conjugative (Sambrook and Russell, 2001). These vectors will not replicate in R. equi and will only be used in E. coli.

pSelAct - This is a suicide vector based on pBlueScript (II) KS. It is able to replicate in E. coli but no R. equi (van der Geize et al., 2008). It will be used for the manipulation of R. equi DNA in E. coli and for the introduction of the deleted version of the gene(s) into the R. equi genome. It is resistant to apramycin and contains cytosine deaminase and uracil phosphoribosy transferase as the counter-selective markers. It contains oriT for conjugation however for conjugation to occur an an accesory plasmid encoding RP4 needs to be present. The conjugative function of the plasmid will not be functional under the conditions of use in this project. This plasmid will be lost from the desired mutant organisms so none of the markers on the vector will be present in the final GMO.

pREV series - These are shuttle vectors that are able to replicate in both E. coli and R. equi. They will be used for the ccomplementation of mutations. They will be used in both E. coli and R. equi. They are non-conjugative and code for apramycin resistant (Mangan et al., 2005)

References

1. Non self-cloning: R. equi DNA will be cloned in pUC18/19 and pSelAct for manipulation in E. coli. R. equi DNA will be extracted from the wild-type strain R. equi 103P+. The pUC series of vectors are commercially available.

2. Self cloning (deletion by allelic exchange): R. equi DNA cloned in pSelAct will be re-introduced into R. equi for the deletion of the genes by allelic exchange. pSelAct will be attained from the R. equi research community.

3. Self cloning (complementation): R. equi DNA cloned into pREV vectors and introduced back into R. equi for the restoration of function of the deleted gene. pREV vectors will be attained from the R. equi research community.

4. Target R. equi genes. This project focuses on genes involved in fatty acid and cholesterol catabolism and associated transcriptional regulators e.g. prpB, prpC, prpD, fadB, choD, choE, hsaD, kstR, and kstR2. The hypothesis is that R. equi uses fatty acids and/or cholesterol for survival in vivo and deletion of these genes will cause attenuation. The rationale for this is that deletion of gene(s) involved in these pathways in the closely related pathogen M. tuberculosis has caused attenuation (Brzostek et al., 2007; Munoz-Elias & McKinney, 2005). It is not possible to give a complete list of the genes that will be deleted as these may change as the project progresses, however, these will be genes involved in the same pathways e.g. fatty acid catabolism, cholesterol catabolism and associated transcriptional regulators.

The aim of this project is to generate deletion mutants of R. equi using allelic exchange. The mutagenesis procedure takes place in two steps. A deleted version of the gene is made in the vector pSel/Act using E. coli as a host for propagation of the vector. This construct is then introduced into R. equi where a single recombination event results in the integration of a deleted version of the gene and the vector sequence into the R. equi genome. The vector is then selected against using the counter-selective markers cytosine deaminase and uracil phosphoribosyl transferase. A double cross over event results in the loss of the integrated vector from the genome and replacement of the wild-type gene with a deleted version.

Complementation experiments involve the re-introduction of the wild-type gene back into R. equi. These experiments will use the pREV vectors and are required to demonstrate that the effects observed are due to gene deletion and are not the result of artefacts.

References

Evaluation of foreseeable effects

The E. coli host strains are non-pathogenic and disabled but the effects of genetically modifying this host strain has to be evaluated. Cloning and manipulation of R. equi genes involved in fatty acid or cholesterol catabolism using e.coli as a host is not expected to alter the pathogenic status or enable the bacterium to survive in the environment. Additionally, these genes will not be expressed in E.coli so the risks presented by this genetic manipulation are minimal. The genetically modified version of E. coli is not expected to be more or less hazardous than the wild-type.

R. equi is a soil organism and hazards could in theory arise if there was a breach in containment. As the route of infection in foals and in man is the inhalation or ingestion of contaminated soil and dust (Takai, 1997; Vervill et al., 1994), if the GMMs were to multiply rapidly within the environment and then foals or humans coming into contact with the contaminated area could be at risk of infection with the GMMs.

However, such hazards are very low as the GM R. equi strains described here are unlikely to be able to survive within the environment or cause disease with a better ability than wild-type. Firstly, the genes that will be deleted are involved in pathways that are used by the bacterium for survival in the soil and in the host therefore if the deletion has any effect, it is expected to result in decreased survival (Hughes & Sulaiman, 1987; Wall et al., 2005, Brzostek et al., 2007, Munoz-Elias and McKinney, 2005).
Secondly, GMMs which carry the complementing plasmid will be expected to be less fit due to additional genetic load. Therefore the GM strains of R. equi are not expected to pose an enhanced threat to human health or the environment in comparison with the wild-type strain.

The deletion mutants of R. equi do not carry any antibiotic resistance markers however, the complementing mutants will be apramycin resistant, therefore the selective advantage of apramycin in the unlikely event of a breach of containment has to be considered. Apramycin is used in animal husbandry however, it is not currently used to treat R. equi infections in foals nor is it used in human medicine. Therefore it is unlikely to confer a selective advantage to the modified strains.

R. equi contains a conjugative plasmid (VapA) encoding for virulence factors, therefore the effects of the genetic manipulation on the mobilisability of the plasmid has to be considered. There is no reason to assume that genetically modifying the genome of R. equi by gene deletion or complementation (as proposed here) will affect the conjugation functions of this plasmid.

The overall assessment of the effects of genetically modifying R. equi as described here is that the modified strains pose no more of a threat to human helath or to the environment than the wild-type.

References

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The RVC does not have facilities suitable for the sterilisation of small animal (mice) carcasses therefore the mice infected with GM R. equi must be collected and incinerated off-site by a licensed GM disposal company. The waste will be bagged and placed in single use plastic containers with lid locks and removed from site for incineration by Peaceful Pets (Norfolk) HSE GM site number 966. Contaminated sharps arising from the in vivo work will also be placed immediately in a sharps bin with lockable lids and removed from site for incineration by the same company.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste generated from the molecular biology laboratory, including plate cultures, will be sealed in plastic bags and stored within a robust stainless steel container before transfer to the auto-clave for inactivation (15 minutes at 121°C) prior to disposal off-site by approved RVC procedures.
All liquid waste generated from the molecular biology laboratory will be disinfected with 5% Trigene overnight before being disposed of down a suitable sink in the category 2 laboratory. 5% Trigene has been tested on concentrated culture (5x108 CFU/ml) and we have seen a complete kill after overnight disinfection (16h).

The waste generated from the in vivo experiments (animal carcasses and bedding) will be bagged and placed in single use plastic containers with lid locks and removed from site for incineration. The cages will be autoclaved prior to washing in an automated cage washing system. Contaminated sharps arising from the in vivo work will also be placed immediately in a sharps bin with a lockable lid and removed from site for incineration.

The waste water from the animal drinking bottles will be disinfected with 5% Trigene before disposal down a suitable sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. It is stated that the lab staff will be screened by Occ Health - should the BSU staff listed also be screened (perhaps they are routinely but I think it should be noted)? All staff that come into contact with R. equi, GM R. equi or unsterilised waste will be screened by occupational health before the project commences (SD4200 - Part B, section 4viii).

2. For the in vivo work - what precautions will BSU staff take when feeding and cleaning out the cages of the immunised animals? (or is it covered by COSHH). The cleaning of the cages at the end of the experiment will be done in a containment level 2 hood with personnel wearing PPE - lab coats, gloves, overshoes and a 3M 9322 P2 face mask (SD4200-Part B, Section 4). COSHH assessments will be done when work commences.

3. It is mentioned that the mice are culled at 4 days post challenge - are the cages cleaned in the interim (ie daily etc) to remove faeces - if so I think that the procedure for handling this should be noted. Routine maintenance (cleaning, feeding, watering) will not be required over this time frame (SD4200-Part B, sections 1i and 4i).

4. Will the animals be housed in the same room as other mice (other experiments) - or will they be in a separate room? The animals will be kept in experimental groups in individually ventilated cages (IVC). The air passing out of these cages is HEPA filtered and will minimise the presence of contaminated cage material in the room. The IVC system is housed in a single room. There will be no other experimental mice in the room (SD4200 - Part B, section 1i).

5. It is not clear in these forms what the pREV shuttle vectors are used for. As I understand, pSel/Act is used for the generation of the deletion mutants, why do the pREV vectors need to be used? The pREV vectors need to be used for complementation of the mutation. This is the restoration of function and shows that the effects seen are due to the genetic modification and not artefacts. It is a standard control in these types of experiments.

6. Clarify that RP4 is not being used? The functions of RP4 are not being used. pSel/Act does not code for RP4 functions, however, the RP4 functions are encoded on VapA, a plasmid found in wild-type R. equi 103 P+. The risks associated with this have been addressed (SD4200 - Part B, sections 1iv and 3iv).

7. Also are sharp bins autoclaved before being taken off site - or are these taken by Peaceful Pets too? The sharps will be placed immediately in sharps bins with lockable lids. They will be removed from site for incineration without prior autoclaving (SD4200 - Part B, secton 4ii).

The role of Staphylococcus aureus genetic variation in host-adaptation

Purposes of the contained use

Meticillin-resistant Staphylococcus aureus remains a major problem for human healthcare providers worldwide. During the past eight years, a pig-adapted strain MRSA ST398 has emerged which spreads rapidly amongst pigs but can also infect humans (Voss et al. Emerg Infect Dis 2005; 11: 1965-6). This project will investigate host-specific characteristics and the potential for naturally occurring exchange of genetic material between colonising strains of MRSA ST398 from pigs and people. Genetic modification of test strains is required to differentiate between pig-specific and human-specific strains. The growth and characteristics of GM strains will be compared to those of the wild-type MRSA ST398 during a 6-week colonisation study on gnotobiotic piglets in isolators. Two similar studies with the wild-type MRSA ST398, which had required comprehensive safety measures, have already been conducted by the group within the past 24 months.

Recipient or parental organism

S. aureus and methicillin-resistant S. aureus (MRSA) are class 2 organisms. S. aureus is a coloniser of 25% of healthy humans. MRSA is a coloniser of approximately 2% of patients admitted to hospital in the UK. As a coloniser, S. aureus and MRSA appear to have no detrimental effect on the host. S. aureus is an opportunistic pathogen. The predominant infection caused by S. aureus and MRSA is a skin infection. However, patients that are immunocompromised can be susceptible to S. aureus/MRSA which can cause serious and even fatal infection. The widespread distribution of S. aureus ensures it is one of the most common causes of hospital acquired infection in immunocompromised patients. Antibiotic resistance is a major concern in hospitals as antibiotics are widely used to prevent infection as well as treat it. Infections of humans by the pig-associated strain MRSA ST398 have been reported and differences in clinical presentation or virulence have not been described (Wulf et al. Eur J Clin Microbiol Infect Dis 2011; Epub ahead of print).

Host/vector system

Suicide vectors for S. aureus will be used to inactivate putative virulence genes. An example is the use of pCN50 (Charpentier et al., 2004, Applied & Environmental Microbiology, 70: 6076-85) which contains a temperature selective replication of origin and chloramphenicol resistance gene for S. aureus, and an origin of replication and ampicillin resistance gene for E. coli. The cloned gene in the vector is knocked out by a resistance gene cassette such as erythromycin. The plasmid is transferred to S. aureus, where it undergoes homologous recombination with the intact gene twice (ie. once on each side of the gene of interest, Campbell integration), and this leads to loss of most or all of the sequence encoding the putative virulence gene (for example sraP) and replacement with the deleted version of the gene, and loss of all the suicide vector genes. These steps will be performed by the team of Dr Jodi Lindsay, St George's, University of London under separate CU2 notifications (GM95/02.4 and GM95/00.1).
Inserted sequence(s): Antibiotic resistance marker, usually erythromycin or tetracycline or chloramphenicol. All of these resistance traits are found in naturally occurring isolates of S. aureus and MRSA in our community.

For all handling of the GMOs by co-workers, training and the Codes of Practice and SOPs set by host-institution will be followed (as stated in the attached Memorandum of Understanding between the RVC and SGUL).

Origin & function

The inserted gene sequence will be an antibiotic resistance marker, either erythromycin, tetracycline or chloramphenicol. The sequence poses no known or likely health hazard. All of these resistance genes are found in many naturally occurring staphylococcal isolates, including S. aureus and MRSA, in our community, in the environment, on humans, animals and wildlife. The gene sequence is derived from one of the pig-associated MRSA ST398 isolates. The insertion of a resistance gene will allow differentiation of the test isolates on selective agar supplemented with the relevant antibiotic. Growth of the wild-type will be inhibited by addition of antibiotic to the agar while the GMO strain will grow. This will enable quantification of colony forming units for each strain, allow assessment of growth dynamics and competition between the strains and inform on behaviour of colonising MRSA on intact skin.

At present, MRSA causes about 25% of all S. aureus hospital infection in the UK, and the majority of MRSA isolates are already resistant to erythromycin. Tetracycline and chloramphenicol resistance is found in about 10% of hospital-associated MRSA isolates, although none of these drugs is routinely used to prevent or treat infection. All isolates in the UK are currently susceptible to glycopeptide antibiotics. Overall, most patients are probably in contact with S. aureus, and do not develop infection. However, resistance to these three antimicrobials should not compromise the outcome of treatment in the case of infection.

Evaluation of foreseeable effects

The replacement of a putative virulence factor with an antimicrobial resistance gene is unlikely to alter the existing pathogenic traits of S. aureus. The deletion of potential virulence genes is likely to produce GMO that are less fit than their parent, and unlikely to present a threat. The addition of antibiotic resistance genes may give the GMO a selective advantage. However, such resistances are already found in naturally occurring human isolates. However, all of these resistance genes are found in many naturally occurring staphylococcal isolates, including S. aureus and MRSA, in our community, in the environment, on humans, animals and wildlife. Nevertheless, the unlikely possibility of increased threat associated with deletion mutants is understood and considered.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Off-site incineration. The RVC has no large incineration facility. Pig carcasses will be sealed in clinical waste bags via the isolator ports, transferred into hard plastic clinical waste bins with firmly closing lids and labelled as GMO content before removal from site. They will be collected by a licensed GM disposal company:

i) from the Camden site by Novus, Vetspeed,A505 Main Road, Thriplow Heath, Nr Royston, Hertfordshire, SG8 7RR

ii) from the Hawkshead site by Peaceful Pets, West Rudham, King's Lynn, Norfolk, PE31 8SY

Transport of bacteria from SGUL to RVC will be in packaging according to packaging Instructions 650 for Biological Substances Category B: Organisms will be transported on agar slopes or in 2ml broth vials contained in a leakproof primary receptacle, a leakproof secondary container and with absorbent material between both, sufficient to soak up the total amount of fluid. These will be packed in a rigid out packaging, robust enough to withstand a 1.2m drop and labelled with name, address, telephone number of the RVC supervisor, a hazard diamond label and marked as 'Biological substance Category B'.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The construction of the GMOs and associated waste disposal will be carried out by the team of Dr *, St George’s, University of London, under her HSE notifications GM95/02.4 and GM95/00.1.
The work at RVC will involve 1. growing the bacteria on solid agar or in small volumes (typically 2ml) of liquid broth in a containment level 2 laboratory (in a class 2 microbiological safety cabinet), 2. transfer of GMO vials into three piglet isolators through a sealed port (disinfection with peracetic acid spray), 3. atraumatic inoculation of gnotobiotic piglets within sealed isolation chambers (isolators), 4. sampling of piglets by swabbing of skin and 5. growth and counting of bacteria in the laboratory (RVC risk assessment attached). Appropriate Codes of Practice, SOP and COSHH documents have been prepared for the procedures involved and all involved personnel are made aware of these.

Comprehensive protocols for safe disposal of containment level 2 organisms are already in place at all sites. S. aureus and MRSA are class 2 organisms and two gnotobiotic piglet experiments have already been carried out by the group within the last 24 months with disposal procedures for MRSA safely implemented.

In the laboratory, small plastic waste, including the swabs from piglets, will be immersed in 1% Virkon overnight before draining off the fluid and disposal in clinical waste bags by incineration (off site, Novus/Vetspeed or Peaceful Pets). Larger plastic items (petri dishes) will be autoclaved (121 degrees Celsius for 15 minutes) before disposal by incineration. Small volumes of liquid waste are deactivated in 1% Virkon before disposal. Sharps (glass slides) will be disposed in sharps containers which will be autoclaved and subsequently incinerated. Fluid and sharps containers will be labelled for GMO use.

At the end of the piglet study, needles will be required for euthanasia of the animals. Piglets will be sedated prior to euthanasia with azaperone (Stresnil, recommended dose per kg bodyweight given rectally by plastic pipettes, followed by a 20-minute quiet time in darkness to achieve maximum sedation). This will minimise the risk of accidental needlestick injury and avoid the need for a second person restraining the animal for euthanasia. Needles used for euthanasia will be disposed off intact and unsharpened together with the syringe body in sharps containers within the piglet isolators (sharps containers are autoclaved and included in isolators prior to study begin). Carcasses will be disposed of as described above (Novus/Vetspeed).

Aerosols will only be generated within the isolators. The isolators are designed to prevent micro-organisms entering or leaving the isolators, and animals are handled through gloves. Isolators will be kept in rooms with requirements appropriate for CL2 animal facility rooms for GMM work (SACGM Part 3, page 59). All material that needs to be introduced into the isolators will go through ports, be sprayed with peracetic acid and an at least 30-minute contact time. Material to come out of the isolators will be transferred into bags or containers (kept inside the isolators before commencement of study), then sprayed out through the port as described above and then directly transferred into clinical waste bags for incineration or (swabs) taken to the containment level 2 laboratory for processing. If the isolators fail, our experiment has failed, so there is enormous incentive to ensure no release of organisms.

At the end of the study, piglets will be sedated and euthanased within the isolators, carcasses transferred into sealed containers through the ports and collected by Novus/Vetspeed.

All small isolator equipment will be bagged as clinical waste before off-site incineration. Isolators and faeces contained in the lower part of the isolator are decontaminated by using Virkon sprays and soaks overnight as far as reasonably practical. Swabs off isolator faecal contents will be taken and the process repeated several times until nil bacterial growth is detected before dismantling the isolators. However, it will be assumed that complete sterility may not be achievable due to the high faecal load. Thus, piglet isolators will be dismantled using protective clothing (Ty-Vek boiler suit, gloves, masks, overshoes). Faeces, plastic films and gloves are bagged as clinical waste and collected for incineration. All metal parts of the isolators will be cleaned with detergents in the in the automated cage washer at 80 degrees and disinfected with 1% Virkon solution. Afterwards floors will get cleaned with detergent and disinfected with Virkon 1%.

Purposes of the contained use

Construction of transposon mutants and site-specific mutants of Mycoplasma species. Analysis of these mutants in vitro and in their natural host animal species for function and phenotype in relation to pathogenicity. Complementation of those mutants using a gene expressed for function and phenotype in relation to pathogenicity. Complementation of those mutants using a gene expressed from an OriC-based plasmid. Screening of pools of mutants for selection (in vitro and in vivo) for mutants less-fit to survive in the animal body.

Recipient or parental organism

Mycoplasma species, including Mycoplasma gallisepticum, Mycoplasma cynos and Mycoplasma hyopneumoniae. These are pathogens of chickens, dogs and pigs respectively. Other, similar mycoplasmas are included in this notification.

Host/vector system

pBSC-1 miniHimar (Mariner) transposon carrying puromycin resistance or tetM, delivered to Mycoplasma sp on a suicide vector such as pUC18. OriC-based plasmid derived from the OriC-region of the Mycoplasma to be transformed to Mycoplasma sp in place of natural replicative plasmids.

Origin & function

The origin of the inserted DNA is bacterial plasmid genes such as antibiotic resistance (tetM) together with components of transposable elements such as miniTn4001PsPuro [Algire et al. (2009). New selectable marker for manipulating the simple genomes of Mycoplasma species. Antimicrob Agents Chemother. 53, 4429-4432], and miniHimar [Bouhenni et al. (2005). Identification of genes involved in cytochrome c biogenesis in Shewanella oneidensis, using a modified mariner transposon. Applied & Environmental Microbiology, 71, 4935-4937.] The intended function is to insert the transposon to cause random mutations.

Secondly, OriC DNA is the region of chromosomal replication origin, derived from Mycoplasma species, used to facilitate the construction of plasmids able to replicate in Mycoplasma species. [Lee et al. (2008). Development of a replicable OriC plasmid for Mycoplasma gallisepticum and Mycoplasma imitans, and gene disruption through homologous recombination in M.gallisepticum. Microbiology 154, 2571-2580]. The intended function is to allow complementation of gene function lost through mutation, and also to insert flanking DNA into mycoplasma species to cause allelic replacement mutations.

Evaluation of foreseeable effects

The GMMs will be mutants of Mycoplasma species derived by either random insertion of a transposon, or by allelic exchange to replace a specific gene with a deleted or mutant form of the gene. Some mutants will be restored to normal function by complementation using the functional gene expressed on an OriC-based plasmid. Apart from the introduction of marker genes such as puromycin resistance or tetracycline resistance, and the inverted repeat sequences of the transposable element, the experiments will be self-cloning, ie. Inserted DNA will be otherwise derived from the host organism.

Hazards to the environment could only arise if the organisms were able to gain access to the host animal population outside the containment facility. This could only happen through direct or indirect contact with other animals or by carriage outside the facility by humans. Such a possibility will be prevented by the measures outlined below.

Such hazard would be very unlikely to lead to disease or harm to the host animals into which they were introduced beyond that which would be caused by the natural parental organisms. GMMs which carry a mutation, or additional genetic load due to a plasmid complementing that mutation, would be less (or not more) fit to survive in the competitive environment of the host animal than the wild type.

Forseeable effects on the environment arising from the intended modifications are expected to make the organisms less fit to survive in the environment or their host animal. Mutation in the GMO are not expected to enhance pathogenicity or ability to spread or survive in the environment and no such natural or engineered mutants have been recorded.

Animal mycoplasmas are highly adapted to their own host. Human disease due to these animal pathogens, which are naturally widespread among livestock, has never been recorded and is therefore unforseeable in these mutant mycoplasmas.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste, including cultures will be sealed in plastic bags, stored within a robust container before transfer to the autoclave for inactivation (121°C for 15 minutes) prior to disposal by offsite incineration. All liquid waste will be mixed with Virkon or hypochlorite to give a final minimum concentration of 1% Virkon or 200 ppm hypochlorite and stored overnight, or alternatively boiled before the residue is flushed away with excess water. Plastic pipettes/pipette tips will be immersed in 1% Virkon or 200ppm hypochlorite overnight before the liquid is drained off, the plastic put into bags for autoclaving and disposal.

Animals such as pigs or chickens, infected with GMM, will be killed on the premises. Carcasses will be opened in the post-mortem room for removal and examination of tissues. Samples for culture may be taken from the lungs to the laboratory. Carcass material will be disposed of by sealing in plastic sealable medibins with a weight limit of 25 kg per bin and removal by a licensed disposal company (e.g. Cambridge Pet Crematorium, for incineration. Alternatively, lung tissues may be homogenised, within a Class 1 microbiological safety cabinet within the post-mortem suite. After sampling for laboratory procedures, remaining homogenised tissue will be autoclaved and then destroyed via the general clinical waste disposal. Bedding waste from the Containment level 2 animal facility will be inactivated by soaking with 1% Virkon for at least 12 hours. Liquid waste is prevented from entering the drains and is treated with an excess of 1% Virkon for at least 12 hours before released into the drains.

Form A section 2b. Does not mention replacement of the kanR sequences with TetR which is mentioned in FormB (section 1iii).
Form B section 1 Third paragraph on antimicrobial selection marker should also address the use of TetR which is mentioned later in the form.
Form B Section 3iii - How measures will be put in place to avoid needle-stick injuries when injecting pigs
Form B Sectio 3 iv "waste disposed of according to guidelines" Does this refer to just "animal waste" or also bedding material - What guidelines are being referred to?

Part A states;
"Waste disposal procedures: Disinfection overnight with 1% Trigene. All contaminated culture plates will be autoclaved before disposal. "However Part B states "Solid and liquid cultures and contaminated waste materials will be disposed of from the laboratory by autoclaving followed by incineration. "Suggesting liquid waste will also be autoclaved. I think it needs to be consistent.

Part B 2 states;
"The antimicrobial selection marker on the miniHamar 1 transposon inserted into M. hyopneumoniae confers resistance to kanamycin which is not used to treat any disease in the pig. Other antibiotic resistance elements may be used." - what other antibiotic resistance elements - should these be listed? Could these be a problem?

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

Use a green-fluorescent protein (GFP) expressing C. jejuni to determine the impact of E. tenella co-infection on bacterial colonisation in the chicken caeca.

**Recipient or parental organism**

Recipient will be Campylobacter jejuni 81-176. This strain has been routinely used within the group for in-vivo trials for more than seven years, first at the Institute for Animal Health and more recently at the Royal Veterinary College, University of London. During this period no pathogenic effects or instability have been detected in chickens.
Host/vector system

The vector is the plasmid pHG101, supporting expression of green fluorescent protein, kindly provided by the University of Saskatchewan under material transfer agreement (MTA). The plasmid contains the following background components: a Campylobacter kanamycin resistance gene, Campylobacter origin of replication (repS), E. coli ColE1 origin of replication, consensus primer (Pc) and a translation initiation region (TIR). The original plasmid also contains a mobility (mob) gene which will be removed by targeted double restriction enzyme digestion and re-ligation prior to use, confirmed by PCR and sequencing.

Origin & function

The plasmid pHG101 was kindly provided by the University of Saskatchewan under MTA. This plasmid was originally constructed using fragments from plasmid AF29255 and plasmid pQSI-25. The Campylobacter origin of replication, ColE1 origin of replication and Campylobacter kanamycin resistance cassette were obtained from plasmid AF29255. The GFP gene was amplified from plasmid pQSI-25. Purified plasmid AF29255 and purified GFP PCR product were digested with enzymes EcoRI and AatII. The two DNA fragments were ligated and transformed into E. coli DH5α, plated out and colonies screened by whole cell PCR. The original plasmid also included a Campylobacter mobility element (mob), although this has been removed by targeted restriction digestion, plasmid purification and re-ligation. Campylobacter jejuni grown overnight from a frozen stock.Growing bacteria will be re-streaked onto a new plate to obtain confluent growth. Plates will be incubated overnight and bacteria harvested with 800 µl electroporation buffer (15% glycerol/9% sucrose) and centrifuged for 1.5 mins at 9000 x g. Supernatant will be decanted and cells resuspended in 800 µl of the same buffer and centrifuged again. Supernatant will be decanted and pellet resuspended in 125 µl of the same buffer and kept on ice. For every 40 µl of cells 1 µg of plasmid DNA (pHG101) will be added and mixed. The mix will be transferred into a pre-chilled electroporation cuvette and cells will be pulsed with 1.25 kV with a constant range of 4-6 mS in a Gene Pulser xcell (BioRad) electroporator (or similar). Immediately 500 µl of SOC media will be added to the cuvette and mixed well. The resultant Campylobacter line will be known as C. jejuni 81-176G. Campylobacter jejuni 81-176G will then be orally dosed to chickens in facilities approved for work with genetically modified Eimeria (at derogated containment level 3) in order to map variation in the colonisation of a green fluorescent protein (GFP) expressing C. jejuni in the chicken caeca in the presence or absence of wild-type E. tenella.

Evaluation of foreseeable effects

Campylobacter jejuni - ACDP Category 2. Campylobacter jejuni can cause gastro-intestinal disease in humans. The vector confers resistance to kanamycin. Nonetheless, the recipient C. jejuni isolate remains susceptible to all antibiotics routinely used to control this pathogen, as such the addition of kanamycin resistance is not expected to incur any additional hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in autoclave bags and placed in solid waste bins for autoclaving (121-125°C for at least 15 minutes). Solid waste is then sent for incineration after autoclaving through the Royal Veterinary College's retained waste disposal supplier.
Liquid waste will either be treated by autoclaving as above or decontaminated using Trigene at a concentration of 1:20 for a minimum of ten minutes prior to drain disposal. Lab coats will be sealed in autoclave bags after use and autoclaved before they go to the laundry. All animal rooms contain dedicated over clothes, boots and disposable gloves which are put on as part of the room entry procedure and removed as part of the room exit procedure. Personal protective equipment will be supplemented with a suitable face mask during periods of C. jejuni infection.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment

JD suggested that the project might be split, with the E. coli part involving mob gene deletion could be handled internally as a separate RA. This would simplify your HSE application.

SM clarified that the entire mob region of the plasmid will be removed and that removal will be verified by genetic analysis (e.g., RA digestion, PCR, sequencing).

FD and MA requested that a more detailed description of waste inactivation be inserted, and specify that treated liquid is disposed down the sink.

JD suggested removal of Clostridium perfringens from abstract, to avoid potential confusion.

OS clarified that the GMO pathogen-infected animals are finally culled, double bagged and autoclaved on-site.

<td>20/06/2019</td>
<td>Identification of carbohydrate-based structures on the surface of Theileria parva</td>
<td>Class 2</td>
<td>Not Applicable</td>
<td></td>
</tr>
</tbody>
</table>
The overall aim behind the proposed work is to identify carbohydrate-based structures on the surface of Theileria parva sporozoites/schizonts which are involved in the very early stages of infection of host cells and subsequently to genetically interfere with the synthesis/expression of these structures. The objectives are to:

1. Identify an efficient transfection system for parasitized (Theileria parva and Theileria annulata (Tp and Ta, respectively) schizonts and sporozoites) cell lines (bovine leukocytes) testing PHMB, Superfect and Nucleofector with fluorescently tagged oligonucleotides (ODN).
2. Determine suitable cell penetrating peptides (CPP) for efficient transfection of parasitized Theileria schizonts and sporozoites cell lines (bovine leukocytes) using different CPP sequences with fluorescently tagged nucleic acid analogues (PNA and MO).
3. Try to target products in the synthesis process of p104, PIM and previously determined glycans of Theileria parva schizonts with different antisense agents (plasmid DNA I dsRNA).

The genetically modified organisms will be Theileria (T.) annulata and T.parva sporozoites and schizonts.

The plasmid to be used at the beginning is a novel foreign protein expression vector pMotif-EF-1a-100, which was derived from pRNAi-GL (Takara, Japan), a conventional mammalian protein expression vector, and can be propagated in E.coli. This plasmid has been published here (Vet Parasitol. 2015 Mar 15;208(3-4):238-41. doi: 10.1016/j.vetpar.2015.01.013. Epub 2015 Jan 25. Transfection of live, tick derived sporozoites of the protozoan Apicomplexan parasite Theileria parva. De Goeyse I, Jansen F, Madder M, Hayashida K, Berkvens D, Dobbelkaere D, Geyser D.) In this vector, the Original CMV promoter gene was replaced with the elongation factor 1 alpha (EF-1α) gene promoter region of T. parva, as used successfully in transfection of Babesia and Plasmodium(Femandez-Becerra et al., 2003, Suarez and McElwain, 2009). The minus 263 to 169 position of the 5' region of the EF-1α orf (TP01_0726) was amplified from the T. parva Muguga strain genomic DNA. The promoter sequence is preceded by a motif sequence, consisting of three tandem putative transcription factor binding sites of T. parva (Guo and Silva, 2016).
Further, a transmembrane Azami Green sequence, preceded by a secretion signal sequence was integrated to visualize transfected parasites. Azami Green is a green-emitting fluorescent protein from a stony coral, Galaxea, which absorbs light maximally at 492 nm and emits the green light at 505 nm. The protein is stable and fluorescence is brighter in cultured cells than EGFP (Karasawa et al., 2003). This plasmid will initially be used to transiently-transfect purified T. annulata and T. parva sporozoites and schizonts, which will be generated from frozen down stabilates. The optimal vector and technique for transfection will need to be determined. Methods to be tested are polyhexamethylene biguanide (PHMB), Superfect, the 4D-Nucleofector system Lonza and cell penetrating peptides (CPPs) to deliver either plasmid DNA or dsRNA.

Origin & function

PHMB has a solid safety record and can be beneficial in wound care (Chindera et al. 2016). In contrast, as typical for cationic polymers, high concentrations are cell toxic and most commonly used as biocides. Although PHMB seems to be a potent antiparasitidal candidate drug, much lower concentrations could also be used as a delivery vehicle for nucleic acid immunomodulators or plasmids which will be examined here. Cell penetrating peptides are synthetically constrained through various chemical modifications that stabilize a given structural fold with the potential to improve competitive binding to specific targets (Haidar et al., 2018). Both, plasmids and CPPs are non-mobilisable and considered as non-hazardous.

References:

Evaluation of foreseeable effects

Theileria annulata and parva are not viable outside the host cells, and are unable to infect non-ruminant cells. Apart from that the transfection is expected to decrease the infectivity of the parasite. The obligately intracellular Theileria sporozoites and schizonts only survive a very short period [hours] outside the tick salivary glands or cell cultures. They are only able to infect ruminant cells after the transmission via specific ticks [Rhipicephalus appendiculatus for Theileria parva and Hyalomma spp. for Theileria annulata], both of which are currently not present within the UK, or after direct inoculation with their host cells.

Vectors used for this project will be plasmid DNA, cell penetrating peptides (CPPs) and PHMB. Both plasmids and CPPs are non-mobilisable and considered as non-hazardous. PHMB in low concentrations as it will be used for this project are non-toxic but are used for beneficial effects instead (see above).

References:
**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

This project will focus on cell culture work. No larger GMOs will be used.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The work will be carried out in a Biological Safety Category 2 laboratory.

Health and Safety

Executive

Surfaces which suspected to be contaminated with Theileria will be decontaminated with 1 % Virkon. Glass-ware, metals or other rigid solids will be soaked in 1 % Virkon solution for 24 hours, steam treated, autoclaved and then either disposed or washed for re-use.

Contaminated solid waste such as plastic, paper, organic matter or fabric will be steam treated, autoclaved and then disposed as clinical waste.

Theileria sporozoites and schizonts reside obligately intracellular in the cells of their hosts [ticks and ruminants] and are therefore very fragile and vulnerable in the environment as well as under laboratory conditions. The required tick vectors [Rhipicephalus appendiculatus and Hyalomma spp.] are not native in the United Kingdom so that the disease can only be transmitted by injecting sporozoites directly into the blood of cattle.

Contaminated liquid waste such as liquid parasite and/or host cell cultures will be treated by addition of 1 % Virkon (by adding approx. equal volumes of 2%) and left to stand for 24 hours before disposal into the drains.

All Theileria parva and Theileria annulata pathogens are stored frozen in liquid nitrogen.

All the processing of the pathogens for freezing are undertaken in a specified pathogen laboratory.

The frozen specified pathogens are stored in the RVC's Liquid Nitrogen storage facility. Access to this storage facility is restricted.

When Theileria Specified Animal Pathogens are moved from one designated facility to another within the RVC, this will be done using properly labelled UN602 standard containers. The containers are never opened outside the Specified Animal Pathogen handling laboratory or other SAPO designated areas of the RVC.

A record of all stored material is kept, and all additions and removals are promptly entered into the records database.

Project Additional Information

Purposes of the contained use
The aim of this project is to investigate the role that innate immune receptors, such as toll-like receptors and C-type lectin receptors, play in bovine TB infection. Assays will be performed to measure the uptake of fluorescently labelled M. bovis BCG (GFP-BCG) by monocyte derived macrophages and dendritic cells in the presence and
absence of antibodies designed to block specific innate immune receptors.

Recipient or parental organism

*Mycobacterium bovis Bacille Calmette-Guerin (BCG) (Pasteur Strain).*

Host/vector system

The vaccine strain of *M. bovis* BCG expressing a mutant Green Fluorescent Protein (GFP) was constructed previously by M. Chambers (Imperial College London, UK). No further modification of this organism will occur on site.

Briefly, the pMOD-12 dual promoter expression plasmid [1] was modified for use. The unnecessary mycobacterial origin of replication was removed. The mycobacteriophage L5 integrase gene [2-4] was inserted to create an integrating vector, pMIN12. The Maxygen pBAD-GFP cycle 3 plasmid was used for its optimised synthetic mutant gene of the GFP [5]. This gene was amplified by PCR and ligated into pMIN12 downstream of the heat shock protein 70 (Hsp70) promoter, which also promotes kanamycin resistance. This new plasmid is referred to as pBright GFP.

References:

Origin & function

GFP is a green-emitting fluorescent protein, originally isolated from the jellyfish Aequorea victoria, which acts as a reporter system enabling real-time visualisation of the pathogen by flow cytometry and UV microscopy [1]. The phage L5 integrase gene was used to enable stable integration of the GFP into the host genome. This system was originally identified in a mycobacteriophage [2] and has been used for over 20 years and allows the stable insertion of reporter genes in to mycobacteria.

The plasmid contains an antibiotic resistance gene for kanamycin to enable selection of GFP positive host mycobacteria. This antibiotic is not used in therapy and has a history of safe use in the laboratory.

References:

Evaluation of foreseeable effects

*M. bovis* BCG (Pasteur) is an attenuated vaccine strain for *M. tuberculosis* and although there are isolated incidences of infection following vaccination (0.06 to 1.56 cases per million vaccinations) [1] the risk to human health is low and can be further minimised by the use of recommended working practises.
The environmental risks of M. bovis BCG are low as there are no instances of it infecting animals in a natural setting, and current knowledge suggests that it cannot survive within the protozoan environmental niche found in soil [2]. The plasmid used to generate the GFP-BCG is non-mobilisable and non-hazardous, its function is to generate a green-fluorescent reporter protein, it is unlikely to confer a selective advantage or increase the virulence/pathogenicity of the BCG.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This project will focus on cell culture work. No larger GMOs will be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work will be carried out in a Biological Safety Category 2 laboratory. Surfaces which are suspected to be contaminated with BCG will be decontaminated with 5% Chemgene HLD. a disinfectant know to be mycobactericidal. Contaminated solid waste such as agar plates will be sterilised by autoclaving at 15 psi, 121 ·C for 15 minutes. The waste will be transferred from the lab to the autoclave in a sealed metal bin. GMO residues in pipette tips, cell culture plates and eppendorff tubes will be sterilised by soaking in a 5% Chemgene HLD disinfectant for at least 16 hours. After sterilisation items will be disposed of as clinical waste. Large 10-50ml cultures, containing high bacterial titres, that need to be disposed of will be sterilised by autoclaving at 15 psi, 121 ·C for 15 minutes. The cultures will be transferred from the lab to the autoclave in a sealed metal bin. Residual bacterial cultures and cell culture supernatants will be sterilised in 5 % Chemgene for at least 16 hrs. Any cells used in uptake assays will be fixed in 4% paraformaldehyde for 30 mins, to kill the BCG internalised by the cells, before being analysing. After analysis they will be disposed of as clinical waste.

N
This is a low risk project. The host is widely used as a vaccine strain, the vector and insert systems are widely used. The RA has correctly identified risks associated with the antimicrobial resistance marker. The waste handling plans are sufficient. The applicants should ensure that workers understand the waste handling procedures and avoid excessive inactivation. All workers on this project must watch the GMO training video.

### Project Additional Information

#### Purposes of the contained use

**Objective:** To transfect Eimeria tenella with constructs designed to express sequences coding for heterologous protozoan, bacterial and viral antigens to facilitate assessment as a vaccine delivery vehicle.

#### Recipient or parental organism

The Eimeria species, including E. tenella, have been rated by the Advisory Committee On Dangerous Pathogens (ACDP) as requiring a containment level of 1. The Eimeria species are completely host-and, in examples, tissue-specific: E. tenella specifically parasitizes the chicken caecae and poses no risk to human health or safety.

#### Host/vector system

The commercially available vector pGEM-Teasy (Promega) will be used throughout these studies, together with a series of vectors developed for the purpose of transfecting Eimeria species parasites (Clark et al 2008. mol Biochem Parasitol 162:77-86) The XL1-Blue MRF Laboratory Escherichia coli strain (deficient in all known restriction systems [(mcrA183, (mcrCB-hsdSMR-mrr)173], endonuclease(endA) and recombination (recA) deficient will be used throughout these studies.

#### Origin & function

DNA templates encoding the Eimeria maxima SAG, Campylobacter jejuni CjaA and Avian influenza hemagglutinin antigens (HA) are already available within the IAH in plasmid stocks (derived by PCR amplification from gDNA or directly synthesised). Thus, there is no requirement to handle either C. Jejunii or the Avian influenza virus. Amplification and manipulation of E. maxima, An ACDP hazard group 1 pathogen, is routine within the IAH. All antigens will be expressed under the control of eimerian stage-specific promoters, limiting antigen production to defined steps of the transfection process which will be controlled as described in section 12.

The primary function of these studies is to generate lines of E. tenella that express heterologous antigens in order to assess the parasite’s potential as a vaccine delivery vehicle. Thus, once created, each line will be assessed for expression of the target antigen (i.e. by RT-PCR and immunolabelling) prior to use to immunise SPF chickens within the IAH experimental facility to monitor correlates of immune protection. Added value will be gained through the phenotypic assessment of all parasite lines generated for divergence from the recipient strain.

#### Evaluation of foreseeable effects

The Eimeria species are antigenically complex micro-organisms and their interaction with the host is mediated by a complex series of proteins expressed in a sequential manner. All three candidate coding sequences described in this application are considered likely to contribute to host/pathogen interaction in their natural context but whilst the application of such non-self proteins might elevate the potential for novel recipient tropism within the chicken, the addition of a single protein to such a complex process is unlikely to have a significant impact. Once cloned, these sequences will be expressed under the control of one or more stage specific promoters, limiting expression to the sporozoite and/or merozoite lifecycle stages.

**I) E. maxima surface antigens (SAGs).** Preliminary unpublished data suggest that SAG proteins expressed by E. tenella mediate parasite/host interaction but not invasion. Single parasite RT-PCR has revealed the concurrent expression of seven distinct SAG proteins. Whilst addition of a single novel SAG gene has the potential to modify the recipient parasite's ability to attach within the host, the possibility of a significant change in tropism is limited.

**II) C. jejuni CjaA antigen.** The C jejuni CjaA antigen has been shown to localise to the inner bacterial membrane where it is thought to function as a component of the ABC transporter system. CjaA acts as a receptor for the amino acids glutamine and cysteine. Thus, whilst CjaA could affect Eimeria/host interaction, expression on the surface of one or more zoite stages of the E.tenella lifecycle via a GPI anchor and not as an internal componant of the cell wall will minimise the influence of any possible effects. Expression of the native CjaA under the control of its own promoter in a Salmonella Typhimurium crp-cya-strain previously yielded no increase in virulence or persistence.

iii) Avian influenza HA's have been shown to play an essential role in mediating host cell entry. Pathogenicity among avian influenza isolates has been linked to the presence of a polybasic amino acid sequence at the HA cleavage site. The HA coding sequences to be used will be obtained by PCR amplification from existing artificially synthesised plasmid constructs which lack a polybasic amino acid sequence at the HA cleavage site. HA antigens have previously been delivered to chickens using viral vectors without severe repercussions (eg fowl pox virus, Newcastle disease virus).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory Eimeria species parasites have never been known to infect humans, thus laboratory handling of all stages of unmodified parasites is appropriately carried out with Hazard Group 1 containment. The transfection process introduces DNA by electroporation into Eimeria sporozoites, a stage of the lifecycle that exhibits severely limited environmental persistence and can only initiate infection following direct cloacal or oral (after bicarbonate gavage) inoculation. Following genetic transformation, the only stage of the parasite that requires additional containment and disposal measures is the oocyst. After recovery, oocysts will be stored in clearly marked, sealed bottles within a designated refrigerator. Bottles of transformed oocysts will be opened only in fumigatable rooms and all manipulations of these oocysts will be carried out in these rooms. Purified sporozoites will be removed to the laboratory for further experiments and these can be safely handled (as outlined above). Doses of oocytes may be removed, double bagged and in sealed containers, and taken to the EAH for infection of animals. All glassware, plasticware, paperware and liquids that contain oocysts, or are potentially contaminated with oocysts, will be fumigated with ammonia before autoclave sterilization.

Experimental Animal House. The passage, handling and disposal of oocysts (the environmentally stable stage of the eimerian lifecycle) will be carefully controlled. Animals are housed in strict isolation and cultured parasites are recovered in rooms which are then sealed for fumigation with ammonia, which destroys oocysts. The EAH facilities used are kept dry throughout all trials to limit oocyst survival and are ammonia fumigated in situ, together with all cages and any waste, at the conclusion of each experiment. All solid waste is removed after fumigation in sealed bags for incineration. Foot baths are removed before each trial commences and water traps are installed. All waste water is removed in sealed containers for autoclaving prior to disposal. Post fumigation all rooms are cleaned and re-fumigated shortly before re-stocking.

### Purposes of the contained use

Monocyte chemoattractant protein 1 (MCP-1) is a chemokine that predominantly affects the chemotaxis and biological activity of cells of the monocyte/macrophage lineage. It is thus thought to play a key role in the infiltration and activation of these cells in chronic inflammatory conditions, including during their accumulation in atherosclerotic plaques and their formation of disease-characteristic foam cells involved in pathogenic fatty streaks. The evaluation of MCP-1 and its role in disease will require production of the protein in-house.

The MCP-1 cDNA will be inserted into a disabled strain of E.coli (K-12 derivative or LS-21) with the intention of achieving maximum expression. There is literature precedent for E.coli producing fully biologically active MCP-1, and such material is commercially available. Point mutations will be introduced at specific residues to enable modification of activity and to determine those residues which are important to activities of the molecule. The native and modified proteins will be purified by conventional means.

### Recipient or parental organism

Disabled E.coli strains such as the K12 derivative DH5x and BL21 are non-colonising and not pathogenic to humans or animals (ref1). They are unlikely to be able to survive outside the laboratory environment. These organisms fall into ACDP hazard group 1.

**ref 1:** Chart H, Smith HR, La Ragione R, and Woodward MJ (2000) Journal of Applied Microbiology 89 (6) 1048

### Host/vector system

Non-mobilisable vectors based on pUC, which has a history of safe use, will be used in the host organism described above.

### Origin & function

The gene for human MCP-1 and MCP-1 variants will be expressed in E.coli to provide material for evaluation of the protein's role in disease and to seek new treatments for any such diseases.

### Evaluation of foreseeable effects

Biologically active MCP-1 might have deleterious consequences if delivered to a responsive tissue, e.g. in the gastrointestinal tract of a research worker (induction of inflammatory reactions, etc). The work does not involve processes which generate aerosols in anything other than minute qualities, and to protect the work all manipulations with the recombinant organism will be carried out in a class 2 biosafety cabinet. Recombinant E.coli could be delivered to a research worker by ingestion, but the organisms are unable to survive for more than very short periods in the mammalian gut and the amounts that could be delivered are likely to be small and for a short duration. Nevertheless, because MCP-1 might have some deleterious effect on the health of research worker, it is prudent to apply some of the measures of containment level 2(CL2), which will effectively reduce the risks to negligible.

The organisms are unable to survive for a significant time outside the laboratory, so pose no threat to the environment. All waste will be inactivated by validated means (routinely by heat treatment).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Waste cultures, supernatants, and cell debris of up to 1 litre will be inactivated by autoclaving in validated autoclaves (>120 deg C > for 15 min); larger volumes will be heat-treated in fermenters (>120 deg C for > 15 min); plastic and other solid waste will be autoclaved as described and/or incinerated. |

### Project Additional Information

**Purposes of the contained use**

The T cell receptor Not1 is part of a nuclear hormone receptor superfamily regulating transcription, and including oestrogen, corticosteroids, vitamins A and D. It was identified as a transcriptionally upregulated gene and is highly homologous to a mouse gene which appears to be essential to normal development. A splice variant of Not1, Not1a, behaves as a dominant negative in reporter assays. In order to analyse the function of the receptor it is desirable to overexpress Not1 and its splice variant in a range of cell lines. The use of a viral approach should overcome the inherent problems associated with expression of receptors in many cell types. The operator will be a designated member of staff with appropriate training in viral practice and containment. The work will be carried out in a laboratory approved for adenovirus work.

**Recipient or parental organism**

The recipient host is E1a- and E3- deleted adenovirus (serotype Ad5) which is replication defective. The virus is able to replicate only in specific helper cells and is unable to cause a productive infection in human hosts. Therefore the host is in the lowest ACDP hazard group, Group 1.

**Host/vector system**

Human or mouse Not1 and Not1a, under transcriptional control of a strong promoter such as CMV, will be inserted into the essential E1 region of the adenovirus genome using the ADEasy vector (or similar) system (Stratagene, Ref 1). Therefore any recombination events which resulted in the replacement of this region wild type E1 would also result in the loss of the inserted gene, precluding the formation of replication competent virus expressing a novel product. Recombinant virus will be produced in helper cells such as the human 293 cell line as described (ref 1).

Ref 1: [http://www.stratagene.com/vectors/expression/adeasy.htm](http://www.stratagene.com/vectors/expression/adeasy.htm)

**Origin & function**

The genes were cloned within SmithKline Beecham from proprietary DNA libraries. The recombinant Adenovirus will be used to infect primary neuronal cell cultures or cell lines in order to study the function of Not1 and analogues in cultured cells.

**Evaluation of foreseeable effects**

Although the novel receptor has no known pathological effects, there is a theoretical risk that expression of a nuclear receptor in tissues might cause up- or down-regulation of gene expression, with unknown effects. Because the DNA cannot replicate, it is anticipated that large doses of virus would be required to cause any such effects in infected tissue: the only likely route of infection would be by airborne particles. The work does not involve processes which generate aerosols in anything other than minute quantities, and to protect the work all manipulations with the recombinant organism will be carried out in a class 2 biosafety cabinet. The measures of containment level 2 (CL2) which will be applied will effectively reduce the risks to negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste cultures, supernatants, and cell debris will be inactivated by autoclaving in validated autoclaves (>120 deg C for > 15 min); plastic and other solid waste will be autoclaved as described and/or incinerated.

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed that a hazard category of CL2 was appropriate because it was anticipated that any adverse effects in operators would be mild, restricted to the exposed site of infection, and of short duration.

The virus is unable to spread to the community.

It was agreed that the work could commence under conditions of ACGM CL2 with use of a Biological safety cabinet for manipulation of cells and virus.

Date Project Ceased: 02/03/2022
Intracellular protein kinases represent important cascades in the control of cell growth and arrest. We intend to investigate the functions of two closely related kinases which are potential therapeutic targets. Exchange of the amino acids at one or two points of the protein sequence allows forms of the kinases which are either constitutively active or constitutively inactive. These forms will be used as tools to assist in defining the role of the kinases.

The work proposed involves the insertion of the naturally occurring protein kinases and their constitutively active and dominant negative forms into defective adenoviral vectors, with subsequent expression in mammalian cells. The use of a viral approach should overcome the inherent problems associated with expression of receptors in many cell types.

The operator will be a designated member of staff with appropriate training in viral practice and containment and the work will be carried out in a laboratory approved for adenovirus work.

The recipient host is an E1a- and E3- deleted adenovirus (serotype Ad5) which is replication defective. The virus is able to replicate only in specific helper cells and is unable to cause a productive infection in human hosts. Therefore the host is in the lowest ACDP hazard group, Group 1.

Recipient or parental organism
The recipient host is a E1a- and E3- deleted adenovirus (serotype Ad5) which is replication defective. The virus is able to replicate only in specific helper cells and is unable to cause a productive infection in human hosts. Therefore the host is in the lowest ACDP hazard group, Group 1.

Host/vector system
The recombinant genes under a strong promoter such as CMV will be inserted into the essential E1 region of the adenovirus genome using the ADEasy vector (or similar) system (Stratagene, ref 1). Therefore any recombination events which resulted in the replacement of this region with wild type E1 would also result in the loss of the inserted gene, precluding the formation of replication competent virus expressing a novel product.

Recombinant virus will be produced in helper cells such as the 293 cell line as described (ref 1).

Ref 1: http://www.stratagene.com/vectors/expression.adeasy.htm

Origin & function
The genes were isolated from human DNA libraries. The recombinant Adenovirus will be used to infect mammalian cell cultures in order to study the function of the kinases and to determine whether they are suitable therapeutic targets.

Evaluation of foreseeable effects
There is a theoretical risk that expression of a kinase in tissues might cause up- or down-regulation of gene expression, with unknown effects. However, because the DNA cannot replicate, it is anticipated that large doses of virus would be required to cause any such effects in infected tissue; the only likely routes of infection would be by
airborne particles or splashes into the mouth. The work does not involve processes which generate aerosols in anything other than minute quantities, and to protect the work all manipulations with the recombinant organism will be carried out in a class 2 biosafety cabinet. The measures of containment level 2 (CL2) which will be applied will effectively reduce the risks to negligible.

