### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: **Y**

Give brief details of the genetic modification safety committee:
Our GM safety committee is comprised of company employees. Currently the committee has four members; three hold PhDs in the life sciences and the fourth is a senior-level technical staff member.

The committee will hold its first meeting in early September 2010 and reconvene monthly thereafter. The committee will consider all of the GM work undertaken at the company as described in submitted Risk Assessment Forms. It will consider all of the GM work undertaken at the company as described in submitted Risk Assessment Forms. It will also be tasked with auditing compliance to all risk mitigation strategies.

Added 28/01/2022 - The GMSC now meets (at least) quarterly and has expanded. It now comprises of; Chair, Nominated Deputy Chair, Biological Safety Officer, external expert, lay person and Departmental Representatives (11 people in total).

For activities involving GMMs, describe the waste management measures which will apply to the activity.
All GMMs used in these Class 1 activities will be effectively 100% inactivated as follows.

For solid waste containing GMMs, the materials will be autoclaved at the appropriate temperature and pressure for an adequate length of time. The autoclaved waste will then be sent for incineration. For liquid waste containing GMMs, a decontamination liquid such as Virkon (peroxygen-based and the referred method) or hypochlorites (bleach) will be used. For example, a working concentration of Virkon will be prepared fresh and then used to dilute the contaminated liquid to 1-2% final. The activity of the Virkon stock solution will be verified by colour indicators. DMM-containing liquids will be held in Virkon treatment for a minimum of 20- minutes. Treated liquids will be disposed down normal drains with running water provided no non-biological hazards are present. Empty containers will be autoclaved.

Both solid and liquid waste will be appropriately labeled. Solid waste will be placed in bio-hazard plastic bags for autoclaving and incineration.

A meeting of the Safety Committee was conducted on September 9th, 2010 to consider the Risk Assessment of certain work conducted at the company using GMMs.

The committee considered the nature of the organisms as well as the details for handling, inactivating and disposing of them and came to the consensus that these activities should be considered Level 1 risks.

The committee approved the procedures outlined for the handling of GMMs. A copy of the Risk Assessment along with more detailed committee comments is attached to this form.
This work is aiming to develop monoclonal antibodies as a drug to treat Ebola. The lenti pseudo-type viruses are classified by the Advisory Committee on Dangerous Pathogens (ACOP) as hazard group two organisms. The viruses will be produced and provided by our collaborator in the University of Westminster and are genetically modified to contain Ebola glycoprotein (GP), which is crucial for the infection of Ebola virus, and non-toxic marker genes, such as luciferase. By looking into the monoclonal antibodies binding to the GP, the Ebola infection will be blocked at this stage.

In vivo work:
These pseudo-type viruses will be used for immunization of Kymice (hybrid of C57/B6 and 129 mouse strains). The mice are housed in the Research Support Facility (RSF) building at the Wellcome Trust Sanger Institute (WTSI) in a purpose built CL2 facility. Serial bleed, terminal bleed and samples (spleen, legs) collection will happen on the same premises. The WTSI has a large scale programme for generating mice. All details of the immunization procedures are approved by the Home Office Licence held by Professor Gordon Dougan/Or Simon Clare and immunizations will be performed in accordance with this approved licence and appropriate project licence holder.

In vitro work:
The immuno-response of mice will be checked by ELISA with the polyclonal serum against the pseudo-type viruses. The leniviruses used for vaccination also serve as reporter viruses in neutralisation assays. Tissue samples (spleens and bone marrows) will be dispensed into single cells, stained for cell sorting. These will be all conducted under BSL II conditions.

Recipient or parental organism
The parentallenti-viruses are CI 2 organism. The recipient organisms (mouse and assay cell lines) are CI1.

In vivo work:
The lenti pseudo-type viruses to be used will include viruses harbouring EboJa glycoprotein and non-toxic reporter gene (GFP or Luciferase). The mice for immunization is a genetically modified outbred strain (C57B6 with 129). These mice won't pose a higher risk to human health or the environment than the parental strains (wild type C57B6 or 129). We anticipate that mice will be infected by the viruses used for immunization and some will go on to develop clinical symptoms. Such mice will be humanly sacrificed according to the methods outlines in Sanger's Home Office License if their clinical symptoms reach a certain well documented level of severity. We foresee no unusual outcomes since the viruses we will use is defected, so can’t replicate. After inoculation, the viruses will be cleared out very quickly by the mouse natural immuno system.

In vitro work:
The lentiv pseudotype viruses we will be using are produced by our collaborator in the University of Westminster who will be responsible for the health and safety assessment and control for the production process. There is good evidence that such replication defective viruses are not pathogenic when tested in mice and a minimum of 3 recombination events are necessary to produce replication competent, recombinant virus. In addition such virus vectors are single cycle infection agents not able to form productive infections or to recombine with endogenous retroviruses and become productively infectious.

There is a very low likelihood that exposure to any components of this project will cause harm. The main risk is accidental infection and transfer of the lentivirus to the laboratory personnel directly handling the lentivirus. This risk is extremely low since all the procedure will be carried out following the requirement for protection of working in CL2. Also the lentivirus is carrying a non-toxic, non-human reporter gene, so the potential harm by insertional mutagenesis/overexpression of cellular genes by random integration is extremely low. The likelihood that this will cause harm is low as the replicative defective nature of the lenti vectors ensures that even in the case of a breach of containment and accidental injection, no virus can spread within or between individuals.

Several serial bleed will be taken after each boost to monitor the titre by ELISA. The ELISA will be performed in a class II hood to provide a control measure to prevent exposure of the operative to any aerosols produced within the hood. Plates will be read on a plate reader outside of the class II lab but prior to removal plates will be sealed with a self adhesive polypropylene seal and surface of plates which are accessible will be decontaminated with distel wipes. Functional activity of immunised mouse serum samples and antibodies will be determined using an E Bola lentiviral infection assay. The assay uses lentivirus expressing the E bala glycoproteins on the surface to infect HEK 293 or Vero E6 cell lines. All work will be carried out in class II hood to minimise exposure to aerosols in accordance with cat II procedures. Plates will be processed on a plate machine outside of the class II lab but prior to removal will be sealed with a self adhesive polypropylene seal and surface of plates which are accessible will be decontaminated with distel wipes. Any plasticware to be removed from the lab will be decontaminated with distel wipes. Concentrated stocks of the lentivirus will be stored in a tocked -80 freezer within the category II lab which has entry control to restrict access to stocks. Liquid waste from in vitro work containing lentivirus will be decontaminated by adding virkon (final 1% v/v) in a class II hood to minimise aerosol exposure when carrying out decontamination process.

Samples of mouse cens and tissue or lentiviral supernatant will be transferred between the Sanger Centre and Kymab but all samples will be packaged well with absorbent materia l, secondary contained in a sealed container specifically for the purpose of CL2 sample transportation and placed in designated packaging with correct safety labelling. All packages will be transported with the relevant safety documentation and drivers are insured to do so.

Host/vector system

Host cell lines
Host cest lines will include: 293T, Vero-E6, murine embryonic fibroblasts.
No cell lines or primary cells used will be from the workers.

The foreseeable effects of the infection of these cells with recombinant retroviruses would be the production of a cell line with altered properties able to establish a tumour in the laboratory workers, but the likelihood of this hazardous event to happen is estimated to be LOW under the strict BSL II procedure.

Mice

All immunization and sample collection work: will be carried out in purpose built CL2 facilities in Sanger center and animal cadavers win be autoclaved before disposal.

Origin & function

Origins of lenti pseudotype virus - These are supplied to us from our collaborator Dr Edward Wright, University of Westminster.
Evaluation of foreseeable effects

 Lentiviral Gene expression
The main risk is accidental exposure of laboratory workers to recombinant lentiviruses. As these lentiviral vectors are self-inactivating, the risk of onwards transmission to another person is impossible. The main risk is therefore alteration of the cellular function of the exposed person through insertional inactivation/activation of tumour suppressor genes/oncogenes respectively, or the alteration of cellular function by gene overexpression or ablation from the transferred genetic material within the vector. THESE ARE EXTREMELY UNLIKELY EVENTS THAT HAVE ONLY OCCURRED IN A CLINICAL SETTING FOLLOWING PROLONGED INFECTION WITH HIGH TITRE RETROVIRAL VECTORS AND SELECTION IN VIVO FOR CELLS WITH ALTERED GROWTH POTENTIAL. THEREFORE THE OVERALL RISKS ARE EXTREMELY LOW.

Mice
All immunization work will be carried out in purpose built CL2 facilities in Sanger center and animal cadavers will be autoclaved within this facility before disposal. Immunocompromised or pregnant workers will not be allowed to work in these facilities. OVERALL THE RISKS OF ADVERSE EVENTS FROM HANDLING GM VIRUSES FOR MURINE WORK ARE LOW.

Together the risks identified within this integrated programme of work can be minimised to acceptable low levels by working to existing laboratory standards and practices in designated Containment Level 2 laboratories. This is supported by the accompanying risk assessments.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All mice are housed in a CL2 laboratory suite built for purpose.
Animal cadavers will be autoclaved within this facility before disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
We operate a number of comprehensive and proven waste management measures which are conducted according to our focal protocol for handling e12 pathogens in both sites (Sanger Center animal house and Kymab CL2 lab). The protocols for the two sites are as follows:

Sanger Centre:
The GMM will be used within a containment level 2 laboratory in which all cultures/liquid waste is decontaminated prior to disposal using a final concentration of 1% Virkon solution for at least 16 hours (concentration validated by manufacturers) before disposal to the drains. Thus drains, sinks etc do not pose a mode of transmission to the environment. Air movement is also strictly regulated in the laboratory environment. Solid biological waste (including cadavers) is autoclaved using temperature cycles and conditions appropriate for the inactivation of biological material. Autoclaving is performed by departmental staff using approved conditions (134 degrees C for 3 minutes per cycle). Plasticware etc is decontaminated with 1 % Virkon solution prior to being autoclaved as described above.

Kymab Ltd:
At Kymab all cultures/liquid waste is decontaminated prior to disposal using a final concentration of 1% Virkon solution for at least 0.5 hours (concentration validated by manufacturers) before disposal to the drains. The virkon will be
added to liquid in a class Is hood to minimise aerosol exposure during the process. Thus drains, sinks etc do not pose a mode of transmission to the environment. waste should be secondary contained in a sealed container if left outside the safety cabinet during decontamination periods. Plastic pipettes should be secondary contained by re-sheathing in wrapper before placing in bins. All solid waste from Kymab is placed in hermetically sealable yellow bins and sent for incineration off site. Air movement is also strictly regulated in the laboratory environment. All the work will be carried out in Cat Is hood to minimize aerosol exposure.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Non-GMM Consent Granted

Consent Granted: Not Applicable

Project notified under transitional arrangements

Tick if notifying a connected programme of work

Withdrawn

02/03/2022
Project Additional Information

Purposes of the contained use

This connected programme of work aims to discover and develop monoclonal antibodies and vaccines against medically-important human targets or pathogens using the Kymouse™ (hybrid of mouse strains C57B6 and 129) platform. The pathogens we will investigate are all classified by the Advisory Committee on Dangerous Pathogens (ACDP) as hazard group two (HG2) organisms and will include:
1) human orthomyxoviruses, including influenza viruses
2) human herpesviruses, including human cytomegalovirus, Epstein-Barr virus and herpes simplex virus 1
3) human pneumoviruses, including respiratory syncytial virus
4) Lentiviral-vectors and lentiviruses
5) Gram-negative bacteria, including Escherichia coli and Acinetobacter baumannii.

Human targets or pathogen-associated antigens will be used for the immunisation of the Kymouse™, which has a human B cell repertoire. No live GM pathogens will be used for immunisations. Once an immune response is observed, tissue samples (spleens, lymph nodes and bone marrow) will be taken and antigen specific B-cells or plasmablasts sorted by flow cytometry. The heavy and light chains of each B-cell receptor will be sequenced and the antibodies synthesised and expressed.

This connected programme will use a number of standard molecular biology/microbiology methods to test the efficacy of these monoclonal antibodies in in vitro systems. In some cases, viruses produced will be derived from defined genotype recombinant sources, such as herpesvirus BACs or reverse-genetics influenza virus and pathogens engineered to express non-toxic marker genes.

Lentivirus vectors containing human or pathogen genes may be used for gene delivery and expression in eukaryotic cells. Genes will be cloned from human and pathogen DNA or cDNA into bacterial vectors that contain bacterial and/or eukaryotic selectable markers and bacterial or eukaryotic expression signals. A 3rd generation lentivirus vector system will be used for this work. To generate lentiviral vectors the gene of interest will be transferred into a modified HIV vector, with viral genes vif, vpu and nef deleted, containing a strong promoter (e.g. CMV or SFFV promoter) driving the expression of a marker, such as GFP, and the single gene of interest from the bacterial plasmids. This will be transfected into eukaryotic cells together with two HIV packaging plasmids (one encoding gag/pol, one encoding rev) and an envelope expressing plasmid (VSV-G) to produce recombinant lentiviruses. These will be used to transduce cell lines and primary cells, producing cells that express the gene of interest and after selection or sorting produce stable cell lines. The resulting stable cell lines will be used to assess antibodies in binding or effector function assays.
The recipient or parental pathogens are all hazard group 2 organisms. The recipient organisms (cell lines or primary human cells) are hazard group 1 or 2. Work with hazard group 3 or 4 pathogens is excluded from this coordinated programme of work.

Identifying and testing monoclonal antibodies against pathogens or pathogen-associated proteins:
Genetic modifications for all pathogens within this body of work will involve insertion of marker genes such as GFP or luciferase or deletion/ modification of pathogen genes to cause attenuation. The foreseeable effects from the production of such recombinant pathogens will be to produce a pathogen that is equivalent to or attenuated relative to wild type. Insertion of oncogenes is excluded from this work.

All pathogens used are ADCP HG2 and will be worked with in CL2 containment facilities.

Pathogens to be worked with include:
HERPESVIRUSES (wild type and recombinant, which may be generated from bacterial artificial chromosomes (BACs));
Herpes Simplex Virus Type 1 (HSV-1)
Human Cytomegalovirus (HCMV)
Epstein-Barr virus (EBV)

These are transmitted primarily as cell-free virus in saliva and through close physical contact. The potential for accidental exposure comes from virus containing medium that is ingested, exposing the oral cavity or via needle stick injuries. With HSV-1 there is also an infection risk to the eye, which may lead to herpes keratitis and ulceration of the cornea. In most people, infection with any of the herpesviruses causes a self-limited primary infection with the potential for the virus to reactivate sporadically.

Herpes Simplex Virus type 1 (HSV-1)
HSV-1 causes cold sores and genital herpes. More than 70% of the population is infected and retains the virus for life in latent form. Herpes infections are most contagious when symptoms are present but can still be transmitted to others in the absence of symptoms. Most infected people do not suffer from recurrent cold sores, but nevertheless occasionally secrete virus in their saliva. Symptoms of herpes include painful blisters or ulcers at the site of infection.

In immunocompromised people, such as those with advanced HIV infection, HSV-1 can have more severe symptoms and more frequent recurrences. Rarely, HSV-1 infection can also lead to more severe complications such as encephalitis or keratitis (eye infection).

Neonatal herpes can occur when an infant is exposed to HSV in the genital tract during delivery. This is a rare condition, occurring in an estimated 10 out of every 100,000 births globally, but can lead to lasting neurologic disability or death. The risk for neonatal herpes is greatest when a mother acquires HSV infection for the first time in late pregnancy.

Human Cytomegalovirus (HCMV)

Human cytomegalovirus (HCMV) causes lifelong infection and has a prevalence of 55-100% within the human population. Primary HCMV infection is generally asymptomatic in healthy hosts but can cause severe and sometimes fatal disease in immunocompromised individuals and neonates. HCMV is the leading infectious cause of congenital abnormalities in the developed world, affecting 1-2.5% of all live births. HCMV intrauterine infection and can cause significant morbidity, including low birth weight, hearing loss, visual impairment, microcephaly, hepatosplenomegaly, and varying degrees of mental retardation. HCMV also causes serious disease in organ transplant recipients and AIDS patients, either after primary infection or reactivation of latent infection. Epstein Barr virus (EBV)

EBV is known to have tropisms for B cells and epithelial cells and in some circumstances, may infect T cells,
EBV can cause infectious mononucleosis (glandular fever). Symptoms include fatigue, fever, inflamed throat, swollen lymph nodes in the neck, enlarged spleen, swollen liver, rash. People who get symptoms from EBV infection, usually teenagers or adults, get better in two to four weeks. However, some people may feel fatigued for several weeks or even months.

After an EBV infection, the virus becomes latent (inactive) within the body. In some cases, the virus may reactivate. This does not always cause symptoms, but people with weakened immune systems are more likely to develop symptoms if EBV reactivates.

There are three major types of B cell malignancy linked to EBV - Burkitt, Hodgkin and diffuse large B cell lymphomas, as well as rarer EBV-associated tumours of B cell origin (PBL- plasmablastic lymphoma and PEL primary effusion lymphoma), which are seen in late stage AIDS patients and heavily immunocompromised individuals. ORTHOMYXOVIRUSES (wild type, produced from reverse genetics systems and recombinant)

Influenza A
Influenza B
Health and Safety
Executive

No influenza viruses classified above hazard group 2 will be used. Some strains of influenza virus that are highly infectious to agriculturally important species (e.g. H5 or H7 'avian' influenza) are controlled under the Specified Animal Pathogens Order 2008, but these will NOT be used in this project. Influenza viruses classified above Hazard group 2 are excluded from this programme of work.

Influenza viruses are airborne pathogens transmitted primarily as foamites. Therefore the primary risk to personnel from GM influenza viruses is exposure to tissue culture medium containing viruses, either as an aerosol or as a large volume exposure to the nose, mouth and eyes (mucous membranes).

Influenza is a contagious respiratory illness caused by influenza viruses that infect the nose, throat, and sometimes the lungs. Influenza A & B can cause the same spectrum of disease, ranging from mild to severe illness, and at times can lead to death. People who have influenza often feel some or all of these signs and symptoms that usually start suddenly, not gradually:
- Fever or feeling feverish/chills, cough, sore throat, runny or stuffy nose, muscle or body aches, headaches, fatigue.
- Some people may have vomiting and diarrhoea, though this is more common in young children than in adults.
- People at high risk from developing serious influenza-related complications include those over age 65, pregnant women, people with chronic medical conditions (such as asthma, diabetes, weakened immune system or heart disease) and young children.

All personnel that work in the laboratories which use influenza will be offered annual influenza vaccinations. Only low pathogenicity laboratory strains of influenza will be used and these may be GM. Different strains of influenza will not be worked with at the same time to avoid the possibility of reassortment between viruses.

PNEUMOVIRUSES
Respiratory syncytial virus

Human respiratory syncytial virus (RSV) causes respiratory tract infections. It spreads easily by direct contact. It is a major cause of lower respiratory tract infections and hospital visits during infancy and childhood. For adults, RSV produces mainly mild symptoms, often indistinguishable from common colds and minor illnesses. For some
children, RSV can cause bronchiolitis, leading to severe respiratory illness requiring hospitalization and, rarely, causing death. Severe disease is most likely to occur in premature infants or the immunocompromised. **GRAM-NEGATIVE BACTERIA**

**Escherichia coli**
Pathogenic strains are classified as hazard group 2. The exceptions are E.coli, verocytotoxigenic strains (eg 0157:H7 or 0103), which are classed as hazard group 3. We will NOT be working with any verocytotoxigenic strains of E. coli. E.coli classified above Hazard group 2 are EXCLUDED from this programme of work.

E. coli bacteria are transmitted primarily by faecal-oral route and normally live in the intestines of people and animals. Most E. coli are harmless and actually are an important part of a healthy human intestinal tract. However, some E. coli are pathogenic, meaning they can cause illness, either diarrhoea or illness outside of the intestinal tract. Extra-intestinal pathogenic E. coli (or ExPEC), is the most common cause of urinary tract infections and Gram-negative bacteraemia. Before the 2000s, ExPEC was mostly susceptible to first-line antibiotics (e.g. cephalosporins and fluoroquinolones) that are often used to treat infections. However, resistance to fluoroquinolones among E. coli is very widespread and they are now ineffective in more than half of patients. Of special concern is that FQ-R is often accompanied by resistance to the cephalosporins.

**Acinetobacter baumannii**
A. baumannii is a Gram-negative bacteria, which is usually considered to be a low-virulent pathogen. It is an opportunistic pathogen in humans, infecting critically ill patients or immunocompromised individuals and can cause serious therapeutic problems in the clinical setting, due to its multidrug resistance to clinically available antimicrobial agents. Acinetobacter causes a variety of diseases, ranging from pneumonia to serious blood or wound infections, and the symptoms vary depending on the disease. Acinetobacter may also "colonize" or live in a patient without causing infection or symptoms, especially in tracheostomy sites or open wounds. Acinetobacter can be spread to susceptible persons by person-to-person contact or contact with contaminated surfaces.

**LENTIVIRAL VECTORS**
Lentiviruses based on Human immunodeficiency virus type 1 and 2 (HIV-1/-2) are classified as Hazard Group 3. However, we will NOT be working with HG3 lentiviruses but modified lentiviral vectors which are suitable for use at Containment Level 2.

The lenti pseudo-type viral particles to be used will be replication-deficient viruses harbouring the genes of interest. There is good evidence that such replication defective viruses are not pathogenic and a minimum of 3 rare recombination events are necessary to produce replication competent, recombinant virus. In addition, such virus vectors are single cycle infection agents not able to form productive infections or to recombine with endogenous retroviruses and become productively infectious.

The viral genes vif, vpu, nef and tat are deleted in this system and for 3’ generation vectors the necessary viral genes are split across four plasmids therefore making each vector attenuated by lack of intact full length genome. Extensive recombination events (a minimum of three) would be needed to produce a replication-competent virus, and there is good evidence that replication-defective viruses are not pathogenic when tested in mice. In addition such virus vectors are single cycle infection agents not able to form productive infections or to recombine with endogenous retroviruses and become productively infectious. If exposure to such viral vectors occurred this would be a very self-limiting infection.

CL2 containment for the molecular biology, bacterial, viral and tissue culture work is sufficient for both the production and use of the GM pathogens mentioned above and for production of lentivirus plasmids and replication defective viral vectors. This level of containment is also sufficient for the transduced cell lines that result from exposure to the viral vector preparations. The primary risk of working with any of the pathogens listed above results from immunodeficiency or infection during pregnancy. Therefore, immunosuppressed workers or pregnant women will be excluded from working with these organisms.
Host/vector system

Plasmids
Cloning plasmids will be pGEM derivatives, pUC series, pBLUESCRIPT series, pcDNA, pCMV/Zeo, and pEGFP-1. We will be using a commercial 3rd-generation system: ViraPower™ Lentiviral expression system (Thermofisher). The components of both these systems are as follows: A pLenti-based expression vector into which the gene of interest will be cloned. The vector also contains the elements required to allow packaging of the expression construct into virions (e.g., 5' and 3' LTRs, 4J packaging signal). The ViraPower™ Packaging Mix contains an optimized mixture of the three packaging plasmids, pLP1, pLP2, and pLPNSVG. These plasmids supply the helper functions as well as structural and replication proteins in trans required to produce the lentivirus. These have been extensively engineered to be self-inactivating and are only capable of a single round of infection.

For construction of GM bacteria expressing GFP/RFP and luciferase, random insertion into the bacterial chromosome with the Tn5 transposon, for example containing kanamycin resistance genes and genes for GFP/RFP and luciferase will be used. Once inserted into the bacterial genome the inserted sequence is nonmobilisable. Bacteria may be transformed with plasmid vectors to allow deletion of specific genes resulting in over production of OMVs. In this example, TolR will be replaced with a kanamycin cassette using the plasmid pAJD433. The plasmid will be removed from the mutant construct resulting in a chromosomally-inserted sequence that is non-mobilisable.

GM viruses will be generated externally by collaborators and will be assessed for effect on activity, and confirmed safe to handle at CL2, prior to transfer to Kymab. They are generated using reverse genetics plasmid systems (e.g. influenza, RSV) or bacterial artificial chromosomes (herpes viruses). Vectors for modification will NOT be handled at Kymab, and residual plasmids become insignificant upon first passage of the virus, which is also performed externally, so there are no risks associated with vectors.

Origin & function

Cell lines/Primary cells
Cell lines, such as (but not limited to) A549, MRC-5, WI-38, Hep-2, RMK, MDCK, 293T, will be obtained from commercial sources (e.g. ATCC) they may require handling at either CL 1 or CL2. Primary human cells (e.g. leukocyte cones) may also be used. These must be handled at CL2. Primary cells from the workers will NOT be used.

Embryonated chicken eggs.
Where high titre influenza virus is required, such that growth in tissue culture would not be practical, embryonated chicken eggs may be used to produce stocks of influenza A or B. The embryonated chicken eggs to be used will be obtained from a commercial source, the eggs being suitable for medical research. The supplier is registered under DEFRA's Poultry Health scheme, which means all disease control programmes are up to the latest UK and EU standards. Prior to infection, embryonated eggs can be handled at CL 1.

Viruses and bacterial strains may be purchased from Public Health England's (PHE) culture collections, for instance the National Collection of Pathogenic Viruses (NCPV) or the National Collection of Type Cultures for bacteria (NCTC). Primary isolates from hospital laboratories and diagnostic service laboratories will be obtained under appropriate agreements and licenses. GM pathogens or those not commercially available may be supplied by collaborating parties, under appropriate licensing agreements.

Evaluation of foreseeable effects

Bacterial hosts
The bacterial host for all plasmid propagations within this programme of work is E.coli K12, which is disabled in key
bacterial functions (i.e. recombination defective) and unable to survive in the environment or pass genetic material onto host bacterial flora following a breach of containment. For the production of lentiviral vectors the lentiviral genome is split over four separate plasmids such that virus production is only initiated when all four plasmids are present in a eukaryotic cell. Therefore there is no risk of lentiviral particles being produced from bacterial culture. Overall the risk of adverse events from the handling of plasmids or bacteria is low.

Lentiviral Gene expression

The main risk is accidental exposure of laboratory workers to recombinant lentiviruses. This risk is reduced significantly by working in microbiological safety cabinets (MSC). As these lentiviral vectors are self-inactivating the risk of onwards transmission to another person is extremely unlikely. The primary risk is therefore alteration of the cellular function of exposed personnel through insertional inactivation/activation of tumour suppressor genes/oncogenes respectively, or the alteration of cellular function by gene overexpression or ablation from the transferred genetic material within the vector. These are extremely unlikely events that would only occur following prolonged infection with high titre retroviral vectors and selection in vivo for cells with altered growth potential. Therefore the overall risks are low.

GM viruses

For all viruses within this body of work genetic modifications will involve insertion of marker genes such as GFP, luciferase or deletion/modification of viral genes to cause attenuation. The foreseeable effects from the production of such recombinant viruses will be to produce a virus that is equivalent to, or attenuated relative to, wild type virus. All viruses used in this programme of work are ADCP hazard group 2 pathogens and both wild type and GM viruses will be handled in CL2 containment facilities. If available, laboratory workers will also receive vaccinations against parental virus strains. Immunocompromised or pregnant workers will not be allowed to work in the laboratory. Overall the risks of adverse events from handling GM viruses within this project are low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Kymab Ltd operates a number of comprehensive and proven waste management measures which are conducted according to our Code of Practice for handling CL2 pathogens:

Liquid Waste:
All cultures/liquid waste must be decontaminated prior to disposal using a final concentration of 1 % Virkon solution for at least 1 hour (concentration validated by manufacturers) before disposal to the drains.
2 % Virkon must be provided in the MSC in a sealable container. Liquid waste is added to this, so minimising aerosol production, to achieve a final 1 % solution. The container must be sealed shut and the external surfaces decontaminated with IPASEPT before removal from the MSC. Inactivating liquid waste must be retained for at least 1 hour before disposal in the sink.
Drains, sinks etc. do not pose a mode of transmission to the environment, as liquid waste has been inactivated.

Solid Waste:
Solid waste (e.g. plates, flasks, tubes) will be sealed (lids tightened or plates taped shut) before being disposed of in yellow biohazard bins. Other solid waste e.g. used gloves, tissue, packaging is also disposed of in yellow bins.

Stripettes:
A final concentration of 1% Virkon must be aspirated up and down in contaminated plastic stripettes prior to soaking in 1% virkon for at least 1 hour. Stripettes are then placed into hermetically sealable yellow bins.

Small plastic ware:
Small plastic ware e.g. tips/eppendors are disposed of in sweetie jars which are retained within the MSC. Once full sweetie jars are sealed and the external surfaces sprayed with IPASEPT before removal from the MSC and disposal in yellow bins.

When yellow bins are full they are hermetically sealed, wiped down with IPASEPT, marked as CL2 waste and removed to the secure collection point where they are collected by the local registered contractor (arranged by Babraham Bioscience Technologies) and sent for incineration off site.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Chair of Genetic Modifications Safety Committee: Biological Safety Officer and Chair of GMSC, a senior manager with an appropriate scientific background. Responsible for ensuring the committee reviews all risk assessments, co-ordinating comments from the committee and communicating with scientists and maintaining the record of GMSC activity. Liaison with HSE, preparation and submission of notifications/applications. Maintenence of statutory records responsible for biological safety and genetic manipulations.

Laboratory supervisor: Responsible for operations, working practice in the laboratory and training, also the primary person responsible for the origin and integrity of recombinant cell lines.

Members: Include a range of individuals with sufficient depth and scope of knowledge in their particular discipline to enable them to understand the risks arising from the normal range of activities undertaken and be able to judge the adequacy of GM risk assessments submitted to the committee. Responsible for highlighting changes in the work to the committee.

The Biological safety Committee will meet monthly and the Genetic Modifications Safty Committee will meet quarterly or ad hoc in case of a request at intervening Biological Safety Committee meetings. The Convergence Biological Safety Committee will interface with Babraham Research Institute BSO to ensure flow of communication and sharing of best practice.

Solid waste from laboratories carrying out GM work at Class 1 will be placed into a suitably labelled hermetically sealable 60L UN approved Type 3H2/Y30/S/2002. They will be sealed by the producer of the waste and removed to a central collection point where they will be placed into a 210L yellow labelled "Eurobins" for collection by the local registered clinical/GM waste incinerator contractor (Vetspeed) in accordance with Babraham Institute procedures (derogation notification to HSE GM105/04.1).

Liquid waste is inactivated chemically. Where possible buffers not containing interfering substances, such as phenol red, will be decontaminated using "Microsol", according to the manufacturer's instructions on correct concentration and duration to ensure complete decontamination, then diluted to drain. Cell culture supernatants will be decontaminated using "Virkon", according to the manufacturer's instructions on concentration and duration of exposure to ensure complete decontamination, then diluted and disposed to drain. Drainage is processed through the Babraham Institute sewage treatment plant which is closely monitored. Volume to drain <10L per week.

Please enter comments of the GM safety committee on the risk assessment

The committee has considered the risk to human health and to the environment associated with the organisms and consider the proposal to be Activity Class 1

Agreed ACGM containment level 1

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

All the GMOs will be eukaryotic cell lines that cannot survive outside of an incubator. Disinfectant protocols will be employed using inactivation with 1-3% Virkon disinfectant for 24 hours followed by autoclaving of all contaminated waste prior to disposal as clinical waste. The process to ensure that autoclaving has occurred will be retention of the autoclave read-out and the use of autoclave tape.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Since no bacterial host is being used, the overall risk is very low

Y

Give brief details of the genetic modification safety committee

The Native Antigen Company GMO Biological Safety Committee has been established to assess risk assessments and give guidance on the effect of any project on the safety to the members of NAC, the safety to co-workers and other members of staff at the premises, the safety to the general public, the risk of cross contamination or recombination, the risk of release into the community of GMOs and any ethical considerations that may be relevant. Its members are drawn from a variety of backgrounds and bring a diverse range of expertise both within and outside of the company itself, from University lecturers to MDs. The Committee meets on an ad hoc basis whenever new GMO projects are proposed.

From our Code of Practice:

Any Solid GMM Biological Waste (including flasks, pipettes, tips etc) is to be fully soaked in 1% Virkon for a minimum of 24 hours, after which it should be bagged in the yellow clinical waste bags no more than 3/4 full and closed with a black cable tie. Full clinical waste bags are put in the locked right hand green cabinet for collection by the waste disposal service where they will be incinerated. Liquid GMM Biological Waste is to have sufficient Virkon powder added to it to make it at least 1% overall and left for a minimum of 24 hours to inactivate any viable pathogenic material. Thereafter it is to be disposed of down the sink with plenty of water. Contaminated sharps such as needles used in banding should be soaked in 1% Virkon for 24 hours then disposed of in the sharps bins provided. Full sharps bins are collected by the waste disposal contractors and incinerated off site. The process of disinfecting with Virkon has been demonstrated to completely destroy any infectivity or viability of every micro organism by independent labs and by the manufacturer of the powder.

Please enter comments of the GM safety committee on the risk assessment

The GMO Biological Safety Committee reported that they were happy for this project to go ahead and agree with the classification and proposed control measures. It was noted that a Risk Assessment number should be used to help track Risk Assessments (this has now been added) and the committee wanted to remind the company to keep all manufacturers literature and product information for any vectors, organisms or cells that are being purchased to add to the background safety information. The Committee also noted that every risk assessment should be reviewed on an annual basis to ensure they are still accurate and applicable.

Pellets and spent growth medium containing viable E.coli cells will be inactivated with the appropriate disinfectant and then discharged. The disinfection processes are in accordance with the manufacturers instructions and expected to achieve a 99.9999% kill (greater than five log reduction in viability). Glassware will be similarly disinfected before reuse.

Solid media and plasticware (pipettes, tips etc) will be disposed of into suitably labelled hermetically sealable bins. The bins are 60 litre UN approved (to Class 3) Type 3H2/Y30/S/2003. They will be sealed by the producer of the waste and removed to a secure central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Under an approved derogation, collections by the local registered clinical /GM waste incinerator contractor will be made three times a week to prevent a build up. The site has 24/7 Security.

The control measures described above are sufficient for the containment of Class 1 organisms and therefore these activities are approved by the Crescendo Biologics GMSC.
### Project Additional Information

#### Purposes of the contained use
- To produce proteins for use in the discovery and development of antibody-based therapeutics.
- To knock-down or knock-out expression of constitutive proteins in human or animal cells or cell lines.
- To test candidate antibody-based therapeutics using the human and/or animal material.

#### Recipient or parental organism
- E. coli K-12 derivatives such as XL1-BLUE, XL10-GOLD, BL21, AVB101, JM109, Rosetta blue, NovaBlue and TG1 are recognised as non-colonising and disabled, and may be considered equivalent to ACDP hazard group 1. These will be used for the production of vectors to be used in the transfection of eukaryotic cells.
- A variety of human and animal cells and cell lines will be used as recipients for the vectors (e.g., HEK293 cells, CHO cells, Dendritic cells, T cells and T cell lines). Cells may be hazard group 1. However, some cells may carry adventitious agents and will therefore be hazard group 2. Human or simian donors of primary blood cells or lymphoid cells will be assessed and only material from Low Risk donors will be used and material will be handled at containment level 2.

#### Host/vector system
- cDNA coding for human or animal genes will be obtained from tissue or isolated from cells or obtained from synthetic sources.
- K12 E coli host cells will be used for the construction and production of vectors. Vectors including pcDNA, pUC, pET, pCR2.1 and pJET based vectors will be used. These are considered to be non-mobilisable. Gene transfer is thus a remote possibility.
- Eukaryotic cells appropriate for the given experiment will be used. In most cases, the introduced genes will not increase the hazards associated with the parent eukaryotic cell lines. However, some genes, such as those encoding for growth factors, may have the potential to increase the rate of tumour growth or metastatic potential of well characterised continuous cell lines that are usually handled as containment level 1. In these circumstances, the cells will be handled at containment level 2. Similarly, some siRNA targets may also increase the potential hazard of the parent cell line and containment level 2 will be used where appropriate. The eukaryotic host cells are likely to retain stringent growth requirements and remain susceptible to dehydration reducing the risk to humans and the environment.

#### Origin & function
- cDNA coding for human or animal genes will be obtained from tissue or isolated from cells or obtained from synthetic sources.
- The genetic material will be used to produce reagents for use in therapeutic antibody discovery and development.

#### Evaluation of foreseeable effects
- It is unlikely that the GMM would survive and become established in the environment. The inserted (or silenced) genes may alter existing traits of the eukaryotic cell lines. In extreme cases, there may be potential for some tumour cells to escape normal immune surveillance and survive and replicate following accidental inoculation. However, the eukaryotic hosts are likely to retain stringent growth requirements and the use of good microbial practice in a containment level 2 facility will be sufficient to limit contact.

---

02/03/2022
with humans and the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Pellets and spent growth medium containing viable E.coli or eukaryotic cells will be inactivated with the appropriate disinfectant and then discharged. The disinfection processes are in accordance with the manufacturers instructions and expected to achieve a 99.9999% kill (greater than five log reduction in viability). Glassware will be similarly disinfected before reuse.

Solid media and plasticware (pipettes, tips etc) will be disposed of into suitably labelled hermetically sealable bins. The bins are 30 litre UN approved (to Class 3) Type 3H2/Y30/S/2003. They will be sealed by the producer of the waste, sprayed with disinfectant and removed to a secure central collection point. Under an approved derogation, collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build up. The site has 24/7 Security.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The Risk Assessment should be used in conjunction with COSHH forms detailing further information on the particular genetic manipulation. All COSHH procedures relating to the particular experimental process should be used in conjunction with the risk assessment.

Project Ref  3106/16.1
Production and in vitro activity testing of 'armed' Enadenotucirev (EnAd) virus for delivery of therapeutic proteins to tumour cells

To genetically modify enadenotucirev (EnAd), an attenuated adenovirus that selectively replicates in tumour cells, to express therapeutic genes (antibody or antibody fragments) that have the potential for treatment of human cancer.

To test activity of the genetically modified virus in non-purified (cell supernatants) or purified form in in vitro assays such as infectivity assays, potency assays, selectivity assays, transgene expression and binding assays using established cell lines or primary immune cells.