The organisms are unable to survive for a significant time outside the laboratory, so pose no threat to the environment. All waste will be inactivated by validated means (routinely by heat treatment). The Adenoviral vectors are unable to replicate in human hosts.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste cultures, supernatants, and cell debris will be inactivated by autoclaving in validated autoclaves (>120 deg C for > 15 min); plastic and other solid waste will be autoclaved as described and/or incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed that a hazard category of CL2 was appropriate because it is anticipated that any adverse effects in operators would be mild, restricted to the exposed site of infection, and of short duration. The virus is unable to spread to the community.

The proposal was approved at CL2 (local guidelines for recombinant adenovirus applied, including use of a Biological safety cabinet for manipulation of cells and virus).

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
Receptor kinases are an important element in the control of the growth of specific cell lines. Specific protein ligands interact with target receptors on the surface of cells to activate receptor kinases, and transmit the signal to control growth or arrest. GSK has identified a range of receptor kinases, and we now intend to identify their ligands, which are potential therapeutic targets. The objective is to express putative kinase ligands and to test them for activity on the various receptors. This proposal covers expression of ligands and putative ligands for receptor kinases for use in the study of receptor kinase activation. The proposed work will typically involve subcloning of the ligand cDNA for expression in disabled E. coli, mammalian cells, and the insect cell/baculovirus system. Inducible expression systems may be used. Modified cDNAs may be expressed with alterations to modulate activity or to produce combined products (tagged ligands for the purpose of tracking or immobilising the ligand).

Recipient or parental organism

E. coli disabled hosts such as K12 strains (e.g. JM109, DH5a); standard insect cell/baculovirus systems; and mammalian cell cultures such as Cos7, HEK293, CHO, SK-N-MC and other neuroblastoma lines.

Host/vector system

E. coli disabled hosts such as JM109, DH5a using non mobilisable vectors (eg. pGEX1, pGEX2T, pET16, pBluescript); expression in insect cell cultures using standard baculovirus systems such as the pFASTBAC vector; mammalian cell lines such as Cos7, HEK293, CHO, SK-N-MC and other neuroblastoma lines, using vectors with poor expression in E. coli (eg. pcDNA3.1, pECE, pCDN, pcDNA1, pCMV5).
Origin & function
The genes were isolated from human cDNA libraries. The objective is to express putative kinase ligands and to test them for activity.

Evaluation of foreseeable effects
A receptor ligand might have a deleterious effect if delivered to a target issue. Therefore, measures to prevent ingestion or inoculation will be applied, including use of a microbial safety cabinet, wearing of gloves, using procedures which minimise aerosols, and avoiding the use of sharps. The work will be carried out at CL2. The measures of containment level 2 (CL2) which will be applied will effectively reduce the risks to negligible.

The organisms are unable to survive for a significant time outside the laboratory, so pose no threat to the environment. All waste will be inactivated by validated means (heat treatment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Project Additional Information**

**Purposes of the contained use**

Intracellular protein kinases represent important cascades in the control of cell growth and arrest. We intend to investigate the functions of two closely related kinases which are potential therapeutic targets. Exchange of the amino acids at one or two points of the protein sequence allows forms of the kinases which are either constitutively active or constitutively inactive. These forms will be used as tools to assist in defining the role of kinases.

The work proposed involves the insertion of the naturally occurring protein kinases and their constitutively active and dominant negative forms into defective adenoviral vectors, with subsequent expression in mammalian cells. The use of a viral approach should overcome the inherent problems associated with expression of receptors in many cell types.

The operator will be a designated member of staff with appropriate training in viral practice and containment and the work will be carried out in a laboratory approved for adenovirus work.

**Recipient or parental organism**

The recipient host is E1a- and E3- deleted adenovirus (serotype Ad5) which is replication defective. The virus is able to replicate only in specific helper cells and is unable to cause a productive infection in human hosts. Therefore the host is in the lowest ACDP hazard group, Group 1.

Date Ackn'd: 20/09/2001

CU2 Project Title: EXPRESSION OF TRANSMEMBRANE RECEPTORS AND THEIR REGULARITY PROTEINS IN MAMMALIAN CELLS USING THE BACULOVIRUS SYSTEM

Class: Class 2

Consent Granted: not applicable

Project notified under transitional arrangements: N

Tick if notifying a connected programme of work: N

In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel membrane receptors in mammalian cells in order
To obtain functional data and to determine the specificity of closely related receptors, Regulatory proteins such as accessory G proteins which modulate the function of the receptor, and may be essential for activity, will also be expressed and evaluated. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines. Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promoters are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.

Ref: Condreay et al (1998) PNAS 96 127

Recipient or parental organism

Baculovirus CL1
These organisms fall into ACDP hazard group 1

Host/vector system

For generation of recombinant baculovirus, shuttle vectors containing the product gene under CMV promoter control are transfected into insect cells (e.g. Sf-9) using standard procedures such as the Bac to Bac expression system (Life Technologies).

(Recombinant cell lines expressing receptors and G-proteins: CL 1)

Origin & function

GSK proprietary libraries

Evaluation of foreseeable effects

The baculovirus is able to transfect mammalian cells, but is unable to replicate in them. Efficient expression of the gene products under control of the CMV promoter is achieved only by addition of an inhibitor of cellular histone deacetylase. It is possible that inappropriate expression of a transmembrane receptor or regulatory protein could have detrimental effects. However, the only likely routes of infection would be mouth, nose or eyes, and the amounts which might enter by such routes (via aerosols or splashes) would be small (microlitres). In addition, baculoviruses are rapidly inactivated (>99% in 30 minutes) by the complement system of normal human serum (Hofmann and Strauss '98). The work will use standard laboratory and bioreactor methods and does not involve processes which would generate significant quantities of aerosols. Needles (sharps) will not be used. Laboratory operations involving production of baculoviruses and transfection of cell lines will be carried out in a microbiologic al safety caninet, which will be sufficient to reduce the likelihood of infection to effectively zero. Bioreactor operations will be carried out under CL2 conditions as defined in table 2 of the GMO Regulations 2000. Typically, the baculovirus will be used to transfect mammalian cells either in multi-well plates (eg 96-well) for assay, or in bioreactors for preparation of batches of cells. Batches of cells will be collected (centrifugation) and washed under CL2 conditions.

The transient recombinant cell lines expressing receptors generated by this system, including low levels of residual virus, are unlikely to pose a risk to health, and may be handled under conditions of CL1 (eg for analysis). Similar stable cell lines have previously been categorised as CL1.

### Project Additional Information

#### Purposes of the contained use

The aim is evaluate and utilise Streptomyces lividans for production of heterologous proteins of biopharmaceutical relevance. Initially murine TNFa will be overexpressed and secreted by Streptomyces lividans to evaluate the conditions required for high level protein production. If successful the work may be extended to use of other Streptomyces species and expression of other cytokines, including novel cytokines. Laboratory work with Streptomyces will be carried out at up to 0.5L volumes. If required, larger volumes of crude product (up to 15L) will be produced from bioreactor cultures.

#### Recipient or parental organism

Streptomyces species such as Streptomyces lividans. These organisms fall into the lowest ACDP hazard group 1.

#### Host/vector system

Non-pathogenic Streptomyces species transfected with non-conjugative plasmids (unable to transfer to other species).

#### Origin & function

GSK proprietary libraries.

#### Evaluation of foreseeable effects

Human and non-human cytokines may have biological activity if delivered to a site of action (eg if ingested or inhaled). The use of Class 2 biological safety cabinets and gloves will reduce the likelihood of harm from laboratory work to effectively zero. For larger scale work, the operation of bioreactors is designed to minimise release through exhaust gases or during sampling of cultures, and the work will be effectively contained at CL2 according to Schedule 8 of the GMO (Contained Use) Regulations 2000.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel kinases in mammalian cells in order to obtain functional data and to determine the specificity of closely related kinases. Kinases are a large class of enzymes found in all cell types which activate their target proteins by...
phosphorylation. Frequently, the target molecule itself will be a kinase, which when activated can progress the signal by phosphorylation of the next enzyme in the signal cascade. The kinases may be modified to modulate their activity and to evaluate the mechanism of action, for example by analysing the effect of single amino acid substitutions. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines.

Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promotors are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.

EXPRESSION OF NUCLEAR RECEPTORS IN MAMMALIAN CELLS USING THE BACULOVIRUS SYSTEM

Class 2

Consent Granted not applicable

Project notified under transitional arrangements N
In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel nuclear receptors in mammalian cells in order to obtain functional data and to determine the specificity of closely related receptors. Nuclear receptors are ligand regulated transcription factors which mediate their physiological effects by modulating the expression of target genes. The nuclear receptors may be modified to modulate their activity and to evaluate the mechanism of action, for example by analysing the effect of single amino acid substitutions. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines.

Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promoters are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.

Recipient or parental organism

Baculovirus CL1.
These organisms fall into ACDP hazard group 1.

Host/vector system

For generation of recombinant baculovirus, shuttle vectors containing the product gene under CMV promoter control are transfected into insect cells (eg Sf-9) using standard procedures such as the Bac to Bac expression system (Life Technologies).

(Recombinant cell lines expressing nuclear receptors: CL 1).

Origin & function

Libraries of human DNA commercially available or from academic collaborators.
The baculovirus is able to transfect mammalian cells, but is unable to replicate in them. Efficient expression of the gene products under control of the CMV promoter is achieved only by addition of an inhibitor of cellular histone deacetylase. It is possible that inappropriate expression of a nuclear receptor could have detrimental effects. However, the only likely routes of infection would be mouth, nose or eyes, and the amounts which might enter by such routes (via aerosols or splashes) would be small (microlitres). In addition, baculoviruses are rapidly inactivated (>99% in 30 minutes) by the complement system of normal human serum (Hofmann and Strauss '98)*. Project Additional Information

Purposes of the contained use
The broad aim of this project is to better understand the replication of hepatitis C virus. The relatively compact hepatitis C virus genome encodes all the proteins and
contains the required genetic elements to replicate in a suitable cell line. We are particularly interested in the structure and function of RNA elements that are involved in the replication process. A better understanding of HCV replication may enable novel therapeutic methods to be developed to limit virus infectivity or spread in the infected host.

**Recipient or parental organism**

The parental organism is hepatitis C virus, an ACDP level 3 human pathogen. At the time of application this virus only undergoes a full replication cycle in the human hepatoma Huh7 cell line. Therefore virus can only be recovered from cDNA under controlled laboratory conditions and can only be cultivated in a specific cell culture system. The virus cDNA is contained in plasmids under transcriptional control of a phageT7 promoter. In the absence of exogenously supplied T7 polymerase there can be no transcription and hence subsequent expression of HCV.

**Host/vector system**

The plasmid vector system is derived from pUC. It is therefore non-mobilisable. It is maintained in standard disabled laboratory strains of E. coli (DH5a, JM101 etc.). Virus production will follow in vitro T7-mediated transcription and transfection of Huh7 cells in culture. Progeny virus will be propagated in Huh7 cells. Huh7 cells are a permanent cell line defective in interferon production. They are the only cell culture system in which hepatitis C replication has been reproducibly demonstrated.

**Origin & function**

The parental genetic material is hepatitis C virus. Initially studies will be based on the genotype 2a JFH-1 infectious cDNA and virus recovered from this clone (Wakita et al., Nature Medicine 11, 791-796). Future studies will include additional genotypes as they become available in other laboratories. The JFH-1 system reproducibly produces infectious virus in Huh7 cells that can be passaged onto fresh cells. Mutations will be introduced into the cDNA into regions we suspect are involved in controlling virus replication. In particular we are interested in short stem-loop structures that are located in the core protein-encoding and NS5b polymerase-encoding regions. Mutations will be introduced to disrupt these structures and duplications of the structures will be introduced elsewhere in the genome. None of the changes are in regions of the virus implicated in influencing the primary tropism of the virus - they are not in the E1 or E2 envelope-coding regions. Mutations will include deletions, substitutions and short insertions.

A similar range of mutations will be introduced into a sub-genomic replicon system in which the structural proteins of HCV are removed and replaced with a reporter gene (luciferase) or an antibiotic coding gene (conferring G418 resistance). The sub-genomic replicon is transcribed in vitro using bacteriophage T7, the RNA transfected into Huh7 cells, and replication 'monitored' by an increase in luciferase activity, or the outgrowth over time of neomycin-resistant colonies in cell culture. The sub-genomic replicon cannot transfer from cell to cell and cannot encode infectious virus.

Some of the substitutions to be introduced will be of analogous regions of other genotypes of HCV. More divergent sequences are not included within the scope of this proposal i.e. the sequences are all derived from hepatitis C virus.

Studies from a number of laboratories have shown that disrupting this type of cis-acting replication elements (that are the targets of this project) is either neutral or deleterious to virus replication. There is no reason to suspect that the mutations to be introduced will enhance replication above that of the parental virus, or that the changes will increase or otherwise influence the tropism or pathogenicity of the recovered virus.

**Evaluation of foreseeable effects**

Hepatitis C virus is exclusively a human pathogen. Transmission is almost exclusively parenteral, with some limited evidence for sexual transmission. There is no evidence for aerosol or faecal-oral transmission of the virus. None of the changes proposed - if they yield viable virus at all - are expected (or designed) to alter the cell, tissue or host tropism of the virus, or influence the route by which the virus can be transmitted. The majority of the changes are expected to be deleterious to virus replication, and to reduce or abrogate virus fitness. There is no reason to expect that the planned changes will reduce the immune response to the virus, which clears infection in about one third of cases. Instead, a less fit virus may be more susceptible to immune clearance.

No vaccine is available to prevent HCV infection. Antivirals - currently ribavirin and interferon, with protease inhibitors shortly - are of limited benefit and lead to viral clearance in a proportion of cases.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For bacterial work, all solid waste and glassware is autoclaved at 121oC for at least 15 min. The autoclave is validated by thermocouple test annually. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal. Both these treatments give a 100 % kill for standard laboratory strains of E. coli.

Cell culture work not involving recovery or propagation of viable virus e.g. transfection and analysis of hepatitis C virus sub-genomic replicons, will be conducted in a level 2 tissue culture laboratory. All cells will be handled in a class 2 microbiological safety cabinet with HEPA-filtered exhaust. Waste is autoclaved or chemically inactivated prior to disposal. All staff handling replicon-transfected cells are trained.

Cell culture studies involving the attempted recovery and propagation of infectious hepatitis C virus will be conducted in a level 3 laboratory. Virus and infected cells will be handled in class 1 microbiological safety cabinets by personnel who have been specifically trained and approved to work in a level 3 facility. All biological waste is inactivated by treatment with a quarternary ammonium detergent and waste is autoclaved within the facility prior to disposal. Virus storage is in vapour phase, liquid nitrogen, within the level 3 facility.

Minutes of the Genetic Manipulation Safety Committee meeting held on January 19th 2007 relevant to the notification

GMSC 695 Professor D J. E
Cloning and mutagenesis of hepatitis C cDNA
This project aims to dissect the role of structured RNA elements in the replication of hepatitis C virus. The study will involve the manipulation (using standard molecular approaches in E. coli host/vector systems) – by deletion, modification and insertion – of stem-loop structures previously predicted by bioinformatic analysis.
The virus cDNA cannot be replicated, or the proteins expressed in E. coli. Expression requires in vitro transcription by bacteriophage T7 polymerase, transfection into a permissive human hepatoma cell line (only one of which has reproducibly been shown to support replication) in which translation occurs. Translation involves cellular factors absent from bacterial cells. The disabled nature of the host, lack of mobilisation or conjugative features of the vector reduce the possibility of environmental risk to effectively zero.

Environmental Risks: Consequence: negligible; Likelihood: low; Overall: Effectively zero.

GMSC 696 Professor D J.E
Analysis of Hepatitis C virus replication using sub-genomic replicons. The aim of this project is to dissect the role of structured RNA elements in the replication of Hepatitis C virus. Functional analysis of the modified stem-loop structures will be undertaken using a hepatitis C virus sub-genomic replicon system. These consist of a virus cDNA from which the coding region for the core, E1 and E2 structural proteins have been deleted and replaced with an antibiotic (or enzymatic) selection marker. Following transfection of susceptible cells with RNA generated in vitro replication can therefore be monitored by an increase in antibiotic resistant colonies, or enzymatic activity. Due to the absence of the structural proteins the sub-genomic replicons is incapable of making virus particles and cannot be transmitted from cell to cell. Replication only occurs in the Huh7 human hepatoma cell line.

Protein expression depends absolutely upon replication in one particular human hepatoma cell line. The sub-genomic replicons alone are incapable of being transmitted from cell to cell. Virus pseudotypes can be generated by co-infecting a replicon-containing cell with a suitable helper virus. However, replication would be restricted to a single passage. In the absence of exogenously added helper virus Huh7 cells are known not to contain any viruses capable of pseudotyping the sub-genomic replicons, and are not known to contain any adventitious agents. The requirement for Huh7 cells is due to the exquisite sensitivity of the replicon to the presence of interferon – Huh7 cells are defective in interferon production. Therefore, transfer to the environment in extremely unlikely, and if it did occur then the likelihood of the genome replicating would be very small. Finally, in the absence of any cell-to-cell transmission, damage would be restricted to a single recipient cell.

Environmental Risks: Consequence: negligible; Likelihood: negligible; Overall: Effectively zero.

GMSC 697 Professor D J. E
Replication of hepatitis C virus – studies using replicating virus system.
The aim of this project is to analyse the role of conserved RNA structures in the replication of hepatitis C virus. Our in vitro and in silico studies have identified a number of stem-loop structures that we believe are implicated in fundamental aspects of virus replication. We propose to modify these structures by mutagenesis, deletion and substitution analysis and determine the effect upon the replication of the virus.

The following points were noted and discussed by the committee:
The project will involve mutagenesis of pre-existing stem-loop structures with the intention of disrupting the structure without altering the encoded protein. The majority of the changes will therefore involve synonymous substitution. It is also proposed to introduce a second copy of the stem-loop structure at an alternative position within the genome – either in a non-coding region, or at a proteolytically cleaved junction of the polyprotein. In these cases the insert will be a 'self' sequence, derived from the same or closely related genotype of HCV.

Changes are expected to have a deleterious effect upon virus replication. All the changes DJE has already constructed in HCV sub-genomic replicons are either detrimental, or have no detectable effect upon replication. None enhance the aspects of replication we are currently able to quantify (i.e. genome copy number per cell).

Furthermore, all the stem-loop structures of interest are located in the region encoding the non-structural proteins of HCV – specifically the NS5b RNA dependent RNA polymerase. There is no evidence that this protein specifically alters the host range of HCV. The virus only replicates efficiently in Huh7 liver cells in culture due to exquisite sensitivity to the presence of interferon – Huh7 cells cannot produce interferon.

Regarding susceptibility to antiviral drugs where treatable, HCV responds to interferon and ribavirin. There is no reason to expect the substitutions to be made to the polymerase will enhance resistance to either of these treatments.

Proposed categorisation: Hepatitis C virus only infects humans. Parenteral transmission to chimpanzees – but not other non-human primates – has been demonstrated, but the virus is cleared and the infected animals only present with transient symptoms (enhanced ALT levels indicative of liver damage). Virus clearance is by the acquired immune response.

Hepatitis C virus is an ACDP level 3 pathogen. GMSC Decision: Con. Level 3.

Environmental Risks: Consequence: severe; Likelihood: negligible; Overall: effectively zero.

### Project Additional Information

#### Purposes of the contained use
The production of transcript RNA from a cDNA 'Replicon' copy of the Foot and Mouth Disease virus (FMDV) genome. The 'Replicon' is a plasmid encoding the FMDV genome with a major deletion within the region encoding the capsid proteins. The RNA will then be transfected into BHK21 cells to analyse the process of FMDV RNA replication in vivo.

#### Recipient or parental organism
The plasmid containing the Replicon will be grown in the bacterial cell line - JM109.

The plasmid will be transcribed in vitro, then replicon-derived transcript RNA will be transfected into Baby Hamster Kidney (BHK) 21 cells.

#### Host/vector system

The FMDV 'Replicon' plasmid DNA was produced by McInerney et al [J. Gen Virol Vol. 81 1699-1702 (2000). The plasmid will be grown and any gene modifications will be performed using pBSKII, pGEM or pcDNA plasmids, all of which are non-mobilisable.

The plasmids will be used to generate Replicon RNA which is non-infectious (as it does not have the FMDV capsid genes to allow packaging). The RNA will then be used to transfect BHK21 cells.

#### Origin & function

The FMDV Replicon will be obtained from the Institute for Animal Health, Pirbright Laboratory, or, constructed at the University of St. Andrews using procedures that are published (McInerney et al., 2000. J. Gen. Virol. 81:1699-1702) without using any form of viable virus.

The JM 109 and BHK 21 cells will be purchased from reputable suppliers.
The function of the genetic material is to analyse FMDV replication processes with the aim of understanding how FMDV replicates within cells. Of particular interest is how the virus proteins alter the flow of membranes within the cell to form vesicular replication complexes. The understanding of this process may provide a means of controlling an outbreak of this virus during the period where animals are vaccinated (emergency 'ring' vaccination), but have no sero-converted.

Evaluation of foreseeable effects

The Replicon can not directly form infectious virus particles as capsid sequences have been deleted preventing the formation of particles to package and transmit the RNA to another susceptible cell.

The biological containment could be breached if the ‘Replicon’ could naturally recombine with another related virus to gain a capsid gene that will allow packaging. Bioinformatic analyses by Dr Ryan has shown that the FMDV sequence is very poorly conserved with any other members of the Picornoviridae. A comparison of sequence similarly amongst genera for which recombination does not occur shows that recombination between replicon-derived FMDV RNA with another member of the Picornoviridae (to form infectious virus particles) is not a realistic risk (details of similarity analyses, probability of recombination are available upon request from Dr Ryan). This question was fully discussed at a meeting of the Genetically Modified Organisms (Contained Use) Scientific Committee (GMO(CU)), and it was agreed this was not a realistic risk.

All plasmids that contain the FMDV capsid gene or related genes will be destroyed before the Replicon will be delivered to the University thus removing the possibility of accidental recombination.

There is a possibility that the Replicon could be stolen and used for malicious purposes. Appropriate security measures will be implemented to stop this occurring.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work with the replicon will be performed in Category 2 containment facilities as defined in the ACGM Compendium of Guidance (ISBN: 0-717601763-7). Appropriate operating procedures will be implemented to ensure only authorised appropriately trained, personnel can work with the Replicon.

As the Replicon does not have the capsid gene, it cannot package FMDV RNA and thus cannot produce infectious virus particles. Also, the Replicon plasmid does not have any eukaryotic promoters thus the plasmid cannot be expressed in susceptible animals. These features will act as a natural biological containment of the Replicon system. To avoid accidental recombination with plasmids that may have FMDV capsid genes, all plasmids which contain the FMDV capsid gene or similar genes will be destroyed before the arrival of the Replicon to the University isolated RNA from the Replicon is inherently susceptible to hydrolysis, thus if any naked RNA escaped from the containment facilities it would be destroyed very quickly.

All waste generated from the work will be autoclaved before disposal. Any spillages of the 'Replicon' will be treated with neat hypochlorite.

To avoid malicious use of the Replicon, it will be stored within a locked box, itself stored within a locked freezer. Comprehensive records will be kept of the use of the Replicon so that all of the plasmid can be accounted for. The control measures will be regularly reviewed and audits undertaken to ensure the containment and security systems are sufficient.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from experiments using the Replicon will be autoclaved at 120 degrees C for 145 minutes at 15 psi.

Spillages will be dealt with by soaking the area in neat hypochlorite.

Any spillages of bacterial or eukaryotic cells into the drainage system will be dealt with by putting neat hypochlorite (500ml) being put down the drain, left for 10 minutes prior to the drain being flushed with running water for 30 minutes to ensure appropriate dilution.
At the first meeting of the School of Biology Safety Committee the properties of replicon-derived RNA was discussed with particular reference to containment. Dr Ryan discussed the scientific aspects of using the replicon, the biological properties of the transcript RNA derived from the replicon and presented a bioinformatic analysis of the similarities between different regions of the FMDV genome and those of similar regions of other picornaviruses. This analysis was performed to quantify the risk of recombination between replicon-derived FMDV and vRNA from other picornaviruses. It was suggested that a further bioinformatic analysis should be performed to determine the maximum length of nucleotide identity between FMDV and other viruses should be performed. This was analysed and Dr Ryan presented the data to a second meeting of the School of Biology Safety Committee. It was agreed that the maximum lengths of sequence identity between FMDV and other picornaviruses was too short to present a risk from RNA recombination between FMDV and other members of the family. The meeting was in (unanimous) agreement that the project required only category 1 containment.

Host/vector system

pUC19 and similar cloning vectors. pRS406 and similar S. cervisiae vectors. pNKBAC39 and similar BAC vectors. pGL3 and similar luciferase vectors. pcDNA3 and similar mammalian expression vectors. pBABE and similar oncoretroviral vectors. pRRL and similar lentiviral vectors. pMD2G, pCMV-dR8.74, pMDLg/pRRE, pRSV-Rev and similar packaging plasmids for lentivector vectors. See http://tronolab.com for maps of lentiviral vectors and packaging plasmids.

Origin & function

The genes to be inserted include jellyfish GFP; firefly luciferase; E. coli lacZ, nfsB; phage Cre; S.cerevisiae FCY1; human CTNNB1, LEF1, HIF1A, TP53, PP1R15A, MMP7, and shRNA targeting human DPYD, APC, CBY, TP53 (for information on human gene symbols see http://www.gene.ucl.ac.uk/nomenclature/). The origins of the materials include the American Type Culture Collection (#ATCC- website www.atcc.org) and other standard scientific suppliers (eg Invitrogen - website www.invitrogen.com).

The function of the genetic material is to generate tumour targeting adenoviruses to treat cancer (so-called 'oncolytic viruses'). The viruses replicate selectively in tumour cells. They contain multiple mutations that attenuate them in normal cells. The attenuating mutations include mutation of the viral promoters and deletion of viral genes. Prodrug-activating enzymes expressed by the virus are used to convert harmless prodrugs into active chemotherapeutic agents. This allows targeting of the active drug to cells infected with the virus. Retroviral vectors are used to modify normal cells (eg, expression of an oncogene) or tumour cells (eg, expression of a tumour suppressor gene). These modified cells are used to confirm that the oncolytic vectors have the correct specificity. Tumour targeting peptides are inserted into the capsid of the oncolytic vector to enhance the infection of tumour cells. The tropism and efficacy of the oncolytic viruses are tested in vitro using cell cultures and in vivo using immunodeficient mice with human tumour xenografts.

Evaluation of foreseeable effects

Adenoviral vectors:
Replication-competent wild type adenoviruses cause acute, self-limiting upper respiratory tract infections. The general population has life-long immunity to these viruses as a result of infection in childhood. The genetic modifications of the virus restrict viral gene expression and viral replication to tumour cells. Intravenous injection of similar genetically modified viruses into patients participating in clinical trials has shown that the viruses cause only minor side effects unless the dose exceeds 10^12 viral particles. The risk of accidental exposure to such large amounts of virus is effectively zero when the virus is used under level 2 containment. Detailed further information of adenoviral vectors is given in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7).

Retroviral vectors:
Pseudotyped retroviral vectors can infect a wide range of cells, leading to integration of the viral genome into the cellular genome and expression of foreign genes. The viruses are replication-defective because essential viral genes are deleted. Expression of oncogenes from the integrated virus increases the risk of malignant transformation of the recipient cell. Actual tumour formation requires infection of the same cell with multiple different viruses, or the use of complex protocols, such as infection ex vivo of a patient's lymphocytes in the context of a clinical gene therapy trial. The risk of these events occurring accidentally is effectively zero under level 2 containment. Detailed further information on retroviral vectors is given in the ACGM Compendium of Guidance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All work with the GMOs will be performed in Category 2 containment facilities as defined in the ACGM Compendium of Guidance. Appropriate operating procedures will be implemented to ensure only authorised, appropriately trained, personnel can carry out this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All plastic waste from experiments will be autoclaved at 120 degrees C for 30 minutes at 15psi.
All media and liquids will be treated with Virkon solution before disposal as per the manufacturer's instructions.
Spillages will be dealt with by soaking the area in neat Virkon.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Four members of the GMSC agreed that this should be a class 2 project.
The comments of the full GMSC for the University of St Andrews will be sent to you when they next meet.

**Project Additional Information**

**Purposes of the contained use**

The purpose of this project is to understand the molecular biology of bunyavirus replication, including structure-function analysis of viral proteins, the role of cis-acting signals within vRNA and the interactions of bunyaviruses with host cells.

**Recipient or parental organism**

E.coli K-12 derivatives (e.g. DH5a), E.coli B strains (e.g. BI-21), S cerevisiae strains AH109 and Y187 (from Clontech) Mammalian cell lines (e.g. vero, BHK, Hep2, mRC-5, 293, HeLa), insect cell lines (e.g. Aedes albopictus C6/36, S. frugiperda).

**Host/vector system**

pUC series, pBluescript, pET series vectors for E.coli. pGBKT7 and pGADDT7 for yeast cells. pcDNA and non-cytopathic Sinbis virus replicons pSinRep for mammalian cells. PIB/V5-His for insect cell lines. pBac vectors for generating recombinant baculovirus systems. Autographa californica nuclear polyhedrosis (AcNPV) derivatives such as AcPAK6 for insect cell lines. Expression in Vaccinia virus vectors pTF7-5 and pSC11 for constructing recombinant vaccinia viruses. Vaccinia virus vTF-7 and MVA-T7. Lentivirus vector pLenti-ires-puro.
**Origin & function**

Bunyaviral genes:
- N-nucleocapsid (binds viral RNA)
- L-viral RNA dependent RNA polymerase
- Gn-viral glycoprotein (receptor binding, cell fusion)
- Gc-viral glycoprotein (Receptor binding, cell fusion)
- NSs - non-structural protein (interferon antagonist; blocks RNA polymerase II transcription)
- NSm - non-structural protein (Localises to Golgi- unknown function)

Cellular genes encoding proteins that interact with bunyavirus proteins:
- HeLa genome library for screening by yeast-2-hybrid assay. Specific genes: Med8 (a component of the Mediator complex involved in the regulation of RNA polymerase II mediated transcription), ARC-32 (mosquitto cell homologue of Med8), other individual genes that encode proteins which interact with bunyavirus proteins once they have been indentified by the yeast-2-hybrid screening.

**Evaluation of foreseeable effects**

**E. coli**

The K-12 cell lines are known to be non-pathogenic (see ACGM Compendium of Guidance (ISBN: 0-7176-1763-7). The E.coli cell lines have been less well characterised than the K-12 strains. BL-21 cells are less well characterised than K-12 strains but have a long history of safe use. A recent publication has shown that BL-21 cells is non-pathogenic ans unlikely to survive in certain host animal systems (Chart, H. et al J. Applied Microbiology Vol 89, pages 1048-1058 (2000)). It is thus considered that BL-21 cell are non-pathogenic, though care will be taken when handling this cell line.

**Baculovirus System:**

The Baculoviruses system have a long history of safe use. The system has been used extensively to infect insect cells with foreign genes and there has been no published evidence that viable recombinant virus has been produced in these cells.

**Yeast Cells**

Yeast cells are considered to be especially disabled host cells and it is not considered that any of the hybrid proteins expressed will alter the biological properties of the host.

**Vaccinia vectors:**

Vaccinia virus can infect humans and is classified as an ACDP category 2 pathogen. None of the inserted genes to be expressed is likely to significantly alter the pathogenicity of the vaccinia vector. Recombinant genes have been targeted in the viral thymidine kinase gene and such recombinants are considered to be attenuated relative to the parent. Therefore containment level 2 which is used to contain the parent virus is appropriate for handling the recombinant virus. The avoidance of sharps will reduce the major route of infection which is subcutaneous inoculation.

**Disabled Lentivirus**

Disabled lentivirus vectors are widely used for expressing foreign genes under level 2 containment. Inoculation of the virus into man could result in integration of the viral genome and expression of the foreign gene. Avoidance of sharps will minimise this route of infection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All work with the GMOs will be performed in Category 2 containment facilities as defined in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7). Appropriate operating procedures will be implemented to ensure only authorised, appropriately trained, personnel can carry out this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All plastic waste from experiments will be autoclaved at 120°C for 30 minutes at 15 p.s.i.
All media and liquids will be treated with Virkon solution before disposal as per the manufacturer's instructions. Spillages will be dealt with by soaking the area in neat Virkon.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Additional Information

Purposes of the contained use

Investigate the effect of lentiviral vectors on the production of choline acetyltransferase and beta-2-nicotinic receptors in localized brain regions of the rat brain

Recipient or parental organism

Use of third generation HIV based pTRIP delta U3 lentivirus system

Host/vector system

The lentivirus will be grown in 293T cells at the Pasteur Institute, Paris

Origin & function

The inserted gene is a short hairpin DNA producing an interfering RNA which blocks production of choline acetyltransferase or beta-2-nicotinic receptor subunits.

Evaluation of foreseeable effects

Inhibition of the production of choline acetyltransferase and beta-2-nicotinic receptor subunits (determined by immunohistochemical and receptor binding methodologies)

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Category 2 containment facilities

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

**Purposes of the contained use**

The purpose of the project is to perturb polycomb epigenetic signalling pathways in mammalian cells in order to investigate polycomb biology and explore the role of polycomb proteins in cancer progression

**Recipient or parental organism**

-
Host/vector system

pUC19 and similar cloning vectors. pRS406 and similar S. cervisiae vectors. pNKBAC39 and similar BAG vectors. pGL3 and similar luciferase vectors. pcDNA3 and similar mammalian expression vectors. pBABE and similar oncortroviral vectors. pPRL and similar lentiviral vectors. pMD2G, pCMV-dR8.74, pMDLgplRRE, pRSV-Rev and similar packaging plasmids for lentiviral vectors. See http://ltronolab.com for maps of lentiviral vectors and packaging plasmids.

Origin & function

The genes to be inserted include jellyfish GFP; firefly luciferase; E.coli lacZ, nfsB; phage Cre; S.cerevisiae FCY1; human EZH2, SUZ12, ESRI, SMII, hTERT, MYC, CTNNB1, and shRNA targeting SUZ12, EZH2, DNMT1 (for information on human gene symbols see http://www.gene.ucl.ac.uk/nomenclature/). The origins of the materials include the American Type Culture Collection (ATCG - website www.atcc.org) and other standard scientific suppliers (eg Invitrogen - website www.invitrogen.com).

The function of the genetic material is to generate tumours from normal cells or to suppress tumour cells in order to investigate tumour formation. Retroviral, lentiviral or adenoviral vectors are used to introduce the genetic material into cells (eg, expression of an oncogene) or tumour cells (eg, expression of a tumour suppressor gene). Different contributions of genes to the transformation process will reflect their role in influencing the tumour phenotype in breast cancer.

Evaluation of foreseeable effects

Adenoviral vectors:
Replication-competent wild type adenoviruses cause acute, self-limiting upper respiratory tract infections. The general population has life-long immunity to these viruses as a result of infection in childhood. Expression of oncogenes from replication-defective virus increases the risk of malignant transformation of the recipient cell. Actual tumour formation requires infection of the same cell with multiple different viruses, or the use of complex protocols, such as infection in vivo of a patients lymphocytes in the context of a clinical gene therapy trial. The risk of these events occurring accidentally is effectively zero under level 2 containment. Detailed further information on adenoviral vectors is given in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7).

Retroviral and lentiviral vectors:
Pseudotyped retroviral and lentiviral vectors can infect a wide range of cells, leading to integration of the viral genome into the cellular genome and expression of foreign genes. The viruses are replication-defective because essential viral genes are deleted. Expression of oncogenes from the integrated virus increases the risk of malignant transformation of the recipient cell. Actual tumour formation requires infection of the same cell with multiple different viruses, or the use of complex protocols, such as infection in vivo of a patients lymphocytes in the context of a clinical gene therapy trial. The risk of these events occurring accidentally is effectively zero under level 2 containment. Detailed further information on retroviral vectors is given in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work with the GMO5 will be performed in Category 2 containment facilities as defined in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7). Appropriate operating procedures will be implemented to ensure only authorised, appropriately trained, personnel can carry out this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All plastic waste from experiments will be autodaved at 120 oC for 30 minutes at 15 p.si. All media and liquids will be treated with Virkon solution before disposal as per the manufacturers instructions. Spillages will be dealt with by soaking the area in neat Virkon.

Please enter comments on the GM safety committee on the risk assessment

Paper/07/07/f- Perturbation of epigenetic signalling in mammalian cells - The Sub-Committee discussed two aspects of this project. The first was the use of lentivirus vectors. After significant discussion of this matter it was agreed that the lentivirus system used would a replication deficient system and thus could be performed in category 2 containment facilities. The second area of discussion was the use of adenoviral vector systems. It was also agreed that the adenoviral vector system could also be carried out in category 2 containment facilities. It was agreed that this work should be categorised as a Category 2 Project.

Action - It was agreed that the Secretary would inform the Sub-Committee's decision.

### Project Additional Information

**Purposes of the contained use**

To identify lipid biosynthetic genes that will allow the disruption of the growth and transmission of Trypanosomes and other parasites.

**Recipient or parental organism**

Trypanosoma cruzi, Leishmania braziliensis, Leishmania chagasi, Leishmania donovani, Leishmania infantum and Plasmodium falciparum are all categorised by the ACDP as category 3 human pathogens.

All other pathogens which may be used will be category 2 or 1.

**Host/vector system**

(I) List of recipient strain(s),

The host strains used are Trypanosoma brucei brucei. Although distinct isolates may be used for the analysis of strain variability, these do not differ in their potential risk with respect to genetic modification. The particular strains used for our experiments in >95% of cases will be:

- Trypanosoma brucei
- Lister S427
- TREU 92714

The other remaining 5% of the work will utilise the following pathogens:

- Trypanosoma cruzi
- CL Bruner
- Y starin
- Leishmania spp m4or mexicafra
- donovani
- tropica
- braziliensis
- mfnantum
- Plasmodium falciparum
- 010
- 3D7
- Toxoplasma gondii
- RH
- E.coli
- DH5αL

pLou3 (MBP)

Genes involved in lipid biosynthesis in the protozoan parasites mentioned above will be investigated by forming knockout, RNAi knockdown and overexpression cell lines. The genes in question will also be overexpressed in E.coli for recombinant expression, purification and activity studies. In a few circumstances complementation & TS or null mutants yeast will allow functional complementation studies.

The genes to be studied will be involved in:

a) phospholipid biosynthesis (including uptake of precursors), remodeling and degradation.

b) glycolipid formation i.e. glycosylphosphatidylinositol anchors and N-glycosylation. i.e. dolichol-phosphate-mannose synthase C3DP-man pyrophosphorylase, PNQase F, SPI anchor de-N-acetylase.

c) Sterol biosynthesis

i.e. the enzymes of the mevalonate pathway i.e. IDI-isopentenyl diposphate isomerase and CYP51- 14- demethylase

Evaluation of foreseeable effects

We expect most genetic manipulation of the parasite to reduce fitness and/or virulence: our experiments to date indicate perturbed expression of the molecules under study in our laboratory reduce virulence.
For example, manipulation of the genes studied to date have in each case either generated no consequence for the parasite, or have resulted in disruption of the parasite morphology, cell cycle or capacity for essential developmental processes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work to be performed in Category 3 containment facilities when they become available in the animal house

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work with parasite pathogens will be carried out in category 3 containment facilities within this University.
Where feasible all items will be autoclaved within a category 3 containment facility.
Where it is not feasible to autoclave, then items will be treated with 1% Virkon. The manufacturers have produced evidence to validate that Virkon will reduce the titre of virus by at least i05

The relevant section of the last University of St And rows Genetic Modification Safety Committee meeting which discussed submission is given below. This project has also been scrutinised by the Health and Safety Committee for the building where the work will be carried out.

University of St Andrews
Report of the Meeting of the Chemical and Biological Hazards Sub-Committee of the University Health and Safety Committee.

A meeting of the above sub-committee was held on Wednesday 17th December 2007 at 2.15pm in the Lochnagar Room, Mansfield House.

Present: - (University Biological Hazards Adviser) (Convenor)  
(Secretary)
CBHSC/07/07 Ratification of New Genetic Modification Projects

Paper07/07gg - Genetic validation of drugs targets in protozoan parasites - The Sub-Committee discussed the use of ACDP Category 2 protozoans and Category 3 protozoans. They were informed that. toes not intend to grow Plasmodium parasites in an arthropod cycle thus there is very limited risk of the protozoan escaping into the environment.

It was agreed that this project has now been ratified and should be categorised as a Category 3 Project

Action - It was agreed that the Secretary would inform the Sub-Committee’s decisiona

The meeting ended at 4.15 pm

### Project Additional Information

**Purposes of the contained use**

Elucidation of fundamental aspects of retroviral replication has and will suggest novel targets for the development of antiretroviral therapies. It is notable that no approved antiretroviral drugs currently target the Gag protein. Towards this aim current areas of research in this project include, 1. Understanding Gag cleavage sites as molecular targets for antiretroviral drug development, 2. Understanding the role of the envelope gp41 glycoprotein long cytoplasmic tail in lentivirus replication and 3. Understanding the role of host factors in retroviral assembly and release pathways with a particular emphasis on determining factors that facilitate envelope incorporation into the assembling particle.

**Recipient or parental organism**

02/03/2022
Viruses:
- Human immunodeficiency virus type 1 and 2 (HIV-1 and HIV-2)
- Simian immunodeficiency virus (SIV)
- Equine infectious anemia virus (EIAV)
- Feline immunodeficiency virus (FIV)
- Murine leukemia virus (MLV)

Host/vector system

Mammalian cell lines:
- Human carcinoma and fibroblast cell lines: HeLa, TZM, P4-P5 MAGI, Ghost and derivatives.
- Human T lymphoid: Jurkat, CEM, HUT78, HUTCC5, H9, SupT1, MT4, M8166.
- African green monkey fibroblasts: COS, Vero
- Crandall feline kidney cells: CrFK.
- Murine fibroblasts: 3T3, Murine lymphoid: EL4
- Canine Thymus: CF2Th
- Equine dermal cells: ED
- Cell lines from the ATCC, HPACC or the NIH AIDS reagent program and partners at NIBSC.

Human primary cells: Human peripheral blood monocytes (PBMCs) and macrophages. Donated from anonymous health volunteers.

Bacterial strains: E. coli (K12 strains), which have been attenuated to prevent survival in non-laboratory environment: e.g. JM107, Stab12, Stab13, Top10, DH5a BL21.

Details of procedures can be found in the attached risk assessment

Origin & function

Reporter genes: L-glactosidase (e.coli), luciferase (firefly), green fluorescent protein (jelly fish) etc. Selectable marker genes (e.g. puromycin resistance gene).

Host proteins known or hypothesized to be required for retroviral replication:
- CD4, CCR5, CXCR4 - T cell and chemokine receptors used for HIV entry.
- Members of the ESCRT complexes (e.g. Tsg101, VPS4, Alix) - Cellular endosomal sorting machinery, which is hijacked by HIV to promote virus release.
- Ubiquitin - binds to proteins as a post-translational modification that labels proteins for protein sorting or proteosomal degradation pathways, known to promote HIV particle release.
- Tetherin/BST-2 - interferon-induced membrane protein that inhibits HIV virus release.
- TIP47 - Lipid cargo protein, which is thought to promote HIV-1 Env incorporation by acting as a bridging molecule between the MA domain of Gag and the Env gp41 protein.
- Calmodulin - calcium-binding protein hypothesized to be involved in HIV replication, as it is known to bind MA domain of Gag and the Env gp41 protein.
- ADAM10 - disintegrin/metalloproteinase hypothesized to be involved in HIV replication

Please note: Should our appreciation of function or new candidate genes be identified, I would amend this risk assessment accordingly using the extension system.

Evaluation of foreseeable effects

Wild type viruses are -
- HIVs: ACDP hazard group 3,
- SIVs: ACDP hazard group 3;
- EIAV, FIV, MLV: ACDP hazard group 1

Details of the effects of the triple and dual vector systems are given in the risk assessment
Category 3 work will be undertaken in the category 3 containment facilities at the Centre for Biomolecular Sciences, North Haugh, University of St Andrews, St Andrews Fife KY16 9ST. Attached is the Standard Operating Procedures for this laboratory. These will be modified for work with HIV and a copy of the modified SOP will be sent to the HSE Biological Agents Unit.

Other work will be carried out in category 2 containment facilities in the new Medical and Biological Sciences Building at the University and in the Centre for Biomolecular Sciences building.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Category 3 waste will be autoclaved - For Plastic Discard, for all plastics/paper waste, 121°C/15 min/small volume select. - For Fluid Discard, for large volume liquid waste, 121°C/15 min/large volume select.

For Category 3 laboratory: Virkon at 1% will be used as a disinfectant as it has been validated to be effective against retroviruses. Contaminated waste will be soaked in virkon solution. Laboratory workers in the CL3 wear disposable gloves, gowns, foot shields and eye shields all of which are removed prior to leaving the facility. All material will be autoclaved before leaving the CL3 facility. The approved standard operating procedures for the CL3 facility will be strictly adhered to.

For category 2 laboratory: Virkon at 1% will be used as a disinfectant as it has been validated to be effective against retroviruses. Contaminated waste will be soaked in virkon solution. Laboratory workers in the CL2 will wear disposable gloves, eye shields and lab coats. All materials will be autoclaved.

There will be no use of sharps materials for this work.

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment
See the following comments from members of the Chemical and Biological Hazards Management Group of the University of St Andrews which acts as the genetic Modification Safety Committee for the University:

I wanted to have a word with B before replying to you on this matter. The points that were raised in our building safety meeting about (i) virus particle 'pseudotyping' (VSV-G protein) and (ii) particle inactivation have been addressed and my rating of this project is Category 3.

Convenor- Chemical and Biological Hazards Management Group

Having read the project and discussed it with B I felt that CL3 is appropriate for this project. B has told me that there will have to be a written change in the SOP to accommodate certain procedure die the use of triton X100 to inactivate the virus before it is removed from CL3 thi is to allow the samples to be used in luciferase assays. Dr A has shown referenced that validate the effectiveness of this method.

JN

As I and PR signed it following a safety meeting attended by many BMS Pls, C, P R, R E, A M and T S I think we have covered the bases at this end. There are some issues that need sorting viz SOP but that’s in hand.

BP

There are portions of this project that fall into each of 1, 2 and 3. Clearly the work at the CNMS cat 3 unit is category 3 work. The work at the Medical School labs is category 2 with some DNA work that is category 1 (the Medical School labs are all category 2 rated space). In terms of maximal rating for each location, Medical School labs - category 2, CBMS contained unit - category 3.

PR

I have read through the GM1 for C A’s project. I agree with their assessment - the work with HIV and SIV viruses should be Cat3. The use of Cat 2 with containment seems reasonable for the other viruses.
Having read both this project, I believe the work with viable HIV and SIV viruses must be undertaken in category 3 containment as should work with the animal pathogen Equine infectious Anaemia Virus.

Work with the disable systems that cannot produce viable virus can be undertaken in category 2 facilities. Where there is a change in tropism of the virus or vectors which may allow expression of potentially hazardous genetic material, this work should be carried out in category 3 containment.

Deputy Director of Environmental, Health and Safety Services.

From a CL3 point of view we are content with approval for those aspects of the work to be done at level 3. The SOPs for handling HIV and related viruses are currently being discussed and will be forwarded for Safety Office information soon. C is also preparing their COSSH assessments.

Director of the Category 3 facilities at the University

## Project Additional Information

**Purposes of the contained use**

- Analysis of the methods of replication Arenaviruses and and expression of Arenavirus proteins

**Recipient or parental organism**

- coli K12 strains (eg DH5a), E. coli B strains, Mammalian cell lines (Vero, BHK, HepG2, HeLa, MDCK, A549, BSR-T7, Huh-7 and 1321N1) and Insect cell lines (Spodoptera frugiperda - SF-9)

**Host/vector system**

- pUC based systems, pGEX, pHISTEV, pGEM-T, pSP72, pMAL-c2X and pET, pcDNA, pcAGGS, pHH21, pUC19, pTVT7R, pBac, AcPAk6, Lentivirus vectors pdl-MCS-R-puro, pdl-MCS-R-blast, plKO-MCS-puro, plKO-MCSblast, pKOTetR

**Origin & function**

- Genes whic produce proteins which interact with Arenavirus proteins, proetins which are involved in the caspase dependent and independent apoptosis pathway and genes for proteins involved in cellular - Arenavirus interactions.

**Evaluation of foreseeable effects**

- Possible risk of expression of Arenavirus proteins involved in pathogenesis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- N/A

- For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Where practicable, all waste products will be autoclaved at 121°C for 15 minutes at 15 psi. Where this is not possible, waste will be treated with 1% virkon.

**Project Additional Information**

**Purposes of the contained use**
Research into the infectivity of Plasmodium knowlesi

**Recipient or parental organism**
Plasmodium knowlesi
K12 E. coli for growing up plasmids

**Host/vector system**
K12 E coli and pHH4 and pMA

**Origin & function**
pknbpaxa and pknbpbxb - Genes related to the infectivity of Plasmodium knowlesi
More details in the attached risk assessment

**Evaluation of foreseeable effects**
There is the potential to affect the infectivity of Plasmodium knowlesi
More details in the attached risk assessment

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
The Plasmodium cells will only be allowed to grow to Merozite stage and thus cannot infect normal insect vectors. All work will be done in microbiological safety cabinets. Accidental infection will be treated with Coartem (from Novartis) which will be administered by a medically qualified person from the School of Medicine.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be treated by autoclaving at 121°C at 15psi for 30 minutes. Liquid waste will be autoclaved at 121°C at 15psi at 30 minutes where possible. Where liquid waste cannot be autoclaved, the liquid waste will be treated by 2-5% Prespt or 2-5% Virkon. All glass ware will then be washed with 5% Decon to ensure that no erythrocytes will survive

N
This work is to investigate the regeneration and plasticity of injured nervous system.

Cell lines will include PC12, RPE cells, iPS cells, rodent primary neuron cells and packaging cell lines HEK293T cells.

Vectors to be used: pcDNA3, pEYFP and similar vectors. Lentiviral vectors will include pMD2.G, pRSV-Rev, pMDLg/pRRE, pLJM, pLKO.1 Details of these vectors can be found in the attached risk assessment.

Origin & function

Neuronal growth promoting molecules including tyrosine kinase receptors (trk), Integrins - Transmembrane receptors that mediate signals between their intracellular matrix. Cell reprogramming factors eg Oct4, Klf4, Sox2, cmyc. Fluorescent proteins and epitope tags eg GFP or V5.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 317/15.3

Date Ackn’d 13/08/2015

CU2 Project Title Introduction of light switchable proteins into mammalian cells using viral transduction

Class 2

Culture Volume

Class 2 < 1 Litre
The aim of the project is to introduce a variety of light switchable proteins into mammalian cells in order to gain light mediated control over neural function.

**Recipient or parental organism**
- Prokaryotic cell lines: XL10Gold, DH5a, Stb13 and other disabled E.coli K12 strains
- Eukaryotic cell lines: HeLa, HEK293, SH-SY5Y, hNSCs (Human h9 derived), commercially available human derived iPSC lines, primary rat neurons

**Host/vector system**
- Bacterial vectors - pc-DNA3.1, pGEM-T, tol2-GFP, pDEST32, pMH14, pG and FCK plasmids
- Viral vectors - Adeno Associated Viruses (AAV)

**Origin & function**
- Channelrhodopsins, Archaeorhodopsins, ASAP1, Phytochrome based dimerizing system (PhyB-PIF), Crytochrome based dimerizing system (Cry2-C1B1), CRISPR/dCas9 gene activation repression system, fusion proteins from dCas9 and Cry2/PhyB, common fluorescent markers (e.g. GFP, mCherry, mOrange2, YFP, dTomato).

**Evaluation of foreseeable effects**
- The bacterial systems will have minimal potential effects on human health or the environment. AAV transfected human cells will have minimal effect as the genome is replicative defective requiring trans co-infection with a second helper virus to allow viable virus be generated.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Containment level 2 facilities as defined in the SACGM Compendium of Guidance

Project Ref  317/16.1

Date Ackn’d  08/06/2016  CU2 Project Title  Analysis of herpesvirus-host cell interactions

Class  Class 2  Culture Volume  ≤ 1 Litre
**Project Additional Information**

**Purposes of the contained use**

The purpose of the work is to: 'This project aims to further our understanding of infection and pathogenesis caused by CMV and, for comparison, other herpesviruses. To this end, we are studying virus-host interactions at the molecular and cellular level.'

**Recipient or parental organism**

Disabled Escherichia coli (E. coli) laboratory strains derived from E. coli K12 (e.g. DH10B, GM169, JC8111, JM109, SURE, SURE2); Disabled E. coli K12-derived laboratory strains, i.e. DH10B, DY380, EL11, EL250, EL350, GS243, GS500, GS1783, SW102, and SW105; Disabled E. coli laboratory strains derived from E. coli K12 (e.g. M15[pREP4]) and E. coli B (e.g. BL21 (DE3), BL21-CodonPlus(DE3)-RIL, Rosetta); Established, fully characterised cell lines (e.g. 293T, H1299, HeLa, NIH3T3, MRC-5, U2OS); Primary cell cultures of murine origin; Primary cell cultures of human origin; Infectious, replication-incompetent retroviruses; Recombinant CMVs

**Host/vector system**

Bacterial expression plasmids pBAD series, pET series, pGEX series, pQE series, pT-E1E2S1 (Uchimura)

Mammalian expression plasmids

Oncoretroviral transfer vector plasmids

Lentiviral transfer vector plasmids
These will be used in combination with a second generation packaging system consisting of the HIV-1 gag-pol/rev/tat plasmid psPAX2 (Addgene plasmid #12260) and VSV-G envelope plasmid pMD2.G (Addgene plasmid #12259).

CMV-BACs
- pMBO131-derived mini-F vectors carrying complete, fully functional wild-type genomes of the human CMV strains AD169, FIX/VR1814, Merlin, PAN, Phoebe, Powers, TB40/E, Towne and TR
- pMBO131-derived mini-F vector carrying the complete, fully functional genome of the murine CMV Smith strain

**Origin & function**

**Human and murine cytomegalovirus**

**Evaluation of foreseeable effects**

There is a potential for human CMV to infect workers though not to spread as it is not stable as an aerosol.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

There will be:

- Biological containment in that murine CMV will not be able to spread to humans and Human CMV will not spread to the murine population which could infect the wild population.
- All work will be undertaken in a category 2 containment laboratory. All work with infectious agents will be carried out in Class II microbiological safety cabinets. Details of full containment can be found in the attached risk assessment.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Where practicable, all waste will be autoclaved prior to disposal, at 121°C at 15psi for 30 minutes. Waste which cannot be autoclaved (e.g. large volumes of culture media) will be treated with 5% Virkon or greater for at least 12 hours prior to disposal.

**Is an emergency plan required according to regulation 20?**

**If yes, tick to confirm that it is attached to this form**

**Tick to confirm that you have attached a risk assessment to this form**

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

**Project Containment**
Project Additional Information

Purposes of the contained use

The proposed work is therefore to introduce HLA-B27 and HLA-A2 as folding and nonfolding variants into short term cultures (up to 3 days) of normal healthy subject derived human blood DC and macrophages using lenti and adeno viral constructs, and then to kill and lyse the cells for subsequent analysis by techniques such as immunoblotting and SWATH mass spectrometry. This will provide a global picture of protein pathways that are being induced by misfolded HLA-B27. In addition modulation of assembly of MHC class I will be achieved using commercially available lentiviral products with nontumour associated components of the MHC class I assembly and quality control pathway.

Recipient or parental organism
Top10: F-, mcrA, II(mrr-hsdRMS-mcrBC), ct>80lacZM15, IIlacX74, recA 1, araD139, II(araleu)7697, galU, galK, rpsL(strR), endA 1, nupG.

293T Cells: Human Embryonic Kidney T Cells.

AdenoX 293 Cells: derived from HEK-293 (Human Embryonic Kidney) stably infected with Adenovirus serotype 5. Produce viable viral vectors upon transfection with a linearized adenoviral vector or viable seed stock.

If a micro-organism, what other organism(s) (e.g. animals, plants) will the recipient strain infect?

Viral particles will be collected from the AdenoX 293 cells and from the HEK-293T cells and used to infect monocyte-derived DCs (moDCs), CD303+CD45+ pDCs, CD1c+CD141+ mDCs and macrophages.

**Host/vector system**

pMDLg/pRLRE encodes a HIV-1 Gag/Pol open reading frame (Dull et al., 1998).

Sequence: [http://www.addgene.org/12251/](http://www.addgene.org/12251/)

pRSV-Rev encodes a HIV-1 Rev open reading frame (Dull et al., 1998).

Sequence: [http://www.addgene.org/12253/](http://www.addgene.org/12253/)

pMD2.G encodes a VSV-G open reading frame (Dull et al., 1998).

Sequence: [http://www.addgene.org/12259/](http://www.addgene.org/12259/)

pRDproLF encodes an envelope protein from the RD114 feline endogenous retrovirus (Ikeda et al., 2003). See reference for sequence.

Lentivirus vector plasmids:

- pCLLhPGK-B27
- pCLLhPGK-B27.C1 01 S
- pCLLhPGK-A2
- pCLLhPGK-A2.C101S

Based on pCLLhPGK-GFP (Dull et al., 1998)

pAdeno X-CMV:

The pAdenoX-CMV (Linear) Vector is a linearized adenoviral expression vector designed to constitutively express a gene of interest in mammalian cells. The ends of the vector serve as the In-Fusion cloning site, allowing direct and rapid cloning of your gene system of interest. Expression of the gene of interest is driven by the constitutively active human cytomegalovirus immediate early promoter (PCMV IE).
pAdenoX-CMV contains a LlE1/LlE3, replication-deficient, serotype 5 adenovirus genome (Ad5) that is engineered for use in gene delivery and expression studies. The Ad5 genome is flanked by inverted terminal repeats (ITR), which are necessary for the replication of adenoviral DNA. The vector also contains a pUC replication origin and an ampicillin resistance gene (Ampr) for propagation and selection in E. coli.

pLenti based vectors sourced commercially from Origene (http://www.origene.com/destination_vector/PS100064.aspx)

Origin & function

HLA-B27:05, HLA-A2:01 and non-folding mutants of both these, with cysteine at position 101 mutated to serine.

The Human Leukocyte Antigen (HLA) is located on chromosome 6. These genes form the human version of MHC class 1 and are present on the surface of nearly every cell. These genes are highly polymorphic. In humans there are multiple HLA types expressed at once, HLA-A, -B and -C. MHC class one presents proteins found inside cells to immune cells to aid prevention of pathology and infection.

Components of the MHC class I assembly pathway such as MHC class I alleles, accessory and chaperone molecules including tapasin, calreticulin, calnexin, protein disulfide isomerase, Immunoglobulin Binding Protein (BiP). All components are not associated with tumorigenesis.

Evaluation of foreseeable effects

Competent E.coli used are non-pathogenic and therefore are not hazardous to humans. Transformation of these cells by our target genes will not increase their pathogenicity or survivability.

pAdenoX-CMV cannot replicate adenoviral vectors on its own therefore transformation into Stellar Competent cells will not cause production of adenovirus. pAdenoX-CMV is derived from pUC and is therefore non-mobilisable.

AdenoX 293 cells (Clontech): An Adenovirus serotype 5 transformed Human embryonic kidney cell line for the production of Adenoviral stocks. Stocks can be produced either by transfection with a linearized Adenoviral vector or infection with viable Adenoviral seed stock. Hazards could arise if an unintended adenovirus were to infect the cell line. This will be prevented by standard culture procedures in sterile conditions. All waste fluids or unused cells will be treated with 3% Virkon. ACDP hazard group 2.

We do not propose to use any oncogenically associated Adenoviruses.

Plasmids to construct lentiviral vector are third generation and do not produce viral particles on their own. Furthermore when combined into HEK-293T cells they will complementarily produce a fractional lentivirus as only gag, pol and rev are expressed. The particles will be non-replicatable and gag and pol are only expressed upon rev promoting their nuclear export. The only HIV genes present will be gag, rev and pol as tat has been replaced with a strong constitutive promoter. The lentiviral vector is packaged by 4 non-overlapping expression constructs, two expressing HIV proteins and the other two, one expressing the envelope of a different virus and the other containing the transgene flanked by self-inactivating (SIN) LTRs. Moreover, all HIV sequences known to be required for encapsidation and reverse transcription are absent from these constructs, with the exception of the portion of the gag gene that contributes to the stem-loop structure of the HIV-1 packaging motif. With respects to infectious virus particles, the vectors will contain self-inactivating (SIN) LTRs and therefore will be unable to replicate.

Inserted gene produces a protein that requires processing by human cells in order to be functional therefore inserted gene is not hazardous on its own or when transformed into competent bacteria. Only potential hazard from adenoviral or lentiviral vector infecting cells. However the adenovirus does not integrate into the host genome meaning
It cannot transfer between cells.

There is no evidence that HLA-B27 is involved with MS. The Adenoviral vectors do not integrate with the host cell genome. If an Adenovirus accidentally infected a human there should be no occurrence of AS unless the individual is already susceptible. The lentivirus particles can integrate into a host cell genome however they are self-inactivating therefore this would not spread to other cells. If the human cell then expressed HLA-B27 the cell would be destroyed by the immune system.

Viral products and associated products will be handled in a level 2 biological safety hood. Workers will wear double nitrile gloves and laboratory coats when using products.

There is little hazard as the genes to be inserted do not fold correctly and cannot be expressed on bacterial cells. Plasmids used are non-mobilisable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work will be done in Category 2 Containment facility. All workers will be HLA-B27 negative and will be tested for this (The named people on this application are not HLAB27 positive, and any future named persons will be tested for HLA-B27 expression by simple flow cytometry of blood obtained from finger prick test (approx. 30-50 microlitres only required.). Biological material will be autoclaved at 121°C at 15psi for 30 minutes where practicable. The disinfectants to be used will either be 2mg/ml Precept (NaDCC (sodium dichloroisocyanurate)) and also 3% Virkon (Pentapotassium bis(peroxymonosulfate)).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological material will be autoclaved at 121°C at 15psi for 30 minutes where practicable. Where this is not practicable, the following chemical disinfectants will be sued 2mg/ml Precept (NaDCC (sodium dichloroisocyanurate)) or 3% Virkon (Pentapotassium bis(peroxymonosulfate)).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Subject: Re: Notification of a GM project from SP School of Medicine
Dear P
I’ve now had a chance to read this proposal. Apologies for the delay in responding.
Overall I think the classification proposed is probably correct. I have the following Q’s.
What would happen if the worker using the engineered Ad or retrovirus is HLA-B27? Is there a danger of an autoimmune response resulting from inadvertent laboratory infection? I appreciate that many of the protein being expressed are misfolding derivatives. How is it proposed that cells expressing these are eliminated? Presumably through a cellular immune response? My immunology is sufficiently out of date that I’m not sure if T cells would be clonally deleted during development if they recognise ‘self’ (which used to be the model). If that’s the case then perhaps an autoimmune response may not happen. Alternatively, perhaps expressing the altered, misfolding, variant of the protein might be presented by a different HLA and induce a response.
I think some additional clarity on these would be useful.
It’s not clear why they keep Virkon in a glass bottle in their Class 2 hood.
Finally, presumably the Ad5 vector system they are using is somehow attenuated? That being the case the ‘hazard to human health’ may be incorrect. The implication there is that it is not attenuated. However, my reading of the relevant manuals suggests that it is a virus in which the E1 and E3 regions have been deleted – this explains the need to passage them in the Adeno-X 293 cells which provide these function in trans. That being the case the resulting recombinant Ads will not be able to replicate in the cells it infects. This needs better clarification – it’s not clear from what is written that the applicants understand the system they are using.
Regards
D

Dear P,

Please find attached the amended GMO notification form and a document in response to the questions raised by Prof. E. Furthermore, the grant for the HSE fee to be charged to is: SMDO-XCA006.

Regards,

FC
Powis Laboratory Postdoctoral Research Assistant

GMO application: The role of HLA-B27 in ankylosing spondylitis

Response to the questions raised by Prof. D. E.

Query: What would happen if the worker using the engineered Ad or retrovirus is HLA-B27? Is there a danger of an autoimmune response resulting from inadvertent laboratory infection? I appreciate that many of the protein being expressed are misfolding derivatives. How is it proposed that cells expressing these are eliminated? Presumably through a cellular immune response? My immunology is sufficiently out of date that I’m not sure if T cells would be clonally deleted during development if they recognise ‘self’ (which used to be the model). If that’s the case then perhaps an autoimmune response may not happen. Alternatively, perhaps expressing the altered, misfolding, variant of the protein might be presented by a different HLA and induce a response.

Response: This is a very good point. The observed data is that MHC class I molecules on normal cells present peptides that inevitably include some fragments derived from MHC class I molecules – since MHC class I molecules are subject to the same misfolding and degradation stresses as essentially every other protein trying to fold in the ER. You are tolerant, as pointed out, by both central tolerance (thymic deletion of autoreactive T cells) and peripheral tolerance (Treg cells and suppressive cytokines etc). If someone was infected with a virus that had a different MHC class I allele, it would be recognised as foreign and CTL, and possibly also NK cells, would kill that infected cell. This is essentially the basis of graft rejection – tissue with foreign MHC is rejected by the host immune system. This covers accidental infection of a worker.
whilst growing or infecting cells.

D does raise the next valid point – what if the person is HLA-B27 positive. The model for AS suggests that it is the increased burden of misfolding that seems unique to HLA-B27 that can push the folding machinery into cell stress and pro-inflammatory cytokine release – so would infection with a B27 virus push susceptible HLA-B27 positive people into AS? I don't think I can absolutely rule out this scenario in theory, however, the clinical observation is that AS requires years to develop, and any expression using our non-replicating virus would be unlikely to last more than a few days in any cell. Further it would likely require a massive dose of virus to infect enough immune cells capable of driving the inflammatory pathway of IL-23 (which is known to be a key driver of AS). These cells are dendritic cells, sparsely distributed around the mucosal surfaces, and it would be again unlikely to ever infect enough cells to drive into AS.

The next point is the number of people who are HLA-B27 positive. This is often stated as 6-8% in UK, but a few years ago for a CSO grant we screened 100 healthy normal volunteers in the med school and working in the Bute Building. We found only 2 positive people. I suspect the St Andrews population – with a high non-UK background typical of a University town accounted for the low percentage. So the chance of being HLA-B27, in St Andrews is lower than normal. Also, based on the 'accepted' 6-8% figure, there are almost 5 million people in the UK with HLA-B27, but the number with AS is around 150,000. So any person with HLA-B27 is at relative low risk of getting AS.

The next issue is what if someone were to accidentally inject the virus infected cells we will make in culture. This is easily resolved, the cells come from outbred normal healthy donors, so express 6 other HLA-A, B and C alleles on them in total. The host immune system would reject these cells based on the incompatibility with these 6 alleles. (To exclude all risk, identical twins will not be allowed to participate).

Perhaps the simplest way to resolve this issue that D correctly raises is to not allow anyone who is HLA-B27 positive to handle virus, or infected cells prior to lysis. Neither of the people on the application are HLA-B27 positive, and we can screen any future person that might be added to this work, using a simple finger-prick and flow cytometry of the white blood cells to determine HLA-B27 expression.

Query: It's not clear why they keep Virkon in a glass bottle in their Class 2 hood.

Response: This was from support information provided by Dr P R, the Virkon is used to flush vacuum aspirator lines and wipe any spills. We can easily replace with a plastic bottle if requested.

Query: Finally, presumably the Ad5 vector system they are using is somehow attenuated? That being the case the 'hazard to human health' may be incorrect. The implication there is that it is not attenuated. However, my reading of the relevant manuals suggests that it is a virus in which the E1 and E3 regions have been deleted – this explains the need to passage them in the Adeno-X 293 cells which provide these function in trans. That being the case the resulting recombinant Ads will not be able to replicate in the cells it infects. This needs better clarification – it’s not clear from what is written that the applicants understand the system they are using.

Response: apologies for the confusion, the Ad5 vector system is attenuated and cannot replicate in infected cells. We will alter the hazard to human health section appropriately.

GMO application: The role of HLA-B27 in ankylosing spondylitis

Dear Colleagues,
Professor E had some concerns about Dr P’s project involving the use of genetically modified organisms. In reply to these concerns, Dr P has re-written the risk assessment and also has attached their reply to these concerns. I would be grateful if you could consider the reply from Dr P. As the risk assessment has been modified I would be grateful if you could consider the modifications to this project and give your considered opinion about what category of project this would be under the genetically modified organisms (contained use) regulations 2014.
Many thanks for your co-operation in this matter.
Best wishes,
PS

Project notified under transitional arrangements N

02/03/2022
Page 6235 of 15326
There are an estimated 46.8 million people worldwide suffering from dementia. Currently, there are no disease modifying treatments for this disease resulting in a $1 trillion global financial burden. The underlying causes and mechanisms involved in Alzheimer's disease (AD) are still relatively unknown involving changes in many genes and in order to develop potential disease modifying drugs, we must investigate these underlying causes more closely and if found would have a conceivable huge global impact. The project aims to introduce genes encoding a variety of proteins involved in Alzheimer's disease into several in vitro cellular assays and manipulate their expression levels to elucidate their role in neuronal activity and metabolic pathways implicated in AD. 17βHSD10/ABAD is known to interact with both Aβ(40 and 42) a hallmark pathology of AD, leading to distortion of the native enzyme structure. In vitro experiments have shown that the interaction between 17βHSD10 and Aβ is cytotoxic with a build-up of reactive oxygen species and toxins leading to mitochondrial dysfunction. Using site-directed mutagenesis the loop-D region of 17βHSD10 was identified as the binding site for Aβ and subsequently a 28-amino acid peptide was synthesised encompassing this region, which was termed the 17βHSD10 decoy peptide. Significantly, inhibition of this interaction was also shown to translate into a cytoprotective effect in cortical neuron cell culture experiments. There is a second approach which also holds merit in treating AD; the direct modulation of 17βHSD10 activity. In vitro experiments with SHSY-5Y cells exposed to the 17βHSD10 inhibitor AG18051, showed a reduction in mitochondrial dysfunction and oxidative stress associated with the interaction between 17βHSD10/Aβ whilst also protecting cells from Aβ mediated cytotoxicity (Lim et al. 2011). Furthermore in 2014, Valasani et al. demonstrated that in cortical mitochondria isolated from mouse brain, 17βHSD10 inhibition was protective against Aβ induced mitochondrial dysfunction, respiratory function and respiration rate (as measured by swelling in response to calcium, cytochrome-c oxidase activity and ATP levels respectively). Proving that inhibiting 17βHSD10 activity is also a viable therapeutic approach for the treatment of AD. To this end lentiviral constructs will be used to create a more AD like environment and used as therapeutic screening platforms against 17βHSD10. Other experiments include investigating the metabolic profile changes in the AD systems and establishing carbon source changes and mechanisms. Each year, genome Wide Association Studies (GWAS) suggest new genes and risk factors that could be involved in AD. Recently, a new gene, FRMD6/Willin was identified as an Alzheimer's disease (AD) risk candidate (Shen et al 2013). Subsequently, FRMD6/Willin was found to be one of the upstream components of the newly emerging Hippo pathway and
can induce the nuclear translocation of a transcriptional co-activator YAP (Angus et al 2012). Preliminary data from the FGM group has shown that FRMD6/Willin is expressed in the mammalian central nervous system (CNS), notably human synaptoneurosome preparations, however its overall function has not been fully investigated in the mammalian CNS. Kibra, a protein found in kidney and brain and Merlin are also reported to be upstream regulators of the Hippo pathway at the same level as Willin (Angus et al 2012).

Importantly, KIBRA has been reported for its role in memory issues (Zhang et al 2014), while genetic mutations within Merlin gene have been linked to schwannomas (Petrilli et al 2016). In addition, YAP has been recently linked to neurite outgrowth (Jia et al 2016) and myelin development (Fernando et al 2016). Also, FRMD6/Willin was reported for its role in peripheral nerve regeneration (Moleirinho et al 2013a). All these findings imply the potential involvement of the Hippo pathway in neuronal behaviour. Furthermore, KIBRA has been extensively reported as a regular for synaptic plasticity in mammalian brain (Tracy et al 2016; Heitz et al 2016), though there is no evidence to directly show KIBRA modulates synaptic plasticity through the activation of Hippo pathway. However, considering that SNPs within Willin gene are AD risk candidates and Willin protein is found in the human synapses, it is of particular importance to investigate its potential role in the CNS. In particular we will establish both overexpression and knockdown gene expression neuronal cell line by using Lentiviruses gene delivery system.

Recipient or parental organism

Typical disabled E. coli strains (e.g. XL10 Gold, DH5alpha, Stbl3, Top10 and other commercially available strains), Standard mammalian cell lines to be used in this project include: HeLa, HT-22, HEK293, SHSY-5Y, A172 and U373 astrocyte cell lines, hNSCs (human H9-derived), commercially available human-derived iPSC lines, primary mouse and rat cortical neurons and primary mouse astrocytes.

Host/vector system

Lentiviruses can transduce both actively proliferating and non-dividing cells. Lentivirus integrate their genetic material into the host cell allowing for stable, longterm expression of the transgene. The lentiviral vectors are based originally on HIV but contain <25% of the HIV genome. They have deletions removing all of the viral genes (gag, pol, env, tat, rev, vif, vpr, vpu and nef). The vector 3’ LTR contains a deletion that inactivates both LTRs in the integrated provirus. Infectious virus particles are produced by transient transfection of the vector plasmid, a gag-pol plasmid and an envelope plasmid into 293T cells. The vectors are replication incompetent and are used under level 2 containment. Replication competent lentiviruses will not be used. For lentiviral vectors the VSV G gene is normally expressed from a plasmid (eg pMD2G) that is transiently transfected into the packaging cell. The viruses produced are replication incompetent because the gag, pol and env genes are not present in the vector genome. The lentiviral vectors are used under level 2 containment and replication competent lentiviruses will not be used. Lentiviral-producing cells will be destroyed at the end of each experiment. For reducing gene expression in cells technology systems such as shorthairpin (sh) RNA targeting gene of interest and shScramble will be cloned into pLKO.1puro lentiviral vector. pSD16 (packaging plasmid) and pSD11 (gag-pol) will be used for viral
packaging. For overexpressing the genes of interest systems such as pLenti6.4/EF1a/gene of interest or the control plasmid pLenti6.4/CMV/V5-MSGW/lacZ will be used for transduction. Viral PowerTM Packing Mix plasmids will be used for viral vector packaging. DNA plasmid will be transfected using chemical transfection (Lipofectamine or other transfection reagents) into packaging cells (HEK293) in order to generate viral particles.

Origin & function

17βHSD10/ ABAD: (or Amyloid-β binding alcohol dehydrogenase) is homotetrameric protein localised to the mitochondrial matrix, with the highest levels of tissue expression (characterised by immunoblotting) found in the brain, liver, heart, kidney and gonads. It is a multi-functional protein with main roles reported to be in fatty acid oxidation and isoleucine degradation. In AD, 17βHSD10 is found to be overexpressed in neurons and inhibiting it's activity has been shown to protect against AD relevant insults.

APP: Amyloid precursor protein, is best known as the precursor molecule whose proteolysis generates beta amyloid (Aβ), a polypeptide containing 37 to 49 amino acid residues, whose amyloid fibrillar form is the primary component of amyloid plaques a hallmark pathology found in the brains of Alzheimer's disease patients.

FRMD6/Willin: a member of the ezrin/radixin/moesin (FERM) domain-containing protein family, (Gunn-Moore et al 2005). Willin is an upstream component of the Hippo pathway which defines a signalling pathway that controls organ size by coordinating the transcription factor YAP (Angus et al 2012). Although most published studies regarding Willin have been conducted on cell lines outside the mammalian CNS, initial studies have shown that Willin along with other components of the Hippo signalling pathway (MST1/2, TAZ and YAP) are present in the adult mouse brain. Additionally, preliminary data from the FGM group has also indicated Willin and KIBRA (another upstream regulator of Hippo pathway) are expressed in human synaptoneurosome preparations of the frontal cortex from postmortem human brain tissue. KIBRA: has been intensively reported as a regulator for synaptic plasticity in mammalian brain (Tracy et al 2016; Heitz et al 2016), though there is no...
evidence to directly show KIBRA modulates synaptic plasticity through the activation of Hippo pathway. However, considering that SNPs within FRMD6/Willin and KIBRA genes are AD risk candidates and FRMD6/Willin protein is found in the human synapses, it is of particular interest to investigate its potential role in the CNS, and its potential role in synaptic plasticity.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable – There will be no use of genetically modified animals in this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Where practicable, all waste will be autoclaved at a minimum of 121°C at 15 psi for 30 minutes. Where it is not possible to autoclave waste, the waste will be treated with at least 1% Virkon. See risk assessment

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Subject: Re: Notification of a Genetic Modification Project by Professor Gunn-Moore

Dear P,

No unfortunately we did not receive these comments before Christmas, however please find attached the GM form where I have incorporated Prof Evans’ comments. All comments have been addressed except the "virkon in glass”, yes there are other options but that is just how it is done in the Medical Building, we are not based in BSRC.

Best wishes

Subject: Re: Notification of a Genetic Modification Project by Professor Gunn-Moore

Dear P,

I've read through this application from F and am reasonably satisfied with what is proposed.

The named genes to be expressed and/or shutoff are not known to be oncogenic and their expression or control under the conditions proposed should not be a problem. I am satisfied with the proposed categorisation of the studies.
I have one particular concern and it’s on the scope of the proposal. We, rightly, encourage applications with breadth to minimise trivial amendments as projects change or expand. However, the statement

In this project, any of the genes in the human genome involved in Alzheimer’s disease may be manipulated using lentiviral transduction. Examples of genes to be manipulated are:

In section iv) on page 5 seems a bit of a catch all. I don’t know how many genes this might include, but with a trait as widespread as AD I suspect that GWAS studies could turn up (or have turned up) all sorts of things. At the most extreme this statement gives carte blanche to look at anything. I don’t know how we could both reduce the breadth and allow flexibility … perhaps something about allowing ‘any gene UNLESS there was well-documented risks in terms of toxicity, oncogenesis etc.’.

They make a repeated point about destruction of lenti producer lines, but no mention of storage of the lentiviruses produced. I assume that they will do this – to avoid the need to make them repeatedly – so consider the destruction of the producer lines a bit of an irrelevance. If so, they should probably clarify the conditions of storage.

As a general point, if they’re using commercial expression systems it would help to name the supplier … I think the main expression system they are going to use is from Thermo Fisher. It makes checking these things a bit easier. This applies to all GM proposals, not just this one.

Two final points … why are they storing Virkon in glass in their category 2 hoods? I’m sure there are suitable plastics for this. Perhaps I’m wrong? Secondly, the GM proposal states that all workers with the Lenti’s will be vaccinated against Hep B. I think this should be a recommendation, rather than a requirement. There is risk associated with all vaccination. If the view of the applicant is that they MUST be vaccinated then the wording should probably be changed to something like “Only workers vaccinated etc. will be permitted to work with etc.” though this might have implications for some current staff.

Regards
D

Subject: Re: Notification of a Genetic Modification Project by Professor G M

Dear P,

I would recommend that Prof G M GM project should be category 2.

As others have mentioned in the past for other projects, if the Virkon in the biological safety cabinet can be put into a plastic bottle, then that may be preferable.

Kind regards,
M

University of St Andrews
Professor G M submitted a Notification of work with GM organisms on the 20th November 2017. To my horror I have realised that I missed this application and have not submitted to this working group for review. This is a wholly unacceptable level of service to Professor Gunn Moore and also to Dr A for which I apologise.

Please find attached the GM project application from Professor G M. I would be grateful if you could categorise this project with respect to the Genetically Modified Organisms (Contained Use) Regulations 2014. Professor G M and Dr A have categorised part of this project which uses lentiviral particles as a category 2 project. I would be grateful if you could especially review this part of the project.

Best wishes,

PS

**Project Ref** 317/18.3

**Date Ackn'd** 14/06/2018

**CU2 Project Title** The biology of Zika virus- replication and recombination

**Class** Class 2

**CultureVolClass2** ≤ 1 Litre

**CultureVolumeClass3-4**

**Non-GMM** Consent Granted

**Consent Granted** Not Applicable

**Project notified under transitional arrangements** N

Tick if notifying a connected programme of work N
Project Additional Information

**Purposes of the contained use**

We propose to investigate the replication and evolution of Zika virus using a reverse genetic approach. Infectious cDNAs for the virus have been generated in other laboratories. From these, viral RNA can be transcribed in vitro, transfected into permissive cells and the recovered virus subsequently characterised. Specifically, we are interested in the RNA structures within the virus genome that influence replication and translation. We are additionally interested in how these viruses evolve, particularly in whether the formation of hybrid or recombinant viruses is a replicative or non-replicative process.

**Recipient or parental organism**

Cell lines - Mammalian: HeLa, A549, RD (all human), Vero (nonhuman primate), BHK (hamster). Insect: C6/36 (Aedes Recipient of albopictus) and AF5 (Aedes egypti i: a clonal line derived from parental organism Aag2 cells) and AF319 (a clonal cell line derived from AF5 which have been engineered using CRISPR-Cas to be defective in expression of Dicer2 [Dcr2]). AF5 and AF319 are described fully in Varjak et al., 2017 DOI: 10.1128/mSphere.00144-17.

**Host/vector system**

E coli K12 strains DH5 JM109 HB101 Also pCC1BAC based plasmids will be maintained in E coli EP1300 cells The genotype of these bacterial cells is given in the attached risk assessment Plasmids to be used are pUC, pEMBL, pBluescript or pGEM all of which are commercially available and well characterized These bacterial plasmids will have antibiotic markers for ampicillin, chloramphenicol or Kanamycin Zika virus cDNAs are maintained in low copy numbers bacmids based on pCC1 Bac

The Zika virus cDNA will be modified by insertion of a T7 promoter and ribozymes hammerhead at the 5 prime end and hepatitis delta virus ribozyme at the 3 prime end of the cDNA as appropriate allowing efficient and high-level expression of full-length RNA in vitro RNA will be transfected into suitable
mammalian or insect cells using Lipofectamine 2000 or equivalent, or electroporated, to allow recovery of virus. Targeted CRISPR Cas knockouts of cellular genes such as XRN1 will use the pAcsgRNA/Cas9 plasmid modified by inclusion of a suitable guide RNA. Full details of this vector are available in the risk assessment.

Origin & function

Zika virus has been isolated from naturally infected humans, monkeys and mosquitoes (the latter of the genera Aedes, Anopheles and Mansonia). Antibodies to the virus have been detected in a wide range of species including domestic sheep, goats, horses, cows, ducks, rodents, bats, orangutans, and carabaos (water buffalo) suggesting that the virus is able to replicate in many species. In cell culture the virus replicates in many placental, neuronal, muscle, retinal, testicular, renal and pulmonary human cell lines. Non-human cell lines from primates, pig, rabbit, hamster, chicken and mosquito also support productive Zika virus replication.

Evaluation of foreseeable effects

None of the viral proteins are known or could be predicted to be toxins, oncogenic, allergens or modulators of growth or differentiation. This is based upon extensive analysis of the closely related Dengue virus, West Nile Virus or Yellow Fever viruses. It should be noted that there are live-attenuated Yellow Fever vaccines which are egg-adapted strains containing multiple attenuating mutations. These viruses still encode the full range of virus proteins and are not toxic, oncogenic, allergenic or known to modulate cell growth or differentiation. Zika virus does encode a cellular protease (NS3) which is a multi-functional protein with additional ATP-dependent helicase (RNA) activity. There are potentially cellular targets for this protease - either specific i.e. naturally targeted for proteolysis during the virus replication cycle - or non-specific, due to conservation of the protease cleavage site. Over-expression of the protease in mammalian cells could therefore be cytotoxic though this would be limited to the cell in which the protease was expressed. All protein expression work will be plasmid-based using non-mobilisable standard over-expression plasmids derived from pBR322-type vectors. Expression of Zika virus full-length RNA will be under control of a bacteriophage T7 promoter engineered into the appropriate region of pCC 1-SP6-ZV preceding the Zika virus cDNA (in place of the SP6 promoter already present). The expression of the fulllength RNA will only occur when purified DNA-dependent bacteriophage T7 polymerase (purchased commercially) is used in vitro with purified modified pCC1-SP6-ZV. Expression in the E.
coli host cannot occur in the absence of SP6 or T7 polymerase which are very tightly regulated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All biological material will be autoclaved at 121 oC at 15psi for 30 minutes where reasonably practicable. Where autoclaving is not practicable, 1 % virkon solution will be used for 1 hour to disinfect cultures. A 5% virkon solution will be used to disinfect spillages of concentrated virus infected cultures

Project Ref 317/19.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4
02/03/2022
Single transcription rate of 16S rRNA by Mycobacterium abscessus under different conditions

The M. abscessus Molecular Bacterial Load Assay (MBLA) uses real-time reverse transcriptase quantitative polymerase chain reaction (RTqPCR) to accurately detect and quantify M. abscessus bacterial load from patient’s sputum samples. The tool targets a variable 16S rRNA region to identify M. abscessus and uses the cycle threshold (Ct) obtained from the experiment alongside a standard curve to calculate an estimated CFU count.

The conversion of 16S rRNA Ct to CFU count is done through the use of a standard curve. This is based on several studies using different mycobacterial species, where rRNA was shown to have a correlation with cell viability. rRNA is shown to have a longer half-life than mRNA but still shorter than DNA, making it ideal as a surrogate for cell viability. It is therefore essential to better understand the rRNA and CFU/ml relationship of M. abscessus. The MBLA always uses the same standard curve regardless of the treatment of the patient. It is important to understand the impact of the currently used antibiotics on rRNA concentration within each cell, as some antibiotics might affect rRNA without having an impact of cell viability.

Moreover, to ensure the standard curve is appropriate to be used to estimate CFU/ml, variability of rRNA concentration within cells under the same condition need to be better understood.

M. abscessus unlike most bacteria has a single copy of 16S rRNA. Due to this I aim to look at the production of 16S rRNA through the use of GFP as a measure of transcription rate. This will allow me to observe the cells at a single level and study the diversity in transcription rate within a given culture. To achieve my aim the cells will be grown normally, as well as being put under stresses such as antibiotics, starvation and acidification.

Recipient or parental organism
Mycobacterium abscessus (NCTC 13031)
E. coli DH5a and E. coli SM10 Lambda pir cells

Host/vector system
pRE107 (backbone pGP704) – sequence can be found at https://www.addgene.org/43829/
sgPal1 (p2Tol-U6-sgPal1-HygR) – sequence can be found at https://www.addgene.org/71483/
sfTq2-C1 (backbone pEGFP-N1 a pUC derivative) – sequence can be found at https://www.addgene.org/117932/
The first gene to be inserted is DeGFP, a destabilized version of GFP (green fluorescence protein). It has a half-life of 2 hours, therefore due to its quick degradation it can correlate to gene transcription rate. Sequence for this gene can be found at https://www.addgene.org/14760/.

The second gene to be inserted is HygR, hygromycin resistance gene. Hygromycin is an FDA approved antibiotic food additive for swine and poultry. It is not used for humans.

The third gene is not going to be inserted into the M. abscessus genome but it is part of the vector that will be electroporated into M. abscessus. AmpR, ampicillin resistance gene (part of vector pRE107).

In the case of an internal control being necessary, two genes will be present in a plasmid electroporated into M. abscessus. One, a super folded version of CFP (cyan fluorescence protein). The second gene is kanamycin resistance gene. Kanamycin is used to treat a range of infections caused by human pathogens (e.g. Serratia marcescens, E. coli).

**Origin & function**

There are no risks with the E. coli recipient organisms as they are E. coli K12 disabled and non-colonizing host bacteria.

M. abscessus is not listed in ACDP, however Public Health England (NCTC) provide M. abscessus strains as ACDP hazard group 2. The countries which have classified M. abscessus have also assigned it Biosafety Level 2 (https://my.absa.org/tiki-index.php?page=Riskgroups&default%5bcontent%5d=ABSCESSUS).

Furthermore, M. abscessus is part of the M. chelonae-abscessus complex and is highly similar to M. chelonae. HSE have assigned M. chelone ACDP hazard group 2.

M. abscessus is ubiquitous in soil and aquatic environments. It is an opportunistic pathogen, which can cause pulmonary disease in vulnerable hosts with underlying structural lung disease, such as cystic fibrosis and bronchiectasis.

It has been implicated in various infections, usually pulmonary usually in the context of severe anatomical or immunological compromise. M. abscessus may be a commensal organisms (non-pathogen) and consequently the presence of M. abscessus in a patient's respiratory sample is not always indicative of M. abscessus pulmonary disease (PD).

Pulmonary disease caused by M. abscessus complex is challenging to treat usually because of the nature of the underlying disease. Although there is no standard treatment, current guidelines suggest the administration of macrolide-based therapy in combination with intravenously administered antimicrobial agents. There is no way to follow the response of patients to antibiotics and the relationship between laboratory tests and patient response is not well understood.

We work on several degenerative conditions for which the pathological mechanisms are not understood, but are linked by likely defects in cellular RNA metabolism. Spinal Muscular Atrophy (SMA) is an inherited form of motor neurone disease and one of the most common genetic causes of death in childhood. It results from expression of insufficient amounts of the survival of motor neurons protein (SMN). In SMA, death of spinal motor neurons leads to progressive muscular degeneration, which is the most debilitating symptom, but SMA also affects other tissue types. SMN has a number of known and predicted roles in mRNA metabolism. There is increasing evidence that similar molecular pathways may be involved in other neurodegenerative conditions such as myotonic dystrophy type 1 (DM1), which is caused by the accumulation of faulty mRNA in foci in the cell nucleus and amyelotrophic lateral sclerosis (ALS), or classical MND, which has a number of different genetic causes as well as the more common sporadic appearance.

Nuclear bodies: new insights into assembly/dynamics and disease relevance.
Sleeman JE, Trinkle-Mulcahy L.
Curr Opin Cell Biol. 2014 Jun;28:76-83. doi: 10.1016/j.ceb.2014.03.004

mRNP assembly, axonal transport, and local translation in neurodegenerative diseases.
Khalil B, Morderer D, Price PL, Liu F, Rossoll W.

We amplify plasmids in E.coli and use these to over-express tagged versions of endogenous proteins in mammalian cell lines or to reduce expression of endogenous proteins in mammalian cell lines. We use cell culture models of SMA involving reduction of SMN expression by shRNA expression in which to study cellular defects in SMA and cell culture models of DM1 expressing artificial mini-genes to mimic the faulty
RNA foci. We plan to develop cell culture models of some of the genetic types of ALS. We are also
developing techniques to differentiate commercially-obtained cells from patients with neuromuscular
conditions into neural and other cell types for further study.

https://www.addgene.org/21915/

c) Tissue culture cell lines:

Human: HeLa (and derivatives), SH-SY5Y (and derivatives), lens epithelial cell lines (various), neural cells differentiated from iPS cells in a collaborators lab, commercial myoblast lines, 293T, primary fibroblast and lymphocyte lines from patients with neurodegenerative conditions and non-affected controls from commercial sources. Our usual source for these cells is the Coriell institute, where strict quality control measures are in place

https://www.coriell.org/0/Sections/Support/Global/QCcells.aspx?PgId=409

The cells are screened for bacteria, mycoplasma and HIV.

Mouse: C2C12, embryonic stem cells, NSC34 motor neurone-like cells. All well characterised commercial lines.

**Host/vector system**

Bacterial vectors: pBluescript (for plasmid propagation only, no promoter), pGEX pGEM, pET, series (plasmid propagation only, no induction of expression). pENTR/D-Topo

Eukaryotic expression vectors: pSG5 family, pEGFP family (expression driven by CMV promoter), pJN1 and pJC3 (2A) vectors and derivatives to express multiple proteins simultaneously, pBi-tet vector and derivatives to express two proteins under a Dox inducible promotor.

siRNA vectors to express shRNAs and miRNAs in mammalian cells: pSuper family, pExtra, BLOCK-IT inducible miRNA system (expression driven by eukaryotic promoters).

Lentiviral Vectors for expression of proteins or shRNAs: pLVX-TetOne-Puro and pLKO-Tet-On

None of these are transmissible in bacteria and they do not contain prokaryotic
promoters for the inserted sequences.

**Origin & function**

Coilin: structural protein of Cajal bodies; NEAT1: structural LNC RNA for paraspeckles; Neurochondrin and other neural specific proteins including NeuroD1, Acs11, Myt11, NCDN and Pou3f2 involved in cellular differentiation. DMPK: gene containing expansion in DM1. SMN, ASF, U2AF, U2B\*, U1A, HTRA2beta, SmB, SmD1, SmD3, SmE, SmN-, U2A\*, U2B\*, U1BP1, U11/1248, 35, 20, 25 and 65, MBNL1, CUGBP1, NONO, PSPC1, FUS, SFPQ. All multi-functional RNA binding proteins, mostly constitutive or alternative pre-mRNA splicing factors. GFP- green fluorescent protein to mark transfected cells mCherry- red fluorescent protein CFP- cyan fluorescent protein YFP- Yellow fluorescent protein mini-SOG-(super oxide generator), APEX2 epitope tags detectable by light and electron microscopy PRMTs- protein methyltransferases involved in methylating proteins Cyclophilin B – mitochondrial protein used as a non-nuclear control. Luciferase- used as a control

**Evaluation of foreseeable effects**

See attached risk assessment

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All work will be undertaken in a category 2 containment laboratory at the Biomedical Sciences Research Complex at the University of St Andrews.

Biological material will be autoclaved at 121oC at 15psi for 30 minutes where practicable. The disinfectant used when autoclaving is not practicable will be 5% Virkon (pentapotassium bis peroxymonosulfate)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Head of the BSRC Building:
SMN protein modifications.
All of the E. coli modifications – whether of SMN or the panoply of other RNA-binding or pre-mRNA splicing proteins – are level 1 activities in my opinion. The host/vector combinations are well-established and will not propagate outside the laboratory. All, whether host or target, are very highly unlikely to be toxins or oncogenes. All of the lentivirus engineering work in E. coli is also a level 1 activity for much the same reasons.
The lentivirus production and use in mammalian cells is proposed as a level 2 activity. I read the paperwork for this system (https://www.takarabio.com/products/gene-function/tet-inducible-expression-systems/tet-on-3g-systems/tet-on-3g-lentiviral) and for pLVX-TetOne-Puro. Expression is doxycycline-dependent and very tightly regulated. The lentivirus particles are packaged into VSV-G envelope proteins (so will have a very broad target host and tissue range) and are based upon HIV-1. These types of vectors are widely regarded as level 2. In my view this is cautious, largely reflecting the insertion and expression of a gene that would

Safety Co-ordinator for the BSRC Building
After consideration, I would agree with E that this project is a category 2 project for the work with lentiviruses thus the project will be category 2.
S after considering this project, I believe it to be a category 2 project.
R
This is a class 2 project due to the use of lentiviral particles.

**Purposes of the contained use**

By 2050 10 million lives could be claimed a year by drug resistant infections. We must develop new strategies for antimicrobial drugs. Often in infections bacteria form biofilms, requiring concentrations of antibiotics up to 1000 fold higher to be treated. Cyclic dipeptides are molecules produced by organisms in all domains of life, and their function is unknown. They can inhibit bacterial growth and/or biofilm formation, albeit by undetermined mechanisms. The majority of the biological effects caused by cyclic dipeptides are inter-species and in some instances inter-kingdom, mediated host pathogen interactions.

We study enzymes from bacteria and fungi involved in the production of different cyclic dipeptides. We characterise each enzyme biochemically and structurally and determine their substrate scope. We will also use the enzymes to produce libraries of cyclic peptides to be tested for various biological activities.

We are also interested in peptide/protein chemistry more generally, and work with transferases and proteases enzymes that are important for protein quality control and maintenance, as well as response to stress.

Six bacterial species have been identified by the Infectious Disease Society of America (IDSA) as being especially dangerous due to their potential multidrug resistance mechanisms and virulence. They are referred to as ‘ESKAPE’ pathogens, which is an acronym for Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa and Enterobacter species. Our work is focused on understanding basic biology, virulence and adaptations to stress in ESKAPE pathogens in the context of peptide/protein metabolism. We are mainly focused is P. aeruginosa and S.aureus but this work will set the stage to compare gram positive and gram negative bacteria more broadly in future work.

Cover the name of the strain of micro-organism(s) and/or animals and/or plants should be provided, as well as the name of the wild-type organism from which it is derived and the extent to which it is disabled. - Strains derived from Pseudomonas aeruginosa PA14 - https://www.phe-culturecollections.org.uk/products/bacteria/detail.jsp?collection=nctc&refl&NCTC%2013619

### Recipient or parental organism

1. UCBPP-PA14 (commonly referred to just as PA14) Wild Type
2. Laat deletion — gene PA14_30270
3. Δate deletion — gene PA2618
4. E aat Date double deletion
5. taat + Prha aat integrated at Tn7 recombinase site — contains a rhamnose inducible promoter controlling expression of aat gene.
6. ate + Prha ate integrated at Tn7 recombinase site — contains a rhamnose inducible promoter controlling expression of ate gene.
7. GFP-PA14 — gene for green fluorescent protein constitutively expressed.

Future work will involve additional deletions of genes encoding putative cyclodipeptide synthases and proteases. It will include similar mutations/deletions in other ESKAPE pathogens. More specifically:

7. Derivatives of Staphylococcus aureus NCTC 12232
8. Derivatives of Acinetobacter baumannii NCTC 12156
When handling bacteria, use good laboratory practice and wear appropriate laboratory coats, protective eye wear and gloves. A Hazard Group 2 organism may cause human disease and may be a hazard to laboratory workers, but is unlikely to spread to the community as it is more likely to only infect severely immunocompromised people. Persons must not be immunosuppressed or taking immnosuppressive medication when working with bacterial pathogens. Checks will be made to ensure any staff/students working in the lab are not immunocompromised or taking immnosuppressive medication.

Purposes of the contained use

Zinc is an essential micronutrient that is required for many biological processes including control of coagulation. When platelets become activated, they release zinc, which in turn binds to plasma proteins and cell surface receptors to regulate the clotting. Currently we do not understand how zinc gets into platelets, how it is stored or how these processes may be altered in diseases associated with abnormal clotting. Elevated plasma free fatty acid (FFA) levels are associated with conditions such as cancer, obesity and diabetes, which also increase the risk of developing thrombotic blood clots. Our studies suggest that the high levels of FFA disrupt zinc handling in the blood potentially leading to thrombotic complications. Here we will examine where zinc is stored in platelets and will characterise the zinc transport machinery involved in controlling platelet zinc flux. Finally, we will look at how zinc and elevated plasma FFAs contribute to platelet functioning.

At present we lack a complete picture of which zinc transporters and/or channels contribute to Zn2+ homeostasis in platelets. In humans there are 24 ZnTs/ZIP transporters, with most cell types possessing multiple transporters. We will extract mRNA and synthesise cDNA to perform an RT-PCR expression screen using gene-specific primers to determine which zinc transporters are present. From this, we anticipate around 10-15 transporters being expressed and relative mRNA expression of those identified will be determined using qPCR (relative to RPLPO housekeeping gene). As validation in human platelets, antibodies directed against 5-6 of the most abundant transporters will be sourced. Suitable antibodies will be used to determine relative protein expression of each in Zn2+-treated (20 pM)/untreated platelets. The antibodies will also be used to determine the localisation of specific transporters (in combination with organelle probes) in platelets. Of particular interest is to determine which transporter(s) is responsible for movement of Zn2+ into a-granules. If we can identify a candidate ZnT for this function then we will follow this up by examining Zn2+ accumulation targeted shRNA knockdown and CRISPR/Cas9 knockout of the relevant transporter(s) in human Meg-01 megakaryocyte-like cells.

Platelet calcium dynamics will also be examined in 96-well plate format (in the presence/absence of zinc and FFAs) using an established method that utilises the Fluo 4 Ca2+ probe. Additionally, knockout and knockdown of calcium transports/channels and the effect on calcium dynamics within platelets will be evaluated. Our preliminary data shows MG23/TMEM109 is highly abundant in platelets. To our knowledge this is the only ER-located Ca2+-permeable channel. Therefore, we will block IP3R using the specific inhibitor, xestospongin C to determine flux. Importantly to complement this, we also require to knockdown and/or knockout MG23/TMEM109 in Meg-01 megakaryocyte-like cells using shRNA and CrispR/Cas9, respectively and examine how agonist-mediated Ca2+ dynamics in these cells is affected.

Transfection of Meg-01 and other megakaryocyte-like cells is difficult using nucleofection/electroporation or lipid-based transfection agents. To date, successful transfection of these cells has only been reported through use of lentiviral delivery. For these experiments we will use commercially available pre-prepared lentiviral particles. We will not be propagating lentivirus in the laboratory ourselves.

Cardiomyocytes also have high abundance of MG23/TMEM109. MG23/TMEM109 may play a key role in disease progression mechanisms in heart failure and affect calcium leak from the sarcoplasmic reticulum (a major Ca2+ store within cardiomyocytes). Pathophysiological (>1 nM) levels of cytosolic Zn2+ can also potentiate MG23-channel activity. Therefore calcium and zinc dynamics will be evaluated in cells targeted with shRNA knockdown and CRISPR/Cas9 knockout of the relevant calcium, zinc and MG23/TMEM109 transporter(s).
Recipient or parental organism

(i) List of recipient strain(s)
Cover the name of the strain of micro-organism(s) and/or animals and/or plants should be provided, as well as the name of the wild-type organism from which it is derived and the extent to which it is disabled.

- Standard mammalian cell lines will be used in this project and include:
  - Megakaryocyte/Megakaryoblast and similar cell lines (such as MEG-01 - ATCC: CRL-2021, DAMI - ATCC: CRL-9792, K-562 — ATCC: CCL-243)
  - Cardiomyocyte and similar cell lines (such as H9c2(2-1) — ATCC CRL-1446)
  - HEK293 and derivative cell lines (such as HEK 293T/17 — ATCC CRL-11268)
- Primary Cardiomyocytes and Megakaryocytes/Megakaryoblasts
- Commercially available human-derived iPSC lines

(ii) If a micro-organism, what other organism(s) (e.g. animals, plants) will the recipient strain infect

Retrovirus
VSVG pseudotyped lentiviral vectors can infect cells from many mammalian species, including human and mouse cells. Replication incompetent retroviral vectors will have been used.

Host/vector system

pCRISPR-LvSG03 and similar premade CRISPR lentiviral particles
psi-LVRu6GP and similar premade shRNA lentiviral particles

Disabling mutations:
1. A deletion in the enhancer of the U3 region of 3′LTR which ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.
2. The RSV promoter upstream of 5′LTR allows efficient Tat-independent production of viral RNA, reducing the number of viral genes that are used in this system.
3. The commercially generated lentiviral particles will be replication-incompetent. None of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal. Therefore, the lentiviral particles generated are replication-incompetent.