Testing of infectivity, potency, selectivity, transgene expression and transgene product binding to target protein will use established well characterised human and murine cell lines with a long history of safe use. These cells will be primarily hazard group 1 however some may carry adventitious agents and will be hazard group 2. Primary peripheral blood cells may be used in some functional experiments to assess activity of expressed transgenes and will be handled under containment level 2. Cells will be cultured in closed culture vessels within an incubator creating the specialised environment required for the propagation of the cells (e.g. an humidified incubator at 37°C with an atmosphere of 5% CO2 and 95% air). Only authorized personnel will conduct the work and it will be take place within a designated laboratory with controlled access via pin entry lock system or card access. Samples will be stored in fridges, incubators or freezers located inside the containment facility.

The host cell range for enadenocutirev virus replication is limited. All animals apart from higher primates do not express the primary receptor for viral entry (CD46). Even when the receptor is present it is insufficient for virus replication to occur due to attenuation of the virus to selectively replicate in human tumour cells (Kuhn et al 2008, PLoS One 3. e2409). Virus replication in infected tumour cells will eventually result in cell lysis. The use of good microbiological practice in a containment level 2 facility will be sufficient to limit contact of any released virus or infected cells with humans and the environment.

Enadenotucirev (EnAd) - an Ad11p/Ad3 chimeric group B attenuated adenovirus that demonstrates selective replication in tumour cells. It has a non-enveloped, icosahedral structure and a linear, double stranded DNA genome replicated by a high fidelity polymerase. The enadenotucirev virus was selected from a library of chimeric adenoviruses for the ability to replicate in colorectal cells at short time points after infection. The virus selected has a minimal genome to permit replication with a wild type
Ad11p backbone, a chimeric E2 region and deletions in E3/4.

Background to safety of Wild type Ad11 virus
In healthy adults symptomatic infections of wild type adenoviruses are rare even though the viruses are ubiquitous in the environment (Schmittzz et al 1983 American Journal of Epidemiology 117, 455-466). Adenovirus infection is usually associated with epithelial surface of the lungs and GI tract, although wild type Ad11 is associated with conjunctivitis and urinary tract infections. Once exposed to a given serotype of adenovirus individuals usually develop lifelong immunity. Immune compromised individuals can be at higher risk. For example adenovirus infections have been reported in transplant patients receiving immunosuppressive drugs and HIV patients (Kojaoghlanian et al 2003, Reviews in Medical Virology 13, 155-171) resulting in viraemia and on rare occasions death if untreated. In such patients withdrawal of immunosuppressive drugs can result in recovery indicating that the wild type virus can be effectively controlled by the human immune system. A specific risk of working with adenoviruses is the the possibility of conjunctivitis with splashes of high titre virus into the eye and the resulting local inflammatory response. Eye protection will be worn and aerosol production minimised when working with high virus titres in the laboratory. Adenoviruses have an ADCP classification of 2.

Safety of enadenotucirev virus
In comparison to the wild type Ad11 enadenotucirev is attenuated in normal cells through loss of genomic sequences and thus presents a reduced risk to human health. It has no gain of function genetic insertions that may increase virulence or pathology from the wild type Ad11. It is also further vulnerable to the immune system due to the absence of the E3 genes which are responsible for hiding virus infected cells from destruction by CTL and NK cells. Harm is unlikely to be caused by accidental release of the virus. The receptor required for virus entry into a cell, CD46, is only present in higher primates and even when the receptor is present virus replication is unlikely to occur due to the selectivity of the virus for malignant cells. Enadenotucirev is sensitive to the antiviral agent cidofovir (Bauzon et al. 2003, Molecular Therapy 7, 526-534). The risk from release of the virus into the environment is minimal due to the limited host cell range for virus replication. Furthermore clinical experience has now been gained in over 50 patients receiving repeated, high doses of EnAd intravenously over periods of up to 12 weeks. At high doses (above 1e12 virus particles) intravenous EnAd causes a transient inflammatory response due to the number of particles interacting with macrophages that resolves over 1-3 days and is consistent with previous clinical trials with other viruses and vaccines. There have been no signs or symptoms of EnAd causing any active infection in any of the subjects. Overall, the clinical experience following multiple systemic injections (at levels more than 1000-fold in excess of natural or accidental exposure) suggests that attenuated EnAd has limited potential of causing human disease.

The enadenotucirev virus will be genetically modified to express transgenes that encode antibodies or antibody fragments specific for tumour associated proteins, proteins that modulate the immune system and for proteins that are not expressed in humans (controls). All cDNA's encoding the transgenes will be generated by DNA synthesis and inserted into the transgene cassettes using PCR and standard cloning vectors.

Transgene expression will be under the control of an inserted mammalian promoter such as CMV or under the control of the endogenous enadenotucirev major late promoter (MLP). Protein expression may also be controlled by other regulator elements including internal ribosome entry sequences (IRES) or P2A peptides. Exogenous promoters such as CMV could potentially drive expression in any mammalian cell types however transgene expression is restricted by the cell types permissive to enadenotucirev virus infection. Expression of the transgene should not alter the enadenotucirev virus host cell range (i.e. cell types it can infect) or potentiate the virus activity.

The genetic material will be used to produce reagents for use in therapeutic antibody discovery and development. Therapeutic biological agents such as antibodies are typically dosed at level of 1-10mg (or higher)/kg of body weight to be efficacious and have higher relatively good safety profiles due to target specificity. Typical culture in the laboratory setting produces antibody/antibody fragments in the ng/ml range from the modified enadenotucirev virus infected cells and thus the quantities produced are unlikely to be of significant risk to human health.

Expression of antibody/antibody fragments targeting tumour specific antigens can be considered relatively harmless to humans. Tumour associated antigens are a class of proteins that are expressed on many tumour types and are sufficiently different from normal cell proteins through their high expression levels on the tumour cells or different modification (e.g. glycosylation).
Antibody/antibody fragments targeting immune modulating proteins may have potential deleterious activities in humans if their expression is not tightly regulated. The use of the tumour specific promoter or virus specific MLP will restrict their expression to cells susceptible to virus infection (human tumour cells) and allow expression transgene expression late in the virus life cycle when the virus is ready to leave the cell. If the inserted product is considered to be less hazardous following tightly controlled expression a less selective promoter may be subsequently used to enhance gene expression and efficacy. Examples of antibodies targeting immune modulating proteins include the clinically approved CTLA4 antagonist Ipilimumab (Starz 2012 Expert Opin Biol Ther), PD1 and PDL1 antagonists (Topalian et al 2012, N Engl J Med., Brahmenr et al 2012, New Englan Journal Med.). Systemic administration of such antibodies can have off target effects thus restriction of the expression of similar agents to the tumour environment through infection with using genetically modified enadenotucirev virus may reduce these effects.

Evaluation of foreseeable effects

Addition of the transgene into the enadenotucirev virus is not expected to impact viral infectivity or the types of cells that enadenotucirev virus can infect or replicate. It is therefore it is unlikely that the GMO would survive and become established in the environment as the enadenotucirev virus is only permissive in restricted cell types i.e. tumour cells. and is highly species specific (higher primates, no reporter replication in rodent cell lines or mouse/rat primary cells). Cells infected with the virus will lyse following the viral replication cycle. The potential harm to human health due to accidental inoculation of the modified virus is minimal due to the cell type specific replication which limits the expression of the transgene to low levels unless in the tumour microenvironment.

In healthy adults symptomatic infections of wild type adenoviruses are rare however for laboratory work the GMO will be handled under containment level 2 to minimise risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be treated as category 2 waste

All areas will be decontaminated after used using 2% Virkon for a 5 minute contact time (6 log kill McCormick et al 2004, AntiViral Research 64 (1): 27-33 or 10% bleach (>4 log kill Rutala et al. 2006 Antimicrob Agents Chemother. 50 (4) 1419-1424.

Liquid waste will be disinfected with 2% virkon for at least 1 hour then discharged to drains.

Solid waste (pipettes, tips, culture flasks etc) will be treated with 2% virkon then disposed of into suitably labelled hermetically sealable bins. The bins are 30 litre UN approved (to Class 3) Type 3H2/Y30/S/2003. They will be sealed by the producer of the waste, sprayed with disinfectant, labelled with a Category 2 hazard sticker and removed to a secure central collection point for incineration under an approved derogation.

All waste disposed of according to the Babraham Research Campus -Hazard Group 2 Waste disposal S.O.P (waste sealed in 30L Euro bins and sent offsite for incineration by Vetspeed (GM authorisation GM898, notification GM105/4.1).

Sharps will be disposed on into sharps bind and sent for incineration as described above for solid waste, however the use of sharps is unlikely to be required.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y
The Risk Assessment should be used in conjunction with COSSH forms detailing further information on the particular genetic manipulation. All COSSH procedures relating to the particular experimental process should be used in conjunction with the risk assessment.

Please enter comments on the GM safety committee on the risk assessment

Waste disposal will be carried out according to an SOP. All solid waste is to be autoclaved before being placed in plastic theatre bins and taken to incineration by a licensed outside contractor. All liquid waste is disinfected using a Virkon solution and following the manufacturers instructions for maximum kill. Non-disposable labware is disinfected prior to re-use. All spills to be cleaned using proprietary reagents e.g. spill kits. No further monitoring is deemed necessary due to the low/zero hazard presented by the cells involved.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All GMO material is documented on arrival onto the site and stored in dedicated areas. Culture is handled and disposed of under the guidance of SOPs and the company's ISO9001 Quality system. Before disposal, all culture is inactivated using disinfectants and, or autoclaving. Dedicated equipment is used for the culturing of microbes and processing of culture. Equipment is cleaned following strict SOPs. No live culture is transported from this site.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment [Y]

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMO committee believes that all GMO activities at SCIPAC fall under containment level 1 (Class 1). We do not envisage exceeding this class in any future work, but will continue to assess projects on a case by case basis before they commence.

Y

Give brief details of the genetic modification safety committee

As our company is currently small (2 members of staff). The GMSC will consist of these 2 individuals both highly experienced in working within GMO legislation and with risk assessment for GMSC. The make up of the GMSC thus contains both management and staff and because of the size of the company is fully representative of the organisation. The GMSC meets at the start of each new project (or monthly) to examine the adequacy of risk assessment and to test conclusions of those assessments through discussion. Even though those creating GMSC forms are the members of the GMSC, the GMSC is not taken as a rubber stamp body but is an essential discipline within the GMO approval process. The GMSC has created a risk assessment proformer as follows:-

The risk assessment process is divided into 4 sections. Section one gathers information about the GMM and assigns a provisional level of containment for the protection of human health. Section 2 considers the work activity and the suitability of control measures identified in section one. Section three considers environmental risks and section 4 determines the Classification and Containment Level.

A completed form is provided as required.

Tick if confidential  

For activities involving GMMs, describe the waste management measures which will apply to the activity

All reagents, plasticware and glassware which have come into contact with GMMs or indeed any intermediate in the creation of GMM, will be inactivated by either, incineration, autoclaving or chemical sterilisation. Incineration will be undertaken for all disposable plasticware (pipette tips, plastic pipettes, loops, spreaders, petri dishes etc).

Autoclaving will be used to sterilise most glassware which is to be reused (on an autoclave "kill" cycle") used in the creation of or use of GMMs. Liquid and solid wastes (bacterial supernatants, pellets and waste cultures etc) will also be inactivated by autoclaving. Chemical disinfection will be used for glassware for which this is more convenient (e.g glass pipettes) and for reusable plasticware that cannot be sterilised (e.g. some centrifuge tubes). The disinfectant to be used will be Virkon, used according to the manufacturers instructions for the disinfection of bacteria (contact time and concentration).

Monitoring of waste steam in ativation will be performed periodically. In the case of autoclaves, autoclave kill cycle efficiency will be determined by validation and calibration annually by thermometric monitoring equipment, by a competent trained individual and the certification displayed.

In the case of chemical disinfection (with Virkon) - efficiency of killing and log fold reduction of the agent is widely available from the manufacturer and the literature. Except where it is necessary to depart from the manufacturers conditions no in house testing of Virkon efficiency will be performed.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

We believe that the constructs proposed in the submission clearly fall within the CL1 assessment.

Specifically the plasmids are well established to be non mobilisable, the host E. coli strains are widely used and known to provide no human or environmental harm or impact. The inserts (which have been previously expressed in the literature) are bacterial genes with no direct human equivalent and we can forsee no direct (or indirect) impact of their expression on either human health or of environmental impact. The disposal methods outlined are more than adequate.

We agree with the conclusion of the assessment that the risk to human health and the environment is effectively zero.

Project Additional Information

The purpose of this work is to further the genetics of Otitis Media (OM) by development of a well characterized intranasal challenge model with defined strains of non-typable Haemophilus influenzae (NTHi) at known CFU doses. This will allow a thorough understanding of the dynamics of nasal carriage, ascending Eustachian tube infection and colonization of the middle ear using in vivo imaging, conventional bacteriology and host inflammatory and immune response. We want to explore the effects of
vaccination as a prophylactic measure, treat the infection using antibiotics and to explore the role of genes in OM pathways using conditional knock out models

Recipient or parental organism

Host/vector system

The vector system is non-typeable (non-capsular) Haemophilus influenzae (NTHi) and genetically modified versions of these strains bearing mutations that reduce virulence

Origin & function

The Haemophilus influenzae strains originate from a collaborators laboratory and/or are available commercially. The intended function of these organisms is to provide a bacterial challenge to an Otitis media model and to develop a full understanding of the dynamics of infection via the nasal passages to the middle ear.

Evaluation of foreseeable effects

NTHi is a highly adapted commensal whose only niche is the upper respiratory tract of its human host. Ordinarily there is passive carriage (in 60-70%) of normal individuals.
NTHi only invades the middle ear secondarily to upper respiratory tract infection with a virus (e.g. common cold or influenza). It does not survive in the environment outside its human host. Transmission between hosts is via aerosol droplets.
NTHi is not a natural pathogen of the mouse and inbred mouse strains develop only transient self-resolving otitis media which lasts 7-10 days

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid culture waste will be rendered non viable by overnight decontamination with Virkon at 3% working volume before disposal to drain.
Tips and loops used during culture procedures will be soaked in 3% Virkon for 24 hours prior to autoclave sterilisation.
All solid culture waste, including sharps in sealed containers, will be collected in Sterilin autoclave bags within lidded metal bins. Solid waste materils (e.g. gloves, plasticware etc) are rendered inactive by autoclaving (100% kill) in a route and goes for high temperature incineraton.
The autoclave is performance validated annually by the manufacturer (Gettinge). Records are kept on site.
Virkon is routinely used as per the manufacturers recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.
Plasticware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
A query was made about the likelihood of worker infection with the Haemophilus influenzae. A discussion about needle stick injury and aerosol eye injury followed and the committee were reassured by the safety measures put in place via the risk assessment and the availability of broad-spectrum antibiotic treatment if required. A question was raised about increased risk to vulnerable staff (such as pregnant women) and information was given detailing that no additional risk was identified for pregnancy and that work will be carried out in an access controlled laboratory with access granted to only those working on the project.

Project Additional Information

Purposes of the contained use

The purpose of this work is to determine the specific role of a variety of genes thought or known to be involved in the pathogenesis of a number of different human diseases.
conditions including but not limited to neurological disorders, developmental disorders, deafness and diabetes.

Recipient or parental organism

primary and established cell cultures derived from mutant and wild type mice and cell lines derived from other mammalian species including but not limited to rat, monkey and human.

Tissue slices ex vivo and maintained in culture

other recipient organisms detailed in section 17

Host/vector system

Lentivirus: established 3rd generation lentiviral vectors originally derived from HIV, defective for replication and contransfected with 3rd generation core packaging plasmids into 293T cells to produce virus containing the gene sequence of interest.

Adenovirus: commercially available 3rd generation replication deficient adenoviral vectors

Retrovirus: commercially available 3rd generation replication deficient retroviral vectors including but not limited to pBABE-puro derived from MoMTV

Origin & function

commercially available SiRNA
commercially available transgenes
cDNA

Evaluation of foreseeable effects

effects on cell biology due to knock-down, altered expression or over-expression of the genes of interest in cell cultures. See section 17 for foreseeable effects on other recipient organisms.

The foreseeable effects on human health are minimal as the vectors being used are 3rd generation and are replication deficient, therefore unable to replicate in the event of an accidental exposure by a laboratory worker. Any inoculation of a laboratory worker with these virus vectors will have a localised effect only and all projects are designed to minimise or eliminate the use of sharps to prevent accidental inoculation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Detailed in section 17

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid culture waste will be rendered non viable by overnight decontamination with Virkon at 3% working volume before disposal to drain.
Tips and loops used during culture procedures will be soaked in 3% Virkon for 24 hours prior to autoclave sterilisation.
All solid culture waste, including sharps in sealed containers, will be collected in Sterilin autoclave bags within lidded metal bins. Solid waste materials (e.g gloves, plasticware etc) are rendered inactive by autoclaving (100%kill) in a validated machine located within the same building. The solid waste then enters the yellow bag clinical waste route and goes for high temperature incineration.
The autoclave is performance validated annually by the manufacturer (Getinge or BMM Weston). Records are kept on site.
Virkon is routinely used as per the manufacturers recommendations :-
Solid surfaces are disinfected with 1% Virkon solution.

02/03/2022
Plasticware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

The committee had no comment to pass forward on this assessment and are happy for the work to go ahead as planned following receipt of notification acceptance.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

Solids (e.g. plastic ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or disinfect with freshly prepared Precept (2x 2.5g tablets per 1L water) for 1hr (minimum), discharge any excess liquids to drains, dispose of solids via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or disinfect with freshly prepared Precept (2x 2.5g tablets per 1L water) for 1hr (minimum), discharge any excess liquids to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes) dispose via clinical waste stream for microwave treatment.

Degree of kill

Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads)

Disinfection - a 1% solution of Virkon disinfectant with a contact time of at least 10 minutes gives a >4.25 log reduction of HIV-1 (data supplied by manufacturer).

Heat treatment or incineration - not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Please enter comments of the GM safety committee on the risk assessment

Topics discussed:
2. Potential hazards associated with transgene cassettes: None.
3. Waste disposal procedures: As outlined in section 6 of this form.
4. Discussed proposal to establish a book to record the receipt, use and disposal of lentivirus samples. Will adopt.
5. On day of viral transduction, will ensure that no one other than the operator is present in the tissue culture lab.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: [Y]

Give brief details of the genetic modification safety committee:

The committee consists of QA Manager, Project Manager- Virology and QC Lab technician. The committee have monthly meetings to review risk assessments, COShh assessments and training records. All staff are trained prior to performing procedures, SOPs are in places for procedures. The committee also review any incoming material for client projects and ensure that adequate information is gathered. This information includes MSDS, COA’s, safety data on the product. No material is allowed on the Arecor Ltd site without the correct paperwork.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

No genetic modification will be undertaken at Arecor Ltd. We will be stabilising attenuated human and animal vaccines. All work will carried out in a class II safety cabinet in a class II lab. Only in vitro work will be performed with these vaccines. The lab is segregated and only trained staff will be working in there. All solid waste will be autoclaved at 130C for 30 minutes prior to disposal. All liquid waste will be auto claved at 130C for 60 minutes prior to disposal down the drain. The autoclave is regulary serviced. If an autoclave run does not complete properly the screen will say failed at the end of the run. In the event of this happening the run will be started again. Autoclaving effectively has a 100% kill of GMMs. Surfaces will be cleaned with 1% Virkon if necessary.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Genetic modification committee are satisfied by the preventative and precautionary control measures that have been put in place to work with these attenuated vaccines. At the monthly meetings risk assessments, safety date and coshh assessments will be reviewed.
**Project Additional Information**

**Purposes of the contained use**

To stabilise attenuated human and animal vaccines. The vaccines are class I and II organisms and will be used in a class II safety cabinet in a class II laboratory. All personnel will be trained and wear appropriate PPE.