Origin & function

In this project, any of the genes in the human genome involved in calcium and zinc dynamics maybe manipulated using lentiviral transduction. Examples of genes to be manipulated are:

- Zinc Transporters (ZnT) 1-10. These transporters control the efflux of zinc from the cytoplasm out of the cell and from the cytoplasm into vesicles
- Zrt- and Id-like proteins (ZIP) 1-14. These transporters control the influx of zinc into the cytoplasm from outside the cell and from vesicles.
- Mitsugumin 23 (MG23/TMEM109). A voltage-dependent, cation-conducting channel localized to the sarcoplasmic/endoplasmic reticulum and nuclear membranes in a wide variety of cells.
- Calcium channels and transporters (such as the inositol trisphosphate receptor and sarcoplasmic reticulum Ca2+-ATPase)

Various manipulation techniques using lentiviral transduction will be used. These include:

- shRNA knockdown
- CRISPR/Cas9 knockout

Additionally, genes maybe introduced for cell selection and visualization of infected cells by fluorescence microscopy. Examples of these genes include:
Evaluation of foreseeable effects

Hazards associated with the recipient organism (e.g. bacterial host or viral vector, animal, plant etc)
Factors to consider include whether the recipient microorganism is listed in ACDP hazard groups 2, 3 or 4. Other relevant factors may be the microorganism's mode of transmission, disease symptoms, host range, and tissue tropism as well as an indication as to whether vaccines or chemotherapeutic agents are available. Information should also be provided on any disabling mutations and whether there is any possibility of any disabling mutations being complemented or reverting. If an animal or plant, are these organisms inherently dangerous (e.g. toxic plants, production of allergens etc)
The lentiviral vectors are based on HIV (ACDP 3). Lentiviral vectors contain <25% of the HIV genome. A deletion in the enhancer of the U3 region of 3'LTR which ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.
The RSV promoter upstream of 5'LTR allows efficient Tat-independent production of viral RNA, reducing the number of viral genes that are used in this system.
The commercially generated lentiviral particles will be replication-incompetent. None of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal. Therefore, the lentiviral particles generated are replication-incompetent. The vectors are normally used under level 2 containment (ACGM guidelines 2B-III-26 for lentiviral vectors). Replication competent lentiviruses will not be used.
(ii) Hazards arising directly from the inserted gene product (e.g. cloning of a toxin gene or oncogene)
Consideration should be given to whether the inserted DNA encodes a toxin, an oncogenic protein, an allergen, a modulator of growth or differentiation (hormone or cytokine) or any other protein, which may result in potentially harmful biological activity. Where the function of the inserted gene is unknown, it may help to describe the function of any known homologues. Please note that even a normal human gene may be harmful if overexpressed, especially if the overexpression is in tissues that do not normally express the protein.
eGFP and mCherry have no known harmful effects. The other human genes or shRNAs/CRISPR/Cas9 listed have no immediate toxicity but are potentially oncogenic. Known or suspected oncogenes, or shRNAs inactivating tumour suppressor genes, will not be cloned into replication competent vectors. Expression of oncogenes or inactivation of tumour suppressor genes by RNA interference (expression of shRNA) using retroviral vectors can result in stable transformation of human cells. The best studied case is transformation of human fibroblasts and mammary epithelial cells (Rangarajan, A., Hong, S. J., Gifford, A., and Weinberg, R. A. 2004, Species and cell type-specific requirements for cellular transformation. Cancer Cell 6, 171-183). To achieve quantitative transformation, multiple changes were required, including expression of telomerase, SV40 large T antigen (targeting p53 and Rb), SV40 small T antigen (targeting PP2A), and an oncogenic mutant of ras (targeting Raf, PI3K, and Ras-GEFs). Transformation of human cells is thus difficult, even with the most potent oncogenes expressed from the most efficient gene transfer vectors (amphotropic retroviruses in this case). A laboratory accident in which the same human cell in a laboratory worker was simultaneously or sequentially infected with multiple retroviral vectors is almost inconceivable under level 2 containment save as a malicious act (essentially, deliberate injection of a mixture of viruses). Gene therapy trials have shown that it is a great deal more difficult to stably express a gene in a human individual than was naively expected based on cell culture experiments. Gene therapy for single gene defects like cystic fibrosis, muscular dystrophy or haemophilia has given no successful long term reconstitution of gene expression, despite the use of a wide range of vectors injected in amounts many orders of magnitude greater than could ever occur in a laboratory accident. A critical factor in the failure of gene therapy has been the immune response to the transgene. Unlike clinical vectors, all laboratory vectors contain, in addition to the primary transgene, antibiotic resistance genes which are non-human and
will provoke a strong immune reaction. There is now evidence from gene therapy trials showing what sort of measures are required to produce malignant disease in vivo in humans. Three patients in a French gene therapy trial have developed leukaemia. All were treated ex vivo with a retrovirus expressing a gene required for lymphocyte proliferation. Because of the nature of the disease, these were the only lymphocytes that could divide when reinfused into the patient. There was thus a massive expansion of the transduced cells, coupled with a lack of any immune response to the vector or transgene. This constellation of events could not conceivably arise in any laboratory accident.

(iii) Hazards arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response)

One factor to consider is whether the inserted gene encodes a pathogenicity determinant, such as an adhesin, a penetration factor or a surface component providing resistance to host defence mechanisms. Another important consideration is whether the inserted gene encodes a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by the recipient microorganism. Consideration should also be given to whether the inserted DNA (or the plasmid sequence) encodes resistance to a drug or antibiotic that might be used for the treatment of a laboratory-acquired infection. If an animal or plant, will the inserted gene affect the tropism of human pathogens, will the modified organism act as a new 'reservoir' for a human pathogen etc.

Genes conferring resistance to puromycin, neomycin and hygromycin are used to select human cells transduced with retroviruses. The presence of antibiotic resistance genes in all commonly used retroviral vectors lessens the risk of retrovirus-infected cells surviving in the human body because the immune system recognizes the transduced cells as foreign and kills them.

(iv) The potential hazards of sequences within the genetically modified organism being transferred to related organisms

Factors to consider include whether widespread dissemination of the inserted gene as a result, for example, of either gene transfer or recombination of the GMM with a wild-type microorganism, would be a matter of concern. If this is the case an important consideration will be whether, in the event of a breach of containment could the genetically modified organism could survive in the environment for long enough for such a gene transfer to take place. Retroviruses are enveloped viruses that are rapidly inactivated in the environment. For these experiments we will use commercially available pre-prepared lentiviral particles. As viral particles will be used, there will be no issues of plasmid recombination. However, infection by the viral particles — even with an "empty vector/ no gene" viral particle - is potentially oncogenic due to genome insertion of the plasmid DNA.

(v) Any other relevant information.

Lentiviral vectors:

Lentiviral vectors are used to stably express foreign genes in cells that are difficult to infect with oncoretroviral vectors, including non-dividing cells and primary human cells. The lentiviral vectors are derived from HIV. HIV is a retrovirus which has the same basic structure as simple oncoretroviruses, with the addition of the accessory genes tat, rev, vif, vpr, vpu and nef. The general approach is similar with lentiviral and oncoretroviral vectors: the vector DNA is transcribed into RNA and packaged into infectious particles in a packaging cell. For these experiments we will use commercially available pre-prepared lentiviral particles. No RNA or DNA for any viral gene is present in the infectious particle. The infectious particles contain viral proteins including the enzymes necessary for reverse transcription and integration, so that the vector can be converted back into DNA and stably integrated into the genome of the target cell after infection. Since lentiviral vectors are derived from HIV, safety was the primary concern during development of the vectors. Maps of the described vectors can be found on https://www.genecopoeia.com/. Some viruses contain two expression cassettes, the first for a transgene (eg GFP under a CMV promoter), the second for a selectable marker (eg the puromycin resistance gene, pac, under an SV40 promoter). The expression cassette may contain a 0111 promoter (U6 or H1), which is used to express short hairpin RNAs (shRNAs) for RNA interference.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Where practicable, all biological waste will be autoclaved at 121°C at 15psi for 30 minutes.
Non-autoclavable waste will be treated with 2% Virkon for at least 1 hour. Spillage will be dealt with by applying 5%
Virkon to the spillage and leaving for 1 hour.
Autoclaved waste or 5% Vorkon treated solid waste will be sent for incineration using the company Tradebe.

Members of the Chemical and Biological Hazards Management Group (which acts as the University Genetic Modifications Safety Committee under the Genetically Modified Organisms (Contained Use) Regulations 2014) have stated:
- YES category 2 project,
- It's a class 2 project in my opinion. Thanks,
I would suggest category 2 for this lentiviral project. Kind regards

### Project Additional Information

#### Purposes of the contained use

These studies will help understand how Pseudomonal aeruginosa causes human disease and thus may allow the development of more effective therapies.

#### Recipient or parental organism

The hosts used are: 1) Pseudomonal aeruginosa. This is a human pathogen, classified therefore as Class II but as outlined above only infects the immunocompromised, patients with cystic fibrosis and those with severe burns. 2) Some constructs will be cloned with the aid of K-12 derived Escherichia coli derivatives. These are metabolically disabled and hence classified Class I. In addition, as they lack type III secretion system, they cannot introduce the cloned Pseudomonal toxins into human cells.

#### Host/vector system

Vectors: We will use pUC based vectors for cloning in E. coli which are mobilisable. We will use as pUC based series of bacterial vectors, termed pUCP, for expression in Pseudomonas; this is driven by the native promoter of the toxins. These vectors cannot readily be transferred to other bacterial species from Pseudomonas.

#### Origin & function

Origin of the genetic material. Genes for the exoS, T, U and Y proteins and their cognate chaperones will be derived by PCR form naturally isolated organisms, or directly from other researchers, again isolated form naturally occurring microbes. Activities of the inserted genetic sequence and of the product. The secreted toxins can produce cell death when introduced intracellularly. They have no oncogenic activity. We will also use antibiotic resistance genes to select for the introduced material in Pseudomonas. These genes are already extremely well spread in naturally occurring Pseudomonads, and thus do not represent an increase in the difficulty of treating Pseudomonal infection.

#### Evaluation of foreseeable effects

Given that the genetic modifications proposed do not alter the intrinsic pathogenicity of this organism, there is no greater risk to human health from the GMMOs than from the naturally occurring microbe. Infection is extremely unlikely to occur in immunocompetent, well individuals exposed to environmental Pseudomonas Aeruginosa. In the laboratory, the application of good laboratory practice reduces this risk even more.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Strict waste management will be implemented. Liquid waste will be decontaminated by treatment with 1% hycolin and left for 15 minutes. This waste will then be disposed of via designated sinks. We have validated that this treatment effectively kills all microbes in the waste. Solid waste will be treated by autoclaving at 123 degrees C for 15 minutes in autoclaves within our building. These autoclaves deal with the clinical waste produced by the hospital microbiology department, and are maintained and validated as providing effective microbicidal action on a regular basis.
The GMSC agreed that this was clearly a Class 2 project. Professor Evans had previously submitted this notification for approval as a class 2 project to GMSC GM31 at Imperial College, London, and also provided the CU2 form and risk assessment from this previous submission. Professor Evans had in effect transferred this project to Glasgow. Notification as a Class 2 Activity to HSE was required.

# Project Additional Information

## Purposes of the contained use

The aim of this project is to generate replication-deficient retroviral and lentiviral vectors that express either established/potential oncogens or shRNA constructs from RNA interference libraries. This will enable the expression of these constructs in target cell populations, followed by selection/identification of these cells based on either the target gene or reporter construct. The goal of this project will be to identify factors that result in cellular processes that cause tumourigenesis of target cells, which may ultimately enable a route for therapeutic intervention.

## Recipient or parental organism

Recipient or parental organism:

Human Primary Cells: Embryonic stem cells - H1, HUES9; Mesenchymal stem cells and CD133+ adherent stromal progenitor cells; Mononuclear cells from peripheral blood PBMCs), bone marrow and cord blood - from normal healthy donors and lymphoid, myeloid and stem cells derived from PBMC's; Endothelial cells derived from umbilical and peripheral vessels; Leukaemic cells derived from consented leukaemia patients.

Cell lines: HL-60, K562 (BCR-ABL=), KG1a; HEK 293T (cells for lentiviral production); AAV-HT1080 (Human fibrosarcoma cell line, for viral titration); PT-67; Phoenix - Amphi.

## Host/vector system

Retroviral Vectors: MIEV, MIGR-1, MSCV-1GFP, pSUPER.Retro, pSUPER.retro.GFP. The retroviral vectors used in this set of studies are derived from the Murine stem Cell virus (MSCV). The genes involved in viral replication, gag, pol, and env have been removed from the retroviral genome, thus ensuring that the retroviral vector is unable to replicate and infect surrounding cells.

Lentiviral vectors: pHIV-7-GFP, pCMV-Rev, pCMV-G, pCHGP-2, pCMV-HIV-1, pLVX-AcGFP1-N1 (or-C1). The gene delivery system which conserve only three of the nine genes of HIV-1 relies on four separate transcriptional units for the production of transducing, offering significant advantages for its biosafety.

## Origin & function

### Human PKC-α, -β-δ-ε-ζ-Θ-Ι-λ unmutated, deletion mutants and full length point mutations

### Human VASP and deletion mutants

### Mouse Notch family mutants and Notch-related proteins

### Small G protein Ras, unmutated, deletion mutants and full length point mutations and related proteins

### Raf kinase, unmutated, deletion mutants and full length point mutations and related proteins

### HoxB4-ERT2 tamoxifen-inducible cassette

### AKR1C3, BCR-ABL, AML (RUNx1), SCL, COX2, ABCG2, BMI-1, PGDS

A number of these genes are confirmed proto-oncogenes (eg. Runx1, Ras, BCR-ABL), and more are potential oncogenes.

### siRNA constructs to all of the above inserts, such as:

- pHIV-7-GFP-sh-SP1 (lentiviral vectors expressing short hairpin RNA against Bcr-Abl)
- pHIV-7-GFP-sh-SP2 (lentiviral vectors expressing short hairpin RNA against Bcr-Abl)

These constructs could potentially behave as tumour suppressors.

## Evaluation of foreseeable effects

Generation of Retroviral supernatants from amphotropic cell lines:

Plasmids encoding the retroviral constructs will be transfected into the packaging cell lines Phoenix-Ampho or RetroPak-PT-67 to produce amphotropic retrovirus. Theses helper free cell lines contain gag, pol and env genes encoded by two separate plasmid expression vectors both of which lack the retroviral cis-acting packaging signal to minimise the likelihood of replication competent virus arising through a single recombination event thus minimising the risk of spread to personnel or the environment.
Transfection into the packaging cell line provides these gene products, permitting production of infective virus. At this stage the virus is capable of infecting human cells, however, further production of virus from an infected cell is extremely unlikely, since the virus lacks the gag-pol and env genes. In the packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney promoters, therefore, removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent. As a result they do not pose a risk to human health or the environment. A risk of minor localised infection does exist when handling the packaged infection virus, and as the inserts may possess a proto-oncogenic effect all steps will be taken to prevent this by using the appropriate level of containment and inactivation procedures - hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

Lentiviral vectors

Parental wildtype lentiviruses are hazard group 3 biological agents. However, third generation lentiviruses can be used at a lower level (Containment Level 1 or 2) depending on the activity and due to the extreme disablement of the vector system. The inserts are biologically active, and may possess a proto-oncogenic effect. The final GMMs are therefore disabled lentivirus vectors capable of expressing high levels of candidate therapeutic genes. A risk of minor localised infection does exist when handling the packaged viral supernatant, therefore all steps will be taken to prevent this by using the appropriate level of containment and inactivation procedures - hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets with appropriate protective handling considerations.

Virally-infected cells will be injected into mice within a category II hood within the Central Research Facility (CRF). Containment and control measures are considered as follows:
- The cells cannot propagate outside the mouse;
- New viral particles cannot be generated from the transduced cells as the viral vectors are replication-competent;
- Host-mouse cells cannot become infected as a result of inoculating the mouse with cells transduced with the vector, as it only delivers the gene of interest and the marker protein GFP and there is no establishment of a pro-virus within these cells, therefore making it extremely unlikely that the left over viral sequences could be rescued by endemic viruses encoded by the host mice leading to cycles of replication;
- Expressed protein may be oncogenic, therefore close attention will be paid to the mice as set out in the home office licence governing this work;
- Exposure to aerosols is minimised by performing all procedures in a category II hood;
- Needlestick injuries will be minimised by training all personnel as required in the home office licence and needles will be used with extreme care and never re-sheathed.

Medical advice will be sought in the unlikely event that a needlestick injury occurs;
- The facility has double doors and animal containment doors to minimise the chance of escape, therefore the chance of animal escaping into the wild is extremely unlikely. However if this were to happen and breeding occurred with a wild type population of mice there would be no transfer of the introduced genetic material as it is not germline expressed;
- Minimal risk to humans from adventitious agents and no environmental hazards envisaged.

If the nature and volumes of the virus to be used and the inserts involved, there will be minimal risk of harmful effect in the unlikely event of human exposure. The likelihood of animals coming into contact with any virus particles is zero. Safe disposal is assured through autoclaving and incineration of all animal carcasses.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

There is a risk of minor localised infection when handling the viral supernatant, therefore all liquid culture waste materials will be incubated overnight in 1x Chloros or Virkon solution before discharging to the sink. All solid waste will be washed with Chloros or Virkon solution before being double bagged in yellow bags and treated as clinical waste (incineration). Contaminated sharps (syringes) will be disposed in sharps bins and treated as clinical waste.

The likelihood of animals coming into contact with any virus particles is zero due to the fact that they will be inoculated with cells that are virally transduced with replication deficient virus. However, safe disposal is assured through autoclaving and incineration of all animal carcasses.
The risk assessment was considered at a meeting of the GM Centre 318 safety committee on September 3rd 2008. The committee consists of experts in genetic modification activities representing all departments within the Faculty. The risk of assessment was approved as a Class 2 project unanimously by the committee.

The risk assessment was considered at a meeting of the GM Centre 318 safety committee on September 3rd 2008. **Significant Change ID**
Anaerobic fluorescent protein is a non-toxic fluorescent protein similar to GFP isolated from Aequorea victoria but without the requirement for oxygen to form its fluorophore. It is routinely cloned into microorganisms to provide a means of visual tracking by observed fluorescence. Neither the gene, nor the expressed protein are considered hazardous and will not confer pathogenic properties onto the host organism. Anaerobic fluorescent protein expression by P. gingivalis will allow for fluorescent imaging of bacteria in vitro and in disease models.

OVA peptides and Hen egg lysozyme are non-toxic proteins isolated from Gallus domesticus and are routinely cloned into microorganisms and routinely used as model antigens in immunology. P. gingivalis expressing these proteins will be used to elucidate immune responses to this bacteria.

Evaluation of foreseeable effects

P. gingivalis is a non-motile, obligate anaerobe and a pathogen of both humans and mice where it's proliferation in the oral cavity results in chronic inflammation leading to gum and bone destruction. The organism mediates disease through several virulence factors such as haemolysins, a polysaccharide capsule, Proteases known as gingipains and a variety of other host targeting enzymes. Genetic modification of this bacteria with the suggested inserts will not increase the hazard to human health as the gene products are not expected to increase virulence of the bacterium.

The genetic constructs inserted into the chromosome confer ampicillin resistance to allow for selection of transformants. However, as this is not the antibiotic of choice for eradication of P. gingivalis it doesn't increase the capacity of the organisms to infect or survive within an exposed individual. Moreover, exposure to wild type (wt) P. gingivalis is unlikely to result in infection without prior depletion of the oral microbiota in susceptible individuals and the GMMO will not have an enhanced ability to infect over the wt. The recipient strain is potentially capable of colonizing the oral cavity of humans and animals, however, this is highly unlikely as for successful colonization as the existing oral flora must be first depleted with antibiotics, followed by repeated swabbing of the teeth to introduce the exogenous strain. Our strain poses no additional threat compared to the bacteria wt. The organisms will not be hazardous to the environment and the gene sequences have been inserted into the chromosome of P. gingivalis using double homologous DNA recombination and are non-mobilisable, prohibiting horizontal transfer of the recombinant DNA. The gene products of the genetic material are non-toxic and will not pose any hazard to human health or alter the virulence of the organism. The genetically altered host organism will not be more or less hazardous than the wild type. There will be no change in oncogenicity, pathogenicity or tropism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The organism poses a risk to human health should inoculation and proliferation in the oral cavity occur. However the organism is unlikely to find a microbiological niche.
Within the microbiota of healthy individuals without prior treatment with antibiotics, to deplete the resident bacteria, followed by repeated swabbing with greater than 10^9 bacteria/dose. Repeated exposure with lower numbers of bacteria does not result in infection in predisposed mice and although the potential exists that infection could occur, the risk is low. If an infection were to occur following exposure then treatment with amoxicillin or a similar broad-spectrum antibiotic would eradicate the GMMO. The GMMO is also susceptible to chlorohexidine mouthwashes which could be used to assist in resolution of infection. Staff/students on a current course of antibiotics should take special precaution while working with the microorganism. In the in vivo PD model it is possible that an animal bite may occur and result in exposure to P. gingivalis at the wound. P. gingivalis is not associated with pathology in humans without the oral cavity, however the potential exists that the organism could survive in necrotic tissue and it has been isolated from both infected and uninfected ulcers of the skin but has not been linked with pathology. Oral or topical broad-spectrum antibiotic use would be an appropriate to eradicate the microorganism in this situation. However, P. gingivalis has not been reported as a causative organism in wound infections and although a theoretical risk exists it should be considered very low. Containment and control measures detailed in the generic GM animal risk assessment will be followed, with special considerations as detailed below:

- Infection of animals will be carried out using good aseptic technique to avoid environmental contamination and to reduce the potential for cross infection.
- Needlestick injuries will be minimised by training all personnel as required in the home office licence and needles will be used with extreme care and never re-sheathed. Medical advice will be sought in the unlikely event that a needlestick injury occurs;
- The facility has double doors and animal containment doors to minimise the chance of escape, therefore the chance of animal escaping into the wild is extremely unlikely. In the event of escape, the spread of infection is extremely unlikely.
- Safe disposal is assured through autoclaving and incineration of all animal carcasses.

All work with GM animals within Biological Services facilities at University of Glasgow is performed to Class 2 containment levels.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For small volume spills, hard surfaces will be disinfected by blotting with absorbent tissue paper and spraying the surface with a 1%w/v Virkon solution, leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towels will then be bagged for disposal as solid waste (below). If spillages come into contact with users affected items (gloves, lab coats, other items) will be treated as for solid waste. All spills will be reported to the appropriate departmental safety officer for the location of the spill. Solid waste (e.g. agar plates containing bacteria) is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. When the lines are no more than 3/4 full, they are removed from the bin, loosely sealed with autoclave tape, labelled with lab number, operator and date and then transported to the autoclave room. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM', which results in their inclusion on a 'run' on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. On that basis the autoclaved material is disposed of in solid waste; removed by authorised waste-disposal specialist companies. The record is kept on file by the autoclave room staff. The routine autoclave regime will be 126°C for 30 min, which has previously been established to produce a 100% kill. Liquid waste from cultures will be sterilised in the culture flasks the same day by addition of Virkon® to a final concentration of 1%w/v, and left overnight, Virkon-disinfected solutions will be disposed of into the waste water supply. Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v Virkon® overnight. Animal carcasses and bedding will be processed as special waste. Thus, if necessary, will be held at -20°C and marked as 'GM'. Storage in this condition will prevent further bacterial growth prior to autoclave, or immersion in virkon (1% w/v) overnight. Carcasses and bedding will then be disposed of through incineration by an authorised waste disposal company, provided through biological services, or as per the guidelines in Biological Services Generic Animal Appendix. Animal cages will be decontaminated by immersion in virkon (1% w/v)

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]
The Risk Assessment (attached) was submitted to the GM Safety Committee Meeting for consideration in December 2011. The RA was considered appropriate. Specifically, there was detailed background to the project and management of activities provided. It was noted that a very specific environmental status is required in the oral cavity to enable establishment of an infection, however the parental microorganism is ACDP Class 2 and since these GMOs were of equivalent virulence it was deemed that Class 2 containment was appropriate. The applicants make specific reference to highlighting issues to staff on the project with respect to being on concurrent antibiotic treatment while working with these GMOs. However, the RA clearly deals with appropriate management and mitigation of risk with all activities planned.

Purposes of the contained use

The aim of this project is to construct and use genetically modified influenza viruses that will allow us to track the virus following infection or track the immune response that the virus generates. The overall aim of our research is to characterise more fully the immune response to influenza virus immunity by vaccination.

The GM influenza virus will be used to infect GM mice that have been approved for use by the local GM committee: GM Centre- 318 Risk Assessment reference numbers: 318/027, 318/030, 318/34, 318/35, 318/36, 318/42, 318/46, 318/48, 318/60, 318/62, 318/63, 318/64, 318/66, 318/67, 318/76, 318/79

Recipient or parental organism

Virus vectors: Established laboratory strains of influenza A virus will be used, namely: A/WSN/33 (H1N1) [WSN] and A/Puerto Rico/8/34 (H1N1) [PR8]

Host/vector system

Plasmid vectors: Viral sequences (e.g. full-length clones of influenza viruses, partial sequences, or sequences of influenza virus ORFs), as well as sequences of other genes (e.g. common genetic reporters such as RFP or GFP) are available in cDNA form or will be generated by RT-PCR. Sequences will be sub-cloned into appropriate DNA plasmids such that RNAs can be transcribed from bacterial promoters (e.g. T7 or SP6), eukaryotic promoters (e.g. CMV, SV40, cellular Poll promoters, cellular RNA Poll promoters), or viral promoters. Plasmids for expression of influenza virus RNA segment sequences will typically contain an RNA Poll promoter and a hepatitis delta virus ribozyme or a mouse RNA Poll terminator. Plasmids contain an origin of replication and a prokaryotic selectable marker (e.g. drug resistance to neomycin or puromycin).

Prokaryotic host cells: Bacterial strains used to propagate plasmids will all be commercially available disabled E. coli derivatives classified as ‘especially disabled hosts by ACDP’.

Eukaryotic host cells: Vertebrate cell-lines of various host species origin will be used (typically canine, or murine), primary murine cells will also be used.

Mice: either mice bred in our facility or purchased from vendors (e.g. Harlan and Charles River) will be infected with the virus in our animal facility

Origin & function

The WSN and PR8 viruses were originally isolated from humans in 1933 and 1934 respectively. The viruses have been propagated in cell lines (in the majority of cases a canine cell line, MDCK) fo many years. The wildtype WSN and PR8 viruses to be used in these studies was provided by Dr B H, Centre for Virus Research, GU. The WSN-OVA-II will be provided by Prof T, Rochester New York, USA.

The viruses have not been attenuated, they replicate normally or potentially less well than the wild-type virus as the addition of genes to small RNA viruses can affect their replication. The modifications we will make, addition of fluorescent or epitope tags, will not make the virus more virulent.

Evaluation of foreseeable effects

Virus vectors: Established laboratory strains of influenza A virus will be used, namely A/WSN/33 (H1N1) [WSN] and A/Puerto Rico/8/34 (H1N1) [PR8]. These viruses are predicted to be antigenically similar to components of the currently available seasonal human influenza vaccine.

Influenza virus typically infects airway epithelial cells, therefore, the most likely route of transmission is via the formation of an aerosol that is then inhaled by the operator. The virus could also be ingested or enter via a splash to the eyes or mouth. The modifications that will be made will not alter the route of viral transmission nor will they increase the virulence of the virus.

Human influenza is typically a non-serious self-limiting infection in otherwise healthy adults, generally acquired by the respiratory route. Severity of infection depends on the strain of virus and health status of the host, but in general tends to fall within a spectrum of asymptomatic to ~1 week of fever and malaise. The laboratory strains of influenza virus which will be used here (PR8 and WSN), are known to be avirulent in humans from volunteer challenge studies and have a >70 year history of safe laboratory use.
The majority of humans are expected to have at least some prior immunity to circulating human influenza viruses such as H1N1, H3N2, and influenza B virus. Immunity to these strains will provide a degree of protection to other HG2 influenza viruses. To boost any natural immunity, all staff handling influenza viruses are offered the annual seasonal influenza vaccine.

Severe illness due to human influenza viruses can occur but is extremely rare, occurring in less than 1% of cases, and is always associated with underlying health conditions such as pregnancy, Immunosuppression, asthma, or other respiratory/chronic diseases. Anyone who might have compromised resistance to disease for any reason (such as pregnancy or immunosuppression) is required to inform the PI and seek advice from the University Occupational Health Advise regarding the need for additional precautions.

Plasmid vectors: Viral sequences (e.g. full-length segment clones of influenza viruses, partial sequences, or sequences of influenza virus ORFs), as well as sequences of other genes (e.g. common genetic reporters such as RFP or GFP) are available in cDNA form or will be generated by RT-PCR. Sequences will be sub-cloned into appropriate DNA plasmids such that RNAs can be transcribed from bacterial promoters (e.g. T7 or SP6), eukaryotic promoters (e.g. CMV, SV40, cellular PolII promoters, cellular RNA Pol promoters), or viral promoters. Plasmids for expression of influenza virus RNA segment sequences will typically contain an RNA PolII promoter and a hepatitis delta virus ribozyme or a mouse RNA PolII terminator. Plasmids contain an origin or replication and a prokaryotic selectable marker (e.g. antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic marker (e.g. drug resistance to neomycin or puromycin). These strains can only survive in a controlled laboratory environment and good microbiological practice should prevent release of viable organisms. These bacteria will be handled at CL1, which is routine practice. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Prokaryotic host cells: Bacterial strains used to propagate plasmids will all be commercially available disabled E. coli derivatives classified as 'especialy disabled hosts' by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic host cells: Vertebrate cell-lines of various host species origin will be used (typically canine, or murine), primary murine cells will also be used. Cells to be used would not survive inside the human body due to immune rejection. Addition of NA, RNA or infection will confer no growth or survival advantage to cells either inside or outside the laboratory.

Either mice bred in our facility or purchased from vendors (e.g. Harlan and Charles River) will be infected with the virus in our animal facility. Infected mice typically clear the virus in 8-10 days post-infection. Live virus is only found in the lungs of infected animals, therefore lungs represent the only source of potential infection. Live animals are very unlikely to transmit virus to humans as influenza infection in mice does not cause sneezing. Isolated infected lungs can pose an infection risk if cell/tissues are handled such that aerosols are generated.

Were the mice to escape from containment, it is unlikely that they would survive long enough to breed with the native population and transfer of the modified influenza virus would be extremely unlikely (naive mice housed in the same cage as infected animals do not become infected).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated fluids/liquid waste (eg. Virus samples, culture supernatants, tissue culture media) and contaminated disposable plasticware (e.g. flasks, tubes, pipette tips) is collected immediately into a >1% Virkon (w/v) solution within the MSCII and left to inactivate fully for a minimum of 12h. Small plasticware is submerged in the Virkon, whilst large flasks are filled with >1% Virkon and the outside surface is disinfected with 70% ethanol. Decontaminated plasticware is disposed in lab autoclave waste bins. Gloves used fo virus work are disinfected with 70% ethanol before putting in autoclave containers.
Autoclaving
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Other
Infected animals are housed in filter cages. In the majority of cases, infected mice clear the virus in 8-12 days post-infection. In all cases bedding and animal carcasses will be autoclaved and incinerated.

Project Ref 318/15.2

Date Ackn'd: 14/07/2015

Use of Candida albicans to infect mice, including genetically modified Candida albicans that may express chicken egg ovalbumin protein (C.alb-OVA).
The aim of this project is to use the Candida albicans fungal strain to allow us to analyse the initiation of innate and adaptive immune responses to fungal infections. Infection of cultured cells and mice with C.alb will enable us to determine mechanisms by which the immune system recognises and responds to fungal infections. Experiments with infected mice will include some where the use of CD4+ T-cells that specifically recognise and respond to OVA-protein will allow us to determine the specific mechanisms by which the immune system recognises and responds to fungal antigens. This project proposes to use C.alb and the C.alb-OVA strain to investigate immune mechanisms induced after infection with fungi, including investigating T-cell mediated mechanisms of immune regulation that are dependent on recognition of fungal antigens.

Recipient or parental organism

Candida albicans, including Candida albicans expressing ovalbumin will be used to infect mice.

Host/vector system

C. albicans strains will be obtained from UK collaborator. No further genetic modification will occur in this project.

Origin & function

The C. alb and C.alb-OVA will be obtained from collaborators at the University of Aberdeen, who have extensive experience in experimentation with C.albicans. C.alb-OVA has been genetically manipulated to specifically express the protein ovalbumin (OVA). The intended function of this is to stimulate C.alb-specific immune responses in vitro and in vivo. In some experiments, the immune response will be analysed using OTII (T-cells) cells that specifically recognise OVA. OTII cells will be adoptively transferred into mice alongside C.alb-OVA infection and subsequent C.alb-specific T-cell responses measured.

Evaluation of foreseeable effects

Pathogenicity in C.albicans is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, the genetic modification of C.albicans to express OVA protein is highly unlikely to increase C.albicans virulence. Furthermore, this C.albicans strain that has been cultured in other laboratories tends to display reduced pathogenicity compared to strains carried commensally by most individuals. The ectopic expression of OVA will be <1% of total cell protein. The ectopic expression of OVA is unlikely to influence virulence at all, and may in fact be expected to reduce C.albicans virulence by adversely affecting growth. OVA expression will also have no benefit in allowing the organism to survive, establish, disseminate with or displace other organisms. The probability of increasing virulence by ectopic expression of a single gene/protein is very low, because pathogenicity is complex and is a polygenic trait requiring a high level of fitness of the C.albicans cells.

The risk of infection of wild mammals (such as rodents) through accidental release of C.albicans or due to escape of infected animals is low because to succumb to such infections, immunocompetent animals must be injected intravenously with relatively high infective doses (<10^4 CFU/g body weight). Mice infected with C.alb-OVA in this...
study will be sacrificied within one week of infection, preventing any severe adverse effects which may be associated with long term candida infection.

C.albicans is a human pathogen which can cause superficial infections of mucosal epithelia, but will only cause systemic infections in severely immunocompromised individuals. C.albicans is carried commensally by at least 60% of the healthy population and most infections arise as an overgrowth of strains already resident in the normal microflora. It is a microorganism of low pathogenic potential that rarely infects human individuals. it only becomes a medical problem in individuals whose immune responses are significantly impaired. Only small amounts of Candida will be used in these experiments (mostly 10^6, rarely 10^8 Candida cells per animal). A healthy human individual would clear these doses from their bloodstream within minutes, therefore risk of infection from the bite of an infected animal is minimal.

Either mice bred in our facility or purchased from vendors (e.g. Harlan and Charles River) will be infected with C.alb in our animal facility. Infected mice will be sacrificed within one week of infection. Live animals are very unlikely to transit the infection to humans as C.albicans is widely distributed and carried commensally in at least 60% of the healthy population. Most candida infections arise as an overgrowth of the strains resident in the normal microflora. Only small amounts of Candida are used in these experiments (mostly 10^6, rarely up to 10^8 Candida cells per animal). A healthy human individual would clear these doses from their bloodstream within minutes. Lab workers are unlikely to be exposed to the following factors which increase the susceptibility to systemic Candida infections:

1) Use of cytotoxic or strongly immunosuppressive drugs
2) Use of catheters/any intravascular prosthetic device
3) Age (very young or very old individuals are more prone to infection)
4) Serious trauma, particularly when the abdomen is involved
5) Abdominal surgery
6) Immunosuppression
7) Long term use of antibiotics.

Lab workers will be made aware of these risk factors and are asked specifically to make their supervisors (or Occupational Health) aware if they are exposed to the risk factors mentioned above. Potential routes of entry into the body include orally, or via cuts, grazes and lesions in the skin, or via the bite of an infected animal. Appropriate clothing must be worn and a strict code of personal hygiene must be followed. Use of sharps should be carried out carefully, with two people involved in holding and injecting to minimise risk of accidents and animal bites.

The risk of infection of wild animals from accidental release of C.alb-OVA or from infected animals is low as immunocompetent animals must be injected intravenously with relatively high infective doses (<10^4 CFU/g body weight) for successful infection. The ectopic expression of OVA protein does nor result in any phenotypic or genetic instability, and Candida has no effective mechanism for horizontal gene transfer that might allow dissemination of genetically modified traits to other organisms.

I acknowledge that the guidelines in the GM Rodent Generic Appendix are sufficient to safely handle and house mice infected with the proposed genetically modified strain of C.albicans (C.alb-OVA).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Under Home Office regulations mice infected with genetically modified C.albicans (C.alb-OVA) will be subjected to an approved Schedule 1 method of humane killing and disposed of by an approved method.

Disinfection
Disinfection to be carried out using 1% Trigene/Distel TM307 which is known to be effective against fungi.
Autoclaving

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

OR

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using chemical indicators (e.g., Browne TST indicator test strips).

Contaminated sharps must be disposed of in sharps bins reserved for this purpose. Any fungal cultures remaining should be destroyed by autoclaving. Any animal samples from infected animals will be disposed of by autoclaving before. Waste from infection suites will be removed from the room in autoclave bags and autoclaved.

Is an emergency plan required according to regulation 20?  N

Please enter comments on the GM safety committee on the risk assessment:

This RA was reviewed by the committee members of GM318 in June 2015, one committee member proposed changes that should be made to the risk assessment with regard to ensuring that animals which received the GM candida albicans were appropriately assessed as GM organisms themselves. The proposer duly edited the submitted RA to incorporate these important aspects. The RA was then approved at containment level class 2.

Project Ref 318/16.1
The aim of this project is to employ transgenically modified reporter Streptococcus pneumoniae to dissect the pathogenesis of experimental murine meningitis and sepsis, and to investigate the generation of antigen-specific immune responses during infection.

Genetically modified Streptococcus pneumoniae strains have been generated in Liverpool by the Kadioglu group. The proposed studies will allow us to apply in vivo imaging and immunological methods developed in Glasgow to track the migration and interactions of bacteria and immune cells.

Recipient or parental organism

Streptococcus pneumoniae strains, including lab-adapted strain D39 serotype 2, but also other clinically relevant serotypes such as 1, 3, 4, 5, 6B, 19F etc., were labeled with a fluorescence protein markers commonly known as green fluorescent protein (or GFP), and red fluorescent protein (or tagRFP), using previously published procedures (Kadioglu et al. 2001 FEMS Microbiol Lett., 194(1): 105-110, Beilharz et al. 2015 Appl Environ Microbiol 81(20):7244-52). The generation of the required reporter gene constructs and subcloning of the insert into the vector plasmid were carried out by the Kadioglu group at the University of Liverpool, under GM554/14. The constructs were expressed in DH5alpha cells before transformation of Streptococcus pneumoniae.

Host/vector system

Vector plasmid-GFP1: the integration construct is erythromycin resistant. For more detail, see below and in: Kadioglu et al. 2001 FEMS Microbiol Lett., 194(1): 105-110

Vector plasmid pKB01_tagRFP: Expresses tagRFP (codon adapted for Streptococcus pneumoniae); under control of Zinc inducible promoter PZn. Plasmid (chloramphenicol resistant) integrates in S. pneumoniae bgaA locus by double cross-over. For more detail, see below and in: Beilharz et al. 2015 Appl Environ Microbiol 81(20):7244-52.

Mice: either mice bred in our facility or purchased from vendors (e.g. Harlan and Charles River) will be infected with pneumococci in our joint research animal facility.

Project Additional Information

Purposes of the contained use

The aim of this project is to employ transgenically modified reporter Streptococcus pneumoniae to dissect the pathogenesis of experimental murine meningitis and sepsis, and to investigate the generation of antigen-specific immune responses during infection.

Genetically modified Streptococcus pneumoniae strains have been generated in Liverpool by the Kadioglu group. The proposed studies will allow us to apply in vivo imaging and immunological methods developed in Glasgow to track the migration and interactions of bacteria and immune cells.
The plasmid pGFP1 contains gfp in the shuttle vector pVA838. The gene, for the mut 3 variant of GFP, was excised as a BamH1–Sph1 fragment from pKEN2, and ligated into pVA838, previously cut with BamH1 and Sph1, to generate pST1. Expression of gfp is from an uncharacterised pneumococcal promoter, isolated from a library of pneumococcal DNA in pST1. Chromosomal DNA was isolated from pneumococcal clinical isolate CCUG10175 (University of Göteborg Culture Collection). DNA was digested with Sau3a and fragments between 0.2 and 2 kb ligated into dephosphorylated BamH1-digested pST1.

RFP gene was first fused to the Zn2-inducible promoter PZn, resulting in construct pKB01-PZn-RFP. The zinc-inducible promoter was then replaced by the competence-induced promoter PssbB, resulting in plasmid pKB01-PssbB-RFP, which was excised from pLA18 using SphI and EcoRI and introduced into pKB01-RFP plasmids cut with the same restriction enzymes.

To produce large amounts of recombinant plasmids, the library was first electroporated into Escherichia coli DH5a. Plasmid DNA was isolated from all transformants and then the pooled DNA used to transform wild-type pneumococcus lab-adapted strain D39, using competence-stimulating peptide. Pneumococcal transformants were selected on Brain–Heart Infusion agar containing erythromycin (1 mg/ml, GFP label) or chloramphenicol (0.2mg/ml, RFP label).

New transformants, containing new fluorescence reporters (particularly infra red shifted fluorescent proteins with enhanced optical performance in vivo), but with the same characteristics as the GFP/RFP transformants above, may be generated in Liverpool for use in Glasgow.

**Evaluation of foreseeable effects**

*Streptococcus pneumoniae* is a microorganism commonly found in the normal upper respiratory tract flora. The fluorescently-labelled pneumococci will be created on a D39 background, a commonly used non-human pathogenic laboratory strain. The genetically altered host organism will not be more or less hazardous than the wild type. There will be no change in fitness, virulence or tropism.

The antibiotic resistance genes chosen to screen for the recombinant pneumococci are not themselves harmful. In addition, selection during our experiments will require antibiotic levels in excess of 50 µg/ml in order to overcome the inherent resistance of the strains. These are levels in excess of any that would be of therapeutic use. Inserting fluorescent markers does not affect fitness or confer any additional virulence. Previous studies have shown the insert DNA to be stable within prokaryotic expression systems.

The green fluorescent protein gene, originally isolated from the jellyfish *Aequorea Victoria*, is routinely cloned into microorganisms to provide a means of visual tracking by observation of the expressed GFP. Neither the gene, nor the expressed protein, are considered hazardous and will not confer pathogenic properties onto the host organism.

Similarly, RFP is a red fluorescent reporter initially derived from the Sea Anemone *Entacmaea quadricolor*. It is optimised for excitation/emission at longer wavelengths, significantly improving confocal and multiphoton imaging. Neither the gene, nor the expressed protein, are considered hazardous and will not confer pathogenic properties onto the host organism.

Current literature suggests that the human upper respiratory tract is the sole niche of *S. pneumoniae* and, thus, that spread occurs via close contact with an infected individual e.g., saliva and respiratory droplets. Therefore, *S. pneumoniae* is not likely to survive in the event of a breach of laboratory containment. The only hazard that might be relevant in this scenario would be the transfer of antibiotic resistance genes to other bacteria. However, this potentiality is very low. The strain will have no plasmid DNA, hence, for gene transfer to occur a series of very low frequency events would have to take place. The transformation was designed such that fluorescent markers such as GFP or RFP are stably integrated into the chromosome and cannot excise or reform.

Other than those hazards intrinsic to *S. pneumoniae*, there are no foreseeable environmental hazards represented by the genetically modified microorganisms described herein.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Either mice bred in our facility or purchased from vendors (e.g. Harlan and Charles River) will be infected with pneumococci in our animal facility. Naïve mice housed in the...
same cage as infected animals do not become infected. However, as a precautionary measure against the unlikely event of transmission between cages, mice infected with pneumococci will be housed in individually ventilated cages (IVC).

Were the mice to escape from containment, it is unlikely that they would survive long enough to breed with the native population and transfer of the modified pneumococci would be extremely unlikely. Similarly, live animal are extremely unlikely to transmit pneumococci to humans, as pneumococcal infection in mice does not induce any forms of sneezing or coughing.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposal of waste materials:

Solid waste is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. When the liners are no more than ¾ full, they are removed from the bin, loosely sealed with autoclave tape (to allow steam penetration during autoclaving), labelled with lab number, operator and date and then transported to the autoclave room on a trolley. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM', which results in their inclusion on a ‘run’ on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. On that basis the autoclaved material is disposed of in solid waste; removed by authorised waste-disposal specialist companies. The record is kept on file by the autoclave room staff. The routine autoclave regime will be 126°C for 30 min, which has previously been established to produce a 100% kill.

Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Liquid waste will be sterilised the same day by addition of Virkon® to a final concentration of 1% w/v, and left overnight. Virkon-disinfected solutions will be disposed of into the waste water supply. Virkon 1% (w/v) solutions are stable for up to 7 days, and thereafter disinfectant solutions will be discarded (the pink colouration fades). (Virkon is a peroxygen compound and disinfection requires a contact period of at least 10 min for 1% w/v solution: see http://www.antechh.com/frameset.html).

Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v Virkon® overnight (polypropylene and polystyrene centrifugation buckets, steel and glass are not corroded by 1% w/v Virkon). Glassware and buckets will then be rinsed in tap-water and dried.

Virkon is extensively used and validated for a large range of disinfection procedures, including medical and laboratory procedures, see: http://www.antechh.com/frameset.html.

Animal carcasses and bedding. These will be autoclaved before disposal. Thus, if necessary, waste will be held at -20°C and marked as ‘GM’. Carcasses and bedding will then be disposed of as conventional biological services waste.

Is an emergency plan required according to regulation 20? 

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
The risk assessment was reviewed by GM Centre 318 safety committee in July 2016 and approved after revision. The committee consists of experts in genetic modification activities representing all departments within the Faculty. The risk assessment was approved as a Class 2 project by the committee and was assigned GM reference number GM318/202.

### Project Additional Information

**Purposes of the contained use**
To evaluate the therapeutic potential of selectively replicating ('oncolytic') virus vectors in human cancers, especially ovarian cancer
To modify and amplify wild-type and deletion mutant oncolytic virus vectors already produced in this laboratory or in the lab of other researchers

**Recipient or parental organism**

The recipient cell lines HEK293, A549, JH293 and Vero will be used. All are commercially available cell lines. Human and murine carcinoma cell lines (especially ovarian cancer lines).

**Host/vector system**

Oncolytic adenoviruses (deletion mutants) and wild-type adenoviruses
Oncolytic herpes simplex virus with deletions in the neurovirulence gene ICP34.5

**Origin & function**

Mammalian genes that are deleted or inserted into the viral genome and have been chosen to perform their intended function: either to increase tumour-specific killing by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways, or to increase the immunogenicity of infected tumour cells. Documentation exists to indicate that this can be achieved safely. No wild-type oncogenes or direct toxins will be inserted.

**Evaluation of foreseeable effects**

The deletions induced in viral vectors are designed to narrow the host range, so that there is reduced replication and killing within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.
Replication-deficient adenoviruses are incapable of replication in cells lacking adenovirus E1 function. Infection of normal human cells as well as malignant cells results in no infectious virion production. The tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated.
The replication competent adenoviruses used will contain mutations within the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. All oncolytic herpes simplex viruses used have ICP34.5 deletion, which dramatically reduces neurovirulence in both human and mice.
The deletions occur in regions of the viral genome that are necessary for replication in normal cells and are complemented by the altered gene expression in cancer cells. The deletions induced in viral vectors are designed to narrow the host range, so that there is reduced replication and killing within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Full containment level 2 will be used, as set out in the Regulations, including appropriate treatments for bulk, contaminated solid waste.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be used, as set out in the Regulations; i.e. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorised staff, including appropriate treatments for bulk, contaminated solid waste.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral supernatants and spent medium will be inactivated using 10,000 ppm free chlorine before removal from the Containment Level II laboratories for final disposal. This process will result in 100% inactivation of infectious virus.
Solid waste will be bagged in biohazard bags prior to removal from the Containment level II lab and then placed in boxes which are sealed prior to removal from the CL2.
suites. Boxes remain sealed and are autoclaved before the contents is removed for collection by accredited waste contractors. Autoclaves produce a digital record of load temperature achieved and are validated by annual thermocouple mapping. This process will result in 100% inactivation of infectious virus. Solid animal waste and animal carcasses, including used cages/soiled mouse bedding, will be bagged in biohazard bags prior to removal from this Containment level II virus room and then autoclaved before collection by accredited waste contractors.

This RA was reviewed by the committee members of GM318 in June 2018. The applicant made requested modifications to the risk assessment. The risk assessment (which is enclosed) was then passed by the committee at Class 2 with reference number 318/217.

## Project Additional Information

### Purposes of the contained use

The aim of this project is to investigate how the immune system responds to a range of viral challenges, focusing on migration of immune cells. This will generate fundamental insights in basic biology, and benefit development of drugs against pathogens relevant for human and animal health.

We will use either virus or virus-like particles (VLPs) depending on the pathogen and research question. VLPs resemble viral particles, but cannot propagate as they do not contain all required genetic material. Therefore they cannot replicate beyond the first round of infection. This makes VLPs a safe alternative to study early events during viral infection. We will study the immune response to 3 different groups of viruses:

1. mosquito-transmitted viruses, which are an increasing threat to human and animal health
2. rabies VLPs, a safe alternative to study early replication and host response to rabies, which kills at least 55,000 people every year
3. polyomavirus, which are harmless in healthy individuals but can cause severe disease in people who are immune compromised, for instance because of co-infection with other viruses, or immunomodulatory treatment such as for multiple sclerosis.

### Recipient or parental organism

We will use a variety of cell lines and primary cultures derived from humans, rodents and arthropods. Wild type or genetically modified mice will be inoculated with the described viruses and VLPs.

### Host/vector system

1. mosquito-transmitted viruses: We will focus on Togaviridae (mostly Semliki Forest Virus), Flaviviridae, and Bunyaviridae. For most of these, plasmids with the full genome, including mutant variants with reporter/immune modulatory inserts are available.
2. Rabies VLPs: Cell lines/plasmids containing the rabies Glycoprotein gene, and separately a plasmid containing the other rabies genes, including mutants with reporter/immune modulatory inserts, which together result in VLPs. If cells are infected with these VLPs, the new viral particles they make lack the glycoprotein which is essential to enter cells.
   As such, these “bald” virus-like particles cannot infect new cells, and are only infectious for a single round of infection.
3. Polyomaviruses: Plasmids containing viruses such as BK and JC virus, which can be used to make virus in permissive cell lines.

### Origin & function

1. Mosquito-transmitted viruses: virus genetic material is derived from viral RNA, possibly altered to investigate impact of the viral genes on the immune response. Genetic markers, for instance encoding fluorescent proteins to trace viral replication, can be inserted in these viral genomes. Additionally, mammalian and/or arthropod genes, or (complementary) microRNA sequences can be inserted to investigate the impact of these on viral replication, dissemination, host immune response and pathology.
2. Rabies VLPs: Viral genomes originate from wild type and lab strains. Additionally genes as described for mosquito-transmitted viruses can be inserted to trace viral replication, or investigate the host immune response.

3. Polyomavirus: Currently no genes can be inserted in these viruses.

Evaluation of foreseeable effects

1. Mosquito-transmitted viruses: Based on extensive use in many labs including ours shows that the proposed safety measures are suitable to protect workers and the environment. Insertion of genetic markers/other additional genes slightly reduces the ability of the viruses to replicate. Some of these viruses can be neurotropic, and we will not change the structural viral genes that may make the viruses more neurotropic in humans. For mouse-infections, mosquito-transmitted viruses are not airborne and as their vectors are not indigenous in the UK, they do not readily transmit between animals in the wild.

2. Rabies Virus-Like Particles: As these VLPs upon infection do not generate infectious virus, this is a very safe alternative to using rabies virus. We have stringent measurements to prevent genetic recombination that could theoretically result in restoration of replication. Importantly, we do not have complete rabies virus which could increase the risk of recombination. Rabies VLPs cannot produce infectious progeny virus and are therefore by nature not transmissible between animals.

3. Polyomaviruses: the human polyomaviruses to be used in this study have very high prevalence in the general population (seroprevalence >50%) and healthy individuals do not experience any clinical signs or symptoms when infected. We will also use a mouse strain which does not infect humans. Polyomaviruses already circulate in feral mice, and lab strains only cause disease in very young or immunodeficient mice. Murine polyomavirus does not replicate in human tissues and thus the risk of contamination is very low. Infection of mice (including GM mice) with the described viruses/VLPs is not expected to result in a survival advantage of mice. The mouse strains we work with do not have a competitive advantage over wild type mice, and are likely to be severely compromised in the wild. None of the genetic alterations in our mice have been associated with improved breeding. Mice infected with these viruses will be kept in designated areas with extra safety measures such as special cages with virus filters to prevent infected animals from spreading GM viruses to other animals.

Our safety measures, which include thorough training of staff, where necessary working in class II biological safety cabinets, wearing PPE such as lab coats and gloves, and suitable disinfection and autoclaving of waste will reduce the likelihood of exposure to an extremely low level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All experiments will be performed at containment level 2 as described in the Regulations:
- infection and dissection will be performed in designated areas, in case of aerosol-transmissible viruses/VLPs in class II safety cabinets. Live infected mice will be held in special filtered or individually ventilated cages to prevent transmission to other mice or humans.
- access to buildings to be worked in is restricted to authorised staff, who are trained to work with mice.
- suitable waste management is in place, infected material and carcasses will be autoclaved before leaving the properties.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2 will be used for all GMM work; virus generation and infection will be carried out in Class II safety cabinets in containment level II laboratories, appropriate waste disposal is established within the building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus-infected liquid and disposable solid waste will be inactivated using Virkon (minimum 1% final concentration) before removal from Containment Level II laboratories. Solid waste will subsequently be double-bagged in biohazard bags and autoclaved locally (121°C for 30 minutes) before either landfill or if hazardous, uplifted and incinerated by an accredited company.

Solid animal waste and mouse carcasses (including soiled mouse bedding) will be bagged and autoclaved locally before collection by accredited waste contractors. Cages will be autoclaved and washed before reuse.

Degree of virus inactivation:
Chemical Sterilization by Virkon: effectively 100% kill.
Autoclaving: effectively 100% kill. Autoclaves are tested annually, and each run is monitored by digital recording of temperature/time profile.
This GM RA was reviewed in April 2019 by the local GM committee GM 318, upon which the applicant made the requested modifications of the risk assessment in response to comments from the committee. The GMRA was approved by GM318 on the 8th May 2019.