**Recipient or parental organism**

Attenuated vaccines are a weakened form of the parent virus. They have all been modified to be less pathogenic than the parent virus because they will be used to vaccinate humans or animals. There are no foreseeable detrimental effects to human health or to the environment because these are vaccines and there are procedures in place, such as working in a class II BSC in a class II lab and effective kill waste disposal methods.

**Host/vector system**

No genetic modification will be performed at Arecor Ltd. All testing will solely be performed in vitro. There is no extended host range. The risk of working with these vaccines is negligible because all work will be carried out by trained personnel in a class II laboratory.

**Origin & function**

The genetically modified organisms will be supplied by clients. The GMM's are attenuated vaccines that will be used in humans and animals to vaccinate them against diseases. At Arecor we are formulating solutions to stabilise the vaccines for greater world-wide distribution. All work will be performed in vitro in a contained class II environment. Prior to importation from outside the EU (if applicable) Defra pathogens will be notified and an import license will be obtained. The origin is the parent virus that causes the disease that the vaccines is being developed against and the function of the genetically modified organism is to vaccinate individuals or animals against diseases.

**Evaluation of foreseeable effects**

The foreseeable effects would not be more severe than infection with the wild-type virus and most likely less so because all GMM's being used at Arecor Ltd have been specifically designed for vaccination purposes. There is no foreseeable effect to the environment because after reconstitution the vaccines shelf-life is approximately 30 minutes at room temperature. If any of these vaccines escaped into the environment they would not be able to survive or disseminate. The likelihood that the GMM will be released into the environment under the requirements of the containment level to protect human health is negligible. The vaccines will only be handled in class II laboratory conditions by trained personnel, there are effective waste disposal procedures in place to ensure a 100% kill of the GMM's. PPE will be worn, there are SOPs in place and risk assessments in place. The lab is limited to authorised personnel only and all manipulations of the vaccines will be carried out in a class II biological safety cabinet.

Arecor believe there is minimal risk to humans, animals and the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste will be treated by autoclaving at 130C for 60 minutes, before disposal to drains. Disposable solid waste which is or may be contaminated with GMMs is also...
inactivated by autoclaving at 130°C for 30 minutes before removal as clinical waste by specialist contactors. The exceptions to the above are:
"Sharps", including scalpel blades, needles (with or without attached syringes), and disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant, and SOAKING IN Virkon for a minimum of 15 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

Expected degree of kill:

Autoclaving achieves effectively 100% kill of all GMMs.

The manufacturer's information indicates efficacy of Virkon against 65 strains of virus over 19 viral families including class III and IV organisms, such as Newcastle disease and foot and mouth. Virkon is recognised by industry and government worldwide as a disinfectant of choice for livestock disease prevention and control. The mode of action of virkon is to achieve deactivation and/or destruction of target organism through general oxidative disruption of key structures and compounds vital to normal activity (e.g. proteins and lipids). It has been demonstrated that 15 minutes exposure to 1% Virkon> 4-6 log10 kill of seed stocks

Please enter comments on the GM safety committee on the risk assessment

Genetic modification committee are satisfied by the preventative and precautionary control measures that have been put in place to work with these attenuated vaccines. At the monthly meetings risk assessments, safety data and coshh assessments will be reviewed.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste to be autoclaved in dedicated GMM autoclave and disposed via drains.

Solid waste (larger plasticware, agar plates) to be autoclaved in dedicated GMM autoclave and disposed via private contractor who handles clinical waste (Dynamiq Cleaning Ltd., Chester House, 1-3 Brixton Road, London SW9 6DE).

Smaller solid waste (pipette tips, microfuge tubes, other small disposable tubes) collected in dedicated disposal bottles, autoclaved, disposal by private contractor (Dynamiq Cleaning Ltd.).

All waste is processed (autoclaved and deposited in dedicated bins for collection) in a dedicated disposal room connected to the laboratories via corridor or service lift (i.e. lift connecting laboratory preparation room with teaching laboratory used solely for transport of materials and associated laboratory personnel between the two rooms; it is separate from public access lifts or staircases).

GMM autoclave to operate at a cycle of 136 degrees C for 10 minutes, achieving a 100% kill for class 1 GMMs, and is serviced annually by Priorclave.

Other(s) Molecular cell biology in cultured eukaryotic cells

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Faculty Management Representative: "To my eyes these are very well-considered documents. Just one small point- with double containment would it be expected that the containers are normally unbreakable or does that not need to be the case or not need to be stated ."

University H & S representative: "It looks fine to me. Does the word 'safe' fulfill the requirement to explain the 'extent to which it is disabled' in Section 2? In Section 5 should 'the most hazardous GM' read the most hazardous GMM'? Should there be a copy of Part 3?"

These comments have been used to modify the form

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The Essen BioScience Ltd genetic modification safety committee will be chaired by the UK lab manager. Meetings will be held quarterly (or upon notification of new GMO activities) and will consist of the Director of Essen BioScience Europe, alongside relevant knowledgable individuals from within the UK organisation or when required the safety officer from the US parent company (Essen BioScience Inc)

Within the cell culture suite there are three routes for waste disposal: yellow biohazard bags, yellow burn bins and sharp bins.

Yellow Biohazard bags are for disposal of lightly contaminated & non-puncturing waste e.g. plastic wrappers, gloves, waste paper, wipes, tissues.

Yellow burn bins are for disposal of all other (including biologically contaminated plastic) waste - pipette tips, stripettes, flasks, etc.

Sharps bins are for disposal of biologically contaminated needles, glass and other sharp objects.

Solid waste (biologically contaminated plasticware) will be either autoclaved (121°C for 30 mins, using indicator tape to verify sterilisation) or chemically inactivated with disinfectant (troclosene sodium or bleach) prior to placing in yellow burn bins.

Once full yellow biohazard bags are closed with a cable tie and sharp and burn bins sealed with locking lids. These are sent for incineration on a monthly schedule.

Biologically contaminated liquid waste is collected and appropriately decontaminated with disinfectant (Presept tablets; troclosene sodium), incubated for 24hrs and discarded down the sink.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The use of well-characterised mammalian cells, such as Chinese hamster ovary (CHO) and human embryonic kidney (HEK293) cells for recombinant expression of human proteins is appropriate under hazard group 1 conditions.

Project Ref 3115/12.1

Date Ackn’d 07/03/2012
CU2 Project Title Expression of fluorescent probes, such as green fluorescent protein (GFP), in

Class 2
Culture Vol Class 2 ≤ 1 Litre
Culture Volume Class 3-4

02/03/2022 Page 12991 of 15326
The labelling of mammalian cells as a method to selectively track biological processes such as proliferation, apoptosis and migration for identifying/understanding modulators of these complex pathways. To this end lentiviral gene transfer systems to express fluorescent probes operating in the green and red wavelengths have been developed. Generation of the lentiviral vectors and the production of virus will not take place in the Essen BioScience Ltd lab, but the use of the viral particles forms the basis of this notification.

Well characterised mammalian cells (e.g. HEK293, HT1080 and HUVEC cells) will be used as the recipient for the fluorescent probes delivered using the lentivirus gene transfer system. These cell lines will be obtained from reputable sources, such as ATCC/ECACC, with appropriate certification regarding the absence of adventitious agents. In all cases the biological safety level of the host cell lines will be 1.

Lentivirus system based on the pLentiLox lentiviral vector map; incorporating either the TagGFP2 or mKate 2 fluorescent markers, with or without the nuclear localisation signal (3xNLS), an internal ribosome entry site (IRES) and either a puromycin or bleomycin (zeocin) selection marker. The human elongation factor-1 alpha (EF1a) promoter is used to drive the expression of the gene(s). Vector maps are included as part of the risk assessment document.

The vectors used are supplied by the University of Michigan and encode the fluorescent probes GFP (green fluorescent protein) or mKate (far-red fluorescent protein). Viral particle production occurs at Essen BioScience Inc. (A A, Michigan) with transfection of HEK293 cells with the vector, alongside the 3 packaging plasmids. The supernatant is harvested containing replication deficient lentivirus.

Both GFP and mKate2 have been widely used as fluorescent probes and are well characterised and are not known to possess any oncogenic potential.

The constructs are third generation lentiviral SIN (self-inactivating) vectors. The vector is packaged using third generation packaging plasmids (3 packaging plasmids). The design of all four vectors used in viral production incorporate safety measures against the generation of replication competent virus. The vectors’ LTRs are self-inactivating.
(SIN), thus restricting mRNA production from integrating vectors to the internal promoter, severely reducing full-length vector transcripts. The lentiviral vector is pseudotyped with the VSV-G envelope serotype providing a greater margin of personal and public safety and reducing the risk of recombination. According to the literature, viruses packaged under these conditions were found to contain no detectable level of replication competent virus.

The vector uses a WPRE element. The post-transcriptional regulatory element (PRE) of the woodchuck hepatitis virus (WHV) improves 3’ RNA processing and thus increases transgene expression efficiency. However, some versions of this element are capable of expressing part of the x protein from WHV which may have oncogenic properties. The WPRE used in the plasmids used in the current study have been modified, mutating the x protein promoter(1488-1492, GCTGA.ATCAT), thus greatly reducing the expression of X protein( see Schambach et al, 2006, Gene Therapy 13, 641-45). Therefore the risk of oncogenic properties has been decreased.

Neither GFP (green fluorescent protein) nor mKate 2 (far-red fluorescent protein) possess oncogenic properties, thus presenting a low risk to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Within the cell culture suite there are four routes for waste disposal: autoclave bags, yellow biohazard bags, yellow burn bins and sharps bins.

Autoclave bags are for the disposal of biologically contaminated solid waste and are autoclaved at 131C for > 30 mins, using indicator tape to verify sterilisation. All solid waste potentially class 2 contaminated will be autoclaved. The autoclave is situated within the building where all work will be conducted.

Yellow Biohazard bags are for disposal of lightly contaminated & non puncturing waste e.g. plastic wrappers, gloves, waste paper, wiped, tissues.

Yellow burn bins are for disposal of lightly contaminated waste which may pose a risk or puncturing the biohazard bags e.g. stripettes.

Sharps bins are for disposal of biologically contaminated needles, glass and other sharp objects (the use of sharps whilst undertaking class 2 work will not be conducted).

Autoclaved waste is placed in yellow biohazard bags, sealed with cable ties and sent for incineration under code 19 01 03.

Once full, yellow biohazard bags will be closed with cable ties and sharps and burn bins sealed with locking lids. These are sent for incineration on a monthly schedule. Storage of waste bags/bins prior to disposal is in locked 770 litre container located within the BioPark security perimeter.

Biologically contaminated liquid waste is collected and appropriately decontaminated with disinfectant (Presept tablets; troclosene soium, 2,500ppm) incubated for 24 hrs and discarded down the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The safety committee approved the risk assessment. It was confirmed that once washed sufficiently, infected mammalian cells could be used at the risk level of the cells prior to infection. The implementation of appropriate training was stated as essential prior to any personnel working with lentiviral reagents. Finally the use of sharps during any aspect of handling the lentiviral reagents is not appropriate and if required a further risk assessment would be needed.

### Project Ref 3115/15.1

- **Date Ackn'd**: 30/09/2015
- **Expression of fluorescent probes, such as green fluorescent protein (GFP) using a lentivirus gene transfer system, into mammalian cell lines potentially contaminated by Hepatitis B virus (HBV)**
- **Class**: 2
- **Culture Volume**: ≤ 1 Litre
- **Non-GMM Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

### Purposes of the contained use

The labelling of mammalian cells as a method to selectively track biological processes such as proliferation, apoptosis and migration for identifying/understanding modulators of these complex pathways. To this end lentiviral gene transfer systems to express fluorescent probes operating in the...
green and red wavelengths will be used, but not developed within the Essen BioScience Ltd lab. The use of hepatocyte cell lines for the study of potential anti-cancer therapies has been well established. Within the current project we wish to combine our existing approaches of using the lentiviral expression system with relevant cell types potentially contaminated by HPV.

Recipient or parental organism

The parental cell types to be used within the project include Hep3b (HB-8064) and SNU-449 (CRL-2234) cells, to be supplied by a client, originally obtained from ATCC. Both have evidence for HPV contamination and as such additional precautions need to be applied to reduce the risk of potential infection.

Host/vector system

Lentivirus system based on the pLentiLox lentiviral vector map; incorporating either the TagGFP2 or mKate2 fluorescent markers, with or without the nuclear localisation signal (3xNLS), an internal ribosome entry site (IRES) and either a puromycin or bleomycin (zeocin) selection marker. The human elongation factor-1 alpha (EF1a) promotor is used to drive the expression of the gene(s). Vector maps are included as part of the risk assessment document.

Origin & function

The vectors used are supplied by the University of Michigan and encode the fluorescent probes GFP (green fluorescent protein) or mKate (far-red fluorescent protein). Viral particle production occurs at Essen BioScience Inc. (Ann Arbor, Michigan) with transfection of HEK293 cells with the vector, alongside the 3 packaging plasmids. The supernatant is harvested containing replication deficient lentivirus. Both GFP and mKate2 have been widely used as fluorescent probes and are well characterised and are not known to possess any oncogenic potential.

Evaluation of foreseeable effects

Host cell lines: HepG3 and SNU-449 cells contains HBV genome integrated into the eukaryotic chromosomes (see Su et al. 2010 for HepG3 and Ku et al 2005 for SNU-449). However there is currently no evidence that these cell lines produce infectious Hepatitis B virus. Lentiviral infection: The constructs are third generation lentiviral SIN (self-inactivating) vectors. The vector is packaged using third generation packaging plasmids (3 packaging plasmids). The design of all four vectors used in viral production incorporate safety measures against the generation of replication competent virus. The vectors’ LTRs are self-inactivating (SIN), thus restricting mRNA production from integrating vectors to the internal promoter, severely reducing full-length vector transcripts. The lentiviral vector is pseudotyped with the VSV-G envelope serotype, providing a greater margin of personal and public safety and reducing the risk of recombination.
According to the literature, viruses packaged under these conditions were found to contain no detectable level of replication competent virus. The vector uses a WPRE element. The post-transcriptional regulatory element (PRE) of the woodchuck hepatitis virus (WHV) improves 3’ RNA processing and thus increases transgene expression efficiency. However, some versions of this element are capable of expressing part of the X protein from WHV which may have oncogenic properties. The WPRE used in the plasmids used in the current study have been modified, mutating the X protein promoter (1488-1492, GCTGA>ATCAT), thus greatly reducing the expression of X protein (see Schambach et al, 2006, Gene Therapy 13, 641-45). Therefore the risk of oncogenic properties has been decreased. Neither GFP (green fluorescent protein) nor mKate2 (far-red fluorescent protein) possess oncogenic properties, thus presenting a low risk to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Within the cell culture suite there are four routes for waste disposal: autoclave bags, yellow biohazard bags, yellow burn bins and sharps bins. Autoclave bags are for the disposal of biologically contaimanted solid waste and are autoclaved at 131C for >30mins, using indicator tape to verify sterilisation. All solid waste potentially class 2 contaminated will be autoclaved. The autoclave is situated within the building where all work will be conducted.

Yellow Biohazard bags are for disposal of lightly contaminated & non puncturing waste e.g plastic wrappers, gloves, waste paper, wipes, tissues.

Yellow burn bins are for disposal of lightly contaminated waste which may pose a risk of puncturing the biohazard bags e.g. stripettes.

Sharps bins are for disposal of biologically contaminated needles, glass and other sharp objects (the use of sharps whilst undertaking class 2 work will not be conducted).

Autoclaved waste is placed in yellow biohazard bags, sealed with cable ties and sent for incineration under code 18 01 03.

Once full, yellow biohazard bags will be closed with cable ties and sharps and burn bins sealed with locking lids. These are sent for incineration on a monthly schedule. Storage of waste bags/bins prior to disposal is in locked 770 litre container located within the BioPark security perimeter.

Biologically contaminated liquid waste is collected and appropriately decontaminated with disinfectant (Presept tablets; troclosene sodium, 2,500ppm), incubated for 24hrs and discarded down the sink.
The safety committee approved the risk assessment. It was confirmed that once washed sufficiently, infected mammalian cells could be used at the risk level of the cells prior to infection. The implementation of appropriate training was stated as essential prior to any personnel working with either the host cells or lentiviral reagents. Although the risk of HBV infection is negligible, as vaccination is available all employees who are to work with these host cells should be vaccinated. Finally, the use of sharps during any aspect of handling the lentiviral reagents is not appropriate and if required a further risk assessment would be needed.

For activities involving GMMs, describe the waste management measures which will apply to the activity

In the event of a spillage, material would be deactivated with an appropriate method (eg bleach/disinfectant solution) and disposed of through an approved licenced waste contractor.
Solid (or frozen) waste including time expired product would be placed in clinical waste bag for incineration through licenced waste contractor

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The committee note that the activities consist solely of receipt, storage and despatch of sealed containers. Any risks to human helath or the environment arising from a leaking or damaged container would be readily dealt with by the routine spillage procedures.
Overall the risk to human health and the envrionment from this activity is very small.

### Laboratories:

Solid biological waste that is not contaminated by any hazardous chemicals which would be released into the atmosphere, or by sharps (including yellow tips etc) which would puncture the bags, is autoclaved.

Sharps (including yellow and blue tips) contaminated with biological waste will be thoroughly decontaminated in Hycollin or autoclaved in an appropriate container (see department safety officer for advice) before disposal with the other sharps.

Liquid Biological waste in plastic containers will be decontaminated with Hycollin or bleach.

Liquid biological waste in glassware will be decontaminated with Hycollin or by autoclaving via the Kill Boxes.

Glassware (flasks, bottles etc.) contaminated with biological waste should have their caps removed and placed in the blue plastic boxes for autoclaving.

Any spills should be cleaned with either bleach or Hycollin.

### Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Autoclaves are routinely serviced and regular checks to ensure autoclave are reaching the required temperatures using thermo logs.

This applies to all glasshouses and CERs marked as 'transgenic' areas.

Disposal of unwanted plants and soil
NB Users should see the Glasshouse Manager for glasshouse and CERs for waste disposal procedures.
If transgenic plants are grown within a glasshouse then by default all plants in the glasshouse are treated as transgenic and these procedures must be followed.

Exceptions to this practice must be made clear and justified in the GMNRA and practical arrangements agreed with the Glasshouse Manager.

Plants and soil shall be put into the black bins marked "Transgenic" and not into any other bins. No soil or tops will be accepted in autoclave bags.

Pots, labels and trays shall be put in the transparent autoclave bags. Clearly separate the items for disposal will be autoclaved.

No bags of mixed items such as soil and plastic pots will be accepted. These will be left for science staff to sort correctly. (v) The soil and tops in the black bins shall be tipped into a steam cart. The cart must not be filled higher than level with top of cart. The cart shall be taken to the autoclave area and attached to the steam line. The contents will be steam sterilized at 100°C for 1 hour.

Care must be taken to avoid spilling plant material onto roadways and paths. Any spills must be cleaned up using the dust pan and brush provided and split material returned to the steam cart.

After sterilizing is complete the contents from the steam cart should be deposited in the compost bays.
After sterilization all autoclave bags containing disposable items shall be put into rubbish skips.

</tbody>
</table>
The oomycetes Phytophthora palmivora, Phytophthora infestans and Phytophthora capsici cause disease on vegetable crops. On the other hand, plants engage in beneficial symbiosis with Mycorrhiza fungi. This research will focus on the host interface with the pathogen and symbiont to address how Phytophthora and mycorrhizal fungi are similarly or differentially perceived and the extent to which they employ the same development plant program to establish interactions. We will identify and characterize genetic elements with common functions in Phytophthora and mycorrhizal colonization. Furthermore, we will elucidate the role of microbial effector proteins in the intracellular accommodation process. More specifically, gene sequences will be generated for genes from host plants and Phytophthora spp. and used in laboratory experiments to determine their subcellular distribution and their biochemical activities. We will also employ a range of other microbial plant pathogens (such as Xanthomonas campestris, Agrobacterium rhizogenes and tobacco rattle virus) to enable delivery of the genes under study or the encoded proteins into host cells. Furthermore, we will explore similarities of fungal and oomycete interfaces by comparative studies between fungal pathogens and oomycete pathogens.

Ultimately, this work will reveal the boundaries between symbiosis and pathogenesis and will provide novel mechanisms for pathogen control.

Recipient or parental organism

Recipients will be strains of prokaryotic (A. rhizogenes, X. campestris pv. Vesicatoria, TRV) and eukaryotic plant pathogens (oomycetes and fungi) some of which are native to the UK environment, some of which will have been imported and held under Plant Health Licence from FERA/DEFRA.

Recipients/hosts will be: Agrobacterium rhizogenes, Xanthomonas campestris pv. Vesicatoria, Phytophthora infestans, Phytophthora palmivora, Phytophthora capsici and Tobacco rattle virus (TRV) without Nematode transmission.

There research could generate transgenic plant pathogens with altered host ranges and pathogenicity

Host/vector system

Vector systems will be:
- Binary vectors and bacterial expression vectors
- Phytophthora expression vectors
- Phytophthora expression vectors (pTOR backbone) (can only be replicated in E. coli)
- The TRV genome, split and embedded in the T-DNA of a binary vector in separate disabled Agrobacterium tumefaciens strains

Origin & function

Vector inserts will be genes from either plants or plant associated microorganisms that are supposedly involved in plant microbe interactions such as microbial effectors;
Candidate eukaryotic plant pathogen effector molecules will be identified from beneficial mycorrhiza fungi and oomycete pathogens including Phytophthora infestans, Phytophthora capsici, Phytophthora palmivora, and the ascomycete fungi such as Blumeria spp., Mycosphaerella sp., Leptosphaeria maculans, Botrytis cinerea, Sclerotinia sclerotiorum, Fusarium spp., Pyrenophora spp. Using bioinformatic approaches.

Genes will be cloned from P. palmivora, P. capsici and P. infestans strains included in this notification. Genes of interest form other plant pathogens will not be cloned via cultivation of these microorganisms but by de-novo gene synthesis or by obtaining DNA fragments through collaboration.

Many of these genes will be transferred back into recipient strains which may be eukaryotic plant pathogens Phytophthora palmivora. Phytophthora capsici and Phytophthora infestans as well as prokaryotic plant pathogens tobacco rattle virus (TRV), Agrobacterium rhizogenes and Xanthomonas campestris pv. vesicatoria.

Stably transformed genetically modified eukaryotic plant pathogens will be inoculated onto host plants and tested for pathogenicity. Host plants include tomato, potato, and Nicotiana spp., sweet potato (Ipomoea batatas), Mirabilis jalapa, cereals (wheat, barley, rice), Brassicus including Arabidopsis thaliana and Legumes (Medicago sp., Lotus sp.). Other species plants may be tested for their ability to support establishment of a plant-microbe interaction.

**Evaluation of foreseeable effects**

**Human Health;**

None of the recipient organisms used in these projects is a human pathogen and does not, therefore, constitute a hazard to human health. The proposed genetic modifications of plant pathogens will not cause the modified strains to become human or animal pathogens and are therefore of no risk to human or animal health.

**Environmental Safety;**

The plant pathogens Tobacco rattle virus (TRV), Phytophthora infestans and Agrobacterium rhizogenes are all present in the local environment, even if the unmodified recipient strains here used may be imported from outside the UK and held under licence from DEFRA. Therefore any risk posed by their potential accidental escape is not related to the introduction of a new plant disease, but rather to any risks relating to their genetic modification. Because these organisms can survive in the UK, GM strains could also survive in the local environment. Some of the genetic modifications could result in pathogens that are more virulent than the recipient strain. However, the recipient strains have relatively low virulence and hence none of the GM strains are likely to be significantly more virulent than naturally occurring isolates of the same species.

The plant pathogens; Xanthomonas campestris pv. Vescatoria, Phytophthora capsici and Phytophthora palmivora are unlikely to be present in the local environment since they are pathogens of subtropical/tropical plants and are unable to survive to be present in the local environment since they are pathogens of subtropical/tropical plants and are unable to survive in the local environment, due both to the absence of suitable hosts and environmental adversity. P. palmivora will be used as a model organism, receiving candidate effector genes from different donor plant pathogens and beneficial microorganisms. The hazard identified is that P. palmivora may have an altered host range and be able to infect plants that may grow in the local environment. However, it is extremely unlikely that the genetically modified P. palmivora will differ from wild type strains in its ability to survive in the UK environment. Moreover P. palmivora is not likely to be present in the UK and therefore not able to reproduce sexually with the GM strain.

The silencing of candidate plant pathogen effector genes could lead to the growth of the GM-pathogen on an otherwise resistant plant host, especially if the silencing resulted in a loss of avirulence determinant(s). However, potato varieties harbouring genes conferring P. infestans resistance remain susceptible to other diverse naturally occurring virulent races of the pathogen.

The silencing of effector genes is not likely to alter the GM-pathogen's host range, but is likely to have a negative effect on virulence.
For genetically modified plant pathogens that could survive in the UK environment. It is envisaged that none of the modifications will lead to races of pathogen that are more virulent than naturally occurring races; the recipient strains are not the most virulent and the most virulent naturally occurring strains will not be modified. Moreover since an important objective of these investigations is to monitor the infection mechanisms of eukaryotic plant pathogens, any significant increases in virulence will be identified.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For plant material infected with GMMs Phytophthora sp., Xanthomonas sp. And TRV, containment level 2 is appropriate.

Xanthomonas or TRV infected plants will be maintained in containment level 2 growth facilities at the Sainsbury Laboratory (SLCU). Standard operating procedures for the use of plant growth facilities and for the disposal of waste will be strictly adhered to.

GM-Phytophthora sp. Will be used only in the laboratory under in vivo conditions in containment level 2.

GM-A rhizogenes containing plant material will be maintained solely under in vitro conditions in containment level 1.

Plant pathogen infected plant material and compost will be killed by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM material will be handled using good microbiological practice (GMP). All GMM material will be autoclaved prior to disposal.

The class II safety cabinet and growth chamber surfaces will be disinfected by virkon/trigene spray and wiping with appropriate disinfectants. All contaminated glassware/equipment will be disinfected after use and before cleaning by autoclaving where possible, otherwise by immersion in disinfectant solution or spray wiped with ethanol.

Residual plant material and compost is placed in lidded stainless steel containers and stored within a latched lidded blue container clearly marked as containment 2 material. The containers are then separately autoclaved. The stainless steel container is autoclaved using the Compost Waste cycle (see below) and the blue container is autoclaved using the Plastic Discard cycle.

Plastic waste is placed within an autoclave bag and stored in a blue container (as above). This is then disposed of using the Plastic Discard cycle.

Oomycete and bacterial cultures an culture plates in the lab will be autoclaved prior to disposal.

Any condensate from CER's is collected into a steel bucket. This is regularly checked and the bucket and water waste then autoclaved using our Fluid Discard Programme (See below). All drains within the growth chamber (CER) are sealed. Any water residue is then limited within the chamber, but should run off occur then this is vacuumed with a clearly marked designated wet vac and waste autoclaved as above.

Autoclave procedures are as follows;

* Soil and plant waste generated in growth rooms are autoclaved in stainless steel containers using the Compost Waste cycle. This has a temperature 134°C for 30 minutes. The whole process also includes 5 negative and positive pushes.

* Plastic waste is autoclaved using the Plastic Discard cycle. This has a temperature of 121°C for 30 minutes. The whole process also included 5 negative and positive pulses.

* All water is treated using the Fluid Discard cycle. This has a temperature of 121°C for 30 minutes. The whole process also includes 6 negative pulses.

Additional information: All autoclaves are validated once a year using maximum loads for each cycle. We have a contract with the autoclave company for 3 additional onsite
service visits. Regular validation using chemical indicators for sterilisation are also carried out.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee (GMSC) will be chaired by the University Biological Safety Officer (BSO); this is a person who has experience of working with GM in another UK University and is thoroughly familiar with the administrative procedures at the University of Worcester at UW. There will be at least four other members of the GMSC, all of whom have familiarity with GM technologies and with the related risk assessments and safety procedures. All of theses (except the trade union representative) have been gained experience in GM at other UK Universities. All scientific members of the GMSC will be involved in research that involves GM technology (although none of this has been allowed to commence at UW until the appropriate permission has been granted).

All GM work will be carried out within the Institute of Science and the Environment (ISE) and its associated Research Centre (the National Pollen and Aerobiology Research Unit or NPARU) on the St John's campus at UW. The GMSC members are drawn from the ISE and NPARU and will report directly to the joint ISE/NPARU Safety Committee which in turn reports to the University's Health, Welfare and Safety Committee.

**Other(s)**

For activities involving GMMs, describe the waste management measures which will apply to the activity

After use, bacteria and plant material will be autoclaved to achieve 100% kill. The material will be autoclaved at 127°C for 35 minutes. The autoclave indicates whether the load has reached temperature for the required time and shows a 'failed load' in this case. We also use temperature strips that provide an additional method of identifying any failure in a run. The autoclave will be routinely serviced and receive an annual Certificate of Calibration.

GM Micro-organism risk assessment
I agree with your assessment that there is not a significant risk to human health or the environment associated with the work described.

I have a number of points that I wish to be considered before the assessment is accepted.

1. I have marked on the form a few minor clerical points (mis-spellings etc). Please place all species names in italics.
2. Major point: The GMO (plant) risk assessment (commented on below) refers to work in which alleles of Arabidopsis resistance genes are transferred to other genotypes of Arabidopsis. This will require preliminary work in E. coli and Agrobacterium. However, this has not been described here. You MUST include in this risk assessment a clear description of the work relating to the work in micro-organisms with Arabidopsis R genes.
3. Major point 1: The GM Micro-organism risk assessment (commented on above) refers to experiments in which genes encoding ‘effectors’ are taken from Hyaloperonospora arabidopsidis and, after work in E. coli and Agrobacterium, are expressed in a plant (Arabidopsis). However, the activities described in this GMO (plant) risk assessment describes work in which alleles of Arabidopsis resistance genes are transferred to other genotypes of Arabidopsis. You MUST include in this risk assessment a clear description of the work relating to the expression in plants of the H. arabidopsidis effector genes.
4. Major point 2: We have organised the risk assessment forms on the basis that one deals with potential risks associated with work on micro-organisms and the other on plants. This division is fundamental to the risk assessment process even where, as quite often, the actual experiments being performed require work with the same sequences in both micro-organisms and plants. I am concerned that the inclusion of information on bacteria in the ‘plant’ document sets a precedent that will confuse future compilers of risk assessments. I have therefore marked several short sections that I suggest you remove from the plant risk assessment document. Actually, the information included on p. 5 (marked) could be transferred to the GMO risk assessment document since it contains more detail than is currently included.
5. Missing information: no submission date has been included (p.1). You have not filled in Tables 1 at the end of the document; see the marked sentence on p.13 for guidance. This is very simple, requiring only crosses in appropriate boxes and a final statement of the containment level, but must be completed.

GM Organism (plant) risk assessment
I agree with your assessment that there is not a significant risk to human health or the environment associated with the work described.

I have a number of points that I wish to be considered before the assessment is accepted.

2. Again, I have marked on the form a few minor clerical points (mis-spellings etc). Please place all species names in italics.
3. Major point 1: The GM Micro-organism risk assessment (commented on above) refers to experiments in which genes encoding ‘effectors’ are taken from Hyaloperonospora arabidopsidis and, after work in E. coli and Agrobacterium, are expressed in a plant (Arabidopsis). However, the activities described in this GMO (plant) risk assessment describes work in which alleles of Arabidopsis resistance genes are transferred to other genotypes of Arabidopsis. You MUST include in this risk assessment a clear description of the work relating to the expression in plants of the H. arabidopsidis effector genes.
4. Major point 2: We have organised the risk assessment forms on the basis that one deals with potential risks associated with work on micro-organisms and the other on plants. This division is fundamental to the risk assessment process even where, as quite often, the actual experiments being performed require work with the same sequences in both micro-organisms and plants. I am concerned that the inclusion of information on bacteria in the ‘plant’ document sets a precedent that will confuse future compilers of risk assessments. I have therefore marked several short sections that I suggest you remove from the plant risk assessment document. Actually, the information included on p. 5 (marked) could be transferred to the GMO risk assessment document since it contains more detail than is currently included.
5. Missing information: no submission date has been included (p.1). You have not filled in Tables 1 at the end of the document; see the marked sentence on p.13 for guidance. This is very simple, requiring only crosses in appropriate boxes and a final statement of the containment level, but must be completed.

Report on risk assessment of genetically modified organisms, Dr M T – M W

The research contained in this proposal appears to be of high scientific value. There is little to be identified in terms of either risk to the environment by contamination or risk to human health. Containment procedures appear to be adequate and monitored effectively by regular servicing and monitoring of autoclave equipment. As long as the following points are rectified on the proposal then there are no reasons to stop the proposal from proceeding.

1. Page 1 - Institute/research centre. This should read “National Pollen and Aerobiological Research Unit”
2. Page 1 – ‘Pichia pastori’ should read ‘Pichia pastoris’
3. Page 1 several typographical errors in the box at the bottom of the page need to be corrected. What does ‘shuffled’ mean?
5. Page 4 – what are the host ranges of these plasmid vectors?
6. Page 4 - the large box. It would be useful to state that these host organisms have a long history of safe use in many laboratories worldwide.
7. Page 4 – the large box. Previously it is stated that some of the genes may be expressed in planta. Should the plant host be added here?
8. Page 5 – upper box – a comment about the non-GM component of this proposal – why are you planning to use anti-His antibodies rather than Ni-agarose columns which is the standard way of purifying His-tagged proteins?
9. Page 5 – upper box – please state the autoclave conditions being used.
10. Page 6 – upper box – in terms of protein expression and isolation you are likely to need much more than 5-15ml of culture. Dependent on level of expression the amount of culture you will need is more likely to be in the range of 100ml – 1litre, possibly even more if proteins are expressed at a very low level.
11. Page 6 – third box – add Agrobacterium to the potential for aerosol contamination.
12. Page 8 – box 3 – you state that H. arabidopsidis is ‘not-toxic or allergenic’. Do you have evidence for this? Otherwise change the wording to ‘not known to be toxic or allergenic’.
13. Page 9 box 2 – change ‘none identified’ to ‘effectively zero’ as the form states.

Report on risk assessment of genetically modified organisms (plants) Dr Mahmut Tor – Mike Wheeler

The research outlined in this proposal is of high scientific value and as long as the conditions outlined below are addressed in full by the researcher I see no problem with proceeding with this research. There appears to be negligible risk in terms of the environment and human and plant health with proceeding with this plan of work.

1. Page 1 - Institute/research centre. This should read “National Pollen and Aerobiological Research Unit”
2. Throughout – ensure all species and gene names are italicised correctly please.
3. Page 3 – box, section 2 – please add antibiotic resistance genes that are being used for selection in E.coli (e.g. kanamycin phosphotransferase). These are noted in the box at the bottom of page 4.
4. Page 5 – change ‘heterologues’ to ‘heterologous’
5. Page 6 - top box. The last sentence suggests that expression of the gen under its native promoter ‘is not expected to cause any significant alterations in phenotype’. In that case why is this experiment being done? I think that it is quite possible that there will be a change in resistance phenotype in Arabidopsis thaliana Col-0 if the mutant version of the gene that it currently contains is supplemented with an active gene. The researcher needs to make this much clearer here.
6. Page 8 – second box. It states that inoculated plants are to be ‘transferred by hand between facilities in the building’ (my underlining). Would it be more appropriate to lessen transfer between parts of the building as this is likely to increase the risk of contamination of the environment either by Agrobacterium or more especially by pollen as no doubt the plants are flowering if they are being used for a ‘floral dip’ method (see box page 1). If transfer between parts of the building must
take place then plants should be contained in a box that is able to be autoclaved to minimize pollen dispersal.
7. Page 8 – box 4 – autoclave conditions need to be made explicit here. In terms of validation please refer to the method of validation outlined in box 6 on this page.
8. Page 9 – box 2 – This box should be filled in in more detail than is there at present.
9. Page 9 – box 3 – There are a couple of issues here. First, release of plants would mean release of the RHAC1 gene under control of 35S which is not something that currently occurs in the wild population of Arabidopsis at present. This needs to be made explicit. There is quite possibly no reason why this would be any particular issue compared to expression under control of the native promoter but this needs to be made explicit. Secondly, insertion of transgenes using Agrobacterium T-DNA transformation inevitable means that the sites of insertions are not under control of the researcher. Therefore it is not possible to say whether there would be an effect or not on wild plants. I agree that this is a negligible hazard but it is one that should be discussed in this section to at least illustrate that the researcher has considered this.

Project Additional Information

Purposes of the contained use

The genetic modification of several commercially available mammalian cell lines to constitutively overexpress or downregulate wild-type / mutant BCAT1 protein for the intracellular functional characterisation of the redox active CXXC motif.

Recipient or parental organism

Immortalised mammalian cell lines.

Host/vector system
Human BCAT1 cDNA pCMV6-Entry Vector construct (OriGene) transformed into E. coli alpha select competent cell and HEK293T hosts.

Host characteristics:
E.coli alpha-select competent cells. Genotype: F- deoR endA1 recA1 relA1 gyrA96 hsdR17(rk-, mk+) supE44 thi-1 phoA ΔlacZYA-argF)U169 Φ80lacZΔM15 λ – cell we be used to expand BCAT1-pCMV6 and BCAT1-pLENTI constructs.