### Project Additional Information

**Purposes of the contained use**

Confidentiality claim - please see section 17.

The aim of the project is to assess the ability of a number of biological active genes to reduce blood pressure, cardiac hypertrophy and other phenotypic changes associated with hypertension in the SHRSP animal model.

**Recipient or parental organism**

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (McGorry, WJ Bautista, DS and Graham, FL: A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative.

All AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is rendered replication-defective by addition of a gH-herpes vector. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is rendered replication-defective by addition of a gH-herpes vector.

In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore the natural topism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use. AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immnogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is rendered replication-defective by addition of a gH-herpes vector.

None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

**Host/vector system**

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans), replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by go-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus).
adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective.

Origin & function
The adenoviral vector DNAs are standard and originated from the laboratory of Dr Frank Graham (McGory, W J Bautista, DS and Graham FL: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vivo to generate high-level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All transgenes will be constructed from full length cDNAs obtained from other research institutes and verified in our own laboratory prior to subcloning into the relevant vectors.

Evaluation of foreseeable effects
There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. Consequence of environmental exposure - 'effectively zero'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.

Purposes of the contained use
The aim of this project is to restrict the tropism of adenoviral and AAV vectors. Currently, both these vector types poorly tranduced vascular cells in vitro and in vivo, but

02/03/2022 Page 6302 of 15326
AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette. Targeting ligands will be incorporated into fiber-deleted vectors as described by von Seggern (Von Seggern DJ, Huang S, Fleck SK, Stevenson SC, Nemerow GR. Adenoviruses vector pseudotyping in fiber-expressing cell lines: Improved transduction of Epstein-Barr virus-transformed B cells. JOURNAL OF VIROLOGY 74: (1) 354-362 JAN 2000). E1 deletion renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwes, M., et al. High-titer AAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). Targeted AAV vectors will be prepared using published methods are produced by replication-defective AAV vector particles (Giord A, Ried M, Wobus C, Lahm H, Leike K, Kleinschmidt J, Deleage G, Hallek M. Genetic capsid modifications allow efficient re-targeting of adeno-associated virus type 2. Nature Medicine. 1999;5:1052-1056). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette. Targeting ligands will be incorporated into fiber-deleted vectors as described by von Seggern (Von Seggern DJ, Huang S, Fleck SK, Stevenson SC, Nemerow GR. cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. The system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH- herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary University of Glasgow. AAV vectors are replication defective.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr Bert Vogelstein (He, T-C., Zhou, S., de Costa, L.T., Kinzler, KW, Vovelstein, B. A simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus.

The targeting ligands (small peptides) have been isolated by phage display technology for their ability to bind vascular endothelial cells in vitro and in vivo. These peptides are selected for incorporation into the Ad and AAV vectors for tropism modification of viral vectors.

Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01 of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.

Consequence of environmental exposure - ‘effectively zero’.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Historical Significant Changes PROJECT TRANSFERRED FROM GM 397 (26/10/07)

Project notified under transitional arrangements Y
Purposes of the contained use

The aim of this project is to restrict the tropism of adenoviral and AAV vectors. Currently, both these vector types poorly transduced vascular cells in vitro and vivo, but are highly permissive for transduction of non-vascular cells. We will use small targeting ligands (peptides) to develop tropism modified adenoviral and AAV vectors and test the ability of these modified viruses to provide cell selective gene transfer in vitro and in vivo. All adenoviral vectors will express reporter genes.

Recipient or parental organism

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the AdEASY system (He, T-C., Zhou, S., de Costa, T., Kinzler, KW, Vogelstein, B.A. simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. Targeting ligands will be incorporated into fiber-deleted vectors as described by von Seggern (Von Seggern DJ, Huang S, Fleck SK, Stevenson SC, Nemerow GR. Adenovirus vector pseudotyping in fiber-expressing cell lines: Improved transduction of Epstein-Barr virus-transformed B cells. JOURNAL OF VIROLOGY 74: (1) 354-362 JAN 2000). E1 deletion renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use. AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating ampiclon and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). Targeted AAV vectors will be prepared using published methods are produce replication-defective AAV vector particles (Girod A, Ried M, Wobus C, Lahm H, Leike K, Kleinschmidt J, Deleage G, Hallek M. Genetic capsid modifications allow efficient re-targeting of adeno-associated virus type 2. Nature Medicine, 1999;5 1052-1056). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10^69 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.
Host/vector system

The adenoviral vectors are generated by recombination in vitro and shuttle vectors containing transgene expression cassette and flanking E1 sequences (He, T-C., Zhou, S., de Costa, LT., Kinzler KW, Vogelstein, B. A simplified system for generating recombinant adenoviruses PNAS. 95:2509-2514, 1998). Following transfection into helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper function necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow, AAV vectors are replication defective.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr Bert Vogelstein (He, T-C, Zhou, S., de Costa LT., Kinzler, KW, Vogelstein, BA simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors; Girod A, Ried M, Wobus C, Lahm H, Leike K, Kleinschmidt, Deleage G, Hallek M. Genetic capsid modifications allow efficient re-targeting and of adeno-associated virus type 2. Nature Medicine. 1999;5: 1052-1056) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). The targeting ligands (small peptides) have been isolated by phage display technology for their ability to bind vascular endothelial cells in vitro and in vivo. These peptides are selected for incorporation into the Ad and AAV vectors for tropism modification of viral vectors.

Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient factor (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells. Consequence of environmental exposure - 'effectively zero'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Laboratory-based experiments: during the production of replicatin-defective adenoviruses, all solid waste (plastics etc) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.
Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Passed with amendments by local GMSC 1.2.2001.

CU2 Project Title: EXPRESSION OF A WILD TYPE MAPKKK AND ITS DOMINANT NEGATIVES USING AMPHOTROPIC RETROVIRAL MEDIATED GENE TRANSFER

Class: 2
CultureVolClass2: < 1 litre
Non-GMM: not applicable

Project notified under transitional arrangements: N

Project Additional Information

Purposes of the contained use:
To produce the GMOs expressing the proteins for use in screening compounds in the process of drug discovery.

Recipient or parental organism

Cloning host
E.coli K12: DH5a - a disabled host. ACDP Hazard Group 1
Top 10 - a disabled host. ACDP Hazard Group 1
These strains are not considered pathogenic or able to persistently colonise humans or animals. They have limited survivability in the environment. They have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. There is no plasmid mobilisation/transfer genes in these host.

Expression hosts
Mammalian cell lines eg. RAW, HEKs ACDP Hazard Group 2
Human primary cells ACDP Hazard Group 2
Host/vector system

All cloning vectors used will be non-mobilisable or mobilisation defective. These all contain antibiotic resistance genes to allow selection. Resistance to this is common and of limited clinical significance.

Vector system No. 1 Amphotropic Replication Deficient Retroviruses (RDRs) (see Section 17 for information on this system). They all include an antibiotic resistance gene to allow selection.

Origin & function

Origin of clone is from a cDNA library. Intended function is to express the clone in order to determine the effect of over-expressing the wild type protein or its dominant negative mutants on the cell lines transduced.

Evaluation of foreseeable effects

The gene of interest encodes the sequence of a MAP kinase kinase kinase. On expression it is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene.

Expression of the inserts in the recombinant organism are unlikely to affect the pathogenicity of the expression host. Contact of the replication deficient retroviruses (RDRs) containing the wild type MAPK KK gene should be avoided, as transduction of MAPK KK into the cells of a worker could result in an unknown effect.

The RDRs are highly labile and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent amphotropic retrovirus capable of expressing functional wild type MAPK KK is produced that productively infects an individual via body fluid contact (eg. sharps injury). The individual therefore would be infected with a potentially damaging retrovirus with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because:

1. The retroviral vectors themselves do not contain any of the functions (gag, pol and env) that are essential for replication. Integration of the vectors results in their inactivation due to a deletion in the 3' LTR. All of these functions must be restored in order to produce a replication competent retrovirus (RCR).

2. Capture events are most likely by homologous recombination with wild type retrovirus. As the homologous regions flank the engineered region of the virus containing the MAPK KK, homologous recombination would result in deletion of the MAPK KK gene.

3. As the tropism of any PCR produced would be dictated by the endogenous retrovirus providing the gag, pol and env functions, homologous recombination with wild type retrovirus would produce a virus which would not pose a significant risk to human health.

4. The RDRs are going to to used to transduce primary human cells and therefore may come into contact with endogenous human retroviruses. However, as the PDRs are based upon a non-primate retrovirus the chance of homologous recombination to produce an RCR is greatly reduced.

5. Endogenous retroviral infection of the transduced cells could provide the functions required to re-package viral genomes in trans. The use of self-inactivating vectors means that following integration of the RDR DNA, the normal retrovirus 5'-LTR promoter is silenced. Expression of the MAPK KK is driven from a promoter that is downstream of the packaging sequence. Hence, all transcripts produced will be incapable of being packaged. There is no evidence to suggest that the deleted 5' LTR has promoter activity.

6. Any RCR produced would be expected to be highly unstable and could be attenuated by contact with surfaces, normal disinfectants and desiccation. The RDRs are not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant.
on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

A more likely scenario is that a worker contaminates himself or herself with an RDR containing wild type MAPKKK. This may result in an increase in the activation of the signalling MAP kinase pathways in the transformed cells. However, the RDRs are highly unstable, attenuated by desiccation and not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

The likelihood of harm to human health occurring is considered negligible due to the containment measures used.

As the survival of the vectors in the general environment is poor and given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are “White Rose Ltd” and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using concentrated disinfectants, either Hycolin solution (Coventry Chemicals Limited) for E. coli work or TriGene (MediChem International) for Tissue culture/RDR work to a final concentration of 2% (as recommended by both suppliers). The solutions are left for 24 hours before disposal via the drain together with copious amounts of water.

Hycolin has been validated using the BS:6905/87 as the modified Kelsey Sykes test, the Australian TGA test, MAFF, ES and MIC tests. Hycolin is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species.

TriGene has been validated using BS6471, BS EN 1276, NF 72-150, NF 72-200, 72-180 and is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species.

As a result of treatment no viable GMMs from Liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y
Please enter comments on the GM safety committee on the risk assessment

This proposal has been approved as risk class 2. It was finally approved after minor modifications at the GMSC meeting on 27.7.01.

### Project Additional Information

#### Purposes of the contained use

To produce the GMOs expressing the protein for target validation and for use in screening compounds in the process of drug discovery.

#### Recipient or parental organism
Cloning host. E. coli K12:

DH5a - a disabled host. ACDP Hazard Group 1
Top 10 - a disabled host. ACDP Hazard Group 1
Other E. coli K12 strains. ACDP Hazard Group 1
These strains are not considered pathogenic or able to persistently colonise humans or animals. They have limited survivability in the environment. They have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. There are no plasmid mobilisation/transfer genes in these hosts.

Expression hosts
Mammalian cell lines eg. RAW, HEKs ACDP Hazard Group 2
Human primary cells ACDP Hazard Group 2
Insect cell lines - especially disabled hosts
E. coli K12 strain - a disabled host
S. cerevisiae - an especially disabled host.

Host/vector system
All cloning vectors used will be non-mobilisable or mobilisation defective.
These all contain antibiotic resistance genes to allow selection. Resistance to this is common and of limited clinical significance.

Vector system No. 1 Amphotropic Replication Deficient Retroviruses (RDRs) (See Section 17 for information on this system). They all include an antibiotic resistance gene to allow selection.

Vector system No. 2 Mammalian expression vectors (see Section 17 for information on this system). They all include an antibiotic resistance gene to allow selection.

Vector system No. 3 Baculovirus expression system (see Section 17 for information on this system).

Vector system No. 4 E. coli expression vectors (see Section 17 for information on this system). These vectors are either non-mobilisable or mobilisation defective. They all include an antibiotic resistance gene to allow selection.

Vector system No. 5 Yeast expression vectors (see Section 17 for information on this system). These vectors are non-transferable. They all contain selection markers.

Origin & function
Origin of clone is from a cDNA library. The intention is to express the protein or mutants thereof, in primary cells or cell lines, to determine the function of the protein. Also it is intended to express the protein for the purposes of developing a screening assay.

Evaluation of foreseeable effects
The gene of interest encodes the sequence of a frp and may modulate wnt/frizzled signalling pathways. On expression it is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene, but may potentially be oncogenic.

Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient retroviruses (RDRs) containing the frp gene should be avoided, as transduction of a frp into the cells of a worker could result in an unknown effect.

The RDRs are highly labile and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent amphotropic retrovirus (RCR) capable of expressing functional frp is produced that productively infects an individual via
body fluid contact (eg. sharps injury). The individual therefore would be infected with a potentially damaging retrovirus with unknown effects. The virus would be
transmissible by body fluid contact.

The likelihood of this happening is negligible because:

1. The retroviral vectors themselves do not contain any of the functions (gag, pol and env) that are essential for replication. Integration of the vectors results in their
inactivation due to a deletion in the 3’ LTR. All of these functions must be restored in order to produce a RCR.
2. Capture events are most likely by homologous recombination with wild type retrovirus. As the homologous regions flank the engineered region of the virus containing
the frp, homologous recombination would result in deletion of the frp gene.
3. As the tropism of any RCR produced would be dictated by the endogenous retrovirus providing the gag, pol and env functions, homologous recombination with wild
type retrovirus would produce a virus which would not pose a significant risk to human health.
4. The RDRs are going to be used to transduce primary human cells and therefore may come into contact with endogenous human retroviruses. However, as the RDRs
are based upon a non-primate retrovirus the chance of homologous recombination to produce an RCR is greatly reduced.
5. Endogenous retroviral infection of the transduced cells could provide the functions required to re-package viral genomes in trans. The use of self-inactivating vectors
means that following integration of the RDR DNA, the normal retrovirus 5’- LTR promoter is silenced. Expression of the frp is driven from a promoter that is downstream of
the packaging sequence. Hence, all transcripts produced will be incapable of being packaged. There is no evidence to suggest that the deleted 5’ LTR has promoter
activity.
6. Any RCR produced would be expected to be highly unstable and could not be attenuated by contact with surfaces, normal disinfectants and desiccation. The RDRs are
not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture
supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

A more likely scenario is that a worker contaminates himself or herself with an RDR containing frp. This may result in an increase/decrease in the activation of the
wnt/frizzled signalling pathways in the transformed cells. However, the RDRs are highly unstable, attenuated by desiccation and not known to be transmissible by aerosol.
Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will
be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

The likelihood of harm to human health occurring is considered negligible due to the containment measures used.

As the survival of the vectors in the general environment is poor and given that the work will be carried out at CL2, the risk of animal exposure is therefore very small.
Thus, the overall risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are
"White Rose Ltd" and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and
contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using concentrated disinfectants, either Hycolin solution (Coventry Chemicals Ltd) for E. coli and yeast work or TriGene
(MediChem International) for Rissue culture/RDR work, to a final concentration of 5% (as recommended by both suppliers) or Virkon for insect cell/baculovirus work to a
final concentration of 1%. The solutions are left for 2 hours before disposal via the drain together with copious amounts of water.

Hycolin has been validated using the BS:6905/87 as the modified Kelsey Sykes test, the Australian TGA test, MAFF, ES and MIC tests. Hycolin is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. Hycolin has also been tested in house under conditions used for decontamination.

TriGene has been validated using BS6471, BS EN 1276, NF 72-150, NF 72-200, 72-180 and is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. Trigene has also been tested in house under conditions used for decontamination.

Virkon has been validated in house under conditions used for decontamination.

As a result of treatment no viable GMMs from liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

This proposal has been approved as risk class 2. It was finally approved after minor modification at the GMSC meeting on 30/08/01.

**Project Additional Information**

**Purposes of the contained use**
To produce the GMOs expressing the protein for target validation and for use in screening compounds in the process of drug discovery.

**Recipient or parental organism**

**Cloning host**
Packaging cell line for replication deficient adenovirus. This packaging cell line has been designed for use with the adenoviral vectors covered by this proposal. The cells complement for two adenoviral gene cassettes essential for adenovirus replication that have been deleted in the vectors. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication competent adenovirus extremely unlikely.

**Expression hosts**
Human primary cells ACDP Hazard Group 2. The cells are non-transformed. No adventitious agents are believed present. For COSHH purposes they should be treated as risk class 2. Cells are from an external source; individuals must not culture their own cells.

**Host/vector system**

Vector system: Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains an inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promoter. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassettes removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenoviral is replication deficient.

**Origin & function**

Origin of cline is from a cDNA library. The intention is to express the protein or mutants thereof, in primary cells, to determine the function of the protein.

**Evaluation of foreseeable effects**

The gene of interest encodes the sequence of a Rab protein (wild-type dominant regenerative/constitutively active mutant versions and a Rab fusion). Rab proteins are localised to the cytoplasmic face of organelles and vesicles involved in the biosynthetic/secretory and endocytic pathways in eukaryotic cells and are thought to play a regulatory role in vesicle transport. Most rabs are ubiquitous and each localises to a particular membrane compartment, although some are cell-type or tissue specific. It is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene.
Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient adenovirus (RDAs) containing the rab gene should be avoided, as transduction of a rab into the cells of a worker could result in an unknown effect. The most likely effect is perturbation of cellular vesicle transport.

The RDAs are transmissible by aerosol and fluid: fluid contact and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent adenovirus (RCA) capable of expressing functional rab is produced that productively infects an individual via body fluid contact (eg sharps injury) or aerosol inhalation. The individual therefore would be infected with a potentially damaging adenovirus expressing a rab protein with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because two adenoviral gene cassettes essential for replication have been deleted in the adenoviral vectors. Production of replication-defective adenovirus requires the use of a specialised packaging cell line which complements for these essential adenoviral genes. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication-competent Adenovirus extremely unlikely. If a member of staff is naturally infected with wild-type adenovirus this may provide an opportunity for complementation of the deleted gene cassettes enabling the generation of RDA in the host. However, recombinant adenovirus can only become replication-competent by exchange of both complete expression cassettes, requiring two homologous recombination events.

A more likely scenario is that a worker contaminates himself or herself with a replication deficient adenovirus (RDA) containing a Rab protein. The likelihood of harm to human health occurring is considered low because:

(1) As with naturally occurring adenovirus, the adenoviral constructs covered by this proposal will elicit a host immune response. This poses a potential hazard if delivered in high quantities. This has been highlighted by a fatality in a gene therapy trial (Science 286 p2244) following the injection of a massive dose of crippled adenovirus (38 trillion virus particles) into the liver. However, the risk to staff is negligible because such large quantities of adenovirus would never be handled, equivalent to over 3L of RDA stock (5-10 million virus particles per microlitre, stored in 0.25 ml alequots).

(2) Replication-deficient adenoviral particles are able to transduce human cells (particularly airway epithelial and gastrointestinal cells). However, these viruses will induce both a humoral and cellular immune response which will lead to targeted elimination of infected cells. This means that rab protein expression will be very short-lived. Hence any potential harmful effects associated with rab protein expression will be transient and will not present a long-term problem.

(3) Transduction is possible through direct fluid-fluid contact and so risk is via entry through open wounds. This presents negligible risk since the use of sharps will be prohibited and as part of standard laboratory practice open wounds will be covered.

(4) Adenivirus is transmissible by aerosol so the highest risk of exposure is via entry through airways and transduction of airway epithelial cells. However, the viral DNA will not be replicated and is not directly integrated into the host genome. Since airway epithelial cells exhibit a high rate of cell turnover any viral DNA will be lost over time and transgene expression will be transient. Following aerosol exposure to RDA it is possible that the viral DNA could be replicated and packaged generating more virions if the host is already infected with naturally occurring adenovirus of the same serotype. However, such virions will be replication-deficient. This could lead to transduction of neighbouring cells and localised spreading of transgene expression. Transduced cells are more likely to be targeted and removed by the host immune response, restricting the spread of RDA. Expression of the rab protein (wild-type or variants) in airway epithelial cells is unlikely to cause harm to the user. This cell type exhibits regulated secretion of lung surfactant. However, there is no evidence that the Rab protein of interest is endogenously expressed, so the absence of relevant affector proteins and target membranes means that this Rab protein is unlikely to participate in vesicle transport in this cell type. However, if low affinity binding between the over-expressed Rab protein and unrelated Rab effectors or target vesicles does occur it is possible that high levels of overexpression could perturb normal vesicle transport in the cell.

Overexpression studies using Rab 11 in HeLa cells provides evidence that Rab overexpression does not effect other transport pathways regulated by other Rab proteins (J.
However, this cannot be ruled out in the case of every Rab protein or cell type so the risk to the user is low following exposure. The overall risk to human health is considered negligible because the likelihood of exposure to aerosols is negligible due to the containment measured used.

Over-expression of a Rab protein in a cell type in which it is endogenously expressed may perturb normal vesicle trafficking. Transduction of cells found circulating in the blood requires fluid:fluid contact via sharps injury or open wounds. This represents negligible risk since sharps are prohibited and open wounds will be covered. Transduction of cells present in the gut requires ingestion of inhalation of virions. However, the risk of exposure leading to transduction is negligible since the vast majority of virions would be inactivated during passage through the stomach. Aerosol exposure may risk transduction of cells located within the lung tissue. However, for this to be possible the RDA would need to breach the epithelial barrier. Moreover, since gene expression will be both transient and localised, accidental exposure is unlikely to have a significant impact on the health of an individual. However, since this cannot be ruled out this presents low risk to the user.

Adenovirus does not directly integrate the transgene into the host genome, however random integration is possible but poses no significant risk since this is a rare event. The risk of potential harm is only significant if the transgene is oncogenic. No Rab proteins are known to be oncogenic. However, one Rab protein (Rab38) is known to be expressed in 80-90% of melanoma, but rarely in nonmelanocytic malignancies (Cancer Research 2000, 60(13)p3584). Rab38 has a unique C-terminus which would allow post-translational farnesylation and palmitoylation, lipid modifications normally occurring in oncogenic ras proteins but not in other rabs. Hence, the Rab protein of interest (a) is not expected to be oncogenic and so random integration poses negligible risk.

There is no evidence that human adenovirus can naturally infect animals, and replication is very limited. However, replication has been shown to occur in the lungs of experimentally infected cotton rats (not indigenous to the UK) administered at high doses. Given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using the concentrated disinfectant TriGene (MediChem International) to a final concentration of 5% (as recommended by supplier). The solutions are left for 2 hours before disposal via the drain together with copious amounts of water.

Tri-Gene has been validated using BS6471, BS EN 1276, NF 72-150, NF 72-200, 72-180 and is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. TriGene has also been tested in house under conditions used for decontamination.

As a result of treatment no viable GMMs from liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This proposal was approved by the GMSC on 23 November 2001 as risk class 2. It was noted that this proposal was on the borderline between class 1 and class 2. Greatest concern would be if constitutive active Rab protein could have effects in epithelial cells. No evidence that it would, but difficult to exclude entirely. Possibility of some effect on transduced cells in lung epithelial layer impossible to exclude. Will be classified as risk class 2 with a requirement to control aerosols being the most important measure needed to reduce risk.

These strains are not considered pathogenic or able to persistently colonise humans or animals. They have limited survivability in the environment. They have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. There are no plasmid mobilisation/transfer genes in these hosts.

### Expression hosts

- Mammalian cell lines eg RAW, HEKs ACDP Hazard Group 2
- Human primary cells ACDP Hazard Group 2
- Insect cell lines - especially disabled hosts
- E.coli K12 strain - a disabled host
- S. cerevisiae - an especially disabled host

### Host/vector system

All cloning vectors used will be non-mobilisable or mobilisation defective. These all contain antibiotic resistance genes to allow selection. Resistance to this is common and of limited clinical significance.

- **Vector system No 1 Amphotropic Replication Deficient Retroviruses (RDRs).** They all include an antibiotic resistance gene to allow selection.
- **Vector system No. 2 Mammalian expression vectors.** They all include an antibiotic resistance gene to allow selection.
- **Vector system No. 3 Baculovirus expression system.**
- **Vector system No. 4 E.coli expression vectors.** These vectors are either non-mobilisable or mobilisation defective. They all include an antibiotic resistance gene to allow selection.
- **Vector system No. 5 Yeast expression vectors.** These vectors are non-transferable. They all contain selection markers.

### Origin & function

Origin of cline is from a cDNA library. The intention is to express the protein or mutants thereof, in primary cells or cell lines, to determine the function of the protein.

### Evaluation of foreseeable effects

The gene of interest encodes the sequence of a wnt protein and may modulate wnt/frizzled signalling pathways. On expression it is anticipated that in some of the listed expression systems the protein will be correctly folded and active. The gene of interest is not a known oncogene, but may potentially be oncogenic.

Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient retroviruses (RDRs) containing the wnt gene should be avoided, as transduction of a wnt protein into the cells of a worker could result in an unknown effect.

The RDTs are highly labile and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.
In the worst-case scenario, a replication competent amphotropic retrovirus (RCR) capable of expressing functional wnt protein is produced that productively infects an individual via body fluid contact (e.g., sharps injury). The individual therefore could be infected with a potentially damaging retrovirus with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because:

1. The retroviral vectors themselves do not contain any of the functions (gag, pol, and env) that are essential for replication. Integration of the vectors results in their inactivation due to a deletion in the 3' LTR. All of these functions must be restored in order to produce a RCR.
2. Capture events are most likely by homologous recombination with wild type retrovirus. As the homologous regions flank the engineered region of the virus containing the wnt gene, homologous recombination would result in deletion of the wnt gene.
3. As the tropism of any RCR produced would be dictated by the endogenous retrovirus providing the gag, pol, and env functions, homologous recombination with wild type retrovirus would produce a virus which would not pose a significant risk to human health.
4. The RDRs are going to be used to transduce primary human cells and therefore may come into contact with endogenous human retroviruses. However, as the RDRs are based upon a non-primate retrovirus the chance of homologous recombination to produce an RCR is greatly reduced.
5. Endogenous retroviral infection of the transduced cells could provide the functions required to re-package viral genomes in trans. The use of self-inactivating vectors means that following integration of the RDR DNA, the normal retrovirus 5' - LTR promoter is silenced. Expression of the wnt protein is driven from a promoter that is downstream of the packaging sequence. Hence, all transcripts produced will be incapable of being packaged. There is no evidence to suggest that the deleted 5' LTR has promoter activity.
6. Any RCR produced would be expected to be highly unstable and could be attenuated by contact with surfaces, normal disinfectants and desiccation. The RDRs are not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

A more likely scenario is that a worker contaminates himself or herself with an RDR containing the wnt gene. This may result in an increase or a decrease in the activation of the wnt/frizzled signalling pathways in the transformed cells. However, the RDRs are highly unstable, attenuated by desiccation and not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

The likelihood of harm to human health occurring is considered negligible due to the containment measures used.

As the survival of the vectors in the general environment is poor and given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

- E. coli K12 strain - a disabled host
- S. cerevisiae - an especially disabled host

Host/vector system
All cloning vectors used will be non-mobilisable or mobilisation defective. These all contain antibiotic resistance genes to allow selection. Resistance to this is common and of limited clinical significance.

- Vector System No. 1 Amphotropic Replication Deficient Retroviruses (RDRs). They all include an antibiotic resistance gene to allow selection.
- Vector System No. 2 Mammalian expression vectors. They all include an antibiotic resistance gene to allow selection.
- Vector System No. 3 Baculovirus expression system.
- Vector System No. 4 E. coli expression vectors. These vectors are either non-mobilisable or mobilisation defective. They all include an antibiotic resistance gene to allow selection.
- Vector System No. 5 Yeast expression vectors. These vectors are non-transferable. They all contain selection markers.

Origin & function
Origin of cline is from a cDNA library. The intention is to express the protein of mutants thereof, in primary cells or cell lines, to determine the function of the protein.

Evaluation of foreseeable effects
The gene of interest encodes the sequence of an inhibitor of apoptosis. On expression it is anticipated that in some of the listed expression systems the protein will be correctly folded and active. The gene of interest is not a known oncogene, but may potentially be oncogenic.

Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient retroviruses (RDRs) containing an inhibitor of apoptosis gene should be avoided, as transduction of an inhibitor of apoptosis protein into the cells of a worker could result in an unknown effect.

The RDRs are high labile and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent amphotropic retrovirus (RCR) capable of expressing a functional inhibitor of apoptosis protein is produced that productively infects an individual via body fluid contact (eg sharps injury). The individual therefore would be infected with a potentially damaging retrovirus with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because:
1. The retroviral vectors themselves do not contain any of the functions (gag, pol and env) that are essential for replication. Integration of the vectors results in their inactivation due to a deletion of the 3’ LTR. All of these functions must be restored in order to produce a RCR.
2. Capture events are most likely by homologous recombination with wild type retrovirus. As the homologous regions flank the engineered region of the virus containing the inhibitor of apoptosis gene, homologous recombination would result in deletion of the inhibitor of apoptosis gene.
3. As the tropism of any PCR produced would be dictated by the endogenous retrovirus providing the gag, pol and env functions, homologous recombination with wild type retrovirus would produce a virus which would not pose a significant risk to human health.
4. The RDRs are going to be used to transduce primary human cells and therefore may come into contact with endogenous human retroviruses. However, as the RDRs are based upon a non-primate retrovirus the chance of homologous recombination to produce an RCR is greatly reduced.

5. Endogenous retroviral infection of the transduced cells could provide the functions required to re-package viral genomes in trans. The use of self-inactivating vectors means that following integration of the RDR DNA, the normal retrovirus 5' - LTR promoter is silenced. Expression of the inhibitor of apoptosis protein is driven from a promoter that is downstream of the packaging sequence. Hence, all transcripts produced will be incapable of being packaged. There is no evidence to suggest that the deleted 5’ LTR has promoter activity.

6. Any PCR produced would be expected to be highly unstable and could be attenuated by contact with surfaces, normal disinfectants and desiccation. The RDRs are not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

A more likely scenario is that a worker contaminates himself or herself with an RDR containing the inhibitor of apoptosis gene. This may result in an increase or a decrease in apoptosis signalling pathways in the transformed cells. However, the RDRs are highly unstable, attenuated by desiccation and not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimised.

The likelihood of harm to human health occurring is considered negligible due to the containment measures used.

As the survival of the vectors in the general environment is poor and given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using concentrated disinfectants, either Hycolin solution (Coventry Chemicals Ltd) for E. coli and yeast work or TriGene (MediChem International) for tissue culture/RDR work, to a final concentration of 5% (as recommended by both suppliers) or Virkon for insect cell/baculovirus work to a final concentration of 1%. The solutions are left for 2 hours before disposal via the drain together with copious amounts of water.

Hycolin has been validated using the BS:6905/87 as the modified Kelsey Sykes test, the Australian TGA test, MAFF, ES and MIC tests. Hycolin is lethal against all common gram-positive pathogens, all gram-negative pathogens and mycobacterium species. Hycolin has also been tested in house under conditions used for decontamination.

TriGene has been validated using BS6471, BS EN 1276, NF 72-150, NF 72-200, 72-180 and is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. Trigene has also been tested in house under conditions used for decontamination.

Virkon has been validated in house under conditions used for decontamination.
As a result of treatment no viable GMMs from liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

This proposal has been approved as risk class 2. It was finally approved after minor modification at the GMSC meeting on 21.09.01.

Project Ref 323/02.5

Date Ackn'd 03/09/2002

CU2 Project Title ADENOVIRAL DELIVERY AND EXPRESSION OF A RGS PROTEIN (A) IN HUMAN PRIMARY CELLS

Class 2 CultureVolClass2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N

Historical Significant Changes

Tick if notifying a connected programme of work Y
**Project Additional Information**

**Purposes of the contained use**
To produce the GMOs expressing the protein for target validation and for use in the process of drug discovery

**Recipient or parental organism**

**CLONING HOST**
Packaging cell line for replication deficient adenovirus. This packaging cell line has been designed for use with the adenoviral vectors covered by this proposal. The cells complement for two adenoviral gene cassettes essential for adenovirus replication that have been deleted in the vectors. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication competent adenovirus extremely unlikely (see Section 17 for more info on this system)

**EXPRESSION HOSTS**
Human primary cells ACDP Hazard Group (see Section 17 for more info) The cells are non-transformed. No adventitious agents are believed present. For COSHH purposes they should be treated as risk class 2. Cells are from an external source; individuals must not culture their own cells.

**Host/vector system**

**VECTOR SYSTEM:** Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains an inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promoter. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassettes removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenovirus is replication deficient. (see Section 17 for more info on this system)

**Origin & function**
Origin of cline is from a cDNA library. The intention is to express the protein in primary cells, to determine the function of the protein.

**Evaluation of foreseeable effects**
The gene of interest encodes the sequence of an RGS protein. RGS proteins (Regulator of G protein Signalling) strongly modulate the activity of G proteins. Their best known function is to inhibit G protein signalling by accelerating GTP hydrolysis (acting as GTPase activating proteins, GAP) by stabilising the transition state conformation.
of G-alpha, thus turning off G protein signals. Some RGS proteins also possess non-GAP functions. Evidence is emerging that besides G protein inhibition, they can enhance G protein activation by serving as effectors or acting as scaffold proteins to gather other regulatory molecules together. When RGS binds activated Galpha it brings with it other functional units. There are also many examples of regulated RGS expression. RGS levels can inhibit rapid induction following physiological signals. Additionally, some RGS proteins exhibit nuclear localisation when overexpressed, suggesting a role in gene activation. It is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene.

Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient adenovirus (RDAs) containing the RGS gene should be avoided, as transduction of RGS into the cells of a worker could result in an unknown effect. The most likely effect is perturbation of G-protein signalling.

The RDAs are transmissible by aerosol and fluid:fluid contact and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent adenovirus (RCA) capable of expressing functional RGS is produced that productively infects an individual via body fluid contact (eg sharps injury) or aerosol inhalation. The individual therefore would be infected with a potentially damaging adenovirus expressing RGS protein with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because two adenoviral gene cassettes essential for replication have been deleted in the adenoviral vectors. Production of replication-defective adenovirus requires the use of a specialised packaging cell line which complements for these essential adenoviral genes. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication-competent Adenovirus extremely unlikely. If a member of staff is naturally infected with wild-type adenovirus this may provide an opportunity for complementation of the deleted gene cassettes enabling the generation of RDA in the host. However, recombinant adenovirus can only become replication-competent by exchange of both complete expression cassettes, requiring two homologous recombination events. (see Section 17 for more details).

A more likely scenario is that a worker contaminates himself or herself with a replication deficient adenovirus (RDA) containing RGS protein. The likelihood of harm to human health occurring is considered low because:

(1) As with naturally occurring adenovirus, the adenoviral constructs covered by this proposal will elicit a host immune response. This poses a potential hazard if delivered in high quantities. This has been highlighted by a fatality in a gene therapy trial (Science 286 p2244) following the injection of a massive dose of crippled adenovirus (38 trillion virus particles) into the liver. However, the risk to staff is negligible because such large quantities of adenovirus would never be handled, equivalent to over 3L of RDA stock (5-10 million virus particles per microlitre, stored in 0.25 mL aliquots).

(2) Replication-deficient adenoviral particles are able to transduce human cells (particularly airway epithelial and gastrointestinal cells). However, these viruses will induce both a humoral and cellular immune response which will lead to targeted elimination of infected cells (see Section 17 for more details). This means that protein expression will be very short-lived. Hence any potential harmful effects associated with RGS protein expression will be transient and will not present a long-term problem.

(3) Transduction is possible through direct fluid-fluid contact and so risk is via entry through open wounds. This presents negligible risk since the use of sharps will be prohibited and as part of standard laboratory practice open wounds will be covered.

(4) Adenovirus is transmissible by aerosol so the highest risk of exposure is via entry through airways and transduction of airway epithelial cells. However, the viral DNA will not be replicated and is not directly integrated into the host genome. Since airway epithelial cells exhibit a high rate of cell turnover any viral DNA will be lost over time and transgene expression will be transient. Following aerosol exposure to RDA it is possible that the viral DNA could be replicated and packaged generating more virions if the host is already infected with naturally occurring adenovirus of the same serotype. However, such virions will be replication-deficient. This could lead to transduction of neighbouring cells and localised spreading of transgene expression. Transduced cells are more likely to be targeted and removed by the host immune response, restricting the spread of RDA. Overexpression is expected to attenuate G-protein signalling. However, the overall effect on cell function is unknown. It is also possible that high levels of RGS protein may affect other signalling pathways in epithelial cells normally controlled by other RGS proteins. The overall risk to human health is considered negligible because the likelihood of exposure to aerosols is negligible due to the containment measured used.
Over-expression of an RGS protein in a cell type in which it is endogenously expressed may perturb normal G-protein signalling. Transduction of cells found circulating in the blood requires fluid:fluid contact via sharps injury or open wounds. This represents negligible risk since sharps are prohibited and open wounds will be covered. Transduction of cells present in the gut requires ingestion of inhalation of virions. However, the risk of exposure leading to transduction is negligible since the vast majority of virions would be inactivated during passage through the stomach. Aerosol exposure may risk transduction of cells located within the lung tissue. However, for this to be possible the RDA would need to breach the epithelial barrier. Moreover, since gene expression will be both transient and localised, accidental exposure is unlikely to have a significant impact on the health of an individual. However, since this cannot be ruled out this presents low risk to the user (for more information see Section 17).

Adenovirus does not directly integrate the transgene into the host genome, however random integration is possible but poses no significant risk since this is a rare event. The risk of potential harm is only significant if the transgene is oncogenic. The RGS protein of interest (a) is not expected to be oncogenic and so random integration poses negligible risk.

There is no evidence that human adenovirus can naturally infect animals, and replication is very limited. However, replication has been shown to occur in the lungs of experimentally infected cotton rats (not indigenous to the UK) administered at high doses. Given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

**Project Additional Information**

**Purposes of the contained use**

This proposal will cover the use of replication deficient adenoviral (RDA) particles to express the cell surface protein heat stable antigen HSA (mCD24). The purpose of these experiments is to allow selection of virally transduced cells using antibodies against HSA.

**Recipient or parental organism**

CLONING HOST
Packaging cell line for replication deficient adenovirus. This packaging cell line has been designed for use with the adenoviral vectors covered by this proposal. The cells complement for two adenoviral gene cassettes essential for adenovirus replication that have been deleted in the vectors. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication competent adenovirus extremely unlikely (see Section 17 for more info on this system).

EXPRESSION HOSTS
Human primary cells ACDP Hazard Group (see Section 17 for more info) The cells are non-transformed. No adventitious agents are believed present. For COSHH purposes they should be treated as risk class 2. Cells are from an external source; individuals must not culture their own cells.

Host/vector system

VECTOR SYSTEM: Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains an inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promotor. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassettes removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenoviral is replication deficient. (see Section 17 for more info on this system)

Origin & function

Origin of cline is from a cDNA library. The intention is to express the protein in primary cells, to determine allow selection of transduced cells.

Evaluation of foreseeable effects

HSA. Heat stable antigen (HSA) was cloned originally from mouse (J. Immunology 145 p1952). At the DNA level, it is most homologous to human CD24, although the mature product products demonstrate limited homology. The mature HSA is a peptide of 27 amino acids, heavily glycosylated, and attached to the cell membrane with a GPI anchor. In the mouse, HSA is expressed on mature granulocytes, thymocytes and B-cells. Expression is generally high in precursor cells, and lost as cells terminally differentiate. Cross-linking of HSA leads to an increase in apoptosis in B-cell precursors. Transgenic mice overexpressing HSA have reduced pre-B-lymphocytes (J. Immunology 156 pp479-88). Cross-linking of HSA can promote activation and proliferation of T-cells. HSA can promote cell adhesion, by binding to P-selectin. 2. In many cases a fluorescent protein will be co-expressed with HSA. It is anticipated that the protein(s) will be correctly folded and active. Neither HSA or the fluorescent protein are known oncogenes, or predicted to be oncogenic.

Expression of HSA in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient adenovirus (RDAs) containing the HSA gene should be avoided, as transduction of HSA into the cells of a worker could result in an unknown effect, although since this is a mouse protein with significant differences at the amino acid level to its closest human homologue, it is unlikely to have functional effects in humans.

The RDAs are transmissible by aerosol and fluid:fluid contact and are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent adenovirus (RCA) capable of expressing functional RGS is produced that productively infects an individual via body fluid contact (eg sharps injury) or aerosol inhalation. The individual therefore would be infected with a potentially damaging adenovirus expressing RGS protein with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because two adenoviral gene cassettes essential for replication have been deleted in the adenoviral vectors. Production of replication-defective adenovirus requires the use of a specialised packaging cell line which complements for these essential adenoviral genes. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication-competent Adenovirus extremely unlikely. If a member of staff is naturally infected with wild-type adenovirus this may provide an opportunity for complementation of the deleted gene cassettes enabling the generation of RDA in the host. However, recombinant adenovirus can only become replication-competent by exchange of both complete expression cassettes, requiring two homologous recombination events. (see Section 17 for more details).
Amore likely scenario is that a worker contaminates himself or herself with a replication deficient adenovirus (RDA) containing RGS protein. The likelihood of harm to human health occurring is considered low because:

1. As with naturally occurring adenovirus, the adenoviral constructs covered by this proposal will elicit a host immune response. This poses a potential hazard if delivered in high quantities. This has been highlighted by a fatality in a gene therapy trial (Science 286 p2244) following the injection of a massive dose of crippled adenovirus (38 trillion virus particles) into the liver. However, the risk to staff is negligible because such large quantities of adenovirus would never be handled, equivalent to over 3L of RDA stock (5-10 million virus particles per microlitre, stored in 0.25 mL aliquots).

2. Replication-deficient adenoviral particles are able to transduce human cells (particularly airway epithelial and gastrointestinal cells). However, these viruses will induce both a humoral and cellular immune response which will lead to targeted elimination of infected cells (see Section 17 for more details). This means that protein expression will be very short-lived. Hence any potential harmful effects associated with RGS protein expression will be transient and will not present a long-term problem.

3. Transduction is possible through direct fluid-fluid contact and so risk is via entry through open wounds. This presents negligible risk since the use of sharps will be prohibited and as part of standard laboratory practice open wounds will be covered.

4. Adenovirus is transmissible by aerosol so the highest risk of exposure is via entry through airways and transduction of airway epithelial cells. However, the viral DNA will not be replicated and is not directly integrated into the host genome. Since airway epithelial cells exhibit a high rate of cell turnover any viral DNA will be lost over time and transgene expression will be transient. Following aerosol exposure to RDA it is possible that the viral DNA could be replicated and packaged generating more virions if the host is already infected with naturally occurring adenovirus of the same serotype. However, such virions will be replication-deficient. This could lead to transduction of neighbouring cells and localised spreading of transgene expression. Transduced cells are more likely to be targeted and removed by the host immune response, restricting the spread of RDA.

5. Overexpression of HSA in airway epithelial cells represents low risk to the user, since studies in mouse have limited the function of HSA to signalling in pre-B-lymphocytes. These are located in the bone marrow which will not be infected from aerosol exposure. In addition, the amino acid sequence of mouse HSA is very different from its human gene homologue, and so is unlikely to be functional in humans, and will most likely be recognised as foreign and be cleared rapidly by normal immune responses. In addition, the likelihood of exposure to aerosols is insignificant due to the containment measured used, so the danger to humans will be negligible.

There is no evidence that human adenovirus can naturally infect animals, and replication is very limited. However, replication has been shown to occur in the lungs of experimentally infected cotton rats (not indigenous to the UK) administered at high doses. Given that the work will be carried out using replication incompetent virus at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" and have been registered with the HSE. Consent Granted not applicable
Non-GMM
Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

To produce the GMOs expressing the protein for target validation and for use in screening compounds in the process of drug discovery.

**Recipient or parental organism**

**Cloning Host**

Packaging cell line for replication deficient adenovirus. This packaging cell line has been designed for use with the adenoviral vectors covered by this proposal. The cells complement for two adenoviral gene cassettes essential for adenovirus replication that have been deleted in the vectors. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication competent adenovirus extremely unlikely.

**Expression hosts**

Human primary cells ACDP Hazard Group 2. The cells are non-transformed. No adventitious agents are believed present. For COSHH purposes they should be treated as risk class 2. Cells are from an external source; individuals must not culture their own cells.

**Host/vector system**

Vector system: Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains an inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promoter. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassettes removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenoviral is replication deficient.

**Origin & function**

Origin of cline is by PCR from genomic DNA. The intention is to express the protein or mutants thereof, in parimary cells, to determine the function of the protein.

**Evaluation of foreseeable effects**

The protein of interest is a G protein-coupled (7TM) receptor. Its activating ligand is unknown. The second messenger responses generated by activating the receptor and the effects of these on a cell are not known. Expression of the GPCR mRNA in the human is restricted; Activation of the GPCR is not expected to occur in the absence of the (unknown) ligand. Expression of the GPCR may alter normal cell function in the presence of the activating ligand.

It is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene.

Expression of the insert in the recombinant organism is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient adenovirus (RDAs) containing the GPCR gene should be avoided as transduction of the GPCR into the cells of a worker could result in an unknown effect.

The RDAs are transmissible by aerosol and fluid/fluid contact and are highly unlikely to transfer this sequence to either humans or other organisms because of the
containment measures used.

In the worst-case scenario, a replication competent adenovirus (RCA) capable of expressing functional GPCR is produced that productively infects an individual via body fluid contact (eg sharps injury) or aerosol inhalation. The individual therefore would be infected with a potentially damaging adenovirus expressing the GPCR protein with unknown effects. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because two adenoviral gene cassettes essential for replication have been deleted in the adenoviral vectors. Production of replication-defective adenovirus requires the use of a specialised packaging cell line which complements for these essential adenoviral genes. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication-competent Adenovirus extremely unlikely. If a member of staff is naturally infected with wild-type adenovirus this may provide an opportunity for complementation of the deleted gene cassettes enabling the generation of RDA in the host. However, recombinant adenovirus can only become replication-competent by exchange of both complete expression cassettes, requiring two homologous recombination events.

A more likely scenario is that a worker contaminates himself or herself with a replication deficient adenovirus (RDA) containing the GPCR protein. The likelihood of harm to human health occurring is considered low because:

1. As with naturally occurring adenovirus, the adenoviral constructs covered by this proposal will elicit a host immune response. This poses a potential hazard if delivered in high quantities. This has been highlighted by a fatality in a gene therapy trial (Science 286 p2244) following the injection of a massive dose of crippled adenovirus (38 trillion virus particles) into a liver. However, the risk to staff is negligible because such large quantities of adenovirus would never be handled.

2. Replication-deficient adenoviral particles are able to transduce human cells (particularly airway epithelial and gastrointestinal cells). However these viruses will induce both a humoral and cellular immune response which will lead to targeted elimination of infected cells. This means that GPCR protein expression will be very short-lived. Hence any potential harmful effects associated with the GPCR protein expression will be transient and will not present a long-term problem.

3. Transduction is possible through direct fluid-fluid contact and so risk is via entry through open wounds. This presents negligible risk since the use of sharps will be prohibited and as part of standard laboratory practice open wounds will be covered.

4. Adenovirus is transmissible by aerosol so the highest risk of exposure is via entry through airways and transduction of airway epithelial cells. However, the viral DNA will not be replicated and is not directly integrated into the host genome. Since airway epithelial cells exhibit a high rate of cell turnover any viral DNA will be lost over time and transgene expression will be transient. Following aerosol exposure to RDA it is possible that the viral DNA could be replicated and packaged generating more virions if the host is already infected with naturally occurring adenovirus of the same serotype. However, such virions will be replication-deficient. This could lead to transduction of neighbouring cells and localised spreading of transgene expression. Transduced cells are more likely to be targeted and removed by the host immune response, restricting the spread of RDA. The effect of expression of the GPCR in airway epithelial cells is unknown. It is considered unlikely to cause harm to the user because the GPCR is not endogenously expressed by this cell, therefore the relevant signalling/effector proteins and ligand may be absent.

5. Transduction of cells present in the gut requires ingestion or inhalation of virions. However, the risk of exposure leading to transduction is negligible since the vast majority of virions would be inactivated during passage through the stomach.

6. Transduction of cells found circulating in the blood requires fluid:fluid contact via sharps injury or open wounds. This represents negligible risk since sharps are prohibited and open wounds will be covered.

7. Adenovirus does not directly integrate the transgene into the host genome, however random integration is possible but poses no significant risk since this is a rare event. The risk of potential harm is only significant if the transgene is oncogenic. The GPCR is not known to be oncogenic.
Aerosol exposure may risk transduction of cells located within the lung tissue. However, for this to be possible the RDA would need to breach the epithelial barrier. Moreover, since gene expression will be both transient and localised, accidental exposure is unlikely to have a significant impact on the health of an individual. However, since this cannot be ruled out this presents low risk to the user.

There is no evidence that human adenivirus can naturally infect animals, and replication is very limited. However, replication has been shown to occur in the lungs of experimentally infected cotton rats (not indigenous to the UK) administered at high doses. Given that the work will be carried out at CL2, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using the concentrated disinfectant TriGene (MediChem International) to a final concentration of 5% (as recommended by supplier). The solutions are left for 2 hours before disposal via the drain together with copious amounts of water.

TriGene has been validated using BS6471, BS EN 1276, NF 72-150, NF 72-200, 72-180 and is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. TriGene has also been tested in house under conditions used for decontamination.

As a result of treatment no viable GMMs from liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Additional Information

Purposes of the contained use
To produce the GMOs expressing modulatory proteins for target validation in the process of drug discovery.

Recipient or parental organism

Cloning host
E. coli K12; Top 10 - a disabled host. ACDP Hazard Group 1. This strain is not considered pathogenic or able to persistently colonise humans or animals. It has limited survivability in the environment. It has auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. There are no plasmid mobilisation/transfer genes in this host.

Expression hosts
Mammalian cell lines ACDP Hazard Group 2. Considered as especially disabled hosts with very limited ability to survive in the environment.
Host/vector system

All cloning vectors used will be non-mobilisable or mobilisation defective. These all contain antibiotic resistance genes to allow selection. Resistance to these are common and of limited clinical significance.

Amphotropic, Replication Deficient Retroviral vectors (RDRs) based on MMLV. They all include an antibiotic resistance gene to allow selection.

Origin & function

Insert DNA will be designed and supplied by an external company. Intended function is to express the encoded protein to modulate the gene of interest in mammalian cells.

Evaluation of foreseeable effects

Encoded protein is expected to specifically modulate the gene of interest. Thus potential effects of expression relate to the gene of interest and are detailed in Section 17.

Expression of the inserts in the recombinant organism is unlikely to affect pathogenicity.

The RDRs are highly labile and are highly unlikely to transfer the insert sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent amphotropic retrovirus, capable of expressing functional insert protein, is produced that productively infects an individual. The individual therefore would be infected with a potentially damaging retrovirus. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because:

1. The retroviral vectors themselves do not contain any of the functions (gag, pol and env) that are essential for replication. Integration of the vectors results in their inactivation due to a deletion in the 3' LTR. All of these functions must be restored in order to produce a replication competent retrovirus.

2. Capture events are most likely by homologous recombination with wild type retrovirus. As the homologous regions flank the engineered region of the virus, homologous recombination would result in deletion of the insert gene.

3. As the tropism of any replication competent retrovirus produced would be dictated by the endogenous (murine) retrovirus providing the gag, pol and env functions, homologous recombination with wild type (murine) retrovirus would produce a virus which would not pose a significant risk to human health.

4. The RDRs are based upon a murine retrovirus the chance of homologous recombination to produce a replication competent retrovirus is greatly reduced.

5. Endogenous retroviral infection of the transduced cells might provide the functions required to re-package viral genomes in trans. The use of self-inactivating vectors means that following integration of the RDR DNA, the normal retrovirus 5' LTR promoter is silenced. Expression of the insert is driven from a promoter that is downstream of the packaging sequence. Hence, all transcripts produced will be incapable of being packaged. There is no evidence to suggest that the deleted 5' LTR has promoter activity.

5. If a replication competent retrovirus was produced it would be expected to be unstable and could be attenuated by contact with surfaces, normal disinfectants and desiccation. Retroviruses are not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited, the use of gloves will be mandatory and the generation of aerosols minimized.

A more likely scenario is that a worker contaminates himself or herself with a replication defective retrovirus (RDR) containing the insert gene. This may result in expression of protein in the transduced cells. However, the RDRs are highly unstable, attenuated by desiccation and not known to be transmissible by aerosol. Transmission would therefore have to be through direct fluid/fluid contact such as a needle stick injury or spilling culture supernatant on an open wound. The use of sharps will be prohibited.
the use of gloves will be mandatory and the generation of aerosols minimized.