HEK293T immortalised cell line, is a highly transfectable derivative of human embryonic kidney 293 cells, and contains the SV40 T antigen. This cell line is competent to replicate vectors carrying the SV40 region of replication. It gives high titers when used to produce retroviruses. It has been widely used for retroviral production, gene expression and protein production. DNA profile: CSF1PO: 11,12; D13S317: 12,14; D16S539: 9,13; DSS818: 8,9; D7S820: 11; TH01: 7, 9.3; TPOX: 11; vWA: 16,19; Amelogenin: X

These host organisms have a long history of safe use in many laboratories worldwide and pose negligible risk to human health for the usage described in this document.

Vector system details:
pCMV6-Entry Vector (OriGene) characteristics include: Myc/DDK tag, f1 ori (origin of repication for f1 phage host e.g. M13), SV40 ori (for replication inside mammalian cell systems carrying the Simian Virus large T antigen e.g. HEK293T immortalised human kidney cells), ColE1 (bacteria host origen of replication; low copy number ~15-20), Neor (neomycin resistance in mammalian cells), Kanr (kanamycin resistance for plasmid recovery in E. coli), CMV promotor (for constitutive expression in mammalian cell host e.g. HEK293T), Kozak (eukaryotic mRNA translatio initiation sequence).

pLENTI-C-Myc-DDK-IRES-Neo Vector (OriGene) characteristics include: Myc/DDK tag, Ori, Neor, CAT (CAMr – cloramphenicol resistance for selection in E.coli host), 5’ LTR (contains upstream RSV promoter in place of TAT), 3’ LTR (contains SIN preventing viral genome self replication). **Note that the vector does not contain gag, pol, rev and VSV-G (essential for viral replication and packaging), thus replication defective**.

OriGene Lenti-Vpak packaging kit characteristics:
The lentiviral replication and packaging genes gag, pol, rev and VSV-G have been separated onto three different plasmids pCMV6-Entry vectors, which have been optimised for transfection use in the Vpak kit.

Description of the system:
Combination of construct with Vpak plasmids will transfect and stably produce pseudo-lentiviral particles containing BCAT1 mRNA via the SV40 promotor in mammalian packaging cell lines that carry the Simian Virus large T antigen e.g. HEK293T cells. These are pseudo-lentiviral particles since VSV-G (Vesicular Stomatitis Virus pseudo-envelope) is used in place of the lentiviral envelope as a safety feature. The pseudo-lentiviral particles packaged by HEK293T cells will subsequently be used to, immortalised mammalian to express or silence wild-type of CXXC motif mutant BCAT1 protein under control of the CMV promotor (Naldini et al, 1996; Burns et al, 1993).

Unlike other retroviruses, pseudo-lentiviral particles can enter non-dividing cells (Lewis et al, 1992). Lentiviral expression is replication defective in target cells, since the only mRNA packaged are those which contain 3’ and 5’ LTR (ψ sequence packaging signal). Only the pLENTI plasmid contains 3’ and 5’ LTR’s, thus only BCAT1 mRNA is transfected and not the mRNA required for lentiviral replication and packaging as they are contained on a pCMV6-Entry Vector (which does not contain 3’ and 5’ LTR’s).

This system is a 3rd generation lentiviral system where the replication and viral packaging genes; *gag*, *pol*, *rev* and *VSV-G are separated onto three separate constructs absent of 3’ and 5’ LTR’s (Dull et al, 1998) i.e. the Lenti-Vpak packaging kit. Thus the packaging of pseudo-lentiviral particles containing mRNA of the gene of interest by HEK293T cells requires co-transfection of four separate constructs. Since neomycin selection is under control of the SV40 promoter, thus only cells carrying the Simian Virus large T antigen will produce pseudo-lentiviral particles in the presence of neomycin – which is a further safety feature. Furthermore, many nucleotide changes have been made to sequences used in these vectors to render sequence similarity to wild strains of the parent viruses even lower. This makes the 3rd generation system extremely safe, which is exemplified through its global usage (Sinn et al, 2005). The generation of replication competent pseudo-lentiviral particles (RCL) requires four
separate recombination events to occur in the HEK293T cells. This can be monitored via RT-PCR (viral replication genes) or ELISA (Sastry et al., 2005). At the time of writing this, no reported cases of RCL generation are evident from the literature. Pathogenicity is negligible.

*gag = group specific antigen (matrix, nuclear capsid and major capsid), pol = reverse transcriptase, protease and integrase, rev = regulator auxiliary gene and VSV-G = replaced rev (envelope glycoprotein)

References:

Origin & function
Human BCAT1 cDNA pCMV6-Entry Vector construct is commercially available as naked DNA in lyophilised form obtained from OriGene.

Functions:
BCAT1 encodes the human cytosolic branched-chain aminotransferase isoenzyme (hBCATc). hBCATc belongs to the fold type-V PLP dependent protein family. The canonical role for hBCATc is to transfer the α-amino group from the branched-chain amino acids, Leu, Ile, & Val to α-ketoglutarate generating glutamate and the respective α-keto acid. hBCATc has a defined role in glutamate signalling in the brain and is the drug target for Gabapentin (an anti-convulsant). There are 5 transcript variations. This project involves transcript variant 5 (the closest match in terms of sequence alignment to Goto et al. J Biol Chem; 280(44): 37246-56). Recent studies indicate that the over-expression of BCAT1 in ovarian (Wang et al, 2015) and nasopharyngeal carcinoma (Zhou et al, 2013) was linked to increased cell proliferation. Whilst the oncogenic role for BCAT1 is undefined, overexpression in certain cancer cells may relate to tumour progression.

Our research has highlighted a potential and novel 'anti-oxidant' role for BCATc which centres on the CXXC motif (Coles et al, 2012). To date these studies have been performed using biochemical analysis on purified wild-type and CXXC motif mutant BCATc protein. The next logical step is to evaluate this process intracellularly. If our hypothesis is correct, we would expect to observe a reduction in the cellular redox potential where wild-type BCATc is over-expressed. No difference will be observed for CXXC motif mutants.

References:

Evaluation of foreseeable effects

The expression of hBCATc protein will be evident in the HEK293T cell line. Expression of hBCATc is under control of a CMV promotor. Expression is constitutive and high. Lentiviral and pseudo-lentiviral genes will also be expressed in the HEK293T cell line, which are under control of the SV40 promotor. These HEK293T cells will constitutively express and package pseudo-lentiviral particle that contain hBCATc mRNA. The pseudo-lentiviral particles will subsequently be used to transduce several immortalised human leukaemia target cell lines, including; THP-1, MV-411, K562, NB-4 and U937. These cells once transduced will stability and constitutively express hBCATc protein under control of the CMV promotor. No other lentiviral or pseudo-lentiviral genes should be expressed in these target cells. hBCATc is a cytosolic protein. Low expression of hBCATc may be observed in the alpha-select cells.

Summary of the key biosafety features of 3rd generation lentiviral systems:

a) 5'LTR is wildtype for 2nd generation and inactivated for 3rd generation.
b) 2nd generation contains 4 lentiviral genes (gag, pol, rev and tat), whereas 3rd generation only contain 3 (gag, pol and rev).
c) 2nd generation uses 3 plasmids in total with gag, pol, rev and tat being expressed on the same construct. Whereas 3rd generation split packing and replication onto separate plasmids i.e. rev is express on a plasmid separate from gag. Thus for 3rd generation systems a total of 4 plasmids are used.
d) For 2nd generation a single-step crossover could cause the wildtype 5' LTR and packaging ψ sequence to be placed in front of the lentiviral genes, thus generating RCL. Whereas for 3rd generation the 3' LTR is truncated, reducing the likelihood of producing RCL, plus the number of recombination to produce RCL events is greatly increased, thus improving the biosafety.

Effects on human health:

Having considered the nature of the modified organisms, the nature of the transgenes added and the nature of the operations in culturing the cells, (to be cultured in class-2 biological safety cabinets), we cannot identify any direct risks to human health. Although no oncogenic role for BCAT1 is defined, over-expression of this gene may promote cell proliferation in certain cancer types. The HEK293T cells will synthesise and package pseudo-lentiviruses (which can transduce primary human cells) and in light of the cancer studies we are not 100% sure how the over-expression of hBCATc will effect the growth and survival of healthy cells. Thus all mammalian cell culture working involving HEK293T cells and the afore mentioned immortalised leukaemia cell lines will be carried out at biosafety containment level 2. This recommendation is in accordance with OrgiGene (suppliers of the 3rd generation lentiviral system we are using) and ATCC (suppliers of the HEK293T cells).

Effects on human health, high risk individuals e.g. immunocompromised, pregnant or breastfeeding women:

Immunocompromised, pregnant and breast feeding women are at risk of pseudo-lentiviral exposure, however, biosafety containment level 2 is sufficient to ameliorate the risk of exposure. Whilst there are no reports of hBCATc directly causing human disease, we are not 100% sure how the over-expression of hBCATc will effect cell growth (no known oncogenic role). To this end, we will adhere to biosafety containment level 2 during these procedures.

Immunocompromised, pregnant and breast feeding women are at risk of pseudo-lentiviral exposure, however, biosafety containment level 2 is sufficient to ameliorate the risk of exposure. Whilst there are no reports of hBCATc causing human disease, we are not 100% sure how the over-expression of hBCATc will effect cell growth (no known oncogenic role). To this end, we will adhere to biosafety containment level 2 during these procedures.
In spite of the potential for BCAT1 to increase proliferation in certain cancer types, it is unlikely that accidental infection with BCAT1 pseudo-lentivirus contracts itself causes cancer.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This project does not involve larger GMOs.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection / inactivation of GMMs in waste and subsequent disposal

Disposal of waste generated inside the biological safety cabinet (liquid, cellular & solid waste e.g. pipette tips etc) will be in 10% hypochlorite solution prepared fresh prior to the tissue culture session (important since hypochlorite loses its activity after 24 hours in solution) and leave for 48 hours (kills enveloped viruses at 1000ppm in <10 minutes). All waste is handled inside the biological safety cabinet (recommend 500 ml Duran bottles containing 100 ml 10 % hypochlorite solution and labelled, in which waste supernatant, cells and pipette tips are ejected). Following 48 hours the waste solution can be disposed of. The tips can be recovered and autoclaved (15 psi; 121 oC / 103.4 kPa, for 15 minutes), along with all other solid waste e.g. flasks, gloves etc. Surfaces inside the class-2 biological safety cabinet must be swabbed with 70% ethanol before and after any cell culture session. 1% Virkon will be used to decontaminate any spills on the surface inside the biological safety cabinet (spill volume should not exceed 10 ml at any one time); decontamination of metal surfaces and parts using 1% Virkon is achieved in <10 minutes. This will be followed by the UV decontamination cycle built into the biological safety cabinet. During this period, the biological safety cabinet will be decommissioned. 10% hypochlorite, 70% ethanol and 1% Virkon are all effective at destroying enveloped viruses, such as pseudo-lentiviral particles as generated here (http://www.cleaning-for-health.org/disinfectant-chart/).

GMO waste supernatants (liquid and cellular) from tissue culture procedures carried out inside the biological safety cabinet will be inactivated using 10 % hypochlorite solution (inactivation occurs at 1000ppm in <10 minutes). Solid waste and any GMO remaining waste will be autoclaved (15 psi; 121 oC / 103.4 kPa, for 15 minutes) in EG071. Autoclave conditions will kill all organisms in 15 minutes.

Monitoring at point of use:

In general, all cell culture work will be carried out using tissue culture flasks (T75 or T25) with screw cap lids, which will contain cells and viral supernatant. Flasks will be labelled clearly labelled ‘Genetically Modified Organisms’ and ‘Lentivirus’. Where 6 well culture plates are used (volume <6 ml), transport between equipment will be carried inside a separately sealed container labelled ‘Genetically Modified Organisms’ and ‘Lentivirus’. No tissue culture flask (or plate) containing packaging cells (HEK293T) or pseudo-lentiviral particles will leave the EG071 laboratory (all of the equipment for cell culture; class 2 biological safety cabinet and 5% CO2 incubator are in EG071). GMO containing tissue culture flasks will be placed on the designated bottom shelf of the incubator. Where 6 well plates are used (volume <6 ml), incubations will be carried out inside a separately sealed container labelled ‘Genetically Modified Organisms’ and ‘Lentivirus’.

Monitoring of waste inactivation methods:

The liquid waste in 10 % hypochlorite solution will be tested for viability following 48 hours by inoculating 5 ml RPMI tissue culture medium and subsequent incubation. If inactivation method is efficient, no growth should be evident after 24 hours.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

02/03/2022  Page 13018 of 15326
The committee requested further clarification relating to the leukaemia cell lines that will be used in the final transductions. These have been added to the document.

The committee requested more detail relating to the respective vector characteristics. This has been completed in full and added to the document.

The committee wanted further clarification relating to the containment of viral producing HEK293T cells, including the volume of liquid culture. This information was completed and added to the document.

The committee was happy to approve the work subject to HSE approval. The committee chair recommended that CU2 was to consulted before work begins.

Please enter comments on the GM safety committee on the risk assessment

**Give brief details of the genetic modification safety committee**

The Genetic Modification Safety Committee (GMSC) comprises of the two qualified individuals: The Biological Safety Officer (BSO) who holds a Chief Scientific Officer position at the company and the Biological Training Officer (BTO) who is an experienced post-doctoral scientist. The specific roles of the BSO will be the management and implementation of health and safety legislation (Management of Health & Safety at Work Regulations) by inspecting the laboratory, ensuring sufficient stocks of disinfectants etc and observing workers and will write regular reports to ensure a safe working environment. The role of the BTO will be the daily implementation of GM safety induction check list and making sure they understand and implement GM safety procedures. The BSO will be immediately informed if there are GM incidences and containment measures will be taken and a report written and filed for HSE inspection. In the context of the GM safety and Contained Use Regulations, meetings between the BSO and BTO will be held six months to review safety measures, disposal issues and implementation of further safety measures will be implemented and a written report will be filed.

The company will use Class 1 organisms that will include bacteria (E. coli) and other microbes such as yeast and pichia. Note that all of the strains used are non-pathogenic for humans. For example the E. coli BL21 strain will be used which is a normal laboratory strain which is considered harmless. The E. coli are BL21 strains are found to be poor gut colonizers even in an animal model highly susceptible to the establishment of a persistent infection (J Applied Micro 89 (2000) 1048-1058). To safeguard human health measures for inactivation of microbes will be done with an autoclave on site, disinfectants and cleaning materials will be available, laboratory coats and gloves will be worn, no drinking/eating will be done at the laboratories.

Waste management: Microbial samples will be placed within a biohazard bag which will be removed by the BTO or technical staff for autoclaving and incineration (ii), in case of spillage, a solution of disinfectant (Virkon 1% w/v in water-stable for 7 days). Spills of infected material will be attended to immediately by laboratory personnel (wearing gloves and lab coats) followed by treatment of the affected area with diluted Virkon disinfectant.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The company's GM safety committee seeks to maintain good microbiological practice for handling of E. coli and yeast cultures, i.e. containment measures for level 1 organisms. Neither the K12 or BL21 commercial E. coli or yeast strains used are considered pathogenic to humans or animals. The E. coli strains used are very unlikely to survive or thrive in the environment as they have auxotrophic requirements or other debilitating mutations. The E. coli strains used would not be hazardous to the environment even if they did survive. The GMOs are unlikely to be any more harmful or better able to survive than the original host. There are no special measures necessary to protect the environment & details of waste disposal and emergency clean-up procedures have been described in Note 6. Agar plates, batch cultures and all other contaminated materials will be autoclaved before disposal. E. coli K12 strains are recognised as non-colonising to humans and are unlikely to persist in the gut, lung, or survive outside of the special culture medium which provides their auxotrophic requirements. The BL21 strains are E. coli B derivatives sold commercially for use with T7 promoter-driven vectors, principally the pET series, and are also found to be poor gut colonizers even in animal model highly susceptible to the establishment of a persistent infection. (J Applied Micro 89 (2000) 1048-1058)

Give brief details of the genetic modification safety committee

We have established a genetic modification safety committee to advise on risk assessment to human health and environment.

The membership consists of the following persons.

- Biological Safety Officer
- Deputy Biological Safety Officer
- Staff Representative
- Safety Officer
- Management Representative

The Biological safety officer will act as a Chairperson and the Deputy Biological Safety Officer will act as a Secretary.

Membership will be renewed annually at the first meeting each year.

The committee may co-opt or invite other persons to be in attendance as it requires, including those are personally involved in the work under consideration.

Responsibilities of Officers

The Biological Safety Officer will be the Chairperson and responsible for receiving proposals on behalf of the committee and ensuring that they are prepared correctly. He/She will monitor compliance with the relevant statutory Regulations and call meetings through the committee Secretary.

Duties of the Members

All the members shall report relevant matters to the Committee and promote safety awareness among all the members of staff. Members shall acquaint themselves with safety as applied to genetic modifications and biological agents.

Meetings

To be held twice annually at not more than six-monthly intervals. A record of the Biological Safety Committee meetings in the form of Minutes to be kept and circulated to Committee members, Safety Committee and Senior Management.
Liquid biological waste: The liquid waste will be collected in sealed glass containers, decontaminated with Virkon or Tri Gene and then discharged.

Disinfectant to be used, exposure time and working concentration:

- **Virkon**: Concentration 1-3%                  Exposure Time > 20min
- **Tri Gene**: Concentration 1:50% dilution    Exposure Time > 20min

Source of validation data: (e.g. manufacturer's data or own studies)

Manufacturer's Data

Solid biological waste: The solid waste (disposable plates, pipette tips, etc) will be collected in autoclavable bags, decontaminated by two cycles of autoclaving and then disposed.
Decontamination by autoclaving cycles.

Each waste bag will be autoclaved at 136 degrees celcius for 60 minutes

Number of autoclaving cycles per bag: 2

Source of validation data: (e.g manufacturers data or own studies)

Manufacturers data

Autoclave maintenance and validation method

Autoclave will be annually serviced by the certified engineer

During the autocalve runs, heat-sensitive autoclave tape will be placed on flasks and test tube racks as a rapid autoclave validation method.

Tubes of Bacillus subtilis spores (3 per autoclave) will be used as biological indicators. They will be labeled and placed at the front, middle and back of the chamber.

After the cycle, the B. subtilis tubes will be allowed to cool down to room temperature. 0.1 ml from each tube will be plated onto separate labeled TSA (tryptic soya agar) plates and will be incubated for 48 hr at 37°C.

Source of validation data: (e.g. manufacturer's data or own studies)

Manufacturers Data

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Tubes of Bacillus subtilis spores (3 per autoclave) will be used as biological indicators. They will be labeled and placed at the front, middle and back of the chamber.

The micro-organisms which will be used in all three projects, MTL-101, MTL-103, and MTL-201 belongs to Hazard Group 1, as designated by the UK Advisory Committee on Dangerous Pathogens (ACDP), that is a ‘biological agent unlikely to cause human disease’. The routine cloning and expression work in attenuated E. coli strains have a long history of safe use and most can be handled safely at Containment Level 1. The low risk host-vector systems will be used in these projects. The general risk assessment as well as risk assessment to human health and risk assessment to the environment is found to be satisfactory. The activity is assigned as class 1 and will be handled at containment level 1 laboratories.