The likelihood of harm to human health occurring is considered negligible due to the containment measures used.

As the survival of the vectors in the general environment is poor and given that the work will be carried out at CL2, the risk of animal exposure is very small. Thus, the overall risk to the environment is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

None

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid GMM contaminated waste will be triple contained in biohazard waste bags/containers and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" (registered with the HSE). This solid waste will be comprised mainly of plasticware used in the culturing of the organisms. As a result of treatment no viable GMMs from solid waste will remain. There will be 100% kill.

All liquid waste is inactivated by chemical means using concentrated disinfectants, either Hycolin solution (Coventry Chemicals Ltd) for E. coli work or TriGene (MediChem International) for tissue culture/RDR work, to a final concentration of 2% (as recommended by both suppliers). The solutions are left overnight before disposal via the drain together with copious amounts of water.

Hycolin has been validated using the BS:6905/87 as the modified Kelsey Sykes test, the Australian TGA test, MAFF, ES and MIC tests. Hycolin is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species.

TriGene has been validated using BS6471, BS EN 1276, NF 72-150, it is bactericidal and virucidal and efficiently kills eukaryotic cell lines. Trigene has also been tested in house under conditions used for decontamination. As a result of treatment no viable GMMs from liquid or solid waste will remain, there will be 100% kill.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

**Project Containment**
### Project Ref 323/04.1

- **Date Ackn'd**: 20/10/2004
- **CU2 Project Title**: Cloning of mammalian pro-forms of two cytokines and the mature cytokines and their expression in E. coli
- **Class**: Class 2
- **Culture Volume Class**: 1 Litre
- **Non-GMM**: Not Applicable
- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

#### Purposes of the contained use

To produce the GMOs expressing the proteins for use in the process of drug discovery

#### Recipient or parental organism

**Cloning hosts**
- E. coli K12 -
- Top 10 - a disabled host. ACDP Hazard Group 1
- Other E. coli K12 strains. ACDP Hazard Group 1

These strains are not considered pathogenic or able to persistently colonise humans or animals. They have limited survivability in the environment. They have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. There are no plasmid mobilisation/transfer genes in these hosts.
Expression hosts
E. coli B834 (DE3) strain - a disabled host. ACDP Hazard Group 1
This strain is an auxotrophic variant of BL21 and is therefore more disabled than BL21. According to HSE guidelines BL21 has considerably less colonisation potential than wild type strains but has greater colonisation potential than K12 strains. BL21 may be considered unlikely to colonise and establish a persistent infection in the gut of a healthy individual.

Host/vector system
All cloning and expression vectors used will be non-mobilisable. These all contain antibiotic resistance genes to allow selection in E. coli. Resistance to these are common and of limited clinical significance.

Cloning vectors:-
Plasmids pCR2-topo & pCR4blunt-topo
E. coli Expression system. Please see section 17 for details of the expression vector.

Origin & function
Origin of the clones will be via PCR amplification from tissue cDNA or a cDNA library. Intended function is to express the clone in order to determine the effect of the ligand on human cell lines and primary cells.

Evaluation of foreseeable effects
The genes of interest encode the sequence of two cytokines. As the genes of interest are both pro-inflammatory cytokines, the abnormal production of either protein or their pro-forms in bacteria and subsequent release is likely to cause a localised inflammation with the other potential side-effects as shown in the clinical trials depending on the amount of cytokine release.

An expression in E. coli it is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene. The DNA constructs would be designed in such a way that none of the cytokine proteins would be secreted from intact viable E. coli ie in the mature cytokine constructs there is no secretary leader sequence and the pro-forms of the cytokine proteins lack the correct and necessary E. coli signal sequences for the protein to be secreted from these cells.

For harm to occur, the E. coli cells expressing the cytokine must be introduced into the body via (a) ingestion or (b) sharps injury. In the first instance (a) the cells introduced are likely to express the cytokine as the subject is likely to have ingested some food containing the inducer of expression. However the E. coli cells need to lyse, releasing the protein. In the process of lysing, the cells that produced the cytokine proteins will be killed. This lysis of E. coli cells could result in the release of varying amounts of cytokine depending on the number of cells ingested. It is known that both cytokines are expressed in E. coli in amounts up to 10-20 mg of active protein per litre. Therefore ingestion of just one ml of induced culture could result in the release of cytokine into the body at concentrations higher than the maximum tolerated dose of a clinical trial. Ingestion is deemed highly unlikely to occur because of the fact that mouth pipetting is not allowed as part of good laboratory practice, gloves will be worn and the production of aerosols minimised. (b) Introduction of the bacteria capable of expressing one of the cytokines via a sharps injury is unlikely to result in harm as the E. coli cells are a non-pathogenic laboratory strain with a long history of safe use. The ability to express the cytokine will not increase their potential to infect a subject and if the cells do get into the blood it is highly unlikely that any extra cytokine protein will be produced as the expression of the proteins is under the control of a very tightly regulated promoter and the inducer will not be present in the blood. Therefore for the cytokine proteins to be released, the cells need to contain the cytokine already before introduction into the body and must lyse releasing the protein. At the site of a sharps injury the subject would respond with a localised inflammation - in the process of healing the wound. The number of cells likely to be introduced into a wound by a sharps injury would be expected to be low. According to the data on phase 1 clinical trials patients dosed sub-cutaneously with either cytokines did not reach the maximum tolerated dose at up to 100ng/kg per patient so to have a severe effect a large number of cells would need to be introduced into the wound. A very severe injury to a worker introducing volumes of culture of 1 ml into a wound is extremely unlikely to occur because of the existing practices in the laboratory - as plasticware rather than glassware is to be used to culture the cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
None
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple-bagged in biohazard waste bags and suitably labelled and incinerated off site. The contractors who will carry this out are "White Rose Ltd" and have been registered with the HSE. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in decontamination procedures. As a result of treatment no viable GMMs from solid waste will remain.

All liquid waste is inactivated by applying by chemical means using concentratred disinfectant, Hycolin solution (Coventry Chemicals Limited) to a final concentration of 2% (as recommended by suppliers). The solutions are left for 24 hours before disposal via the drain together with copious amounts of water.

Hycolin has been validated using the BS:6905/87 as the modified Kelsey Sykes test, the Australian TGA test, MAFF, ES and MIC tests. Hycolin is lethal against all common gram positive pathogens, all gram negative pathogens and mycobacterium species. Hycolin has been tested in house and shown to cause a 100% kill at working concentrations between 0.25-2%.

As a result of treatment no viable GMMs from liquid or solid waste will remain.

Procedures and relevant training and safety inspections are in place to ensure that all personnel deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The cytokines described in this assessment will be expressed in an active form in E. coli. It is likely that they will be expressed at levels that could cause harm to a worker if ingested or introduced into a wound in large volumes. This is based on literature descriptions of l.v dosing of the cytokines to human cancer patients where detrimental effects were noticed at relatively low levels of exposure. The maximum tolerated dose for l.v administration was 5ug - a level likely to be present in 1 ml of a bacterial culture. Although it was agreed that to sustain this level of exposure it would require a severe injury to a worker resulting in an open wound, it was felt that the likelihood of this being realised was low rather than negligible. To minimise exposure, the assessment recommends that the wearing of gloves is mandatory and that specific measures are implemented to control aerosol dissemination. These measures take the Containment Level required to 2. In addition, the GMSC recommended that plastic flasks should be used for cultures being grown for expression purposes, as a serious cut from a broken glass flask was viewed as being the most likely source of exposure.

The COSHH risk of handling active cytokines during purification should also be highlighted in the assessment.

The proposal was passed as Risk Class 2 notifiable to the HSE.

**Purposes of the contained use**

To produce the GMOs expressing the protein for target validation and for use in screening compounds in the process of drug discovery.

**Recipient or parental organism**

**Cloning Host**

Packaging cell line for replication deficient adenovirus. This packaging cell line has been designed for use with the adenoviral vectors covered by this proposal. The cells compliment for two adenoviral gene cassette essential for adenovirus replication that have been deleted in the vectors. No sequence overlap exists between the packaging cell line and the adenovirus vectors preventing homologous recombination and making the emmergence of replication competent adenovirus extremely unlikely.

**Expression Host**

Human primary cells ACDP Hazard Group 2 The cells are non-transformed. No adventitious agents are believed present. For COSHH purposes they should be treated as risk class 2. Cells are from an external source; individuals must not culture their own cells.
Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains and inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promoter. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassette removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenovirus is replication deficient.

Host/vector system

Replication Deficient Adenovirus (RDAs). The adenoviral genome has been divided between two vectors (adapter and helper). The adapter plasmid contains and inverted terminal repeat (containing the origin of replication) and the packaging signal (a series of AT-rich sequences). An essential adenoviral cassette has been deleted and replaced by the gene of interest under the control of a promoter. The helper cosmid contains the remainder of the adenoviral genome with some adenoviral gene cassette removed. Two of the deleted adenoviral gene cassettes are essential for replication hence the resulting adenovirus is replication deficient.

Origin of clone is by PCR from cDNA. The intention is to express the protein or mutants thereof, in primary cells, to determine the function of the protein.

Evaluation of foreseeable effects

The protein of interest is a kinase. It is involved in inactivation of kinase cascades. Over-expression of the dominant negative kinase may EITHER inhibit NF-kB activation, OR have the same ability to activate as wild type kinase. Therefore the over expression of a kinase dominant negative mutant could cause the down regulation potentially leading to increased apoptosis of infected cells exposed to certain stimuli. On the other hand over expression of the dominant negative mutant could cause activation of the same pathways in the cells.

It is anticipated that the protein will be correctly folded and active. The gene of interest is not a known oncogene.

Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts listed above. Contact of the replication deficient adenovirus (RDAs) containing the kinase cDNA should be avoided as transduction of the cDNA into the cells of a worker could result in activation of the cells resulting either in a localised inflammation or apoptosis of the transduced cells.

The RDAs are transmissible by aerosol and fluid:fluid contact but are highly unlikely to transfer this sequence to either humans or other organisms because of the containment measures used.

In the worst-case scenario, a replication competent adenovirus (RCA) capable of expressing functional Kinase is produced that productively infects an individual via body fluid contact (e.g. sharps injury) or aerosol inhalation. The individual therefore would be infected with a potentially damaging adenovirus expressing the kinase protein which then causes a localised inflammation. The virus would be transmissible by body fluid contact.

The likelihood of this happening is negligible because two adenoviral gene cassettes essential for replication have been deleted in the adenoviral vectors. Production of replication-defective adenovirus requires the use of a specialised packaging cell line which complements for these essential adenoviral genes. No sequence overlap exists between the packaging cell line and the adenoviral vectors preventing homologous recombination and making the emergence of replication-competent Adenovirus extremely unlikely. If a member of staff is naturally infected this may provide an opportunity for complementation of the deleted gene cassette enabling the generation of RDA in the host. However, recombinant adenovirus can only become replication-competent by exchange of both complete expression cassettes, requiring two homologous recombination events.

A more likely scenario is that a worker contaminates himself or herself with a replication deficient adenovirus (RDA) containing the kinase. The likelihood of harm to human health occurring is considered low because:

1) As with naturally occurring adenovirus, the adenoviral constructs covered by this proposal will elicit a host immune response. This poses a potential hazard if delivered in high quantities. This has been highlighted by a fatality in a gene therapy trial (Science 286 p2244) following the injection of a massive dose of crippled adenovirus (38 trillion virus particles) into the liver. However, the risk to staff is considered negligible because the quantities of particles used in this work will be about 1000x less than this.

2) Replication-deficient adenoviral particles are able to transduce human cells (particularly airway epithelial and gastrointestinal cells). However, these viruses will induce both a humoral and cellular immune response which will lead to targeted elimination of infected cells. This means that kinase protein expression will be very short-lived. Hence any potential harmful effects associated with the kinase protein expression will be transient and will not present a long-term problem.

3) Transduction is possible through direct fluid-fluid contact and so risk is via entry through open wounds. This presents negligible risk since the use of sharps will be prohibited and as part of standard laboratory practice open wounds will be covered.

4) Adenovirus is transmissible by aerosol so the highest risk of exposure is via entry through airways and transduction of airway epithelial cells. However, the viral DNA will not be replicated and is not directly integrated into the host genome. Since airway epithelial cells exhibit a high rate of cell turnover any viral DNA will be lost over time and transgene expression will be transient. Following aerosol exposure to RDA it is possible that the viral DNA could be replicated and packaged generating more virions if the host is already infected with naturally occurring adenovirus of the same serotype. However, such virions will be replication-deficient. This could lead to transduction of neighboring cells and localised spreading of transgene expression. Transduced cells are more likely to be targeted and removed by the host immune response, restricting...
the spread of RDA. The effect of expression of the kinase in airway epithelial cells would be either to cause activation of the cells or apoptosis of the cells.

5) Transduction of cells present in the gut requires ingestion or inhalation of virions. [ ]. However, the risk of exposure leading to transduction is negligible since the vast majority of virions would be inactivated during passage through the stomach.

6) Transduction of cells found circulating in the blood requires fluid:fluid contact via sharps injury or open wounds. This represents negligible risk since sharps are prohibited and open wounds will be covered.

7) Adenovirus does not directly integrate the transgene into the host genome, however random integration is possible but poses no significant risk since this is a rare event. The risk of potential harm is only significant if the transgene is oncogenic. The Kinase is not known to be oncogenic. Aerosol exposure may risk transduction of cells located within the lung tissue. However, for this to be possible the RDA would need to breach the epithelial barrier. Moreover, since gene expression will be both transient and localised, accidental exposure is unlikely to have a significant impact on the health of an individual. However, since this cannot be ruled out this presents low risk to the user.

There is no evidence that human adenovirus can naturally infect animals, and replication is very limited. However, replication has been shown to occur in the lungs of experimentally infected cotton rats (not indigenous to the UK) administered at high doses. Given that the work will be carried out at under class 2 containment, the risk of animal exposure is therefore very small. Thus, the overall risk to the environment is negligible.

## Project Additional Information

### Purposes of the contained use

Mycobacterium bovis BCG engineered to express the Green Fluorescent Protein (GFP) as a reporter protein will be used to determine the feasibility of using fluorescent imaging to monitor cell infection and subsequent bacterial determination.
Mycobacterium bovis bacillus of Calmette and Guerin (BCG) is an ACDP class 2 organism. BCG is an attenuated strain of the pathogenic species M. bovis and since 1948 has been given in a live form intradermally as a vaccine for neonates, children and adults to protect against tuberculosis. The genetic basis for its attenuation is now known. It has three deletions (RD1-RD3) relative to its progenitor M. bovis, and 10 deletions (RD1-RD10) relative to the human pathogen M. tuberculosis, which encompass 119 open reading frames (Behr et al., 1999 Science 28: 1520-1523). It has a history of safe use and it was estimated in 1991 that 2.5 billion people had by then been vaccinated with BCG. It can cause adenitis and disseminated BCG infection (BCGosis) is a recognized but rare consequence of BCG vaccination, and traditionally has been seen in children with severe immune deficiencies. Its frequency is reported as less than 5 per million vaccinees. All these complications are rare and amenable to antibiotic therapy.

Recipient or parental organism

Mycobacterium bovis bacillus of Calmette and Guerin (BCG) is an ACDP class 2 organism. BCG is an attenuated strain of the pathogenic species M. bovis and since 1948 has been given in a live form intradermally as a vaccine for neonates, children and adults to protect against tuberculosis. The genetic basis for its attenuation is now known. It has three deletions (RD1-RD3) relative to its progenitor M. bovis, and 10 deletions (RD1-RD10) relative to the human pathogen M. tuberculosis, which encompass 119 open reading frames (Behr et al., 1999 Science 28: 1520-1523). It has a history of safe use and it was estimated in 1991 that 2.5 billion people had by then been vaccinated with BCG. It can cause adenitis and disseminated BCG infection (BCGosis) is a recognized but rare consequence of BCG vaccination, and traditionally has been seen in children with severe immune deficiencies. Its frequency is reported as less than 5 per million vaccinees. All these complications are rare and amenable to antibiotic therapy.

Host/vector system

Plasmid pSMT3 is an E.coli - Mycobacteria shuttle vector (De Smet et al., 1999 Microbiology 145: 3177-3184). The E.coli origin of replication is from pUC18 while the Mycobacteria origin is a 1.25kb fragment from the Mycobacterium fortuitum var fortuitum cryptic plasmid pAL5000. The plasmid pSMT3 is non-transferrable in both E. coli and Mycobacteria and expresses the selectable hygromycin resistance gene from Streptomyces hygroscopius and GFP under the control of the constitutive hsp60 promoter from Mycobacteria tuberculosis.

The plasmid pHLEG4 is an E.coli - Mycobacteria shuttle vector that expresses an unstable form of GFP(Carroll et al., 2005 Applied and Environmental Microbiology 71(6); 3077-3084 and Blokpoel et al., 2003 J. Microbiol. Methods 54; 203-211). The E.coli origin of replication is from pUC18 while the Mycobacteria origin is from the Mycobacterium fortuitum var fortuitum cryptic plasmid pAL5000. The plasmid pHLEG4 is non-transferrable in both E. coli and Mycobacteria and expresses the selectable kanamycin resistance gene from Tn903 and can express GFP under control of the Tet inducible promoter.

The integrating shuttle cosmid vector pYUB178 (Pascopella et al., 1994 Infect Immun 62:1313-1319 ) contains an E.coli origin of replication derived from pUC19, the L5 attP site, the L5 integrase gene, the kanamycin resistance gene from Tn903, the lambda cos sequence. The plasmid is non-transferable in E.coli and mycobacteria. The L5 mycobacteriophage attachment site (attP) and integrase gene (int) mediate site-specific integration into the attB site of the mycobacterial chromosome. The green fluorescent protein is inserted into the vector under the transcriptional control of the Mycobacteria bovis hsp65 promoter.

Origin & function

The green fluorescent protein is a well characterised reporter gene with no known associated health hazards. The production of BCG with GFP will be at other establishments. BCG engineered in the same way has been produced previously. No changes have been evident when tested for changes in virulence or effects on cytokine production or surface molecule expression by antigen presenting cells in vitro (Luo et al., 1996 Clin Diag Lab Immunol 3: 761-768). Hygromycin and kanamycin have no clinical application in the treatment of tuberculosis and so use of the hygromycin and kanamycin resistance genes will not compromise any treatment. These strains will retain sensitivity to isoniazid and rifampicin, the antibiotics normally used to treat M. bovis infection. BCG as the established vaccine strain for human use is avirulent and no effect on virulence is forseen. The project involves small-scale work for research purposes and all contaminated material will be inactivated by autoclaving prior to disposal. Therefore, the environmental or personal risk from using these strains is no different from that of the parental strain.

Evaluation of foreseeable effects

The green fluorescent protein is a well characterised reporter gene with no known associated health hazards. The production of BCG with GFP will be at other establishments. BCG engineered in the same way has been produced previously. No changes have been evident when tested for changes in virulence or effects on cytokine production or surface molecule expression by antigen presenting cells in vitro (Luo et al., 1996 Clin Diag Lab Immunol 3: 761-768). Hygromycin and kanamycin have no clinical application in the treatment of tuberculosis and so use of the hygromycin and kanamycin resistance genes will not compromise any treatment. These strains will retain sensitivity to isoniazid and rifampicin, the antibiotics normally used to treat M. bovis infection. BCG as the established vaccine strain for human use is avirulent and no effect on virulence is forseen. The project involves small-scale work for research purposes and all contaminated material will be inactivated by autoclaving prior to disposal. Therefore, the environmental or personal risk from using these strains is no different from that of the parental strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Consumables (mainly plasticware e.g. pipettes, tubes, multiwell plates) will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). The autoclave is situated in the same building and in close proximity to the laboratory where the activity will be carried out. Once autoclaved, the waste will be disposed of via the industrial waste stream for incineration. Pre-prepared plastic vials containing 10E8 cfu/ml recombinant M.bovis BCG will be opened in Class II hoods. The vials and all consumables used will be discarded into sharps bins within the hood. At the end of each working day the sharps bin will sealed within the hood and transferred to the autoclave. All 96 well plates will be sealed before transferring to the autoclave. Trigene at 2% will be used as a surface disinfectant. Trigene has been demonstrated by the manufacturer to be an effective disinfectant against M.bovis when used at this concentration for this purpose. Agar plates will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), and then disposed of via clinical waste stream for incineration.

The waste produced is 12 - 14 cubic meters of liquid per week containing modified Saccharomyces cerevisiae. This material is heat treated at 80 degrees C for 10 minutes in a kill tank. A sample of each batch is monitored for inactivation. The heating of the kill vessel has been validated by thermocouple.

The resulting slurry is collected by a registered waste organisation by tanker and 50.1 of biocide (Tego2000) is added to help restrain bacteria from living on the dead yeast, the slurry is pressed at the waste collection centre and the yeast is then incinerated.

Each kill cycle is sampled for growth and this information is captured on controlled worksheets and a Laboratory Alert Notices is issued if samples grow.

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to assess the ability of a number of biological active genes to reduce brain damage.

**Recipient or parental organism**

These adenoviral or adeno-associated viral vectors will be produced and characterised in Department of Medicine and Therapeutics, University of Glasgow (HSE centre number GM 397). All adenovectors to be used in this study and E1-deleted first generation adenoviral vectors based on the pJM17 system (McGorry, W. J. Bautista, D. S. and Graham, F. L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on cesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Dept of Medicine and Therapeutics, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

**Host/vector system**

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette.
cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Dept of Medicine and Therapeutics, University of Glasgow. AAV vectors are replication defective.

Origin & function

The adenoviral vectors DNAs are standard and originated from the laboratory of Dr Graham (McGrory, W. J., Bautista, D. S. and Graham, F.L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All transgenes will be constructed from full length cDNAs obtained from other research institutes and verified in our own laboratory prior to subcloning into the relevant vectors.

Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wild type virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes, or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. Consequence of environmental exposure - 'effectively zero'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcases will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.
Passed with amendments by local GMSC 25th September 2002.

Project Ref 331/02.1
The aim of the present study is to transfect primary human keratinocytes with HPV11 DNA. Several workers have reported transient, low level episomal replication of viral templates in this system (Mungal et al. (1992) J. Virol 66 p3220-3224; Thomas et al., (2001) J. Virol 75, p7564). These cells will be plated on Methocel and the subsequent replication of HPV genomes will be monitored by PCR and/or Southern blots. The transfected cells will be dosed with small molecular weight compounds to assay for anti-viral activity.

The recipient host cells are commercially available primary keratinocytes isolated from normal human tissue, (Clonetics TM) which have been screened for HIV-1, hepatitis B and hepatitis C. These cells have a finite life span of 15 doublings.

Origin & function

The construct pHV11 is available from the ATCC (number 45151) and represents the entire genome of the low risk HPV11 cloned into the BamH1 site of pBr322. This recombinant DNA is amplified and cut with BamH1 to release the HPV11 DNA. This is recircularised with ligase and used to co-transfect primary keratinocytes with a neomycin selectable marker. The intention is to grow the transfected host cells on methyl cellulose, which induces partial differentiation and therefore provides a semi permissive environment for HPV replication. The episomal HPV DNA will increase in copy number but will not produce viral particles due to lack of capsid protein expression (Ruesch et all, (1998) J. Virol 72 pp5016-5024). The replication is evident for 24-72 hour, after which the cells are lysed and DNA is purified, and then used as a template in PCR studies and/or Southern lots, which quantitate the amount of HPV replication achieved.

Evaluation of foreseeable effects

HPV11 encodes E6 and E7 proteins which interact with p53 and Rb, respectively. However, because HPV11 is a "low risk" virus, these interactions are unlikely to
transform the host cell. Therefore, the transfected cells would retain their limited life span of 15 doublings. Other early genes such as E1, E2 will be expressed which will co-operatively bind to the URR within the HPV genome and sustain episomal replication to approximately 50-100 copies per permissive cell. No late capsid protein will be expressed in this system (see above). The E5 protein will be expressed in the keratinocyte membranes and may enhance mitogenic signaling via the EGF receptor. A common feature of these systems is the integration of HPV DNA into the genome of the host cell, which can occur within a short time frame. This integration would invalidate the assay and therefore the cells would be disposed in 1% Virkon.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation sought for this activity

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk of escape of GMO's to the environment, all contaminated waste streams generated during the course of this work will be decontaminated within the laboratory block. Cultures will be grown within leak proof vessels. Fermenters will be set up in such a way that accidental spillage will be contained. Virkon disinfectant will be added to liquid waste prior to disposal. The efficacy of Virkon disinfectant has been validated by an independent consultancy on behalf of Pfizer Ltd under conditions representative of the in use conditions applied in our biological research laboratories.

Solid waste will be autoclaved prior to incineration.

The only foreseeable release of viable waste from our facility is on the form of aqueous waste that has been inadequately treated, possibly in the event of an accidental spill to a sink. Such waste is emitted via our drainage system to our own Waste Water Treatment Facility (WWTF) before final discharge to the River Stour. Processing via the WWTF is such that the viable concentration will be massively diluted. The retention time within the WWTF is approximately 5 days. The HPV11 transfected keratinocytes have limited survivability in a hostile liquid environment away from its natural host or an enriched laboratory environment and is unlikely to remain viable after this period of time. Additionally the treatment regimen in the WWTF includes a 24hr disinfection step. Waste is held at elevated pH for 24 hours prior to discharge following neutralisation. Thus the risk of viable organisms entering the local environment is effectively zero.

Is an emergency plan required according to regulation 20?

Project Containment

| Laboratory Activities | Glass Houses | Growth Rooms |

02/03/2022
Project Additional Information

Purposes of the contained use

The aim of the project is to identify genes required for survival of fungal pathogens which could represent potential targets for the development of new antifungal drugs. Various genes will be deleted with concomitant insertion of a selectable marker. The resulting mutant strains will be assessed for their ability to grow in vitro and then inoculated into rodents to assess their ability to cause infection.

Recipient or parental organism

Parental organisms will be class 2 fungal pathogens, including Candida albicans, Candida glabrata, Candida spp and Aspergillus fumigatus.

Host/vector system

In some cases a non-mobilisable, linearised E. coli plasmid will be used to transfer the gene deletion cassettes. Such plasmids are unable to replicate in fungi. In other cases, no vector will be used - the gene deletion cassette will be transferred as a linear piece of DNA.

Origin & function
The genetic material involved will consist of 4 elements:
1. Small fragments of the 5' and 3' ends of the fungal gene which is intended to be deleted. These will target integration of the deletion cassette to the gene of interest through homologous integration. The purpose of this DNA is to create a deletion of a fungal gene.

2. In some cases, the genetic material will contain a fungal promoter, such as MAL2 or MET3, which is induced by nutritional supplements. The purpose of this is to place a fungal gene of interest under control of a promoter which can be regulated. The promoter is only switched on under specific growth conditions in the laboratory and can be switched off by changing growth conditions. The promoter is switched off under growth conditions in a rodent. In this way, fungal cells can be grown up, then the promoter switched off to evaluate the effects of losing the gene function (similar to deleting the gene).

3. A selectable marker. This will most often be a metabolic gene derived from the fungal host which will complement an auxotrophic mutation in the host strain, eg. URA3, HIS3, LEU2 for Candida sp or pyrG, hisB for Aspergillus. It may also be an antibiotic resistance gene, eg zeocin resistance, or a fluorescent marker gene. The purpose of the marker is to allow selection for fungal cells which have taken up the deletion cassette DNA.

4. In some cases, the genetic material will also include E. coli plasmid sequences. Non-mobilisable vectors will be used. The plasmid will contain an E. coli origin of replication and selectable marker such as ampicillin resistance. Neither of these elements are functional in fungi, therefore the plasmid can not be replicated or transferred and can only be maintained when it integrates into the fungal genome. The E. coli DNA has no purpose in these experiments - it is merely left over from the cloning work to create the deletion cassette.

Evaluation of foreseeable effects

The purpose of the project is to delete, or switch off, genes which are believed to be required for growth and pathogenicity of fungal cells, therefore the expected outcome is that the genetic modification will result in a fungal strain with impaired growth and pathogenicity. In the worst case, the genetic modification may have no effect on these characteristics and we will end up with a strain which has characteristics similar to the host organism. There is no known examples where deletion of a fungal gene has resulted in increased growth or pathogenicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation sought for this activity.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk of escape of GMOs to the environment, all contaminated waste streams generated during the course of this work will be decontaminated within the laboratory block. Cultures will be grown within leak proof vessels. Virkon disinfectant will be added to liquid waste prior to disposal. The efficacy of Virkon disinfectant has been validated by an independent consultancy on behalf of Pfizer Ltd under conditions representative of the in use conditions applied in our biological research laboratories. Solid waste will be autoclaved prior to incineration. Animal experiments are carried out in a secure unit. Following completion of experiments, the animals are euthanased and the carcasses autoclaved within the unit. Single use overalls are worn in the animal unit and these are autoclaved following use. Disposable hats, gloves, face masks and shoe covers are worn and are incinerated after use.

The only foreseeable release of viable waste from our facility is on the form of aqueous waste that has been inadequately treated, possibly in the event of an accidental spill to a sink. Such waste is emitted via our drainage system to our own Waste Water Treatment Facility (WWTF) before final discharge to the River Stour. Processing via the WWTF is such that the viable concentration will be massively diluted. The retention time within the WWTF is approximately 5 days. Genetically modified Candida species and Aspergillus fumigatus have limited survivability in a hostile liquid environment away from their natural host or an enriched laboratory environment and is unlikely to remain viable after this period of time. Additionally the treatment regimen in the WWTF includes a 24 hr disinfection step. Waste is held at elevated pH for 24 hours prior to discharge following neutralisation. Thus the risk of viable organisms entering the local environment is effectively zero.
The membership of the GMSC approved the risk assessment without further comment or need for clarification.

Project Ref 331/05.3

Date Ackn'd: 29/11/2005
CU2 Project Title: The generation of infectious HCV from HCV plasmids transfected into human hepatoma cells.

Date Project Ceased: 21/12/2011

Class: Class 3
CultureVolClass2: Non-GMM
CultureVolumeClass3-4: not exceed 100ml

Consent Granted: Yes

Project notified under transitional arrangements: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

Generation of infectious HCV will enable the infection of susceptible cells to identify potential targets for anti-HCV therapeutics.

**Recipient or parental organism**

The GMO will have the characteristics of "wild-type" HCV from which it was derived in that it will be fully infectious, can be transmitted only through exposure via infected blood, sexual contact with an HCV carrier or puncture wounds with contaminated material. All work involving HCV will be performed under Category III containment following a code of practice that will define our safe working practices. This will be largely based on our current code of practice written for work involving HIV, which has been performed safely on this site since 2001.

**Host/vector system**

Initially, human hepatoma cell-lines will be used for this work, but as other cell lines or primary cells become identified that are able to support the replication of HCV, then they could be used. Should another cell line be identified as permissive, we would undertake a risk assessment and may potentially include it in future work where the risk assessment concludes that the risk profile is unaltered. The human hepatoma cell line currently identified for this work, is HuH-7 a cell line that is well established and has a history of safe use within Pfizer and worldwide.

**Origin & function**

The origin of the genetic material is from a patient infected with HCV who developed fulminant liver failure. The virus was isolated from his serum and virus sequenced. If the virus can be successfully grown, then work involving other isolates from different geographical locations and different serotypes would also be used. It may also be required to subclone genes of interest from one virus into another to determine the role they play in the viral life cycle and susceptibility to antiviral therapy.

**Evaluation of foreseeable effects**

Infectious HCV is a pathogen capable causing significant human disease. Acute infection may be resolved without further complications in between 30-50% of those exposed. Those who go on to chronic carriage, defined as being HCV RNA positive for >6 months, are at a high risk of significant liver disease, which may take up to 20 years to develop. There are currently no fully effective treatments available for HCV infection and the end stage treatment for HCV liver disease is liver transplantation. There is no evidence for transmission by exposure to infected aerosols, only through the routes detailed above so the likelihood of accidental exposure through release would be minimal. There is no evidence for productive infection of any species other than chimpanzee with human HCV isolates, so that although this is a high risk pathogen for humans, accidental exposure to the environment would have no significant impact.

Our existing code of practice for HIV is being updated to additionally accommodate HCV appropriate practices. All extracted air from these laboratories is HEPA filtered, so that in the event of a spillage of infectious material, there would be no discharge of infected aerosol to the environment. All work with infectious material would take place within class I or class I/III MBSCs. There would be secondary containment of all infectious material for transfer within CL3 labs and during culture periods in incubators etc. Our current disinfection protocols have been shown to work against a range of enveloped viruses similar to HCV. These include the use of Virkon at 2% for treatment of contaminated lab waste such as cell culture ware and cell culture fluid or other infectious liquids. Post disinfection liquid waste is disposed to the onsite Waste Water Treatment Facility (WWTF) where a further cycle of treatment including disinfection takes place prior to discharge. Solid waste from the labs is autoclaved before being sent for incineration on-site. The labs are on a pre-scheduled programme of vapourised hydrogen peroxide fumigation to allow routine shutdown and maintenance. The same fumigation process may be used in the event of spillage of infectious materials outside of a Microbiological Safety Cabinet.

Due to the lack of a reproducible cell culture system for expansion of HCV, information such as the stability of virus outside the body, in cell culture fluid for example, is unknown.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Information to justify derogation.

The derogation sought for this activity, and the information to justify it is the same as that submitted to the HSE and granted previously .. Your ref GM331 dated 24th March 2005.

The controls indicated below ensure that the transfer of (treated) waste to an autoclave that is not ‘en suite’ does not lead to a significant risk of exposure:

Disinfection procedure

* All materials that have been in contact with the virus (plastics and liquid) are immersed in 2% Virkon disinfectant within a functional microbiological safety cabinet for an overnight period of not less than 16 hours. Waste comprises either a) loose lab plastics (plastic tubes, pipettes and microtitre tips) which are fully immersed in approx 2 litres of 2% Virkon, or b) multiwell plates containing assay liquid to which Virkon is added to create a 2% final concentration.

* Post overnight disinfection - liquid waste from a) is discarded to the drainage

* Post overnight disinfection - solid waste ie disinfected lab plastics from a) and multiwell plates containing small volumes of disinfectant are transferred to a bin for autoclaving. See below.

* Disinfected solid waste (see above) is transferred into leakproof stainless steel autoclave bins within the CL3 laboratory.

* Lids are placed on the bins and taped in place with autoclave indicator tape.

* The external surface of each bin is wiped with 70% ethanol within the CL3 laboratory.

* Bins are then taken from the CL3 laboratory into the CL3 Annex (still within the CL3 suite) and placed onto a robust trolley. Nb. Our CL3 Code of Practice requires that open virus is only handled inside the MSCs within the CL3 laboratories and thus risk of contamination or exposure within the annex is extremely limited. When stock virus is transported from the store into the laboratory via the CL3 annex double containment is employed at all times and external surfaces are surface disinfected.

* The wheels of the trolley are sprayed with 70% ethanol before exiting the CL3 suite.

* Before exiting the CL3 suite a member of CL3 staff confirms that the corridor area between the suite and the autoclave is not occupied (this operation will routinely take place at the end of the working day at which time the rest of zone 2 will typically be unoccupied).

* The trolley is then wheeled directly to the autoclave and bins transferred. The robust construction of the trolley, the short and unobstructed distance and the fact that the area is otherwise unoccupied all combine to make the risk of an accident that could result in spillage highly unlikely. In this context it is also important to emphasise that all of the waste contained within the autoclave bins has been disinfected prior to loading into the autoclave bins. The transfer operation is estimated to take approx 2 minutes.

* The autoclave cycle (134 degrees C/15 mins) is initiated.

* A sign is placed on the ‘dirty’ side of the autoclave to indicate that in the unlikely event of cycle failure the autoclave may only be accessed by CL3 suite staff. This is because the autoclave cycle would always ‘fail to safe’ enabling it to be accessed from the ‘dirty’ side only.

* Autoclave waste is removed following successful completion of the cycle and is subsequently sent for on-site incineration by CL3 staff.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste would be treated for a minimum of 12 hours by exposure to at least 1% Virkon before being sent to the onsite WWTF for treatment prior to discharge. The efficiency of this disinfectant protocol has been externally validated on our behalf for numerous organisms including enveloped viruses likely to have a similar profile to HCV. The WWTF process includes a 5-day holding period and a 24-hour disinfection cycle. Any solid waste coming into contact with HCV would also be treated with 2% Virkon for at least 14 hours prior to disposal. All solid waste would be autoclaved prior to incineration in line with the Pfizer site guidelines. In case of a spillage outside of the MBSCs and in the case of access to the containment facility for maintenance procedures, the area would be fumigated with hydrogen peroxide using a validated process carried out by an external contractor under Pfizer supervision. These processes have been shown to kill viruses related to HCV, but have not been definitively shown to kill HCV due to the absence of a reproducible cell culture system.
The risk assessment was discussed at the Genetic Modification Safety Committee (GMSC) meeting on 27th September 2005. A copy of the risk assessment was circulated to the full GMSC membership who gave it their approval.

Project Ref 331/08.1

Date Ackn’d: 04/09/2008
Date Project Ceased: 06/03/2009

CU2 Project Title: Construction and use of Lentivirus vectors for the expression of heterologous proteins and inhibitory RNA sequences in mammalian cells.

Class: Class 2
Culture Volume: < 1 litre
Consent Granted: Not Applicable

Non-GMM: Yes
Historical Significant Changes: 16/11/2009
Withdrawn: No
Tick if notifying a connected programme of work: Yes
Historical Date of Additional Info: 16/11/2009
Significant Change ID: 331/08.1a
**Project Additional Information**

**Purposes of the contained use**

The lentivirus vector system will be used for the following experimental purposes:

1. To evaluate gene function in normal body cell biology and disease by overexpression or RNAi-mediated knockdown of the relevant gene function in primary cultured cells from normal and diseased tissues.
2. To generate stable cell lines expressing genes of interest to be used in the development of cell-based screening assays and disease-relevant in vitro cell models. These assays will be used to explore gene function and to screen compounds for activity at drug targets.

**Recipient or parental organism**

Recipient organisms will be cultured mammalian cells.

**Host/vector system**

The lentiviral vector systems used for these studies will be third generation replication-defective lentiviral vector systems. Only gag, pol and rev genes from HIV will be employed and these will be supplied in trans to facilitate virus packaging. All other HIV genes have been deleted. Examples of commercially available vectors with these properties include invitrogen's ViraPower (pLenti vectors), and Stigma's pLKO.1 vector systems.

High titre virus stocks will be generated by cotransfecting a 293FT packaging cell line with transfer and packaging vectors.

**Origin & function**

Genes to be overexpressed will be derived from human or other relevant mammalian species (e.g. rodent, dog, non-human primate). Genes will be those considered to be of potential relevance in disease processes and will be overexpressed in cultured cells to determine their functional activity and to enable discovery of novel drugs targeting the gene product. Genes will include those encoding cell receptors, ion channels, enzymes and regulatory proteins from cellular signalling pathways. Genes will be derived from in-house cloning efforts or from academic or commercial sources.

Inhibitory RNA sequences will be targetted to genes considered to be of potential relevance in disease processes. Targetted genes will include those encoding cell receptors, ion channels, enzymes and regulatory proteins from cellular signalling pathways. Inhibitory RNA sequences will be obtained from commercial sources.

**Evaluation of foreseeable effects**

The risk associated with overexpression or knockdown of individual genes will be considered on a case by case basis and reviewed locally by the GM safety committee prior to work being started. Particular consideration will be given to genes that may be oncogenic or immunomodulatory.

VSV-G pseudotyped lentivirus strains will be used and these strains will have the ability to infect human cells and cells from other mammalian species. However, because these strains are replication defective, the virus can only carry out a single round of infection. Structural genes and other components required for packaging the viral genome are separated onto three plasmids and have been engineered so as not to contain any homologous sequences to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. Cells that may contain virus sequences able to mobilise the lentivirus vectors by providing structural genes in trans will be excluded from these experiments.

Provirus insertion into the host genome will occur with high frequency and while this is unlikely to generate a harmful phenotype in the cultured mammalian cell (host cells from workers will not be used), there is a low probability of infection of a worker e.g. through accidental inoculation with packaged virus. Integration and long term expression of the recombinant gene or cDNA encoding inhibitory RNA could occur. There is a theoretical risk of transformation of cells by insertion of oncogenes or by knock-down of tumour suppressor genes. Because of the replication-defective nature of these vectors, this could only occur at low frequency and therefore unlikely to have a detrimental effect as a single event is unlikely to result in cellular transformation. Lentiviruses can also act as insertional mutagens. The
likelihood of this occurring is reduced by the use of a self-inactivating vector which disables the LTR regions in the integrated vector and thus reduces the risk of oncogene activation at the site of insertion. Additionally, because the vector is replication-defective, the level of exposure that might occur following accidental introduction of the virus will be low and thus reduces the probability of virus insertion at a site likely to promote tumourigenesis. However, because these vectors incorporate strong heterologous promoters and because provirus insertion is a feature of retrovirus biology, work with these vectors is assessed as a class 2 activity and the use of appropriate containment is used to minimise exposure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk of escape of GMO's to the environment, all work will be performed in containment level 2 biology laboratory. Cultures will be grown within leakproof vessels. All contaminated waste streams generated during the course of this work will be decontaminated on site. Virkon disinfectant will be added to liquid waste and left for a defined contact period prior to disposal. Solid waste will be autoclaved and subsequently incinerated prior to disposal. Additional information on disinfection procedures is included in departmental safety manuals. The only foreseeable release of viable waste from our facility is in the form of aqueous waste that has been inadequately treated, possibly in the event of an accidental spill to a sink. Such waste is emitted via our Waste Water Treatment Facility (WWTF) before final discharge to the River Stour. Processing via the WWTF is such that the virus concentration will be massively diluted and will not reach the river Stour for approximately 5 days after leaving the laboratory. The treatment regimen in the WWTF includes a 24hr disinfection step. Thus the risk of viable organisms entering the local environment is effectively zero.

Please enter comments on the GM safety committee on the risk assessment

This project was discussed with the HSE during a routine inspection by the Biological Agents Unit of the Pfizer facilities in April 2007. Under the new guidance from SACGM the Lentivirus work could be assigned as a class 2 activity. The HSE recommended that a generic notification and risk assessment should be submitted as a broad connected programme of work covering all Lentiviral vector work when the next Lentivirus project was proposed. Individual assessments would then be written at Pfizer for each proposed project but there would be no need to notify HSE of any future projects unless they fell outside the connected programme. A copy of the risk assessment was circulated to the full GMSC membership who gave their approval.

Project Containment

Laboratory Activities  Glass Houses  Growth Rooms

02/03/2022
Use of Staphylococcus aureus strains that have been genetically modified to eliminate or prevent expression of genes contributing to virulence.

The main parental organism is Staphylococcus aureus Newman strain. This strain was derived from a clinical isolate in 1954 and has since been widely used as an experimental laboratory strain. This strain is antibiotic sensitive and does not exhibit a highly pathogenic phenotype. Knock-out of virulence genes in other antibiotic resistant S. aureus parental strains exhibiting a similar level of pathogenicity will be subject to approval by the local GM safety committee.

Defined genetic deletions in virulence genes will be introduced into the genome of the parental strain by transposon mutagenesis or by homologous recombination using plasmids that are otherwise propagated in E.coli laboratory strains.
Genes that are known to be involved in pathogenicity of S. aureus will be disrupted by transposon mutagenesis or excised by homologous recombination. This modification will knock-out the expression of the genes and may introduce an antibiotic resistance (erythromycin or tetracycline) gene for selection of the modified strains. Knock-out of specific genes involved in virulence will be subject to risk assessment and approval by the GM safety committee.

**Evaluation of foreseeable effects**

The knock-out of alk genes under current consideration has been shown to render resulting strains less pathogenic than the isogenic parental strains. Current knock-out constructs harbour gene cassettes that confer erythromycin or tetracycline resistance. The risk of conferring resistance to erythromycin or tetracycline is considered insignificant since neither is the drug of choice for therapy of infection with the S. aureus Newman strain.

The risk associated with the knock-out of further individual genes will be considered on a case-by-case basis and reviewed locally by the GM safety committee prior to work being started. Particular consideration will be given to genes that may be global regulators of virulence and the use of antibiotic markers will be avoided or restricted to those that are not used for therapy of infection with S. aureus.

**Project Containment**
Project Additional Information

Purposes of the contained use

Parapoxvirus ovis (PPVO) strain D1701 will be used for the following experimental purposes:
1. To provide information on the characteristics of the expressed heterologous proteins.
2. To provide information on optimal growth conditions.
3. To produce pre-GMP master seed material.

Recipient or parental organism

Host/vector system

The parapoxvirus strain D1701-VrV used as a vector was extensively attenuated by more than 170 passages leading to attenuation by rearrangement of limited terminal
regions of the genome which is accompanied by gene deletion (E2L), the substitution of the amino acid isoleucine (position 115) in the viral 1L-10 (virulence factor) which is described to be very critical for retaining the stimulatory activity of human 1L-10 and the deletion of the VEGF-E gene (virulence factor of parapoxviruses and three further regions of its genome.

Origin & function
The vector contain the foreign gene will be infected in different mammalian cell culture systems to investigate its growth. Genes to be expressed will be derived from E.coli (only ßgalactosidase) and relevant mammalian viruses (e.g. cat, dog, pig, cattle, etc). No human virus gene will be expressed. Genes will be those considered to be of potential relevance in disease processess particularly with regard to protection, and will be expressed in cultured cells to determine their functional activity.

Evaluation of foreseeable effects
The primary host of parapoxviruses are ungulates. However, humans (and cats) can be alternate hosts reacting with localised epidermal lesions which heal without scaring. Although the parapoxvirus vector was demonstrated to be safe in permissive (sheep) and non-permissive animals (pigs, dogs), there is no data available for humans. Therefore, the risk for humans using the parapoxvirus (ACDP hazard group 2). For laboratory workers, ingestion, parental inoculation, and droplet or aerosol exposure of mucous membranes or broken skin are possible routes of infection. Work with this virus will be undertaken in a class 2 MSC using asceptic technique to reduce the risk of infection. Sharps will not be used. Infection through a direct contact with infected person or animal involves a substantial transfer of infectious virus through a cut or other break in the skin, which minimizes its ability to spread. Expression is under control of a synthetic early-late poxvirus promoter eLP-1 designed for protein expression in the mammalian cell. No expression will occur outside of the mammalian cell host. Damage should be considered on a case by case basis taking into account all known properties of the expression product or closely related proteins whose properties may be reflected.

In the event that a spillage does occur the quantity of the resultant spill will be such that it can be disinfected and a clean up operation performed within the confines of the laboratory without significant risk of escape to the environment.

**Project Additional Information**
### Purposes of the contained use

This assay will support an exploratory project seeking an antiviral cure for HBV infection

### Recipient or parental organism

Huh7 and HepG2 human liver cell lines

### Host/vector system

The HBV A938 strain (subtype adw2) will be cloned into a variety of commercially available vectors (pGEM7Zf+; pUC19, pCMV Script). This virus strain was chosen because the genome is well characterised and has been used extensively in the literature. The 3221 bp genome has been fully sequenced (Priesler-Adams et al [1993] Nucleic Acid res 21 p2258; Accession number X70185). Variants of HBV sequence to either C, S, P or X genes may be used in the assessment of barriers to drug resistance

### Origin & function

The expected result from the transfection of Huh7 cells with HBV sequences will be the production of HBV titres, including a proportion that will be infectious to humans. Occupational exposure in the laboratory setting would require a puncture wound (likely as a result of a needle-stick injury, injury with other contaminated sharp instruments), or as a result of contamination of the mucous membranes (eyes, nose and mouth transfer or via aerosols). Acute infection of non-immune non-vaccinated adults ranges from asymptomatic or mild disease to rarely fulminant hepatitis. Disease is more severe among adults ranges from >60 years. The fatality rate among non-immune, non-vaccinated infected cases reported to Center for Disease Control (CDC) is 0.5% - 1%. The risk for chronic infection varies according to the age at infection and is greatest among young children. Approximately 90% of infants and 25% -50% of children aged 1-5 years will remain chronically infected with HBV. By contrast, approximately 95% of non-vaccinated adults recover completely from HBV infection and do not become chronically infected (CDC, website).

Once inside a non-immune, non-vaccinated host, HBV is transported in the blood to the liver where it infects liver cells. The incubation period of acute HBV infection is about 75 days but it ranges from 45 to 200 days. The virus spreads efficiently in the liver and causes a spectrum of disease, ranging from acute hepatitis to more chronic liver disease and liver tumours. Asymptomatic infection and illness without jaundice does occur, particularly in the immunocompromised. The likelihood of a non-immune non-vaccinated colleague developing chronic infection is inversely related to age at the time of infection. Viral protein is secreted into the blood and its presence is useful marker of infection (usually HbsAg). Theses chronically infected individuals, who may be totally without symptoms, also present a major risk to non-immune health care workers and others accidentally exposed by, for instance, a needle-stick injury. In addition, the continued presence of viral proteins is associated with progressive liver damage (chronic active hepatitis and cirrhosis) and increased risk of primary liver cancer. Much of the damage to the liver in chronic cases is believed to be as a result of immune responses to the infection.

### Evaluation of foreseeable effects

The expected result from the transfection of Huh7 cells with HBV sequences will be the production of HBV titres, including a proportion that will be infectious to humans. Occupational exposure in the laboratory setting would require a puncture wound (likely as a result of a needle-stick injury, injury with other contaminated sharp instruments), or as a result of contamination of the mucous membranes (eyes, nose and mouth transfer or via aerosols). Acute infection of non-immune non-vaccinated adults ranges from asymptomatic or mild disease to rarely fulminant hepatitis. Disease is more severe among adults ranges from >60 years. The fatality rate among non-immune, non-vaccinated infected cases reported to Center for Disease Control (CDC) is 0.5% - 1%. The risk for chronic infection varies according to the age at infection and is greatest among young children. Approximately 90% of infants and 25% -50% of children aged 1-5 years will remain chronically infected with HBV. By contrast, approximately 95% of non-vaccinated adults recover completely from HBV infection and do not become chronically infected (CDC, website).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk of escape of GMO's to the environment, all work will be performed in containment level 3 biology laboratory. Cultures will be grown within leak-proof...
vessels. All contaminated waste streams generated during the course of this work will be decontaminated on site. Virkon disinfectant will be added to liquid waste and left for a defined contact period prior to disposal. Solid waste will be autoclaved and subsequently incinerated prior to disposal. Additional information on disinfection procedures is included in departmental safety manuals. The only foreseeable release of viable waste from our facility is in the form of aqueous waste that has been inadequately treated, possibly in the event of an accidental spill to a sink. All water from the CL3 Suite is held in an intercept tank and can be subjected to heat treatment before release if necessary. Such waste is emitted via our Waste Water Treatment Facility (WWTF) before final discharge to the River Stour. Processing via the WWTF is such that the GMO concentration will be massively diluted and will not reach the river Stour for approximately 5 days after leaving the laboratory. The treatment regimen in the WWTF includes a 24hr disinfection step. Thus the risk of viable organisms entering the local environment is effectively zero.

The risk of infection to humans near the Sandwich site would also be effectively zero. In humans, direct contact with another infected person is the normal route of infection and involves a substantial transfer of infectious virus. We note that other non-human primate species can be infected with HBV (gibbon, gorilla and tree shrew (Tupaia belangeri) if injected with high HBV titres. The location of the facilities reduces this xenotropic transmission risk to zero.

The risk assessment for this work has been approved by the local Genetic Modification Safety Committee.

Project Additional Information

Purposes of the contained use
To investigate the ability of HIV pseudotypes expressing different envelope to infect CD4+ lines expressing one or more chemokine receptor family. Infection will be determined by detection of luciferase activity.

Recipient or parental organism
HIV-1 pseudotyped virus (derived from HIV-1 clone pNL4-3) variety of mammalian cell lines.

Host/vector system

Origin & function
pNL4-3 HIV clone (pNL4-3-Lu-R+/E-) and HIV env clones obtained from Gladstone Institute, USA. The DNA clones will be co-transfected into mammalian cell lines to generate pseudotyped virus.
The pseudotype virus lacks a functional envelope gene, it is, therefore, unable to propagate in infected cell lines. As a consequence the pseudotype is considered to be non-pathogenic. The nef gene has been replaced with luciferase as a marker.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

**Purposes of the contained use**

Generation of herpes viruses containing natural proteins linked to a marker - Green Fluorescent Protein (GFP). This will allow detection of fusions in living cells and analysis of pathways involved in virus assembly. Use of mutated proteins linked to GFP will further aid understanding of mechanisms involved.