SOP 4384445 EHS Committee. Meetings take place on a monthly basis which include safety representatives from all departments on site including management. Site Director chairs the meeting.
Committee members will be volunteers from any department and are elected in line with the Health and Safety (Consultation with Employees) Regulations.
Membership shall be for a minimum of twelve months.
When their term of office is near to an end, Committee members will be responsible, along with the departmental manager, in finding a replacement volunteer member if they no longer wish to carry on this activity.
EHS Committee meetings will be held every month at Kingsland Grange and quarterly at Lingley House.
The meeting will require that at least 90% of the committee members are present.
Members who will be absent from any meeting, for whatever reason, should notify the EHS Advisor as soon as possible before the meeting and nominate upwards for another employee to attend.
EHS Committee meetings shall be conducted to an Agenda e.g
Minutes of last meeting/action items review.
Accidents / Incidents / Near Misses / Property Damage / Occupational Health
Inspection findings
Policies/Regulatory Compliance
Personal Protective Equipment (PPE)
Biosafety / GMM
Review of metrics
Environmental Matters
Any Other Business
Minutes will be taken at each EHS committee meeting and shall be reviewed by the EHS Advisor and the Senior Management committee representative who signs and dates the minutes as being a true record.
The minutes will then be communicated to the site no more than 7 working days after the meeting and a copy posted on the EHS notice board and site Shared Public Drive

Any Solid waste will be autoclaved and incinerated
Glassware will be treated with disinfectant at the recommended concentration for the stipulated length of time before being washed and autoclaved.
I. SOP for disinfection of CL1 waste for drain disposal
1. Effectiveness:
All liquid waste will be treated with disinfectant and autoclaved (e.g. Trigene at the recommended concentration).
2. Recommended Personal Protective Equipment:
   • Lab coat
   • Latex or nitrile gloves
   • Safety glasses
3. Concentration:
The appropriate concentration of Trigene at the recommended concentration shall be used dependant on volume of waste.
4. Contact time:
An appropriate contact time of Trigene with liquid waste is >180 minutes before drain disposal. After >180 minutes of contact, disinfected liquid waste is poured down the sink and the drain is flushed with copious amounts of water.
II. SOP for autoclaving CL1 liquid waste for drain disposal
1. Effectiveness:
   Autoclaving is an effective means of sterilizing CL1 liquid waste. Sterilization refers to the complete killing of all living organisms, including spores. The autoclave is validated for effectiveness at each use by using Indicator tape autoclave which conforms to BS7893, 1997 and BS EN 867-2, 1997
2. Recommended Personal Protective Equipment:
   • Lab coat
   • Latex or nitrile gloves
   • Heat resistant gloves
   • Safety glasses
3. Procedure:
a. Collect BL1 liquid waste in autoclavable, leak proof containers that are never more than ¾ full.
b. Place containers in an autoclavable tray in the autoclave. LOOSEN each container top and place indicator tape on each top.
c. Adequate cycle time varies depending on load, type of autoclave, and secondary containment.

Project Additional Information

Purpose of the contained use
The aim is to produce viral vectors that are not infectious to humans which can be used to calibrate or control molecular biological extraction, amplification and detection processes and systems (e.g. diagnostic assay for RNA viruses) by utilising the pathogen target sequence in the recombinant BVDV.

Recipient or parental organism
The recipient organism is a non cytopathic BVDV (NCP7) which contains a deletion of the CP7 specific 27 nucleotide insert. The cDNA of this construct has been further modified by the insertion of four unique cloning sites in the 3’ UTR (Baroth et al., JGV, 2010, 91, 1213-7). BVDV is a member of the Pestiviruses genus, in the family Flaviviridae and is an animal pathogen. Bovine viral diarrhea is a disease of cattle, it causes a mild infection in adult animals, however if
a fetus is infected in the first third of gravidity a persistent infection occurs, if infection with another BVDV occurs it
can be fatal. Symptoms of the virus infection include fever, diarrhea, respiratory disease and a discharge from the
eyes and nose. Most BVDV infections in adult animals are self limiting and there is no effective treatment. Cattle in
the UK can be immunised against BVDV using an inactivated vaccine.

Host/vector system

The Vector
The vector is BVDV NCP7 which harbors four unique restriction sites in the 3' UTR (NCP7 MCS) (Baroth et al., JGV,
2010, 91, 1213-7). Construction of the recombinant BVDV will be via a subclone which contains a fragment of
approximately 1200 base pairs of the BVDV 3' UTR in a pblue script vector, once the target sequence has been
inserted in to the subclone it will be transferred back into the NCP7 MCS vector.

The Host
The host cell line is Madin-Darby Bovine Kidney (MDBK) cells, it was derived from kidney cancer of an apparently
normal Bos Taurus and is BVDV free. MDBK cells would not be able to survive outside of the laboratory culture
conditions.

Origin & function

Quantitation standard and internal controls for molecular diagnostic kit / products based on quantitative PC2
technology, origin as host vector system as described above. The aim is to produce viral vectors that are not
infectious to humans which can be used to calibrate or control molecular biological extraction, amplification and
detection processes and systems (e.g. diagnostic assay for RNA viruses) by utilising the pathogen target sequence in
the recombinant BVDV.

Activity

Evaluation of foreseeable effects

The Insert
Recombinant BVDV will contain RNA inserts. This insert will be located in the 3' UTR of BVDV and will therefore not be
translated, only replicated. The inserts will pose no risk of infection to the natural host of the insert, the environment and
no further risk of infection to cattle. E.g. an insert is genetic material from HCV, a member of the genus hepacvirus of the
family Flaviviridae this is a human pathogen.

Human health considerations
The parental BVDV is non infectious into humans and poses no threat to human health. The inserts however, can be
derived from human pathogens, but are situated in the 3' UTR of the BVDV and thus not translated, posing no threat to
human health. This insert is a small portion of a human pathogen genome which is not infectious when isolated from the
parental virus and is thus not a threat to human health.

Environmental considerations
The recombinant virus is able to replicate and release infectious virus to similar levels observed for the parental wild type
(WT) virus. If this was released into the environment it would pose a risk to animal health, this risk would be very low
due to the instability of the virus when exposed to the environment and when it is outside of its normal transmission
route. The main transmission route is generally by direct contact with that are infected with BVDV.

Level II containment and following good microbiological practice will be implemented in the laboratory. Access to the
laboratory will be restricted to personnel trained to work with category II contained microorganisms when work with
infectious agents is in progress. A sign on the door will notify people of the microorganism being used, the personal
protective equipment required and entry and exit procedure if required. Work will be performed whilst wearing personal
protective equipment and biosafety procedures for handling the virus will be outlined in the standard operating
The virus will normally be completely inactivated with \( \beta \)-propiolactone, an agent used in inactivate BVDV for vaccines, before it leaves the facility.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Determination of final classification and containment measures

WT BVDV is classified as Class II, it is a common virus and whilst most BVDV infections are self limiting except if the fetus is infected during early pregnancy the virus can cause a persistent infection. There is no effective treatment against BVDV, however, cattle in the UK can be immunised against BVDV using an inactivated vaccine.

The genetic inserts are from human viral pathogens and pose no risk to human health or the environment.

The recombinant BVDV will replicate less efficiently or to a similar level to WT parental NCP7 BVDV, it is therefore allocated to Class II, GMM activities of low risk for which level II containment is appropriate to protect human and animal health as well as the environment.

The GMM activity is therefore classified as Class II.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Once the RNA has been introduced into the MDBK cell line the RNA can replicate and produce infectious virus.

- Gloves will be worn when handling infectious material
- Once RNA has been transfected into MDBK cells pipette tips will be washed with disinfectant and discarded into a sharps bin or bag located in the BSC II tissue culture hood.
- Pipettes (disposable stripettes) will be washed out with disinfectant and then discarded into pipette disinfection chambers that are filled with disinfectant. After being soaked overnight the pipettes will be autoclaved and disposed of by incineration by an authorised third party.
- Plastic wear that has come into contact with MDBK cells that are infected with BVDV will be soaked in disinfectant for at least the minimum time indicated on the chosen disinfectant or overnight.
- All waste once treated with disinfectant will be autoclaved and incinerated.

To bring virus out of the hood and opened on the bench in the laboratory to do downstream work cells will either be fixed or lysed in the BSC level II tissue culture hood.

No floor drains are present in the lab and potential of spillage is low.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Please enter comments on the GM safety committee on the risk assessment
SOP 4384445 EHS Committee. Meetings take place on a monthly basis which include safety representatives from all departments on site including management. Site Director chairs the meeting. Committee members will be volunteers from any department and are elected in line with the Health and Safety (Consultation with Employees) Regulations. Membership shall be for a minimum of twelve months. When their term of office is near to an end, Committee members will be responsible, along with the departmental manager, in finding a replacement volunteer member if they no longer wish to carry on this activity. EHS Committee meetings will be held every month at Kingsland Grange and quarterly at Lingley House. The meeting will require that at least 90% of the committee members are present. Members who will be absent from any meeting, for whatever reason, should notify the EHS Advisor as soon as possible before the meeting and nominate upwards for another employee to attend. EHS Committee meetings shall be conducted to an Agenda e.g Minutes of last meeting/action items review. Accidents / Incidents / Near Misses / Property Damage / Occupational Health Inspection findings Policies/Regulatory Compliance Personal Protective Equipment (PPE) Biosafety / GMM Review of metrics Environmental Matters Any Other Business Minutes will be taken at each EHS committee meeting and shall be reviewed by the EHS Advisor and the Senior Management committee representative who signs and dates the minutes as being a true record. The minutes will then be communicated to the site no more than 7 working days after the meeting and a copy posted on the EHS notice board and site Shared Public Drive

Give brief details of the genetic modification safety committee

Immune Targeting Systems (ITS) has established a GM safety committee chaired by the Research and development Director and members include the responsible person for the health and safety and at least one member of the scientific staff. ITS will employ an external health and safety advisor to provide additional advice if and when required. The GM safety committee will follow regulations and guidelines in accordance with the Genetically Modified Organisms (Contained Use) Regulations 2000.

ITS’s projects involving the use of genetically modified cells will require a risk assessment and review by IT’s GM Safety Committee before work will commence.

Decontamination and disposal procedures will be followed according to guidance described in IT’s operational handbook. Decontamination procedures will use Virkon solution which is a reliable broad spectrum high level disinfectant. Virkon is effective against Hepatitis A, B, and C, HIV, MRSA, VRE, Norovirus, Influenza A Virus. Virkon is rapidly effective killing 99.999% of micro-organisms in less than 10 minutes, even in the presence of organic matter. The manufacturer recommends using Virkon at 1%.

All work surfaces including equipment, the MSC enclosure or other surfaces will be decontaminated with 1% Virkon solution (Hard surfaces) or 3% Virkon solution (for absorbent surfaces). All disposable items such as plasticware and pipette tips will be decontaminated with a 1% Virkon solution overnight before disposal to the clinical waste bag prior to autoclaving. GMM material will be inactivated by exposure to excess volumes of 1% Virkon solution for 24 hours. Prior to disposal in the autoclaved clinical waste. Monitoring of the 121°C, 1.5 hour autoclave cycle is achieved using a chart recorder and records of individual autoclave cycles are tracked. Autoclaved waste is disposed of in the general clinical waste.

For animal carcasses' will be incinerated.

Please enter comments of the GM safety committee on the risk assessment

ITS's GMSC reviewed the risk assessment for the project 'Assessment of antigen-specific T cells responses induced by vaccination with fluoropeptides to induce effective anti-tumour responses on 26.05.2011. The risk assessment was considered to be appropriate for the GMM used. The GMSC also agreed that the classification as a class 1 activity was appropriate.

For all risk class 1 and 2 activities involving GMMs, Trigene Advance will be used as the general disinfectant/decontaminating agent and has been shown by the manufacturer to be effective against bacteria, viruses and cells.

For general disinfection on non-soiled surfaces, Trigene Advance will be used at 2 part concentrate in 100 parts water (2% v/v) which is greater than the manufacturer's recommended concentration. 2% Trigene will be sprayed over the surface, the surface wiped with blue towel, then rinsed with milliQ water and wiped followed by spraying with ethanol and wiped.

For disinfection and cleaning of surfaces in the presence of split media containing 10% serum, the media would be mopped up with a paper towel (which would be placed in a yellow clinical waste bag) and 2% Trigene used to decontaminate the area as above as recommended by the manufacturer.

All spent contaminated growth media containing E. coli, mammalian cells or serum within plasticware will be decontaminated by adding Trigene advance to 5% v/v and allowed to stand for 24h before disposal down the drain.

All contaminated plastic pipettes will be immediately sluiced with 5% Trigene before disposal into plastic clinical waste e.g. plastic gloves and paper waste.

Validation of inactivation of waste disinfectants. The concentrations of Trigene disinfectant to be used are based on the manufacturer's recommendations for these organisms, taking into account the protein concentration.

Solid waste containing GMOs that has not been decontaminated e.g. plastic petri dishes containing agar growth media and live bacterial colonies (risk class 1) will be placed in sealed leakproof clinical waste bins which will then be placed in autoclave bags and autoclaved to inactivate the GMOs. These will then be bagged and treated as normal clinical waste. The autoclave is routinely inspected and maintained according to the manufacturer's instructions.

All inactivated clinical waste material is double bagged and sealed and kept in leak-proof containers. All clinical waste (bagged and in incineration bins) will be taken off site by the accredited company SRCL (formerly White Rose) for disposal by incineration.
The generation of replication deficient lentiviral particles will be carried out in a designated class 2 safety cabinet and transfected and transduced cells likely to have "live" lentiviral particles will be incubated in a designated incubator.

An up to date record of all the genes used in this programme of work as well as the workers involved in generating the replication deficient lentiviruses is to be kept.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The intention is to generate cell lines which can be used with cancer research for the evaluation of tumour cell growth and proliferation in both in vitro and in vivo settings. Mammalian cells, including epithelial cells, mesenchymal stem cells (MSCs), fibroblasts, and endothelial cells will be transduced using lentiviral particles with fluorescent markers (Green, Red, Yellow, etc., Clontech) or luciferase markers (Firefly, Renilla, Promega), driven by a constitutive or inducible mammalian promoters (CMV, EF1α, s100a4, etc) in order to label the cells with these markers, so that cell numbers/proliferation and biological processes can be monitored. The cells will also be transduced with genes or shRNAs (small hairpin RNAs that cause gene knockdown) against genes involved in tumorigenic processes, including for example growth factors and their receptors, proteolytic enzymes or oncogenes.

The transduced cell-lines will be co-cultured in various 2 dimensional and 3 dimensional in vitro models to examine the role of the target genes on cell viability, effects within cells and cell-cell interactions. In addition, the transduced or transfected cells will be used to establish xenografts in rodent models, to study the effects of anti-cancer research agents and the effect of target gene up-regulation or knock down on tumours within that in vivo system.
Recipient or parental organism

During routine cloning non colonising or disabled strains of E. coli K12 will be used e.g. DH5α and XL1-blue. These have a long history of safe use and are non-pathogenic.

The recipient cell lines will be human MSCs, primary tumor- and normal tissue-derived fibroblasts, and a variety of colorectal, pancreatic, prostatic, mammary, gastro-oesophageal, ovarian, lung, melanoma, leukemic, glioblastoma, renal, and bladder epithelial tumour cell lines, including those in the NCI-60 panel, as well as primary human tumour derived cells, and cells of endothelial origin. All work will be performed at containment level II as some of the cell-lines to be used require this level of containment due to the potential of endogenous pathogens (e.g. primary tumour samples).

Host/vector system

Non-viral vectors

All vectors to be used are standard non-mobilisable or mobilisation defective plasmids in E. coli.

Replication-deficient lentiviral vector systems

Examples of the lentiviral vectors to be used are from the Lenti-X system (Clontech) for constitutive or inducible gene expression, and the TripZ system (OpenBiosystems) for inducible shRNA-mediated knockdown. These systems produce lentivirus particles which are third- or fourth-generation viruses, according to SACGM guidelines because the viral components required to make infectious particles are enclosed on multiple plasmids separate from the expression vector. These viral components gag (nucleocapsid), pol (reverse transcriptase) env (envelope protein, determines cells which can be infected) and rev (involved in translation of gag and env) must be transiently transfected into the virus-producing cells (the standard HEK293T cells will be used for this purpose) along with the expression vector, in order to produce viral particles. Typically 4 packaging plasmids containing these essential lentiviral genes are required. None of the packaging plasmids contain effective LTRs or Ψ packaging sequence, and none of the HIV-1 structural genes are present in the packaged viral genome, and therefore never expressed in transduced cells, so no new replication-competent virus can be produced following transfection of the HEK293T cells, the genes are not transferred into the viral particles created, or the cells transduced by these particles, unless multiple recombination events occur which bring all of the viral components into the expression vector. This specific series of recombination events is considered extremely unlikely. Although the replication deficient viral particles produced by the HEK293Ts are able to transduce a broad range of human cell-types, including primary cells, no further viral particles are reproduced by the transduced cells.

Origin & function

The inserted genes encode for either
a) Coloured fluorescent proteins (GFP or RFP from bacterial and marine sources) or luciferase protein (from firefly or Renilla) which will be used to monitor cell numbers/proliferation/promoter activity. No harmful effects on cell biology are known to be associated with these gene products.

b) DNAs encoding potential human oncogenes and tumour suppressor genes from commercial sources, including growth factors (e.g. gastrin, TGF-beta, hepatocyte growth factor) and their receptors (e.g. CCK-2R, c-met), transcription factors (e.g. Snail, Slug, Zeb, Twist), proteolytic enzymes (e.g. matrix metalloproteinases), genes involved in cell cycle (e.g.PLK-1) genes involved in cell metabolism, genes encoding for kinases, involved in protein synthesis and degradation.

c) shRNA (small hairpin RNAs that cause gene knockdown) against specific target genes that may be involved in tumorigenic processes, including for example growth factors and their receptor, proteolytic enzymes, kinases and potential oncogenes. These are typically obtained from commercial sources as cloned DNAs.

Evaluation of foreseeable effects

The most hazardous GMM used will be the lentiviral particles enabling expression of potential oncogenes and tumour suppressor genes.

Rationale for this statement:

With regard to the unmodified vector, these are third generation lentiviruses which are replication deficient and thus can be handled at containment level 1. SACGM guidance states: “Replication defective vectors that cannot infect human cells can generally be considered class 1. For replication defective retroviruses and letiviruses capable of infecting human cells, if the risk assessment demonstrates they are adequately attenuated, it is possible to designate the activity as class 1:- Factors supporting this classification will include: low risk of generation of Replication Competent Viruses (e.g. a third generation packaging system), self inactivating (SIN) LTR and non-harmful insert. However, contaminated sharps represent a significant hazard (see paragraph 31), and their use should be excluded for vectors that can infect human
cells, if the activity is to be designated class 1.