**Recipient or parental organism**

Routinely used mammalian cell lines, e.g. Vero, COS, etc. all are well characterised and authenticated with a history of safe use.

**Host/vector system**

HSV-1 strains, e.g. HSV-1 strain 17, Macro Plaque and tsB7.

**Origin & function**

Native marker genes fused to the marker gene for Green Fluorescent Protein (GFP) which is available commercially. Work involving mutated genes will also be undertaken. GFP has fluorescent activity which enables the location of the fusion protein to be determined. Insertion will be into the natural region of the gene under investigation. Gene sequences of interest are either regulatory, for transcription initiation, or are structural.
The inserts display no potential for a pathogenic phenotype. Expression will be identical to that of native viral genes. The recombinant virus will be identical to the parental strain except for expression of the desired candidate gene linked to GFP.

If the modification were to affect the virus it is most likely to disrupt the function for example, by the recombinant protein being too large to permit viral development. No effect on viral susceptibility to anti viral drugs such as acyclovir is envisaged.

The likelihood of an environmental hazard is negligible as herpes virus particles are labile and inactivated by drying.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (tissues, gloves, plasticware) is autoclaved at 121°C for 15 minutes (as measured in load) to give effectively 100% kill.

Sharps (needles used in gradient harvest) are disinfected by contact with 1% Virkon overnight prior to disposal into a sharps bin. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Waste media is inactivated by addition of Virkon tablets to a final concentration of not less than 1% and left overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Pipettes are decontaminated by complete submersion in 1% Virkon overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

If the use of glassware is unavoidable, this is decontaminated by complete submersion in 1% Virkon overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM Safety Committee on the risk assessment

The assessment has been approved by the Marie Curie Research Institute Biological Safety Committee for work at containment level 2.

Project Containment
Replication deficient lentiviral constructs encoding shRNAs will be used in the study of microtubule-associated proteins.

Historical Date of Additional Info
transferred to GM 13

Recipient or parental organism
Cell lines with a history of safe usage within the scientific community. Any primary cells used are isolated from sources held in a controlled environment and should therefore be free of pathogens. Any E.coli variants, cultured cells and replication-deficient lentivirus particles produced cannot survive outside the laboratory. Neither the generated virus particles nor the transduced cells are pathogenic to animals or plants.

Host/vector system
Well characterised E.coli K12 derivates, such as TOP1O. Lentiviral particles are designed for use in gene therapies and thus have the potential to infect human cells in vivo, however as none of the HIV-1 structural genes are actually present in the packaged viral genome, they are not able to propagate in vivo.

Lentiviral constructs encoding shRNAs targeted against murine microtubule-associated proteins will be transferred, using lentivirus, to cell lines. shRNAs will be used to bring about RNA interference, silencing the targeted genes and enabling studies on the function of microtubule-associated proteins. Other constructs expressing microtubule-associated proteins with epitope tags or fluorescent proteins will also be produced in order to allow live cell imaging and biochemical experiments.

Origin & function

Lentiviral constructs encoding shRNAs targeted against murine microtubule-associated proteins will be transferred, using lentivirus, to cell lines. shRNAs will be used to bring about RNA interference, silencing the targeted genes and enabling studies on the function of microtubule-associated proteins. Other constructs expressing microtubule-associated proteins with epitope tags or fluorescent proteins will also be produced in order to allow live cell imaging and biochemical experiments.

Evaluation of foreseeable effects

Inserts display no potential for a pathogenic phenotype. The likelihood of an environmental hazard is negligible as none of the particles produced can survive outside the laboratory. Neither the generated virus particles nor the transduced cells are pathogenic to animals or plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Maximum culture volume is 500ml supernatent. Liquid waste is deactivated by contact with a solution of 2% Hycolin bactericide for 12-24 hrs in accordance with the manufacturer's instructions. Solid waste material is bagged and autoclaved within 24 hours. The autoclave cycle runs for 30 mins at a minimum of 134°C at a pressure of 2.22 bars which provides a deliberate overkill. Autoclaves are tested annually to validate that the correct temperature and pressure have been reached for the required time. Heat reactant tape is used to provide verification that each load reaches the correct conditions.

Date of Significant Change

**Project Additional Information**
**Purposes of the contained use**

Determine whether high levels of Ang1, which influences the permeability of blood vessel walls to circulating plasma proteins, affect tumour growth and sensitivity to treatment (combretastatin and other). In detail:

Ang1adeno (constructed elsewhere) will be propagated in human kidney 293 cells to high titer and harvested. Mammalian cells will be infected with this replication-defective adenovirus and assayed for ang1 production and function. Ang1adeno will be administered and effect of treatment (CA4P or other vascular targeting agent) analysed some time later.

**Recipient or parental organism**

Long term established cell lines will be used, which are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive autonomously outside the laboratory. Cell lines to be used include: human HEK293, human HT29, murine CaNT. Since the virus has been constructed elsewhere, there is no need for bacterial amplification. For in vivo transduction adenovirus will be be administered. No infectious virus has every been recovered from transduced animals or humans, even if viral genome was detectable by PCR amplification.

**Host/vector system**

A gutless adenovirus (replication deficient recombinant human adenovirus 5) will be used to deliver angiopoietin 1 (Ang1). This adenovirus is deleted for E1 (transcriptional regulator, required for assembly of infectious particles) and E3 (evasion of host immunity) and can only be propagated in specific, modified cells (human embryo kidney HEK293)). It is therefore unlikely to spread from the transduced cells to humans or any other organisms. However, owing to the nature of production of these viruses, there is a possibility of reversion to wild-type viruses by recombination with viral genes stably expressed within 293 cells, thus producing wild type virus. In the adenovirus used in this project (Adenoquest, Q-Biogene) the transgene (Ang1 has been inserted into the region where E1 has been deleted. That should ensure the loss of the transgene in the event of recombination to generate wild-type, replication efficient virus.

**Origin & function**

The gene to be used is of human origin. Angiopoietin 1 is involved in the maturation phase of angiogenesis. It is a growth factor which acts on tyrosine kinase receptors specifically on endothelial cells. Over-expression of Ang 1 or treatment with exogenous Ang 1 results in vessels which are particularly resistant to leaking. Ang 1 acts as an endothelial cell survival factor preventing apoptosis. In this project Ang1adeno will be used to determine whether high levels of circulating Ang1 affect treatment.

**Evaluation of foreseeable effects**

Overall, the risk posed by this project is low. Mammalian cells (rodent and human) are very low risk as they are unable to survive in a non-histocompatible host. Unmodified Ad5 is associated with mild respiratory infections in children. The majority of the population is likely to have antibodies to the wild type virus, and therefore the immune system would rapidly clear any new potential infection. The virus however is non-enveloped and relatively resistant to desiccation. Unmodified Ad5 is a biological hazard group 2, and the replication deficient Ad5 virus is likely to be less pathogenic. However, due to the nature of the insert, the GMO is potentially more hazardous than the replication-deficient virus. There is no evidence in the literature that Ang1 is oncogenic. Ang1 poses a very low risk to humans and the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste, including liquid waste, will be inactivated by 2x autoclaving (temperature probes and autoclave tape will be used, and printouts per batch kept for validation) and chemical means (Vircon), as appropriate. Waste will be transferred in sealable containers. Solid waste will additionally be incinerated prior to disposal. These measures...
should kill all viable microorganisms.

Class II safety cabinets will be serviced twice a year (containment and functional validation and certification by approved contractors) following formaldehyde fumigation. All contaminated areas, equipment (including cryostats and microscope stages) and plastic waste will be cleaned after each use using Vircon and 70% ethanol or IMS. Containment: all work will be carried out in designated laboratories using good laboratory practice following the Gray Cancer Institute codes of practice (see risk assessment for further details).

Is an emergency plan required according to regulation 20?

Project notified under transitional arrangements
### Project Additional Information

#### Purposes of the contained use

To efficiently express Rho proteins in human and rodent endothelial cells using replication-defective adenoviruses. The aim is to determine whether Rho proteins are involved in the functional response of tumour blood vessels to tubulin binding agents and whether by modulating their expression this response can be altered. This project will involve the expression of Rho proteins using replication-defective adenoviral vectors in normal or tumour-derived human or rodent endothelial cells and the effect of treatment (combretastatin or other vascular targeting/tubulin-binding agent). Subsequently analysed.

Primary viral stocks (supplied by UCL) will be amplified by further rounds of infection in human kidney 293 cells. Virus will be harvested, purified and used to infect mammalian cells.

#### Recipient or parental organism

Human kidney cell line 293 will be used for purification of recombinant adenoviral particules. Primary cell lines as well as long-term established cell lines as well as that have no capacity to survive autonomously outside the laboratory will be infected with the adenoviruses. Cell lines to be used include: human or rodent primary endothelial cells and transformed human endothelial cell lines. No infectious virus has ever been recovered from transduced animals or humans, even if viral genome was detectable by PCR amplification. Since the viruses have been constructed elsewhere, there is no need for bacterial amplification.

#### Host/vector system

Replication deficient recombinant adenovirus strain 5 deleted of regions 1 and 3 (Ad5 1 3) containing cDNAs for Rho, Rac, cdc42, B-galactosidase, or GFP (Wojciak-Stothard et al, J cell Science, 2001, 114:1343-1355). This adenovirus is deleted for E1 (transcriptional regulator, required for assembly of infectious particles) and E3 (evasion of host immunity) and can only be propagated in specific, modified cells (human embryo kidney HEK293). It is therefore unlikely to spread from the transduced cells to humans or any other organisms. However, owing to the nature of production of these viruses, there is a possibility of reversion to wild-type viruses by recombination with viral genes stably expressed within 293 cells, thus producing wild type virus. In the adenoviruses used in this project the transgenes were inserted into the region where E1 has been deleted. That should ensure the loss of the transgene in the event of recombination to generate wild-type, replication efficient virus.

#### Origin & function

Human cDNAs encoding the small GRPases Rho, Rac, Cdc42, B-galactosidase and GFP (supplied by Dr Ridley, see Wojciak-Stothard et al, J cell Science, 2001, 114:1343-1355). The intention is to inhibit or activate specific intracellular signalling pathways by expressing these proteins transiently in cultured mammalian cells. Cells will be subsequently exposed to tubulin binding agents used as anti-vascular agents in the treatment of cancer. B-galactosidase and GFP will be used to identify cells that have been infected.

#### Evaluation of foreseeable effects

Adenoviruses are able to infect mammalian cells. The viruses used here are replication-defective, and therefore will not multiply in mammalian cells or spread between organisms. Safety procedures are in place so that the risk of a worker infecting their own cells with the adenoviruses is extremely low. Although the viruses are replication defective, adenoviral DNA can persist for several weeks in cells, and thus the proteins could potentially damage the cells infected. Infected cells are normally rapidly evaluated.

02/03/2022
cleared by the immune system, as most people have previously been infected with adenoviruses. There is no indication that Rho family proteins would hinder clearance of cells by the immune system. The waste disposal procedures eliminate the possibility of live adenoviral particles escaping from the Category 2 laboratory where they are handled, therefore the risk to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be deactivated with hypochloride (10,000 ppm active chloride) for at least 6 h and then disposed of down laboratory sinks. Pipette tips, culture dishes and pipettes will be deactivated with hypochloride (2,500 ppm active chloride) for at least 6 h and then autoclaved twice at 138 degrees C for 30 min and then disposed of by incineration. Solid waste will be autoclaved twice as above and then disposed of by incineration. Waste will be transferred in sealable containers. Temperature probes and autoclave tape will be used, and printouts per batch kept for validation. These measures should kill all viable microorganisms.

Class II safety cabinets will be serviced twice a year (containment and functional validation and certification by approved contractors) following formaldehyde fumigation. All contaminated areas, equipment (including cryostats and microscope stages) and plastic waste will be cleaned after each use using Vircon and 70% ethanol or IMS.

Containment: all work will be carried out in designated laboratories using good laboratory practice following the Gray Cancer Institute codes of practice.

Is an emergency plan required according to regulation 20?

Project Additional Information

Purposes of the contained use

We aim to produce immortalised, transformed mouse embryo fibroblasts (MEFs). These MEFs are derived from knock-out, transgenic mice which express only single isoforms of the vascular endothelial growth factor (VEGF: 121, 164 or 188).

In detail:
DNA from plasmid vectors containing the Simian Virus 40 (SV40) large T antigen or activated ras will be prepared from transfected E. coli cultures. The plasmids will then be transfected by non-viral methods (Ca-phosphate or similar) into specific packaging cells (BOSC 23). BOSC cells contain the packaging signals required to produce infectious ecotropic retroviral particles. High titre virus will be harvested from the BOSC cells and used to transduce mouse embryo fibroblasts (MEFs). The MEFs will first be immortalised, using SV40 large T antigen, and subsequently transformed to tumourigenic cell lines using activated ras. The 'fibrosarcoma' cells can then be used to form tumours in mice.

The vectors (pBABE and pLXSN) will be transfected into E. coli Top10 cells and the DNA prepared (Maxi prep). These E. coli are multiple auxotrophs, recombination deficient. The packaging cells, BOSC 23, are a human kidney cell line which has undergone a range of modifications. Human embryonic epithelial kidney cells were transformed and immortalised using sheared human Ad5, producing the cell line 293. These were further modified for high transfectability by addition of a temperature sensitive (ts) SV40 large T antigen, producing cell line 293T/17. In several further steps the retroviral genes gag, pol and env were inserted to produce a helper-free packaging cell line, BOSC 23 (Pear et al., PNAS, 1993). BOSC 23 cells are specifically used as ecotropic (mouse specific) envelope-expressing cells which produce infectious retrovirus at high titer.

The retrovirus will subsequently be used to infect mouse embryo fibroblasts (MEFs), derived from transgenic mice. These primary cells have a limited life span unless they are immortalised. No known risks are attached to their use.

Mammalian cells are very low risk as they are unable to survive in non-histocompatible hosts.

Recipient or parental organism

The vectors (pBABE and pLXSN) will be transfected into E. coli Top10 cells and the DNA prepared (Maxi prep). These E. coli are multiple auxotrophs, recombination deficient. The packaging cells, BOSC 23, are a human kidney cell line which has undergone a range of modifications. Human embryonic epithelial kidney cells were transformed and immortalised using sheared human Ad5, producing the cell line 293. These were further modified for high transfectability by addition of a temperature sensitive (ts) SV40 large T antigen, producing cell line 293T/17. In several further steps the retroviral genes gag, pol and env were inserted to produce a helper-free packaging cell line, BOSC 23 (Pear et al., PNAS, 1993). BOSC 23 cells are specifically used as ecotropic (mouse specific) envelope-expressing cells which produce infectious retrovirus at high titer.

The retrovirus will subsequently be used to infect mouse embryo fibroblasts (MEFs), derived from transgenic mice. These primary cells have a limited life span unless they are immortalised. No known risks are attached to their use.

Mammalian cells are very low risk as they are unable to survive in non-histocompatible hosts.
The retroviral vectors to be used are based on the Moloney murine leukemia virus (MoMuLV), or on both MoMuLV and Moloney murine sarcoma virus (MoMuSV), pBABE and pLXSN, respectively. They are ecotropic, i.e., they will only infect mouse cells due to the virus envelope carried within the BOSC cells. The retroviral vectors (pBabe and PLXSN) have most of the viral structural genes missing, so that these vectors cannot replicate (Morgenstern and Land, NAR, 1990; Clontech). To prepare viral stocks, packaging cells are used which contain the complementary genes in the form of an integrated provirus, but lacking the sequence recognized by the packaging apparatus. Thus, the packaging provirus produces all the proteins required for packaging of viral RNA into infectious virus particles but it cannot package its own RNA. Instead, RNA transcribed from the transfected vectors is packaged into infectious virus particles and released from the cells. The resulting virus stock is termed helper-free because it lacks wild-type replication-competent virus. Production of wild type virus by homologous recombination is largely eliminated by multiple genetic changes of the packaging cells and the vector, and more than two crossover events would be required for generation of replication competent virus (Pear et al., 1993).

The retroviruses to be used here are ecotropic infecting only mouse cells. The risk to humans is therefore very low, but care has to be taken not to endanger the in-house mouse colony. The wild type virus is oncogenic in mice. This risk is greatly reduced because the viruses are replication deficient and can only be propagated in specific packaging cells. Additionally, retroviruses require close contact and dividing cells for transmission, and their survival in the environment is poor.

**Host/vector system**

The SV40 large T-antigen (adenovirus EB1 55k protein, SV40 Tag) causes cell transformation in tissue culture and in animals. Unlike many other oncogene products that must act co-operatively to fully transform cells, the T antigen alone can convert primary cells to tumorigenic cells. SV40 Tag binds and inactivates cellular tumour suppressor gene products, including Rb and p53. It interferes with p53 leading to a reduction in cellular apoptosis and subsequent immortality. SV40Tag cooperates with ras oncogene to transform rat embryo fibroblasts (Cavender et al., J Virology, 1995).

Oncogenes are mutated forms of proto-oncogenes which function to control cell proliferation and differentiation. When proto-oncogenes mutate to become oncogenes the result is excessive cell multiplication leading to malignant transformation. The largest class of oncogenes are signal transducers that act as proteins which transmit signals from a receptor to their cellular target. These include the Ras family. Uptake of GTP activates Ras. Activated Ras phosphorylates the first member of a three-enzyme cascade (MAPK kinase cascade). Activated MAPK has an immediate impact upon a variety of cytoplasmic processes and a later impact upon gene expression, where it phosphorylates a transcription factor increasing expression of its target genes. The cytosolic effects of MAPK are accomplished by phosphorylation of inhibitors (Inh) of translation initiation factors. (TIFs). The phosphorylation changes the affinity of the inhibitor for the TIF, releasing and activating the TIF. The result is increased translation of target mRNAs in the cytosol.

Both SV40Tag and activated ras function as oncogenes able to transform the target cells. Both genes are controlled by strong constitutive promoters.

**Origin & function**

Overall, the risk posed by this project is low. Although the genes used to immortalise the cells are oncogenic, the ecotropic retrovirus is replication deficient and infects only mouse cells. Risk to human health is therefore low. The BOSCs and immortalised MEFs carry a very low risk to human and animal health as they are unable to establish themselves in non-histocompatible hosts. Once the oncogenes have integrated in the MEFs, and no life virus can be demonstrated, cells can be handled safely at level 1.

**Evaluation of foreseeable effects**

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste, including liquid waste, will be inactivated by 2x autoclaving (temperature probes and autoclave tape will be used, and printouts per batch kept for validation) and chemical means (Vircon), as appropriate. Waste will be transferred in sealable containers. Solid waste will additionally be incinerated prior to disposal. These measures should kill all viable microorganisms.

Class II safety cabinets will be serviced twice a year (containment and functional validation and certification by approved contractors) following formaldehyde fumigation. All
Contaminated areas, equipment (including cryostats and microscope stages) and plastic waste will be cleaned after each use using Vircon and 70% ethanol or IMS. Containment: all work will be carried out in designated laboratories using good laboratory practice following the Gray Cancer Institute codes of practice.

**Project Additional Information**

**Purposes of the contained use**
We will investigate whether acute modulation of angiopoietin (Ang 1/2) or vascular endothelial growth factor (VEGF) activity in tumours can affect tumour vascular permeability and tumour response to vascular targeting agents (eg combretastatin A4-P). We will produce stably transfected tumour cells using the inducible Ecdysone or Tet-on/Off systems.

**Recipient or parental organism**
Bacterial hosts are multiple auxotrophs unable to survive in humans or the environment; the mammalian cells are long established cell lines (a tissue culture system where the vector does not have the ability to transfer DNA to other cells).

**Host/vector system**
The vectors are specifically designed as inducible systems which require specific inducing agents (Muristerone A, tetracyclin or similar) for gene expression, without inducing agents basal gene expression is very low; they are commercial plasmids (pIND and pVgRXR (Invitrogen); pTRE and pTet-on/pTet-Off (Clontech)) which are designed to express the genes of interest in mammalian cells but not in bacteria; the vectors are non-mobilisable.

**Origin & function**
The growth factor-encoding genes are unlikely to cause any damage to humans or the environment. The properties of the growth factors are well known and documented in the literature. Ang 1 and 2, and VEGF are of human origin and are involved in the maturation phase of angiogenesis. They are growth factors which act on tyrosine kinase receptors specifically on endothelial cells. Although they might give cells a growth advantage, they do not induce tumorigenicity, and therefore pose a low level of risk.

Ang1: Over-expression of Ang1 or treatment with exogenous Ang1 results in vessels which are particularly resistant to leaking. Ang1 acts as an endothelial cell survival factor preventing apoptosis.

Ang2: Ang2 counteracts blood vessel maturation/stability mediated by Ang1. Ang2 induces de-stabilisation of blood vessels during the process of angiogenesis.

VEGF: VEGF induces endothelial cell proliferation, migration and tube development. Both VEGF and Ang1 act as endothelial cell survival factors, preventing apoptosis. Adenoviral delivery of VEGF has been used for coronary artery disease and other cardiovascular diseases in over 14 gene therapy protocols worldwide.

The growth factors are not oncogenic and pose a low risk to humans and the environment.

**Evaluation of foreseeable effects**
Overall, the risk posed by this project is low. The GMO, namely bacteria (auxotrophs) and mammalian cell lines (low risk) are considered low risk. The growth factors are not oncogenic and pose a low risk to humans and the environment. HSE definition: Oncogenes make cell tumorigenic or give growth advantage, but oncogenes that give growth advantage without inducing tumorigenicity are low level of risk.

Comments from the GMAG Safety Committee meeting held on 26 November 2002:
The Committee came to the conclusion that this project should be presented to the HSE as a level 2 project, not as a level 1 project as initially envisaged, due to the nature of the growth factors involved.

The maximum culture volume that could be released as liquid waste would be in the order of 200 mls. per day, although it would normally be less than this. At present this is treated with a Biocide prior to disposal via drains, but this is about to be changed in favour of autoclaving for 20 minutes at 120 deg. Contaminated plasticware is autoclaved as above prior to collection and subsequent incineration by an accredited waste disposal contractor.

The maximum volume of deactivated culture waste that will be disposed of at any one time will be 0.5 litre. All liquid and solid contaminated waste will be deactivated through autoclaving. This method of deactivation has been validated for the relevant autoclaves by attempted culture of routinely used strains of E.coli from autoclaved waste - no bacterial growth was observed from the waste. The deactivation method will be monitored through the use of temperature sensitive strips placed in the waste.

<td>Investigation into TB Associated Genes in Host Responses to BCG Infection using a</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
The project involves using BCG-EGFP for visualization of BCG infection of macrophage in culture to analyse cellular gene expression changes after infection. Experiments will include the preparation of BCG-EGFP and subsequent infection of primary human macrophages.

**Recipient or parental organism**

The parental organism is Bacillus Calmette-Guerin (BCG) vaccine strain.

**Host/vector system**

Plasmid pTKmx for generation of BCg-EGFP is a mycobacterium-E.coli shuttle vector that harbors a promoterless xylE reporter gene downstream of a transcriptional terminator. This shuttle introduce enhanced green fluorescent protein gene (egfp) into BCG.

**Origin & function**

The green fluorescent protein (GFP) is protein composed of 238 amino acids (26.9kDa), which exhibits bright green fluorescence when exposed to blue light. GFP was first isolated from the jellyfish Aequorea victoria. GFP has been optimized for brighter fluorescence and higher expression in mammalian cells, thus the modified GFP called enhanced GFP (EGFP).

**Evaluation of foreseeable effects**

BCG vaccination are effectively used for prevention of TB in the world, and complications of BCG vaccination are uncommon. BCG has been confirmed as effective and safe in the control and prevention of TB in human for more than 60 years. Cattle are the natural host of BCG.

EGFP has been a popular marker for both cellular and molecular research for decades and no harmful effects of over-expression have been reported. Therefore, the severity of accidental infection with BCG-EGFP should not exceed that of BCG vaccinations.

BCG-EGFP has been used for research purposes for over 20 years and accidents using BCG-EGFP have not reported. Therefore it is not expected to have any effect on the pathogenic or environmental survival characteristics of the unmodified BCG host.

The members of research team have no contact with cattle or other bovine species.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Culture and application of BCG-EGFP will be carried in full Containment Level 2 laboratories.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All discarded cultures, media and materials for tissue culture/bacterial culture and infection will firstly be treated with Trigene (1:20). Trigene has a wide spectrum of activity against viruses, some fungi, and bacteria. 5% Trigene has been tested specifically on mycobacteria cultures and has been shown to be 100% effective. After Trigene treatment, flasks, plates and tubes etc will then be autoclaved - this is standard operating procedure for the CL2 laboratories in the Department of Medicine. Autoclaves are routinely tested using "spore strips".

Liquid waste will be disposed to the drain. These measures will reduce the likelihood of all hazards to negligible (100% kill). The overall risk is therefore effectively zero with the proposed waste management measures.

Experiments are planned to infect primary macrophage cultures using an EGFP-tagged BCG. Although a hazard group 2 organism, BCG vaccination is effectively used for prevention of TB - complications of BCG vaccination are uncommon. An EGFP-tagged variant would be unlikely to alter the natural pathogenicity/tissue tropism of BCG. The committee agreed with the risk assessment of the work as a Class 2 activity. All work will be carried out in the Department of Medicine's containment level 2 laboratories.
Identifying human genetic variants that control gene expression in macrophages upon Mycobacterium tuberculosis (MTB) infection

Date of Significant Change

Project Additional Information

Purposes of the contained use

The project involves using:

- MTB-GFP (green), MTB-mCherry (red) and MTB-Charge3 (red) for visualization of MTB infection of cultured macrophages to monitor phagocytosis and analyse cellular gene expression changes upon to infection. Experiments will include the preparation of MTB-GFP/mCherry/Charge3 and subsequent infection of primary human macrophages.

- MTB-luxAB will be used to monitor survival of bacteria after infection. Experiments will include the preparation of MTB-luxAB and subsequent infection of primary human macrophages.

- MTB transposon mutants will be used in the same manner to study the role of certain genes in the above mentioned procedures.

Recipient or parental organism

The parental organism is Mycobacterium tuberculosis H37RV laboratory strain

Host/vector system

MTB-GFP:
plasmid pATB51

MTB-mCherry:
plasmid pCHERRY3 (Addgene ID 24659)
vector backbone: pSMT3-S (5582 bp, hygromycin resistant), insert: mCherry (1450 bp, synthetic gene)/, promoter: Psmyc, host: DH5alpha
MTB-Charge3: plasmid pCHARGE3 (Addgene ID 24658)
vector backbone: pSMT3-S (5582 bp, hygromycin resistant), promoter: Psmyc, insert: Turbo (1450 bp, synthetic gene), host: DH5alpha

MTB-luxAB:

MTB transposon mutants:

Origin & function

The inserted plasmids have no eukaryotic promoter, they encode a green fluorescent protein (EGFP)/red fluorescent protein (mCherry, Charge3) or luciferase gene.

The green fluorescent protein (EGFP) exhibits bright green fluorescence when exposed to blue light. GFP was first isolated from the jellyfish Aequorea victoria. GFP has been optimized for brighter fluorescence and higher expression in mammalian cells, thus the modified GFP called enhanced GFP (EGFP).

Red fluorescent proteins (mCherry, Charge3) are synthetic genes derived from DsRed, which was isolated from Discosoma striata. They have red-shifted excitation and emission maxima.

luxAB genes were originally subcloned from Vibrio harveyi into vector SMT1 and are expected to generate luciferase, an oxidative enzyme that catalyses light-emitting reactions.

Evaluation of foreseeable effects

The genetic modifications made by the insertion of fluorescent genes do not alter the virulence nor pathogenicity of the MTB H37Rv strain. Therefore, the foreseeable effects remain the same as for the parental strain.

Any gene function abolished or modified in the transposon library could result in a GMM that could have
A) no change in properties
B) reduced ability to grow or cause disease.

In these cases (A and B) the direct hazard of the inserted gene product results in a GMM that is less than or equal to that of the parental wild-type organism.

C) could, hypothetically, have a phenotype altered in favour of increased pathogenicity. For instance:

(i) Deletion of a repressor of virulence could result in bacteria in which genes normally only expressed during a particular phase of infection are switched on permanently. This may at first sight imply an increased hazard, but this is unlikely as the mechanism of pathogenicity in MTB is based on the ability to switch multiple sets of genes on and off at e.g. specific times.

(ii) Deletion of a growth repressor could increase replication; this is highly unlikely as the slow growth rate of mycobacteria is considered to be controlled by e.g. ribosome number. Thus, again, multiple genetic manipulations would be required to influence growth rate. Also, there is no evidence to suggest that increased growth rate would lead to an increase in TS virulence.

(iii) Deletion of a dominant antigen involved in immune recognition could allow the bacteria to avoid recognition and cause more disease. This is, again, highly unlikely as immune recognition is a multiple-antigen dependent event and it is known that TS deletion mutants of dominant antigens have reduced or unaltered virulence. Also, this would be highly unlikely as mycobacteriophages used for Mtb transposon mutant library deliver the transposon of interest in a gene-specific mechanism which allows a single and specific gene deletion for each mycobacteria.
With all this in mind, we believe it acceptable for the MTB transposon mutant library to be treated as hazard group 3 organism, exactly as the wild-type bacterium. In essence, GMM pathogenicity is unlikely to increase, and infectious route highly unlikely to change, therefore there is no increased exposure hazard risk or disease risk. It is also likely that many of these transposon mediated changes arise by natural mutation in the environment and many uncharacterised clinical strains of M.tuberculosis may well have such altered phenotypes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The present notification does not contain any larger GMO.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Cultures and applications of the MTB strains described in the present notification will be carried in full containment level 3 laboratories, already routinely handling MTB, therefore no derogation is requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

After work, surfaces will be disinfected with 70% ethanol allowing a contact time until complete dry of ethanol, then with 10% Distal for a minimum of 10 minutes. Liquid waste will be discarded into 100% Distal. As the effective concentration of Distal is lower than 10%, any dilution made by addition of liquid waste will not reach a final concentration below 10%. Solid waste will be sterilised by autoclaving in the CL3 autoclave followed by incineration on the Hospital site. All surfaces in the CL3 laboratory will be disinfected with 70% ethanol and then 10% Distal on a weekly basis. Microbiological safety cabinet shall be fumigated prior to a cabinet service/inspection and always after any spills of infectious material. This is standard operating procedure for the CL3 laboratories in the Department of Medicine. These measures will reduce the likelihood of all hazard to negligible (100% kill). The overall risk is therefore effectively zero with the proposed waste management measures.

**Please enter comments on the GM safety committee on the risk assessment**

Experiments are planned to infect monocyte-derived macrophages using a EGFP/mCherry/Charge3/luxAB-tagged and mutant MTB. Although a hazard group 3 organism, the tagged variants would be unlikely to alter the natural pathogenicity/tissue tropism of MTB. The committee agreed with the risk assessment of the work as a Class 3 activity. All work will be carried out in the Department of Medicine's containment level 3 laboratory (Rm 5801). This laboratory is already registered and is routinely using un-modified MTB.

02/03/2022
The aim is to characterise genetic factors expressed by Hazard Group I or 2 (HG1 or HG2) bacterial associated with infection or colonisation of vertebrates. We study multiple HG1 and HG2 bacteria including Salmonella enterica, Citrobacter rodentium (a mouse specific pathogen), Shigella sonnei, Clostridium difficile, Listeria monocytogenes, Klebsiellas, Staphylococci, Pneumococi, Enterococci, Aeromonas spp and Escherichia coli. Any Enterohemorrhagic E. coli (EHEC) used at CL2 do not encode verotoxins. Specific HG2 organisms excluded from this risk assessment are those on the Schedule 5 list of bacteria as well as Vibrio cholerae, Neisseria meningitidis, Bordetella pertussis/parapertussis and Corynebacterium diphtheriae. The allowed bacteria are associated with infections that can be acquired by different routes including oral, respiratory, parenterally through damaged body surfaces or via the urogenital tract. We also study commensal and environmental bacteria that do not normally cause infection. The aim of this work is to better understand the mechanisms by which these bacteria colonise or infect their hosts. We are also interested in how they avoid therapies such as vaccines and antibiotics by acquiring resistance. Our work may lead to the development of new antibiotics or vaccines.

Functional analysis of virulence-associated factors through genetic manipulation requires that the genes encoding them be mutated and the resultant phenotype characterised through various assays. It is also essential to confirm that any reduction in virulence is indeed due to the mutation created and not by so called ‘off target’ effects involving non-targeted genes. Mutagenesis is performed by a variety of techniques that involve introducing mutated DNA back into the targeted host bacteria. Validation is performed by reintroducing the wild type gene on a plasmid/chromosome and confirming restoration of the wild type phenotype in the complemented strain. E.
coli K12 routinely acts as an intermediate host for manipulating cloned DNA prior to reintroduction into the recipient bacteria. Antibiotic resistance genes and other non-toxic biological reporter genes (e.g. LacZ, CAT, GFP, Lux etc.) can be introduced into the recipient during manipulation. The recombinant bacterial products of this work are, however, sensitive to the antibiotics recommended for therapy of human infection.

To characterise bacterial proteins of interest we will overexpress these in calcium competent, non-virulent E. coli K-12 or B (DE3) strains using the pET vector system (transformation and induction by isopropyl β-D-1-thiogalactopyranoside, IPTG), and subsequently purify them for protein-based assays. The proteins will in most cases be fused with affinity tags such as 6HIs or FLAG tags to aid purification.

Individual or blocks of genes will be mutated using a variety of approaches including transposition, transduction, the one step lambda red system, other PCR-based systems, via suicide vectors or using recombinase/PCR approaches. Targeted genes may be amplified by PCR or recovered from chromosomal digests and cloned into existing suicide, expression or other vectors. Initially, the cloned genes may be introduced into a permissive intermediate host - E. coli K12, analysed (e.g. digests and sequencing) and then to their final host - a strain for mutagenesis or protein overexpression. Since we are sometimes working on related enteric pathogens that can share some virulence determinants and mechanisms of infection (e.g. S. enterica, E. coli, Citrobacter) we may introduce plasmids from one source into strains from other named species backgrounds. In some experiments non-toxic reporter genes and antibiotic resistance genes will be introduced into the mutated target gene.

Host bacteria include: -

K-12 and B derived E. coli (for the purposes of this project will be used only under containment level 2 requirements).
Salmonella enterica (all non-hazard Group 3 serovars) including disabled S. Typhi
E. coli (EHEC used at CL2 are verotoxin-negative).
Citrobacter rodentium
Shigella sonnei
Campylobacter spp
Listeria spp
C. difficile
Klebsiella spp.
Aeromonas spp
Staphylococci
Streptococci
Yersinia spp (all non-Hazard Group 3 species – specifically excluding Y. pestis)

Recipient or parental organism

We can use all wild type HG2 organisms as targets for mutagenesis except those mentioned in section 6. These bacteria are capable of causing diseases in humans and are classified below according to the main phenotypic characteristics. K-12 derived E. coli is a common intermediate host. The targeted bacteria include: -

Gram-negative enterics

The bacteria normally live in the intestines of humans and other animals where they can be part of the normal flora. Some are capable of causing enteric diseases (gastroenteritis, diarrhoea, inflammation etc.) and some can spread systemically in compromised hosts. They are normally spread via oral ingestion and not by aerosols.

Salmonella enterica (all non-hazard Group 3 serovars)
E. coli (EHEC used at CL2 are verotoxin-negative).
Citrobacter rodentium
Shigella sonnei

**Gram-positive pathogens**

Can live on body surfaces but can form skin and wound infections. Can live in the respiratory tract.

- *Clostridium difficile*
- Enterococci spp
- Staphylococci
- Streptococci
- Pneumococci
- Listeria spp

**Others**

These can cause a variety of infections in humans. Common hospital-acquired bacteria

- Acinetobacter
- Pseudomonads

We use a variety of well characterised plasmid vector systems in addition to the hosts described in the previous section.

**Host/vector system**

We use a variety of well characterised plasmid vector systems in addition to the hosts described in the previous section.

Mob indicates mobility status (Mob + or -).

Tra indicates ability to self-conjugate (+ or -)

BoM is Basis of mobility and cannot be mobilised

The vectors include:

- pCVD442, (AmpR, Mob+, suicide vector can only grow in strains that have pir)
- PWSK29, (AmpR, derived from pBSKII and pGL339)
- pHG75, (AmpR, TcR, Mob-, Tra-, Bom-)
- TopoXL, (KanR, Mob-, Tra-, Bom-)
- pGEMT, (AmpR, Mob-, Tra-, Bom-)
- pUC18/19, (AmpR, Mob-, Tra-, Bom-)

- pET28a (KanR)
- pET22b (AmpR)

AmpR (Ampicillin resistance), KanR (Kanamycin resistance), CmR (Chloramphenicol resistance), TcR (Tetracycline resistance). None of these antibiotics would be used to
treat clinical disease associated with these pathogens.

Origin & function

Most of the DNA used in manipulations originates from the same bacteria we are targeting (homologous gene replacement). Antibiotic resistance genes and other non-toxic biological reporter genes (LacZ, CAT, GFP, Lux etc.) can be introduced into the recipient during manipulation. The recombinant bacterial products of this work are, however, sensitive to the antibiotics recommended for therapy of human infection. Genes may be introduced in expression vectors into non-hazardous E. coli K-12 or B strains for over-expression and purification of recombinant proteins. The recombinant bacterial products of this work are not likely to be hazardous and the recombinant bacteria will remain sensitive to the antibiotics recommended for therapy of human infection.

Evaluation of foreseeable effects

The mutants are characterised to confirm the nature of the introduced mutation (e.g. by DNA sequencing). They may then be analysed by a variety of phenotypic approaches including growth characteristics, antibiotic sensitivity, infection of mammalian cells, DNA/RNA/protein analysis, metabolomics, imaging etc. Complementation can be attempted to restore the wild type phenotype by introducing a wild type copy of the gene(s) back into the mutant bacteria via a plasmid or by introducing a copy into the genome. Occasionally, we may introduce a non-toxic reporter gene such as one encoding green fluorescent protein or β-galactosidase back into the targeted bacteria to monitor gene expression activity or ‘tag’ the bacteria to facilitate phenotyping.

We ensure that we do not move genes around that can potentially create a microorganism with enhanced virulence. For example, we would not introduce a gene encoding a known toxin into a non-toxic variant. Thus, there is no reason to assume that any of the mutants we generate will result in an enhanced virulence, although this cannot be completely excluded. Potential hazards to humans and the environment are mitigated by good practice, containment and training. In case of pregnancy or other immunocompromising conditions, the group leader is to be informed as early as possible (as outlined in the associated handbooks and SOPs).

In a normal healthy individual infection is a possibility. The infection route can be via mucosal surfaces or perforations in the skin. A number of symptoms can be associated with infections including diarrhoea, fever, general malaise etc. If good practice is adhered to, there is very little risk of individuals or other laboratory workers being infected. Some of these bacteria can infect animals but these are not present in the contained environment where experiments are performed. Care is taken to minimise contamination of surfaces or the formation of aerosols (e.g. via the use of disinfectants, protective clothing and safety cabinets). There is controlled access to the facilities and individual are trained to the appropriate standards.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All culture and application of bacteria will be carried in full Containment Level 2 laboratories.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We operate a number of comprehensive and proven waste management measures which are conducted according to our local protocol for handling HG2 pathogens. This protocol has been in use for many years and involves the autoclaving of clinical waste material, chemical inactivation of liquid waste followed by autoclaving and careful management of waste movement. The GMM will be used within a containment level 2 laboratory in which all bacterial cultures, glassware etc. is decontaminated prior to disposal. Thus drains, sinks etc. do not pose a mode of transmission to the environment. Air movement is also strictly regulated in the laboratory environment. Solid biological waste is autoclaved using temperatures, cycles and conditions appropriate for the inactivation of biological material. Autoclaving is performed by departmental staff using approved conditions. temperature is 121 C for 30 minutes. Glassware etc. is decontaminated, as described above, prior to being autoclaved.

All disinfectants are used according to the manufactures instructions. We have validated the killing activity on each pathogenic species and look for 100% kill. Validation assays are routinely performed.
Risk assessment was presented to the Department of Medicine's Biological Safety Committee and then to the Department of Medicine's over-arching Safety Committee and authorised as Class 2 activities.

Please enter comments on the GM safety committee on the risk assessment

</tr>
</tbody>
</table>
### Purposes of the contained use

We seek to understand the host & pathogen interactions that occur during tuberculosis (TB), which in humans is caused by Mycobacterium tuberculosis (Mtb). Discoveries made using our zebrafish-Mycobacterium marinum (Mm) model system will be tested for their applicability in the human-Mtb system in vitro.

### Recipient or parental organism

Mycobacterium tuberculosis strains H37Rv. Rifampicin or isoniazid mono-resistant strains may also be used, and also clinical strains (excluding XDR strains) may be used to test results observed in laboratory strains, but none of these will be drug-resistant.

Escherichia coli K12, and a range of mammalian cell lines such as monocyte cell lines THP1 and MonoMac6, and the macrophage cell line J774.2

### Host/vector system

- Mtb-GFP (green), Mtb-mCherry (red) and Mtb-Charge3 (red)/Mtb-luxA and plasmids pATB51, plasmid pATB51, plasmid pCHARGE3, pSMT
- Mtb transposon mutants will also be used - phage: PhiMycoMarT7, insert T7 promoter, transposase gene, E. coli ori

### Origin & function

1. Strains will be made fluorescent by expressing either GFP, mCherry, Charge3, luxAB or other derivatives of these proteins.
2. A Mtb transposon library will be used to knock-out any gene in Mtb, which will then be screened for specific phenotypes. Knocked-out genes will then be complemented by either the identical gene from Mtb or from related Mycobaterial species to see if the wild-type gene activity can be rescued.
3. Mtb strains with deletions in specific genes, or gene fusions with epitope tags of fluorescent proteins, may also be generated using CRISPR/Cas9.

### Evaluation of foreseeable effects

The genetic modifications made by the insertion of fluorescent genes do not alter the virulence nor pathogenicity of the Mtb H37Rv strain. Therefore, the foreseeable effects remain the same as for the parental strain.

Any gene function abolished or modified in the transposon library could result in a GMM that could have:
- A) no change in properties
- B) reduced ability to grow or cause disease.
- C) could, hypothetically, have a phenotype altered in favour of increased pathogenicity. For instance
  - In these cases (A and B) the direct hazard of the inserted gene product results in a GMM that is less than or equal to that of the parental wild-type organism. In the case of (C): (i) Deletion of a repressor of virulence could result in bacteria in which genes normally only expressed during a particular phase of infection are switched on permanently. This may imply an increased hazard, but is unlikely as the mechanism of pathogenicity in Mtb is based on the ability to switch multiple sets of genes on and off at e.g. specific times. (ii) Deletion of a growth repressor could increase replication; this is highly unlikely as the slow growth rate of mycobacteria is considered to be controlled by e.g. ribosome number. And multiple genetic manipulations would be required to influence growth rate. Also, there is no evidence to suggest that increased growth rate would lead to an increase in TS virulence. (iii) Deletion of a dominant antigen involved in immune recognition could allow the bacteria to avoid recognition and cause more disease. This is highly unlikely as immune recognition is a multiple-antigen dependent event and is highly unlikely as immune recognition is a multiple-antigen dependent event and it is known that TS deletion mutants of dominant antigens have reduced or unaltered virulence.
  - In essence, GMM pathogenicity is unlikely to increase, and the route of infection is also highly unlikely to change; therefore there is no increased hazard associated with the GMMs and the risk of disease is unchanged.
Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Full Containment Level 3 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All Containment Level 3 waste (solid and liquid) will be autoclaved (134°C for 15 min), before removal for offsite incineration. It is expected that this will achieve 100% kill.

Project 2019/1 is to study the mechanism of infection of Mycobacterium tuberculosis, a hazard group 3 pathogen. Strains of M. tuberculosis to be grown include strain H37Rv, clinical isolates and naturally occurring multi-drug resistance (MDR) strains. Extreme drug resistance (XDR) strains will not be grown. All strains will be characterised for antibiotic resistance/susceptibility to ensure appropriate antibiotics are available should a worker be potentially infected. Strains will be grown on plates and in small scale liquid cultures. In addition to wild type strains, M tuberculosis will be genetically modified: (i) strains will express fluorescent proteins such as GFP, mCherry, LuxAB and their derivatives to allow visualisation by fluorescence light microscopy, (ii) a transposon library will be used to knock-out any potential gene in M. tuberculosis and plasmids will be used to express either identical or analogous genes from Mycobacterial strains to see if the phenotype arising from the knock-out can be complemented, (iii) the CRISPR/Cas9 system will be used to introduce mutations or tags to potentially any gene in M. tuberculosis. None of hgenetic modifications will increase the pathogenicity of M. tuberculosis or its ability to survive in the environment. None of genes expressed are toxic or oncogenic. The project is therefore correctly classified as Activity Class 3 and all handling of M. tuberculosis strains will be performed in a Class I MSC in a Containment Level 3 laboratory.

</tr>
</thead>
<tbody>
<tr>
<td>Ectromelia virus (ACDP group 1).</td>
</tr>
<tr>
<td>Mammalian cell lines (established, commercially available) (ACDP group 1).</td>
</tr>
</tbody>
</table>

### Origin & function

**Origin**: Sequences will be amplified by polymerase chain reaction using viral, parasitic or cellular DNA as a template, or will be subcloned from pre-existing plasmid clones.

**Function**: The biological properties of the genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the location and function of proteins. Reporter and selectable genes will be inserted into viral genomes to inactivate specific viral genes and to identify the resulting recombinant virus.

The biological effects derived from inactivation of genes in poxviruses (vaccinia or ectromelia viruses) or from the replacement of ectromelia virus genes by homologous genes will be determined in vivo in a mouse model of infection.

### Evaluation of foreseeable effects

The insertion or reporter or selectable genes into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

The eukaryotic vectors used (vaccinia, retrovirus) are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing foreign genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.

Whereas vaccinia virus and cowpox virus can replicate in a number of mammalian species, ectromelia virus is restricted to mice. Recombinant poxviruses lacking specific genes are expected to be attenuated and to transmit poorly between individuals. No change in tissue tropism or host range of the vectors expressing foreign genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.
The ectromelia virus mutants lacking immunomodulatory genes are expected to be attenuated. Insertion into ectromelia virus mutants of related genes from other poxviruses or herpesviruses, or mouse/human genes, with similar functions, is unlikely to increase ectromelia virus virulence to levels higher than wild type. However, if an increased virulence is observed, it is unlikely to change the tissue and host tropism of ectromelia virus (highly restricted to mice), and therefore to represent a greater hazard to human health than wild type ectromelia virus.

## Project Additional Information

### Purposes of the contained use

1. Understanding the biochemical and molecular basis for the function of receptors for the constant (Fc) region of IgG, FcgammaRs and 2. Dissecting the role of viral gene products in lytic replication, the establishment of latency and immune evasion.

### Recipient or parental organism

The cell lines we wish to transfect are murine B-cells lines and primary human dendritic cells and macrophages. None of these cell types are readily transfectable using standard transfection technology, necessitating the use of lentiviral vectors based on human immunodeficiency virus type 1 (HIV-1).

### Host/vector system

A three plasmid transient transfection system will be used to generate recombinant, replication-defective retroviruses. 293T cells, a human cell line carrying SV40 T antigen will be transfected with (a) An HIV-1 'self inactivating vector' (SIN). (b) An HIV -1 derived retroviral sequence © a plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein.

### Origin & function

1. Human and mouse cDNAs encoding Fcgamma receptors and their gamma chain subunits.
2. Human and mouse cDNAs encoding the soluble tyrosine kinase lyn.
3. MHV68 cDNA encoding M2 gene products.
4. Mutant forms of the above genes which will include point mutants and deletion mutants of putative functional domains.
5. The reporters His, FLAG, GFP, and lacZ.

Cells transduced with these genes will be used for the study of the effect of wild type and mutant Fcgamma receptors on the response of cells to immune complexes and opsonised bacteria. We hope to examine their role on phagocytosis, endocytosis and intracellular trafficking of immune complexes, cytokine production and antigen presentation using techniques established within this laboratory.

**Evaluation of foreseeable effects**

The genes to be expressed are not known to be harmful and so the classification of the work is determined largely by the nature of the host/vector systems. The lentiviral (HIV) vectors are disabled, self-inactivating (they are unable to propagate following transfection) and multi-component. Hence the risk of generating replication competent viruses (bearing the transgenes) is extremely low.

The lentiviral binding protein has been replaced by VSV G protein which confers potentially a much broader host range/tissue tropism. In response to this, these vectors will be at class 2. Furthermore, the VSV protein pseudotyping represents an aerosol/ingestion opportunity for infection in addition to the percutaneous risk associated with HIV. Therefore the risk assessment indicates the use of a microbiological safety cabinet for operator protection. Although complement sensitive, vectors bearing the VSV glycoprotein are reported to have increased environmental stability emphasizing the importance of paying due regard to principles of GMP/GOSH.

While there is a theoretical potential for animal infection with these virus vectors, all lentivirus work will be carried out in a building where no live animal work is undertaken thus minimizing the risk. Furthermore, as with inadvertent human contact, the viral vectors are self-inactivating and the expressed proteins are not known oncogenes. Thus the consequences of expression in a few cells would be minimal.

The worst case scenario therefore for an exposed individual would be infection of pre-cancerous cell by viral vector expressing immune evasion protein perhaps allowing tumour progression. The most accessible tissue is lungs, but likelihood is small (pre-cancerous tissue would be very much a minority tissue in healthy persons) and virus is always handled in a safety cabinet. This scenario is considered highly unlikely to occur, as all evidence to date suggests that insertion of the M2 protein into other cells would not enhance proliferation or permit immune evasion. Moreover there is no evidence that pre-malignant bronchial epithelium is surveyed by the immune system, and there is no data to suggest that a protein stimulating B cells could enhance immune evasion by epithelial cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be treated for 24 hours with 2% Virkon or Presept tablets, then gelled if necessary with Vernagel in a sealable container. This is double bagged and transferred to a waste autoclave, and then incinerated on site.

**Purposes of the contained use**

For a viral infection to be successful the virus must survive in the presence of the host immune response. Viral survival strategies have evolved to modify or evade these host immune responses including the modification of host immunoreceptors. This project addresses the modification of host immunoreceptors by the human herpesvirus and lentivirus families.
Human herpesviruses are a family of enveloped double-stranded DNA viruses. There are three subfamilies: alphaherpesvirinae [herpes simplex viruses 1 and 2 (HSV-1, 2); varicella zoster virus (VZV)], betaherpesvirinae [human cytomegalovirus (HCMV), human herpesvirus-6 (HHV-6) and human herpesvirus -7 (HHV-7)] and gammaherpesvirinae [Epstein-Barr virus (EBV) and Kaposi's sarcoma herpesvirus (KSHV)]. The herpesviruses are ubiquitous pathogens of all vertebrates, although infections are usually highly species specific. All herpesviruses apart from KSHV and HSV-2 infect the majority of the human population (seroprevalence of HSV-1, VZV, HCMV, HHV-6 and -7, EBV is 50-100% depending on the population studied, whereas HSV-2 approximately 20%, KSHV 1-50% depending on the population studied). One common feature of all herpesvirus infections is lifelong viral persistence after primary infection despite a strong cell-mediated immune response. Each virus can generate a latent infection in certain cell types. In immunocompromised individuals, such as recipients of organ transplants and patients with advanced HIV infection, reactivation of herpesviruses such as VZV, HCMV, EBV and KSHV, has the potential to cause severe disease.

Human immunodeficiency virus (HIV) is the lentivirus that causes AIDS. This condition is characterised by progressive failure of the immune system, which allows opportunistic infections and cancers to thrive. HIV-1 establishes chronic infections, affecting approximately 33 million people worldwide. Despite considerable advances in HIV science, the goal of eradicating HIV- remains elusive.

There is already considerable evidence of immunoreceptor modulation by herpesviruses and lentiviruses; for example, MHC class I is removed from the cell surface by HSV, HCMV, EBV and KSHV as well as HIV. This proposal aims to investigate novel mechanisms and consequences of viral manipulation of host immunoreceptors during infection. We aim to investigate both (a) the role of individual viral genes on host immunoreceptors (herpesviruses and lentiviruses), as well as (b) whole viral infection in both lytic and latent phases (herpesviruses only). (a) We will clone individual viral genes into delivery vectors, and deliver them to relevant cultured host cells. We will then characterise the effects of these modifications on the host cell. (b) We will generate herpesviral and disabled HIV-1 stocks in established human cell lines from viral seed stocks in established human cell lines from viral seed stocks or bacterial artificial chromosomes encoding the viral genome. Clinical isolates and their genetically modified derivatives will be used as well as laboratory adapted strains. In vitro infection of human cell lines and primary cell lines will then be carried out to model both lytic and latent viral infections. We will then characterise the effects of these viral modifications on the host cell. Viruses with deletions of, or tags attached to individual genes will be utilised in order to further characterise cellular effects.

**Recipient or parental organism**

Recipients will be various mammalian cells in culture. Most are well characterised and considered ACDP hazard group 1. Cells from volunteers are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs). Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture. Culture cells expressing the viral genes may be altered in particular surface proteins they express but those changes will not over ride the especially disabled nature of the cells.

The herpesviruses to be studied as detailed above are all ACDP hazard group 2 and will therefore be handled at CL2 within a class II microbiological safety cabinet (MSC). Pregnant or known immunocompromised individuals will not perform any of this work. The modified herpesviruses should be no more pathogenic than wild type. Although there are virus deletion mutants with increased virulence over their parent (for example deletion of A41L in vaccinia virus), to our knowledge, herpesvirus deletion mutants that show increase in virulence have not been described.

Viral gene delivery vectors (retroviruses, lentiviruses) to be used are those typically considered class 1 GMMs, and will all be self-inactivating, and therefore once packaged, are unable to propagate. A three plasmid transient transfection system will be used to generate the recombinant retroviruses and lentiviruses, thereby decreasing the likelihood of recombination within the packaging cell lines to generate replication competent virus. The retroviral vectors are based on the Moloney murine leukaemia virus in which the gag, pol and env genes have been deleted. Gag and pol are supplied in trans on a packaging plasmid. We will generate VSV-G pseudotyped virus in order to deliver the virus particles to human cells. The lentiviral vectors are based on an HIV-1 self-inactivating vector (SIN) containing a deletion in the U3 region of the 3’ LTR of the virus. In addition, the gag, pol, env, nef, vpu and vpr genes have been deleted. Again, a second packaging plasmid encoding gap, pol, rev and tat will be used along with the plasmid encoding VSV-G to make pseudotyped viruses that will enter human cells. A packaging plasmid encoding nef, vif, vpu and vpr may also be used, in order to improve transduction efficiency of primary human cells. While VSV-G increases host range and their tropism and mode of transmission may also be altered from that exhibited by wild-type retroviruses, aerosol risk to the airway epithelium appears limited but the inability to infect the apical cell surface. The AdZ adenoviral vector system will be used to generate recombinant adenoviruses. These vectors carry a deletion of the E1 gene region rendering them replication incompetent.
in non-complementing cell lines. In addition, the E3 region (important for viral pathogenesis and immune evasion) has also been deleted making them less pathogenic in humans. They are those typically classed as class 2 GMMs and remain so as the inserts are placed within the deleted regions. All three types of viral vectors will be harvested and used in a CL2 laboratory.

The molecular clone that encodes the disabled HIV-1 to be used in this project is derived from the HIV-1 backbone and is currently approved for use when working under CL2 conditions in the Department of Medicine at Addenbrooke's Hospital, Cambridge. To increase the safety of the system, the vector components are segregated onto 2 plasmids: an HIV-1 molecular clone with a critical env deletion and a second plasmid expressing the VSV-G envelope protein. None of the individual plasmids is capable of generating infectious viral particles and, to avoid the generation of replication competent virus via homologous recombination, the constructs do not contain overlapping homologous sequences. Since none of the cell lines or vectors carry intact env-encoding sequences, infectious HIV particles cannot be produced.

The viruses and viral delivery vectors we will use are ACDP hazard group 2/class 1 GM. The viruses are deactivated by treatment with trigene, virkon or 70% EtOH and autoclaving. Therefore following the waste procedures outlined below should eliminate risk of spread to the environments. Many of the herpesviruses are also strictly human specific, therefore there is no risk of spread to other animals or plants. The viral vectors are all replication disabled so will be unable to disseminate in the wider animal or human populations.

Modifications will be to add a tag such as a fluorescent protein to viral proteins, or to delete or disrupt viral genes and subsequently restore them. Expression of tags is not expected to be detrimental to human health or the environment. Deletions/disruptions to viral genes are not expected to increase infectivity/pathogenicity. Herpesvirus genes cloned into viral gene delivery vectors may confer an ability to alter immune responses to infected cells. However, the large number of viral immune evasion genes encoded by the human herpesviruses demonstrates the need for a virus to encode more than one immunoavasin in order to effectively evade human immune responses. We will only express a single herpesviral gene in each gene delivery vector. As the vectors are disabled, any accidental infection of the epithelial cells of the researcher would be localised. Transduced cells would not be able to produce viral particles. Due to the high turnover rate of epithelial cells, any localised infection would not be expected to be long lasting.

Pseudotyped env-deleted HIV-1 viral particles are replication deficient, but theoretically able to transduce epithelial cells of the researcher. If this occurred, all HIV-1 proteins except env would be expressed, but no replication competent virus would be formed. This protein expression would not be expected to cause harm, and the Mammalian tissue culture cell lines (eg HFF2, THP-1, KG-1, HeLa, U373, U937, Huh7, HCT116, Jurkat, Daudi, NK-92, NK-L, HL60, 220, T1, 293, Ramos).

Primary human cells (eg monocytes, dendritic cells, T cells, B cells, NK cells).

Human herpesviruses including HSV-1 (eg strains: F, KOS, 17, SC16), HSV-2 (eg strains: 333, HVD), VZV, EBV, HCMV (eg strains: Toledo, Merlin, TB40/E, VR1814/FIX-BAC and laboratory adapted strains AD169 and Towne), HHV-6, HHV-7 and KSHV.

A disabled HIV-1 virus with a critical env deletion will also be used.

Bacteria: Top10, Sure 2, alpha-select, clean genome.

Viral gene delivery vectors including retroviruses, lentiviruses and adenoviruses.

Bacterial artificial chromosomes (BACs) that cover the genomes of the herpesviruses and adenovirus serotype 5 so that insertion/deletions in the viral genome can be generated in vitro prior to the generation of recombinant viruses.

Standard cloning vectors (such as TOPO and pcDNA3) and BAC shuttle vectors will be used to clone viral gene disruptions (such as truncations) and to add inserts/tags onto viral genes or to rescue deletion viruses. In addition, these cloning vectors will be used to express individual viral genes to allow their study in host cells.

The HIV-1 molecular clone with the env deletion will be used for targeted gene disruption in vitro prior to the generation of lentiviral particles.
Inserts will be used to label herpesviral and lentiviral genes to enable their visualisation during viral infection (such as the YFP, GFP or RFP fluorescent tags) or to simplify biochemical analyses of viral genes (such as HA, Strep, Myc and Flag tags). To examine the biological role of individual herpesviral and lentiviral genes, gene deletions/disruptions and subsequent reconstitutions will also be used.

Expected biological action of inserted DNA/RNA or transcribed/translated gene product:
The inserts will be commonly used markers/tags as detailed above. Apart from fluorescence, these tags are biologically inert; their expression should not increase viral virulence or fitness.

Deletion or disruption of viral genes is not expected to increase virulence. For reconstitution of deletion viruses, only the original gene will be re-inserted and therefore no increase in virulence over the original strain is expected. No modifications will be made that are designed to introduce new biological activities into viral proteins. Over-expression of viral genes in viral gene delivery vectors should not pose any risk additional to use of the viruses themselves.

**Evaluation of foreseeable effects**

Pseudotyped particles have previously been classified as class 2.

Bacterial artificial chromosomes and plasmids will be used to generate recombinant virus. These contain antibiotic resistance markers which could in theory present a problem to the user if they become infected with the bacteria in which the plasmids/BACs were grown. However, in practice the bacterial strains we use are highly attenuated and unlikely to cause disease, while the antibiotic resistance markers encoded by these plasmids/BACs (Ampicillin, kanamycin and chloramphenicol) are active against antibiotics which are no longer in general use in clinical practice. So whilst the plasmids/BACs pose no threat in a bacterial culture, once transfected into eukaryotic cells the recombinant DNA can be packaged into infectious virions and transfection will therefore be carried out in a CL2 laboratory and subsequent cultures treated as live virus.

The disabled nature of the bacterial hosts will not be altered by the plasmids or BACs in use - no expression is anticipated and would not in any case be compatible with bacterial systems. The bacterial strains we use are highly disabled and unable to replicate to any extent outside the lab. Never-the-less, appropriate control measures, including disinfection (with virkon) of liquid cultures and autoclaving of bacterial plates, will be taken.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Conventional molecular biology techniques will be used for cloning in a CL1 laboratory. Bacterial artificial chromosomes and viral gene delivery vectors will be transfected into mammalian cell lines in a CL1 laboratory then transferred to the CL2 laboratory within 24 hours of transfection (to allow us to evaluate transfection efficiency with a fluorescence microscope). All manipulation of liquid will be carried out in a class II Microbiological safety cabinet (MSC) to reduce the risk of aerosol dissemination. Tubes for ultracentrifugation of virus for the production of concentrated virus stocks will be loaded in MSC into buckets that will be sealed and transported to the ultracentrifuge in secondary containers. Similarly, once the ultracentrifugation is complete, the tubes will be transported back to the CL2 laboratory and the buckets opened in the MSC to allow the virus to be resuspended and aliquoted. Since there is no -80°C storage facility in our CL2 laboratory, small aliquots of virus will be transported to 5.29 in secondary containment for storage. Fluorometric and microscopic analysis will be conducted on fixed samples, and protein and nucleic acid analysis will be conducted on material which has been lysed in the CL2 facility prior to transport to the laboratory.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The ultracentrifuges available for concentrating virus preparations are outside of CL2 labs. Virus preparations will be sealed within the centrifuge tubes and buckets within the MSC in CL2 and transported in a shatterproof container. The surfaces of centrifuge tubes and transport containers will be decontaminated with detergent prior to removal from CL2 and only be re-opened once returned to the MSC in CL2. The ‘comments’ section of the ultracentrifuge logbook will be used to warn other users that the centrifuge contains a CL2 organism. Following centrifugation, the buckets will be returned to the MSC in the CL2 for processing. The buckets will then be immersed in detergent in the MSC prior to removal back to 5.14 for cleaning, rinsing and drying.

The -80 degree freezer for storing virus preparations and supernatant is also outside of the CL2 labs. Vessels containing supernatant and concentrated virus preparations will be decontaminated with Trigene and put into a shatterproof container for transport to and storage at -80 in Lab 5.19
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be disinfected with Virkon overnight, gelled using Vernagel, double bagged, sealed and labelled for autoclave then incineration according to the Department CL2 procedures. All solid waste will be double bagged and labelled for autoclave then incineration (pipettes will be disinfected in 1% trigene before removal from MSCs to prevent drips). Work surfaces will be wiped down with trigene and 70% ethanol. Small spillages will be mopped up immediately with tissue and disinfected with 1% trigene or 2% virkon. Large spills will be covered with absorbent paper and then sprayed with 10% trigene or 2% virkon, and then mopped up after 30 minutes. The absorbent material will then be disposed of in the solid autoclave waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Mechanisms of protein degradation - using (i) overexpression or depletion of tagged or untagged genes involved in protein breakdown in lentiviral and retroviral systems

Date Ackn'd 16/09/2019

Date Project Ceased

Class

CultureVolClass2 < 1 Litre

Consent Granted

Project notified under transitional arrangements N
All mammalian cells have to control their protein content to remove damaged proteins and regulate cell growth. Any disruption in cellular protein levels can cause uncontrolled cell turnover or the accumulation of misfolded proteins that occur in neurodegenerative conditions. The major mechanisms for controlling intracellular protein levels are through ubiquitination, proteasomal degradation and autophagy. This project aims to address how ubiquitinated proteins are differentially selected and efficiently delivered to the proteasome for degradation. The research encompasses several main themes:

1) How different polyubiquitin chains are decoded.
Specificity in the ubiquitin system is generated by the ability of ubiquitin to form eight different polyubiquitin chain linkages. Each type of ubiquitin linkage must be correctly interpreted to facilitate the desired outcome, and ubiquitin binding proteins (UBPs) provide this critical link between chain recognition and cellular fate. For example, we showed chain-specific UBPs facilitate lysine-48 chains to bind the proteasome but block lysine 63-chains from binding this degradative complex. UBPs for other polyubiquitin chain types were unknown, but we have identified UBPs that selectively recognize lysine-11 polyubiquitin chains, an abundant linkage with a critical role in regulating mitosis. Using biochemical and cell biology approaches we aim to investigate the function and physiological importance of these lysine-11 specific UBPs.

2) How ubiquitin binding proteins regulate protein turnover.
We will use forward genetic screens in near-haploid human cells (KBM7) to identify genes required to regulate the degradation of proteins by the proteasome. By the insertion of random mutations into cells expressing fluorescent proteasome reporters, we can identify genes required for the efficient degradation of these ubiquitinated substrates. Retroviral gene traps and CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) technology will be used in the screens. As ubiquitination is also involved in non-proteasomal degradation, we will examine how ubiquitinated proteins are recruited to autophagy and lysosomal pathways.

3) Regulation of the hypoxia response pathway.
We will use forward genetic screens and proteomics to determine novel genes in the regulation of hypoxia inducible transcription factors (HIFs, a pathway critically regulated by ubiquitination). Genes identified as regulating HIFs will be characterized in cell line based assays and primary cells (macrophages and fibroblasts) for their importance in the hypoxia response. Other oxygen-dependent regulatory mechanisms, for example oxidative phosphorylation and protein hydroxylation, will also be studied. To investigate these aims we will use lentiviruses and retroviruses to:
a) Generate stable mammalian cell lines encoding UBPs, ubiquitin enzymes, genes regulating protein breakdown or oxygen consumption of cells using pHRSIN vectors.
b) Use shRNA with pSIREN vectors to confirm the function of genes identified in the mutagenesis screens.
c) Generate stable knock-out or knock-in (tagged) cell lines of genes identified in the genetic screens using CRISPR technology in lentiviruses encoding the Cas9 nuclease and guide RNAs (sgRNA) (pLKO-TRC).
d) Use stable and tetracyclin-inducible shRNA and sgRNAs. These stable cell lines with be utilised to further characterise the cellular effects of genes required in the regulation of the ubiquitin proteasome system.

Recipient or parental organism

Mammalian tissue culture cell lines (eg HFF2, THP-1, KG-1, HeLa, U373, U937, Huh7, HCT116, Jurkat, Daudi, NK-92, NK-L, HL60, T1, 293, Ramos).
Primary human cells (eg monocytes, dendritic cells, skin fibroblasts, muscle cells, T cells, B cells, NK cells).
Bacteria: Top10, Sure 2, alpha-select, clean genome.

Host/vector system

Viral gene delivery vectors including retroviruses, lentiviruses, and adenoviruses.
The lentivirus and retrovirus plasmids contain the WPRE-X
2nd generation retrovirus and lentivirus packaging systems will be used.

Origin & function

Plasmids and other nucleic acid vectors:
Standard cloning vectors (such as TOPO and pcDNA3) and BAC shuttle vectors will be used to clone gene disruptions (such as truncations) and to add inserts/tags onto genes or to rescue deletions. In addition, these cloning vectors will be used to express individual genes to allow their study in host cells.
Inserts:
Inserts will be used to (i) label genes to enable their visualisation during physiological and biological studies of protein degradation (such as the YFP, GFP or RFP fluorescent tags), (ii) encode proteins involved in the ubiquitin proteasome system, autophagy or the hypoxia response, with no known toxicity or oncogenicity, or (iii) to simplify biochemical analyses of genes of interest (such as HA, Strep, Myc and Flag tags). To examine the biological role of individual genes, gene deletions/disruptions and subsequent reconstitutions in the ubiquitin proteasome pathway, autophagy, lysosomal function and the hypoxia response pathway.

Evaluation of foreseeable effects

The inserts will be commonly used markers/tags as detailed above. Apart
from fluorescence, these tags are biologically inert; their expression should not increase activity of the target genes.
No modifications will be made that are designed to introduce new biological activities into the proteins. Over-expression of genes involved in the ubiquitin proteasome system, autophagy and hypoxia response should not pose any additional risks. Uncharacterised genes will only be introduced into viruses when they have been better characterised using standard mammalian expression vectors and shown to function in the recognition of ubiquitin chains, protein degradation, autophagy or hypoxia regulation, and therefore unlikely to be either toxic or oncogenic.

The maximum culture volume that could be released at any one time is 10 litres. All waste is deactivated either by adding 1% Virkon or by autoclaving. Autoclave tape that undergoes a change in colour, is used to monitor that the autoclaving process is carried out correctly. Tissue culture waste is regularly inspected to ensure that plastic ware is not disposed of without first being deactivated. Information about how to deactivate and dispose of waste is provided in the departmental safety handbook, the standard operating procedures and an annual safety seminar attended by all new members of the department.

Project Ref 357/07.1

Role of MEF2 transcription factors in neuronal differentiation and function.

Class 2

< 1 Litre

Consent Granted

Not Applicable
We are interested in understanding the function and regulation of the myocyte enhancer factor-2 (MEF2) family of transcription factors in neurons. The purpose of the contained use is to investigate the role of this transcription factor family by using recombinant Lentiviruses to express reporter genes to monitor MEF2 activity, gain and loss of function mutants of MEF2 proteins, activators and inhibitors of MEF2 factors, and short hairpin RNAs to down-regulate their expression.

Recipient or parental organism

HEK 293T cells, neuronal cel lines, primary neurons, glial cells, and neural progenitor cells isolated from rodent brains in dissociated and slice cultures.

Host/vector system

Recombinant Lentiviral vectors.

Origin & function

The Recombinant Lentiviral will encode proteins that will allow us to investigate the role of the mammalian myocyte enhance factor-2 (MEF2) family of transcription factors in neuronal differentiation and function. The genetic material will encode MEF2 reporter genes, gain and loss of function mutants of MEF2, activators and inhibitors of MEF2, and short hairpin RNAs against transcription factors.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Lentiviruses will be produced in HEK 293T cells by an established 3 plasmid approach in a containment level 2 tissue culture facility with restricted access. The recombinant lentiviruses produced in 293T cells are capable of only a single round of infection and will be used to infect neuronal cell lines, primary neurons, glial cells and neural progenitor cells where there are replication-defective. Infection of cells will done in containment level 2 facilities. Use of sharps will be eliminated in all procedures involving the use of lentiviruses. At the end of the experiment, all cells and waste material that makes contact with virus will be treated with detergent (1% Virkon) for 30 minutes ans autoclaved before disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste material that makes contact with virus will be treated with detergent (1% Virkon) for 30 minutes and autoclaved before disposal. This is expected to kill effectively 100% of lentiviruses.

The risk assessment was reviewed by the Departmental Biological Safety Committee comprising the Departmental Biological Safety Officer, Departmental Safety Officer, the school of biological sciences Safety Officer and 4 other members of staff. The committee was satisfied with the risk assessment and noted that access to the containment facility where the work will be carried out needs to be restricted.

**Project Additional Information**

**Purposes of the contained use**
- Identification of novel cancer genes using Crispr/Cas9 screening approaches.

**Recipient or parental organism**
- Primary mouse mammary cells from wild-type and transgenic mice, primary human mammary cells and primary naked mole-rat cells.

**Host/vector system**
- pMSCV retroviral expression vector and third generation HIV-1-based self-inactivating and replication disabled lentiviral expression vectors (pKLV, pCDH, pLKO, pGIPZ and pTRIPZ vectors and/or similar)

**Origin & function**
- Lentiviral transduction of cells in vitro to deliver Cas9 and gRNA vectors.

**Evaluation of foreseeable effects**
- Initiating, enhancing or blocking cell death, proliferation or differentiation or transformation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Virkon (a peroxygen compound) used at a concentration of 1% is known to have a wide range of microbial activity and is bacteriocidal against many human viruses, including HIV. All tissue culture material and disposable plastic ware will be soaked for a minimum of 18-24hrs in a freshly prepared 1% Virkon solution (manufacturers guidelines for 100% kill). The fluid is then disposed down a laboratory sink with excess water. Solid waste is then double bagged in biohazard bags and incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Biological Safety Committee have approved this risk assessment with minor alterations applied.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

A broadly cross-reactive meningococcal vaccine developed by Novartis Vaccines is currently undergoing phase 3 outer membrane proteins – factor H binding protein (fHBP) fused with a further protein GNA2091), GNA2132 (fused with a further protein GNA1030 and Neisserial adhesion A (NadA). The vaccine also has an outer membrane vesicle component. fHBP is a virulence factor that binds the human complement factor H thereby enhancing bacterial survival in the host. The function of GNA2132 is unknown though it has been implicated in heparin binding, which may also lead to enhanced survival within the host. NadA is avirulence factor involved in host cell adhesion and invasion.

In order to predict the efficacy of the vaccine in England and Wales it is necessary to characterise native case isolates for fHBP, GNA2132 and NadA in terms of a) genetic variation, b) surface expression levels and c) serum bactericidal antibody (SBA) susceptibility to pre and post-vaccination sera – the gold standard assay for predicating Men B vaccine efficacy (there is no reliable animal model for meningococcal disease). To enable the evaluation of surface expression, e.g. by Whole cell ELISA and Immunoblotting, it is necessary to compare wild type native isolates against negative control (gene-knockout) isolates such that e.g. non-specific antibody binding may be accounted for. Similarly, in order to evaluate SBA susceptibility, knockout isolates of a) each gene, b) different combinations of 2 genes and c) all of the genes, will be required to help elucidate the SBA activity against any single antigen. Single and multiple knock out strains have been developed for these antigens, for the purpose outlined above, by Novartis vaccines (Sienna, Italy). It is our intention to obtain these isolates from Novartis for use in the present study.

**Recipient or parental organism**

The knockout strains will be required for comparison with the wild type strains used in the immunoassays and are therefore required to be wild-type in all respects other than that of the gene/s being disabled. The GMM constructs will therefore be treated as wild -type. A deficit of one or more of the antigens - fHBP, GNA2132 and NadA is likely to significantly reduce invasivenesses and the ability in the host.

**Host/vector system**

fHbp, NadA and gna2132 knockout isolates and combination thereof were constructed at Novartis Vaccines, Siena, Italy. Briefly, In order to generate Neisseria meningitides mutant strains lacking the main antigens contained in the vaccine, three knockout plasmids were constructed for the deletion of all or part of the respective antigen-coding gene and replacement by allelic exchange with an antibiotic resistance cassette. Using standard cloning procedures, upstream and downstream flanking regions of the gna2132 and fhbp genes were amplified by PCR from the MC58 genome and cloned on either side of an erythromycin resistance cassette into the pBluescript (Pharmacia) cloning vector, generating the knockout plasmids pBSUDgna2132:Erm and pBSUDfhbp:Erm, respectively. For the generation of the NadA knockout construct, the nmb1994 gene and surrounding upstream and downstream regions were amplified by PCR from the MC58 genome and cloned into the pBluescript cloning vector, and subsequently an internal HinclI fragment at the 5’ end of the coding region was substituted with the erythromycin resistance cassette, generating pBS961:Erm. For generation of the single knockout mutants, the knockout plasmids were linearised and transformed into the wildtype strains. Erythromycin resistant colonies were selected and checked by PCR for correct insertion due to a double homologous recombination event and colonies with correct PCR profile were further analysed by Western Blot for the lack of expression of the respective antigen.

For generation of a single Nm derivative strain lacking the expression of two or three antigens, a stepwise deletion by allelic replacement strategy was used in-which double-knockouts were constructed using Erythromycin and Kanamycin cassettes and triple-knockouts were constructed using Erythromycin, Kanamycin and Chloramphenicol cassettes.

**Origin & function**

The function of the genetic material, i.e. antibiotic resistance genes, is to enable the selection of isolates in which the genes of interest have been successfully removed.

The erythromycin (Erm) cassette contains a Streptococcus pneumoniae gene for rRna adenine N-6-methyltransferase. This protein produces a dimethylation of the adenine residue at position 2058 in 23S rRNA, resulting in reduced affinity between ribosomes and erythromycin resulting in erythromycin resistance.
The Kanamycin (Kan) cassette contains the Campylobacter coli aphA-3 gene. The gene product is an aminophosphotransferase (APH) that inactivates kanamycin by transferring the γ-phosphate of ATP to the hydroxyl group in the 3’ position of the pseudosaccharide.

The chloramphenicol (Cin) resistance cassette contains the Campylobacter coli chloramphenicol acetyltransferase (cat) gene. The enzyme chloramphenicol acetyltransferase covalently links acetyl groups to the chloramphenicol molecule. This in-turn prevents chloramphenicol from binding to the ribosome – its site of action.

The knockout isolates and their respective antibiotic cassettes are listed in the table below:

Evaluation of foreseeable effects

The pathogenic traits of these strains are likely to be lessened since isolates lacking nadA (that previously harboured the gene) are likely to be less invasive whilst fHbp deficient isolates are less likely to survive within the host due to the loss of a virulence factor shown to be important in this respect. Strains deficient in gna2132 may also be less likely to survive within the host since the GNA2132 antigen is has been shown to bind hepin - also proposed to enhance survival within the host.

The single gene knockout strains were all constructed using Erythromycin resistance cassettes. Double-knockouts were constructed using Erythromycin and Kanamycin cassettes and the triple-knockouts were constructed using erythromycin, kanamycin and chloramphenicol cassettes. These antibiotics do not constitute first line therapeutic/prophylactic antibiotics against meningococci (current guidelines include penicillin, cefotaxime or ceftriaxone for therapy and rifampicin, ciprofloxacin or ceftriaxone to eradicate carriage in close contacts/exposed individuals). The presence of one or more exogenous antibiotic resistance genes may also place a disadvantageous burden on these strains.
Meningococci are obligate human pathogens and survive only within the human nasopharynx.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A - all GMOs will be treated as wild-type in accordance with the level 2 containment stipulated above

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMO waste procedures are the same as those of wild-type meningococci and these are designed to achieve 100% kill with zero viable GMOs remaining after treatment. Contaminated laboratory waste is rendered safe by immersing in trisgene solution within the safety cabinet (liquid waste) or is placed into dry disposal jars for autoclaving in room 2.01 and then removal for incineration. All laboratory bench surfaces are routinely disinfected with 1% trisgene solution after work is completed. Safety cabinets are wiped down with tristel duo and tristel duo impregnated wipes. In the event of a major spillage the room is immediately evacuated after turning on all safety cabinets. The Head or Lead Biomedical Scientist and Safety Officer are informed. When it is deemed safe to clear the now dried spillage, tristel-fuse is used to flood the area. A local Code of Practice for working with meningococci is in use; this is a detailed document covering safety aspects of all cultural activities with live meningococci whether GMO or wild type. It gives details of vaccination requirements, operation of safety cabinets, disinfection and disposal procedures, centrifuge operation and emergency procedures and other topics. All staff are required to read and understand the document before commencing any work with meningococci.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The local GMO committee reviewed the risk assessment and local application form at length and were generally happy with the contents. The committee asked for more detail of working with meningococci to be added; in particular the means of controlling aerosol production and ensuring worker safety training. This detail has been added to the risk assessment.

**Project Additional Information**
Purposes of the contained use
To conditionally immortalise human muscle cells in order to obtain long-lived clones that can be expanded in tissue culture and form muscle in-vivo.

Recipient or parental organism
Retrovirus - amphotropic encoding human telomerase and a temperature sensitive mutant of SV40 large T antigen Replicatsin defective. Transduced human muscle cell.

Host/vector system
Primary human muscle cells to be transfected by a recombinant, disabled retrovirus. Inserts - human telomerase and a temperature sensitive SV40 large tumour antigen.

Origin & function
The retroviral supernatent is obtained from the Group below and there is no culture to be done at the CSC of the original packaging cell lines. Ref: O'Hare et al Proc Natl Acad Sci (2001) 98:646-651

Evaluation of foreseeable effects
Immortalisation of the target 1 muscle cells that one incapable of replicating the retrovirus. There is a small potential risk that the operators own cells could become transformed - but this is thought unlikely as the transforming gene is temperature sensitive (33C), and would be operating at opt containment level 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
1 muscle cells will be handled in a Class II Safety Cabinet. The cells will be incubated in a separate CO incubator in a category II laboratory.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste Culture Supernatant and disposable plastics are all autoclaved - giving 100% cell kill. A thermocouple probe is placed in the waste to ensure the correct temperature is reached. A chart recorder, records that the discord cycle passes. The waste then goes into the hospitals clinical waste stream and is tagged and traceable.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
- Sharps are not to be used.
- Retrovirus Supernatant is to be stored in a clearly marked, locked container.

Project Additional Information

Purposes of the contained use

How epithelial and ribroblast cells are immortalised, transformed and maintain drug resistance and to identify novel gene products involved in cell models of tumourigenesis.

Recipient or parental organism

Mammalian cell lines, all with a history of safe use and not expected tp represent a hazard to human health.

Host/vector system
Helper vectors: pRSREV, pMD2G, pMDL RRE
Lentiviral vectors: pWPTS, pWPXL, pWPI, pLVTHM, pLKO.1 or its derivatives.

Origin & function

Host cells are of human origin and may be primary, transformed or cell cycle-arrested. The inserts will be mammalian and viral cDNAs and shRNAs; regulatory nucleic acid sequences and genes conferring resistance to antibiotics. Some cells will have a very limiting proliferative ability in culture before reaching an irreversible growth arrested state, and these cells are difficult to transfected by standard methods. The use of recombinant retroviral infection as a means of delivering the appropriate DNA into cells is required.

All lentiviral vectors are based on HIV-1 but lack of all viral auxilliary genes, ie vpr, vif, vpu and nef. Second generation helper packaging plasmids will be used to produce replication-incompetent virus. The auxiliary proteins and the VSV-g envelope protein are provided by three separate helper plasmids that contain no regions of homology to the HIV-1-based vectors. Cell lines created by retroviral infection will be maintained by selection with the appropriate antibiotics (either blasticydin, neomycin hygromycin or puromycin). It is important to note that the lentiviral vectors contain the woodchuck post-transcriptionally regulatory element (WPRE). Due to recent concerns about their potential oncogenicity (Gene Therapy AOP 28 Oct 2004), the GTAC has recommended as a precaution to use such vectors at category 2 containment level.

Evaluation of foreseeable effects

The host strains are not pathogenic and inserted gene products encode for wild type, mutated or tagged versions of mammalian and viral cDNAs of genes involved in tumourigenesis and drug resistance. None of the vectors or inserts has mobilisable elements. It is not expected that over-expression of any of the genes to be used would alter existing properties of the cell lines they will be transfected into. None of the cell lines to be used are capable of colonising a healthy individual and we do not expect the proposed manipulations to change this. The mutations will not affect virulence, infectivity or stability and the pathogenicity will not be altered from the wild-type. All the genes are likely to be expressed in humans and their products may be biologically active, therefore, the recombinant gene could cause drug resistance if expressed. Some mammalian cell lines may be made antibiotic resistant, however, since these would be unable to establish themselves outside of the laboratory there is no risk to human health. There is no deliberate intention for the product to be harmful to health. It is highly unlikely they would provoke a toxic or allergic response, or act as a hormone.

There is very limited risk that harmful genes could exist in the cDNA libraries, ie 0.0001%. Stable cell lines expressing different transgenes involved in tumourigenesis will be generated by retroviral transduction and expression of some transgenes and/or suppression others have been proposed to be involved in tumourigenesis (Hannahan and Weinberg, 2000). Genes involved in the acquisition of drug resistance could have potentially oncogenic properties. However it is known to be a multifactorial event and since they will never be used at the same time in transfection or transduction experiments with other potentially transforming genes it is considered that the oncogene cannot act alone to cause tumours. When expressed alone in normal cells many of these oncogenes do not result in transformation but elicit protective programmes such as apoptosis or senescence, thus preventing oncogenesis. The amphotropic viral vectors would be able to infect humans but could not replicate except in the most unlikely event that they recombine with an endogenous retrovirus. Even then it is unlikely that expression of a single oncogene or suppression of a tumour suppressor would cause tumours, as multiple genetic alterations (4-6) are required for inducing tumours. Safeguard mechanisms exist impeding the accumulation of these alterations in the organisms instead of unrestrained proliferation they induce growth arrest or apoptosis. Limited volume non-concentrated cultures, will be made in a Class II cabinet. Risks of aerosol contamination of staff and environment minimised by enclosing the plates and tubes outside of the cabinet. No sharps will be used and the laboratory will have restricted access. Containment Level 2 labels will be posted and personnel trained in emergency procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For liquid waste inactivation with Microsol 3 (Anachem Ltd) at dilutions of not less than 1/100, 30 min minimum contact time, as specified by the manufacturer.

02/03/2022
The committee considered the risk assessments valid and appropriately classed as category 2 and requiring level 2 containment. The laboratories are suitable for this.

The committee was fully convinced that Project 57 and 59 are part of a connected programme of work, being carried out by the same PI and his team. The reason for two assessments was to allow him to explain the work more fully. The same PI is collaborating on another project, using the same techniques and materials provided by him. This project is particularly directed at chemotherapy drug resistance in cell models of tumourigenesis. We ask that they all be considered as a connected programme within our institute.

**Project Additional Information**

**Purposes of the contained use**

How cell cycle proteins and proteosomes control chromatin structure and their potential role as tumour suppressors/oncogenes in carcinogenesis

**Recipient or parental organism**

**Human Cells, primary, transformed or cell cycle-arrested**

The recipient cell lines will be the following human cells: human embryonic derived epithelial and fibroblast cell, HMECs, NHK, HPrEC, Wi-38, TIG, IMR-90, breast cancer cells (MCF-7, T47-D, ZR-75-1, MDA-MB-231, SK-BR-3), prostate cancer cells (LnCaP, PC-3, DU-145) and other common human cell lines obtained from the ATCC. All of these cells have a history of safe usage and are not expected to represent a hazard to human health.

**Host/vector system**

**Bacterial plasmids and HIV-1 based lentiviruses. Contain WPRE. Especially disabled E.Coli K12 or B derivatives (egDH1, DH5, HB101, JM101, JM105, JM109, TG2, SUREtm, XL1-Blue, BMH-71-18 mutS and ES1301 mutS or derivatives AuxotrophicSaccharomyces cerevisiae mutants for YAC propagation**

**Origin & function**

**Plasmid Vectors:**

PGEM series, pUC series, pAlter, pcDNA3, pTOPO, pCineo, pcDNA3pBUDCE4Yac4 and their derivatives.

**Helper vectors:**

pRSREV, pmMD2G, pMDL RRE

**Lentiviral vectors:**

Pwpts, Pwpxl, pWPI, pLVTHM, pLKO.1 or its derivatives

All lentiviral vectors are based on HIV-1 but lack of all viral auxilliary genes, i.e. vpr, vif, vpu and nef. Second generation helper packaging plasmids will be used to produce replication-incompetent virus. The auxiliary proteins in one hand, and the VSV-g envelope protein in other hand are provided by three separate helper plasmids that contain no regions of homology to the HIV-1 based vectors.

**Mammalian tissue culture cells:** 293T cells will be used to produce replication-incompetent virus. The auxiliary proteins in one hand, and the VSV-g envelope protein in other hand are provided by three separate helper plasmids that contain no regions of homology to the HIV-1 vectors. Three separate recombination events would be required to produce replication-competent virus. The combined choice of the multiple packaging plasmids and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment. Human cells expressing different oncogenes will
be generated by infection with lentiviruses. Cell lines created by retroviral infection will be maintained by selection with the appropriate antibiotics (either blasticydin, neomycin hygromycin or puromycin). It is important to note that the lentiviral vectors contain the woodchuck post-transcriptionally regulatory element (WPRE). Due to recent concerns about their potential oncogenicity (Gene Therapy AOP 28 Oct 2004), the GTAC has recommended as a precaution to treat this vector as category 2 containment level.

**Evaluation of foreseeable effects**

Selection of successful transformation into recipient cell lines will result in acquisition of antibiotic resistance. Effects of introduced genetic modifications may result in senescence, apoptosis, cell cycle arrest, inhibition of growth, increased proliferative rate, changes in sensitivity to DNA damaging agents depending on candidate gene introduced. Since all experiments are limited to cultured cell lines only, none of the effects will be passed onto intact organisms/animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For liquid waste inactivation with Microsol 3 (Anachem Ltd) at dilutions of not less than 1/100, 30 min minimum contact time, as specified by the manufacturer. The supervisor ensures appropriate training and use of the disinfectant. The disinfectant has been validated by the manufacturer to kill 100% of organisms in use. The validation credentials are checked periodically as a monitor to ensure this disinfectant is still suitable.

Solid waste materials are collected separately from other lab waste and subjected to autoclave decontamination. The cycle is set for discard and it is well established that a circle of 134°C for 15 mins with full steam penetration to the centre of the load is sufficient to kill 100% of retroviruses, bacteria and tissue culture cells. A probe is inserted into the load centre to ensure monitoring of each cycle, which is recorded. The autoclave has a quarterly check and an annual 12-point thermocouple test to ensure efficiency of cycle. Should the autoclave fail a run-checked by the operative using printout and error message - the loads are not released to the clinical waste route until a fully validated run has occurred.

Project Ref 363/08.1

Date Ackn'd 22/12/2008

Identification of regulatory components of the AMPK/AMPK-related kinase cascades and downstream pathways using shRNA knock-down and overexpression studies.

Class 2

Consent Granted Not Applicable

Non-GMM

Project notified under transitional arrangements N

Recipient or parental organism

The lentiviral transfer vector, pLKO.1 and retroviral expression vector, pMSCV come in E.coli strain DH5 alpha T 1R. HEK293T cells will be used to packaged these vectors into virus, and the viruses will be used to transduce mammalian cells including HEK293, HEK293T, COS, HeLa, primary mouse hepatocytes, Tcells, IMR90 fibroblasts and stem cells.

Host/vector system

The aim of this project is to screen for components involved in the regulation of and downstream components of AMP-activated protein kinase (AMPK) and AMPK-related protein kinase cascades. During this study, lentivirus and retrovirus will be used to package shRNAs targeting potential proteins involved in regulation of these cascades, and cDNA of components of the pathways. The effect of this knock down or overexpression in cells will be studied with regard to phosphorylation status of AMPK and/or the AMPK-related kinases, and known downstream effects.
Vectors: pLKO.1 vector  
Sigma-Aldrich 'packaging vector'  
Sigma-Aldrich 'envelope vector'  
pMSCV retroviral expression vector (Clontech)  
pCL-10A1 Retrovirus Packaging Vector (Imgenex)

**Origin & function**

HEK293T cell will be co-transfected with lentiviral packaging mix (envelope vector and packaging vector) and shRNAs in the lentiviral transfer vector, pLKO.1. A combination of specific shRNA clones against a single target will be co-transfected together to give a mixed population of shRNA.

To produce retrovirus, HEK293T packaging will be cotransfected with retrovirus packaging vector and retroviral expression vector, pMSCV, containing specific sDNAs for kinases involved in the AMPK/AMPK-related kinase signaling cascades.

In both cases, the HEK293T packaging cells will transcribe this DNA, synthesise viral RNA and proteins, and package a viral particle. These viruses will be used to transduce various types of mammalian cells. The shRNAs target a selection of known proteins and will be used to knock down proteins in the AMPK and AMPK-related kinase signalling pathway either individually or in groups. The retroviral transduction will result in overexpression of AMPK and AMOPK-related kinases, or other components of the signalling pathways.

To produce retrovirus, HEK293T cells will be cotransfected with retrovirus packaging vector and retroviral expression vector, pMSCV, containing specific sDNAs for kinases involved in the AMPK/AMPK-related kinase

**Evaluation of foreseeable effects**

The shRNAs to be used in these experiments come in lentiviral (HIV)-plasmid (pLKO.1) and will be cotransfected into packaging cells (HEK293T) alongside plasmids for packaging proteins (MISSION lentiviral packaging mix, Sigma-Aldrich) to produce lentiviral particles. The lentiviral vector systems have been developed with enhanced safety features. It is a third generation lentiviral vector system, with three plasmids consisting of:

1. The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions.
2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping.
3. The shRNA transfer vector, which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging.

The retroviral vector system is a two plasmid system, with a MSCV Retroviral expression vector, derived from the murine stem cell PCMV virus (PCC4-cell-passaged myeloproliferative sarcoma virus), and a Retrovirus packaging vector. The multi plasmid approach increases the safety because viral structural genes have been placed on different genetic units, and multiple recombination events must occur before replication competent virus structural genes have been placed on different genetic units, and multiple recombination events must occur before a replication competent virus would be generated. Furthermore, areas of homology have been minimized to decrease the chance of homologous recombination. Virulence genes have been removed from the viral plasmids. Both the Lentivirus and retrovirus to be produced in this study are replication incompetent, due to the elimination of wild-type enhancers in the long terminal repeat region. The vectors contain a self-inactivating 3'LTR that renders them unable to produce infectious virus when it integrates into the host chromosome.

To minimise the possibility of self inoculation, personal protection measures will be taken, for example needles will not be used when handling biological agents and appropriate personal protection will be used (Lab coat, gloves, safety glasses). To minimise any possible aerosol effects of the viral stocks, appropriately capped centrifuge bottles and screw-capped tubes will be used. Trigene advanced has been shown to completely inactivate lentivirus and retrovirus at a final concentration of 1:100 and so will be used to thoroughly clean everything involved in these experiments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A
Liquid waste will be treated with Trigene Advance at a final concentration of 1% for 30 minutes, shown by the manufacturer to give a complete deactivation.

Solid GM waste material is collected separately in designated 30 litre yellow bins or autoclavable Sharpsafe bins, clearly labelled as GM waste and with the group name. When operator has agreed to receive it, waste will be brought over to the autoclave for treatment. All routes must be internal, and the GM waste must never be left unattended. Gloves and lab-coats should be worn. In the event of spillage during transport to the autoclave, the area must be isolated and then promptly cleaned with 1% Trigene.

The operator loads the autoclave and runs the plastic discard cycle (134°C for 15 minutes) which has been established sufficient to kill 100% of retroviruses, bacteria and tissue culture cells. The temperature probe is put into the waste of the bin to ensure waste in the centre of the bin is inactivated and monitors every run. Chart paper supply and printouts are checked before and after each run. Should the autoclave fail a run the loads are not realeased to the clinical waste route until a fully validated run has occurred. The run number is recorded and the traces and printouts are kept until the waste will have been finally disposed of as clinical waste. All staff operating the autoclave have been trained in manual handling and are also trained in appropriate spillage procedure. 1% Trigene is the disinfectant to be used in case of inactivated waste being spilled in or out of the autoclave. The autoclave has quarterly checks and an annual 12-point thermocouple test to ensure the efficiency of the cycle.

Project Ref 363/10.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
To study the plasticity of cells

Purposes of the contained use
To identify epigenetic mechanisms involved in regulating the reprogramming of somatic cells to iPS and to study the effects of knocking down target genes on cell differentiation and reprogramming. Reprogramming will be induced by co-expression of various transcription factors and enzymes in lentiviral vectors. Lentiviral vectors containing a variety of shRNA or DNA target sequences will be used for the knockdown and over expression studies. Lentiviral vectors where chosen because they enable the transduction of primary and non-dividing cells.

Recipient or parental organism
Lentiviral vector constructs are provided commercially as bacterial cultures of E. coli (DH5alpha strain). The LB agar E. coli stab cultures will be sub-cultured on LB agar plates before a bacterial colony is grown in large amounts in LB medium. Vector plasmid DNA will be isolated from the culture using a Qiagen plasmid purification kit. HEK293T cells will be used to package the plasmid vectors into replication incompetent virus. Recipient cells of the lentivirus include various primary mouse somatic cells and cell lines.

Host/vector system
Vectors:
Expression: pLKO.2 containing target shRNA (Thermo Scientific) pLove containing transgene (Addgene)
Packaging: pRSV-Rev, pMDLg/pRRE (Addgene)
Envelope: pND2.G (Addgene)

Origin & function
Delivery of the target gene into mouse somatic cells and cell lines will be achieved using lentiviral systems based on HIV-1. For example, the four pluripotency factors (OSKM) are cloned into the lentiviral vector pLove and the shRNAs that target transcription factors are cloned into the transfer vector pLKO.1 For some of the gene knockdown experiments, a combination of shRNA clones against a single target will be co-transfected together to give a mixed population of shRNA.

In both cases the HEK293T packaging cells will transcribe the DNA, synthesize with viral RNA and proteins, and package a viral particle. These viruses will be used to transfect various types of somatic mouse cells. The pluripotency factors are well described and have been shown, repeatedly, to produce iPS. The shRNA's will target a
selection of transcription factors and enzymes that we believe are involved in cell differentiation and reprogramming.

**Evaluation of foreseeable effects**

The OSKM transcription factors to be used in these experiments have been cloned into the pLove lentiviral vector and will be co-transfected into packaging cells HEK293T’s together with plasmids for the packaging proteins (Addgene) to produce lentiviral particles. For the shRNA’s the target gene is contained within the lentiviral vector pLKO.1 and will be co-transfected into the packaging cells (HEK293T). We are using a third generation lentiviral vector system. The 3rd generaton packaging system offers maximal biosafety but is more cumbersome to use as it involves the transfection of four different plasmids into the 293T producer cells (two packaging plasmids, an envelope plasmid, and the lentiviral vector). For safety purposes the lentiviral vectors pLKO.1 and pLove contain a chimeric 5’LTR in which the HIV promoter has been replaced with RSV (pLKO.1) or CMV (pLove), thus making them TAT-independent. The multi-plasmid approach increases the safety of the system because viral structural genes are contained on different constructs, thus multiple recombination events would have to occur for a replication competent virus to be generated. Moreover, virulence genes have been removed from the plasmid vectors and the lentiviral vectors contain a self-inactivating 3’ LTR that renders them unable to produce infectious virus when it integrates into the host chromosome.

To reduce the possibility of self inoculation needles will not be used and personal protection in the form of lab coat, gloves and safety glasses will be worn. To avoid generating aerosols only screw capped tubes and bottles will be used for processing and storing the viral stocks. The detergent Trigene Advanced has been shown to completely inactivate lentivirus at a final concentration of 1:00 for 30 minutes. Trigene will be used to decontaminate any plasticware used during the experiments and to clean the class II cabinet used to conduct these experiments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be treated with Trigene Advanced at a final concentration of 1% for thirty minutes, manufacturers recommendation to give complete deactivation. All plasticware used and discarded during these experiments will be soaked with Trigene Advanced overnight.

Solid GM waste, after appropriate soaking in Trigene and rising, will be collected in autocalvable sharpsafe bins, clearly labelled as GM waste with the group name. The waste will be autoclaved. The autoclave operator runs the wast on the plastic discard cycle (134C for 15 minutes) because these conditions are established to kill 100% of retroviruses, abcteria and cells. A temperature probe monitors each autoclave run to check that the desired temperature conditions are reached. The temperature during each run is recorded on chart paper. The wste is only released to the clinical waste routed after a fully validated run. All staff operating the autoclave have been trained in manual handling and are also trained in appropriate spillage procedure (use of 1% Trigene as disinfectant if any inactivated waste is spilt in or out of the autoclave).

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to determine genetic modifiers of cardiocascular traits. The function of candidate genes, identified through proteomic or genetic screens, will be evaluated in vitro using functional genomic approaches prior to progressing to in vivo studies. See attached document for full details

**Recipient or parental organism**

Bacterial cells (for cloning and protein expression) and Mammalian cell lines (for expression of cloned sequences) including: E. coli Top 10, E. coli BJ5183, 293 cells (or
Host/vector system

Shuffle vectors (pShuttle or pAdTrack), Replication deficient Adenovirus (pAdEasy-1, -2) and other relevant commercial vectors from recognised suppliers (e.g. Stratagene, Invitrogen).

Origin & function

We propose to study genes that regulate cardiovascular phenotypes. Over-expression of any gene product has potentially deleterious effects whether oncogenic, apoptotic or affecting other cellular functions. However, to have detrimental effects the abnormal gene needs to be continually expressed or transferable. For the reasons given below this does not apply to in vitro low titre adenoviral work and it is believed that the inserted sequences are not capable of transducing cells. That said, if any particular gene is known to have oncogenic properties, work using adenovirus expressing that gene will be undertaken in a microbiological safety cabinet. Sequences will be expressed in the above mentioned mammalian cells using the Shuttle vectors or adenoviral vectors generated. The gene/protein expressed is not expected to be harmful to environment or operator. Although viral, bacterial and mammalian genes can be expressed in humans, recombinant type V adenovirus mediated-transgene expression is epigenetic, transitory and non-transferable (replication deficient i.e. the virus does not propagate). Therefore if the correct procedures are followed, this procedure is unlikely to be harmful to the environment or operator.

Evaluation of foreseeable effects

As the plasmids specified are not expected to produce biologically harmful products, these experiments should not be harmful to the user or the environment. The plasmids are incapable of propagation outside of laboratory setting. Replication deficient virus was confirmed as E1 deficient by qPCR using a safety protocol developed by Dr Cook. Despite this, care will be taken to reduce possible sources of contamination. Appropriate PPE will be used when handling the reagents (lab coats, gloves etc). Mammalian cell culture will be carried out in a relevant cell culture hood. Screw-capped centrifuge bottles and eppendorfs will be appropriately capped and handled to avoid aerosol. Vessels (e.g. flasks and falcon tubes) will be securely placed in the shaking incubator in secondary containers to prevent spillage of bacterial cultures and potential damage to the vessels themselves. In the event of spillage, the spill will be contained with paper tissues, and the affected area decontaminated with Trigene. In the event of a tissue culture spillage the same procedure will be followed except after decontamination with Trigene, the area will also be cleaned with a 70% ethanol solution as a further step to ensure that the area is sufficiently clean for further tissue culture. All paper waste will be disposed of as GM solid waste.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Solid GM and tissue culture waste will be disposed of as outlined in section 8b of the attached document. Liquid waste will be treated with either Trigene according to manufacturer's instructions, or Virkon (1-3% solution) for a minimum of 8 hours. Virkon is active as long as it retains its pink colouration, which is easily verified visually.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with Trigene Advance at a final concentration of 1% for 30 minutes, shown by the manufacturer to give complete deactivation. Solid waste material is collected separately in designated 30 litre yellow bins or autoclavable Sharpsafe bins, clearly labelled as GM waste and with the group name. When operator has agreed to receive it, waste will be brought over to the autoclave for treatment. All routes must be internal, and the GM waste must never be left unattended. Gloves and lab-coats should be worn. In the event of a spillage during transport to the autoclave, the area must be isolated and then promptly cleaned with 1% Trigene. The operator loads the autoclave and runs the plastic discard cycle (134C for 15 minutes) which has been established sufficient to kill 100% of retroviruses, bacteria and tissue culture cells. The temperature probe is put into the waste of the bin to ensure waste in the centre of the bin is inactivated and monitors every run. Chart paper supply
and printout are checked before and after each run. Should the autoclave fail a run the loads are not released into the clinical waste route until a fully validated run has occurred. The run number is recorded and the traces and printouts are kept until the waste will have been finally disposed of as clinical waste. All staff operating the autoclave have been trained in manual handling and are also trained in appropriate spillage procedure. 1% Trigene is the disinfectant to be used in case of inactivated waste being spilled in or out of the autoclave. The autoclave has quarterly checks and an annual 12 point thermocouple test to ensure the efficiency of the cycle.

Project Ref 363/11.1

Date Ackn'd: 25/08/2011

CU2 Project Title: Hormone signalling and energy homeostasis: defining the central nervous system molecules and circuits through the use of virally-mediated gene expression

Class: Class 2

CultureVolClass2: < 1 Litre

Non-GMM: Consent Granted

Project notified under transitional arrangements: [No]
The purpose of this project is to investigate the signalling mechanisms and neuronal networks involved in the regulation of energy homeostasis and endocrine function. The work carried out under this application will lead to the production of mice in which specific genes are manipulated in the central nervous system using virally mediated gene transfer. Replication deficient lentiviral particles expressing genetically modified constructs (eg intracellular signalling molecules, ion channel proteins, short interfering RNA (siRNA)) will be injected into mouse brains. Insertion of loxP sites into the viral constructs will limit expression to only the neuronal populations that express cre-recombinase (promoter driven in transgenic mice). This approach may overcome developmental issues that arise from traditional transgenic mice models since it can be used to manipulate genes only in the adult. Neuronal specific expression of light-sensitive ion channel proteins (i.e. channel-rhodopsin or halorhodopsin) will be used to link acute neuronal excitability with behavioural output (i.e. energy homeostasis, reward). Together these approaches will permit examination of the brain circuits that regulate appetite and bodyweight.