The lentiviral system to be used is a third generation system producing virus particles which are replication deficient, thereby minimising the possibility of the resulting stable cell-lines producing viral particles. However the genes encoded in the lentiviral particles are potential oncogenes and tumour suppressors; upregulation of oncogenes and downregulation of tumour suppressor genes is potentially carcinogenic. The greatest risk would be associated with accidental infection of someone during handling of the viral particles with the viral particles themselves which may be oncogenic. To reduce the likelihood of this occurring, the viral particles will be handled at containment level 2 in a microbiological class 2 safety cabinet, gloves will be worn by the worker at all times and no sharps will be used. However, even in this worst case scenario, no further infectious virus would be produced by the individual's infected cells and only single genes can possibly be modulated. NB modulation of multiple genes is generally thought to be involved in transformation of cells, thus reducing the risks involved with accidental infection. Other GMOs to be generated:

The replication deficient viral particles will be used to stably transduce primary tumour cells and cell lines. After a short period of culture the GMM cell lines created from lentiviral transduction will be free of any functional virus and will not therefore be of any harm to human health and the environment. The cell lines are unlikely to be harmful even if accidentally injected into a worker as the worker's immune system would naturally clear foreign cells. No workers will be allowed to work on their own or a colleagues endogenous cells.

The original replication deficient viral stock (applied at up to 2.5 million per ml to achieve a multiplicity of infection (MOI) of 50, the upper end of range recommended) will have been diluted more than 10xlog10-fold following 5 washes (10ml reduced to 100ul at each wash), and in addition, these viruses can survive in culture conditions for only a few days. Transduction efficiencies vary for different cell-lines and for all cell-lines, transduction efficiency is correlated with MOI (Zhang et al, 2004). The significance of controlled conditions in lentiviral vector titration and in the use of multiplicity of infection MOI (from 32 to 2) resulted in a reduction of the transduction efficiency from 80 to 20% in the cell-line most susceptible to transduction, and to below 10% in the other cell-lines. A 10xlog-fold reduction in the viral titres is regarded as more than adequate to ensure the absence of any functional virus in the culture supernatant, and the transduced cells can then be handled at containment level 1. There will be no free or functional lentivirus particles present when lentivirus-transduced cell lines are implanted into recipient mice, so the establishment of xenografts can also be performed at containment level 1.

However, the animals to be used are kept at containment level II and thus, this work will also be carried out at this level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Generally mutant mice e.g. MF1 nude or NOS/SCID mice will be used. However occasionally transgenic mice may be used for the Xenograft models. There is a lower risk of infection in workers derived from bites (than from animals naturally existing in the wild) due to high health status of animals. The consequences of all environmental hazards from these animals are of either an equal or lower risk to that which is posed by animals naturally occurring in the wild. The containment and control measures in place are:

1. All transgenic rodents are housed in isolators with independent supplies of filtered air and water or quarantine approved rooms.
2. All waste is bagged up and disposed through an approved waste disposal contractor.
3. Rederivation is carried out by trained staff. All equipment is sterilised before and after each use.
4. All carcasses are disposed through an approved controlled waste disposal contractor.
5. Site pest control policies are in place using a combination of rodent barriers and the services of pest control companies.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For all risk class 1 and 2 activities associated with this programme of work, Trigene Advance will be used as the general disinfectant/decontaminating agent and has been shown by the manufacturer to be effective against bacteria, viruses and cells.

For general disinfection on non-soiled surfaces, Trigene Advance will be used at 2 part concentrate in 100 parts water (2% v/v) which is greater than the manufacturer's recommended concentration. 2% Trigene will be sprayed over the surface, the surface wiped with blue towel, then rinsed with milliQ water and wiped followed by spraying with 70% ethanol and wiped.
For disinfection and cleaning of surfaces in the presence of spilt media containing 10% serum, the media would be mopped up with a paper towel (which would be placed in yellow clinical waste bag) and 2% Trigene used to decontaminate the area as above as recommended by the manufacturer.

All spent contaminated growth media containing E. coli, mammalian cells or serum within plasticware will be decontaminated by adding Trigene advance to 5% v/v and allowed to stand for 24h before disposal down the drain.

All contaminated plastic pipettes will be immediately sluiced with 5% Trigene before disposal into plastic clinical waste bins. All plastic ware will be placed after decontamination in yellow clinical waste bags together with other solid waste e.g. plastic gloves and paper waste.

Validation of inactivation of waste disinfectants. The concentrations of Trigene disinfectant to be used are based on the manufacturer's recommendation for these organisms, taking into account the protein concentration.

For generation of replication deficient lentiviruses, the use of sharps is forbidden. Specific separate class 2 microbiological safety cabinets and CO2 incubator will be designated for use with the repication deficient lentivirus.

Solid waste containing GMOs that has not been decontaminated e.g. plastic petri dishes containing agar growth media and live bacterial colonies (risk class 1) will be placed in sealed leakproof clinical waste bins which will then be placed in autoclave bags and autoclaved to inactivate the GMOs. These will then be treated as normal clinical waste. The autoclave is routinely inspected and maintained according to the manufacturer's instructions.

All inactivated clinical waste material is double bagged and sealed and kept in leak-proof containers. All clinical waste (bagged and in incineration bins) will be taken off site by the accredited company SRCL (formally White Rose) for disposal by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Handling of transduced cells following 5 passages is assigned to class 1. However, it will be carried out at containment level II since many of the mammalian cell lines to be used are assigned to class 2.

Generation and handling of the lentiviral particles are assigned to class 2.

The generation of replication deficient lentiviral particles will be carried out in a designated class 2 safety cabinet and transfected and transduced cells likely to have "live" lentiviral particles will be incubated in a designated incubator.

An up to date record of all the genes used in this programme of work as well as the workers involved in generating the replication deficient lentiviruses is to be kept as an appendix at the end of this risk assessment.

Risk assessment PRA1 approved, subject to minor amendments.

**Purposes of the contained use**
The targeting of cancers using viruses has significant therapeutic potential. The virus used in this work has been modified to increase specific targeting of tumour cells. This project will assess the antitumoural activity of this modified virus.

**Recipient or parental organism**
- Mice bearing tumour xenograft or allograft of human or mouse origin.
Host/vector system

HSV-1 with alteration of the genome in two regions resulting in the inactivation of 2 genes (ICP34.5 and US12).

Origin & function

Inactivation of two specific genes will result in reduced viral replication in normal tissue, while maintaining replication in tumour tissue.

Evaluation of foreseeable effects

The genetic modifications to HSV will make it safer than the parental strain, and reduce viral replication in healthy tissue. HSV with deleted ICP34.5 has been used in phase I clinical trials (PMID 10845724), with confirmation of safety and tumour selectivity reported. Viral strains with mutation of ICP34.5 and US12 have previously been characterised and used for in vivo studies (PMID 11333900).

Modified HSV can be infectious to humans with primary infection being usually mild (results in fever blisters or cold sores, usually on the face and lips which crust and heal within a few days). It is not related to livestock or avian species. Modified HSV contains modifications reducing its virulence and replication in normal tissue.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For this programme of work, Distel will be used as the general disinfectant/decontaminating agent. This is a halogenated tertiary amine compound with a blend of surface active disinfectants and detergents that has been shown by the manufacturer to be effective against bacteria, viruses and cells.

For general disinfection of surfaces, Distel will be used at 5% v/v, which is higher than the manufacturer's recommended concentration. 5% Distel will be sprayed over the surface, the surface wiped with blue towel, followed by spraying with 70% isopropanol and wiped.

In the event of a spillage, the area will be disinfected with 10% Distel.

All spent contaminated liquid and consumables will be placed into a sealed container and decontaminated with 5% Distel overnight.

All decontaminated materials will be placed in clinical waste bins for disposal by incineration.

Following completion of the work, the Class II biosafety cabinet will be disinfected and fumigated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

02/03/2022
It was noted that the material will be handled as class 2. It was noted that the modifications to the virus make increased the safety of the material.

### Purposes of the contained use

To assess anti-tumour efficacy of an attenuated vaccinia virus in mouse models of cancer.

### Recipient or parental organism

Attenuated virus will be used to treat mice, which will either be non-tumour bearing (to confirm tolerability at doses tested) or tumour bearing (to assess anti-tumour efficacy).

### Host/vector system

The viral vector has been attenuated with mutations in the RR1(J2R) and TK1(I4L) genes. Green Fluorescent protein (GFP) gene has been inserted by homologous recombination in TK1 locus. The genetic modifications will reduce viral replication and virulence.

### Origin & function

RR1 mutation reduces viral replication, while TK1 mutation will reduce the virulence of the virus. Green Fluorescent Protein, which is a fluorescent protein exhibiting green fluorescence when exposed to light in the blue or ultraviolet range.

### Evaluation of foreseeable effects

Attenuated vaccinia virus CTx_oVV1-GFP with RR1 and TK1 mutations (western reserve strain). Exposure can potentially occur from mouse urine, droppings, saliva or nesting material.

With appropriate containment and PPE, risks will be very small. If exposure does occur, symptoms are mild, and asymptomatic infection is common in healthy individuals. When symptoms do develop, they consist of a mild rash and low grade fever. In rare cases (usually immunocompromised individuals), a more serious rash can develop, along with fever, tiredness, headache and backache.

If exposure does occur, the following actions will be taken:

a. Sharps injury (needle stick and subcutaneous biological exposure)
   • Wash exposed area thoroughly for 15 minutes using warm water and sudsing soap.

b. Skin Exposure (non-intact skin)
   • Immediately go to the sink and thoroughly wash the skin wound with soap and water.

b. Skin Exposure (non-intact skin)
   • Immediately go to the sink and thoroughly wash the skin wound with soap and water.

c. Splash to Eye(s), Nose or Mouth
   • Immediately flush the area with running water for at least 15 minutes.
   • For eyes, use the eye wash for 15 minutes while holding eyelids open.

d. Inhalation
   • Move out of contaminated area. Get medical help.

e. Splash Affecting Garments
   • Remove garments that may have become soiled or contaminated and place them in a double biowaste bag.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Distel will be used as the general disinfectant/decontaminating agent. This is a halogenated tertiary amine compound with a blend of surface active disinfectants and detergents. It has been shown by the manufacturer to be effective against viruses.

For general disinfection on non-soiled surfaces, Distel will be used at 2 part concentrate in 100 parts water (2% v/v). 2% Distel will be sprayed over the surface, the surface wiped with blue towel, then rinsed with milliQ water and wiped followed by spraying with 70% ethanol and wiped.

For disinfection and cleaning of surfaces in the presence of liquid, the liquid would be treated with 5% Distel, mopped up with a paper towel (which would be placed in yellow clinical waste bag) and 5% Distel used to decontaminate the area.

All spent contaminated liquid will be decontaminated by adding Distel to 5% v/v and allowed to stand for 24 h before disposal. All contaminated plastic pipettes will be immediately sluiced with 5% Trigene before disposal into plastic clinical waste bins. All plastic ware will be placed after decontamination in yellow clinical waste bags together with other solid waste.

All inactivated clinical waste material is doubled bagged and sealed and kept in leak-proof containers. All clinical waste (bagged and in incineration bins) will be taken off site by an accredited company for disposal by incineration.

Is an emergency plan required according to regulation 20? N

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

### Level 1 (GMMs)
- Laboratory: Yes
- Animal Unit: Yes
- Growth Room: 
- Glass House: 
- Large Scale: 

### Level 2 (GMMs)
- Level 3 (GMMs)
- Level 4 (GMMs)
- Non-microbial
- Other (please specify): Tick if confidential

Give brief details of the genetic modification safety committee

The genetic modification safety committee will compromise of at least 3 biologists (2 senior research scientists and 1 biology group leader), one of whom will be an assigned Biological Safety Officer or Deputy Biological Safety Officer. This committee is responsible for safety issues concerning genetically modified organisms and will meet on a monthly basis to assess all proposals to work with GMOs. The meetings will be chaired by the Biological Safety Officer, or a Deputy Biological Safety Officer, and minutes of the committee meetings will be captured and stored electronically.
Disinfection Procedure (All Sites) - GMOs will be fully inactivated using Chemgene or Virkon disinfectant used according to the manufacturer's recommendations. An autoclave is also available which will allow heat inactivation of GMOs in the event of an emergency spill.

Waste Disposal (BioCity) - Solids: Solid waste, once inactivated by Chemgene (2 % (v:v) for general cleaning, 20 % (v:v) for higher risk disinfection) or Virkon (1-2 %) disinfection, will be double bagged in yellow biohazard bags, sealed and will go into the lab biohazard waste stream. All waste awaiting incineration will be stored in leak proof containers which will allow easy disinfection if required. Laboratory waste will be collected by an external waste management contractor (Stericycle) for processing off-site. Liquids: Liquid waste, following Chemgene or Virkon inactivation (2 % or 1-2 % respectively, overnight) will be disposed of via a suitable aqueous waste route.

In Vivo Procedures (Nottingham) - Spillages are likely to be small volumes only – the area will be disinfected with 1 % Virkon (contact time 10 minutes); absorbed onto absorbent pad and disposed in clinical waste bin. Stock AAV will be disinfected with 1% Virkon for at least 10 minutes before being absorbed onto absorbent material and disposed in the clinical waste stream. Sharps and other consumables in direct contact with the AAV will be bagged/sealed and autoclaved in the licensed establishments autoclave at 135 oC for 30-45 minutes in line with validated cycle. Bedding/enrichment materials will also be autoclaved in this way before cages are washed under normal washing procedures. Carcasses will be disposed by incineration via the licensed establishment's GMO clinical waste stream.

In vivo Procedures (Alderley Park) - For in vivo studies, following IMPACT testing GM cell lines will be grown under standard tissue culture conditions using validated inactivation/disinfection procedures with approved waste streaming. Culture volumes will be <10 litres. All liquid waste (e.g. spent tissue culture media) will be inactivated using 2 % Virkon for a period of at least 1 hour, before discharging to drain flushed with copious amounts of water. Cage waste will be single bagged in yellow bags with black ties and sent for incineration offsite. Animal carcasses and tissues will be double bagged with red ties and sent offsite for incineration. Sharps will be placed in Sharpsafes, sealed, then autoclaved and sent for incineration.

Waste Disposal (Alderley Park) - All waste will be streamed according to the Alderley Park Site waste guidelines. Contaminated solid waste will be inactivated in a centralised autoclave that operates under an environmental permit. All solid waste will be transported to the autoclave in drop-sided wheele bin to the autoclave facility by trained waste operators. The autoclave has a sterilising cycle of 125 oC for 30 minutes and once completed the waste will be sent for incineration. Liquid waste will be inactivated using 2 % Virkon for a period of at least 1 hour, before discharging to drain flushed with copious amounts of water.

Tick if you are claiming exemption from disclosure for sections of the risk assessment
Please enter comments of the GM safety committee on the risk assessment

The GMO risk assessment has been presented to the genetic modification safety committee. Summary findings: The health and environment risks with the handling of GMOs has been reduced to low, acceptable levels by the use of trained staff, procedural and containment controls and personal protective equipment.

Non-GMM Consent Granted

Project notified under transitional arrangements

Tick if notifying a connected programme of work

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To identify and optimise research compounds for progression to candidate drugs. Working as a contract research organisation and also on internal research programmes.

Recipient or parental organism

Mammalian cells including HEK, CHO, HeLa, and THP-1. All cells will be handled under Class II containment.

Host/vector system

Standard mammalian expression vectors including Pcdna3.1 and derivatives. Plasmids/vectors will be non-mobilisable or mobilisation defective.

Origin & function

Mammalian genes encoding for major classes of cellular proteins e.g. receptors, ion channels, and enzymes. The sequence of the coding regions will be known and
Evaluation of foreseeable effects

There is expected to be a very low risk of potentially harmful effects associated with the genetically modified organisms in terms of changes to host cell pathogenicity or toxicity to humans. The GMOs will have negligible ability to survive independently in the environment if accidentally released from containment. The likelihood of potentially harmful effects being realised as a consequence of exposure to the operator or environment is negligible. The intended protein classes (see above) would represent gene sequences where any hazardous biological effects are considered unlikely because of the known properties of the protein. It is highly unlikely that these proteins could be delivered to a site in the body in an active form. Mammalian cell lines are especially disabled hosts and vectors are non-transmissible. No foreseeable adverse effects to the environment are expected due to the containment and control measures put in place.

Working Practices - The named laboratory for GMO work will comply with HSE Containment Level 2 facilities and working practices. Stock GMO material will be stored in a fully maintained freezer with access restricted to named personnel only. All handling of GMOs will be performed in a Class II biological safety cabinet. All operators will wear the appropriate PPE i.e. lab coats, gloves and safety glasses and will be fully trained in the safe use of GMOs by an experienced user. The use of sharps will be kept to a minimum and all contaminated sharps will be disposed of in a dedicated sharps bin. Aerosol generation will also be minimised e.g. by using sealed centrifuge tubes that will only be opened in a Class II cabinet. In addition, the laboratory will be maintained under negative pressure. Scientists not directly involved in the GMO work but who share the laboratory facilities will be made fully aware of the working procedure. GMOs will not be transported from the designated laboratory to other areas/buildings.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The risk assessment for working with GMOs requires all control measures to be necessary and in place

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Type/form of waste - The majority of waste will be in liquid form (e.g. spent tissue culture medium, media in microtitre plates), but some solid waste will also be generated (e.g. stripette tips, reagent vials)

Disinfection Procedure - GMOs will be fully inactivated by Trigene Advance disinfectant used according to the manufacturers recommendations (MediChem International Ltd) Trigene is an industry leading disinfectant composed of halogenated tertiary amines that have broad spectrum activity against bacteria, fungi, virus spores, mycobacteria and protozoa. This reagent is DEFRA approved and uses nanotechnology to carry the active ingredients through cell walls for rapid and complete cell death (apoptosis), rather than inhibiting cell activity as with conventional disinfectant products. It is non-hazardous (non-toxic, non-corrosive) and is fully biodegradable. Please see attached document for manufacturers microbiological report describing effectiveness of inactivation. An autolave is also available which will allow heat inactivation of GMOs in the event of an emergency spill. For specific decontamination methodology, see attached risk assessment.

Waste stream - Solids, Solid waste, once inactivated by Trigene disinfection overnight (2% (v/v) for general cleaning, 20% (v/v) for higher risk disinfection), will be double bagged in yellow biohazard bags, sealed and will go into the lab biohazard waste stream. All waste will be collected by an external waste management contractor (PHS Waste Management) for processing off-site. Liquids: Liquid waste, following Trigene inactivation (overnight) will be disposed of down the laboratory drains and flushed with copious amounts of water.

**Project Additional Information**

**Purposes of the contained use**

Knockdown of the indicated genes will be used to confirm phenotypic changes observed via treatment with drug candidate molecules are through molecule engagement.
with the intended protein target.

### Recipient or parental organism

The cell lines to be transformed with the lentiviral vectors will be immortalized human cancer cell lines. These cell lines are able to propagate in mammalian culture conditions but are unable to survive outside of a laboratory setting. The cell lines selected for transformation do not harbour any other viruses and are checked regularly for mycoplasma infection to reduce the risk of any events which may generate replication competent virus.

### Host/vector system

The cell lines will be transformed with a lentiviral vector based on HIV. This vector will be purchased from the reagent supplier Sigma-Aldrich as a product from their mission shRNA line. These virus are prepared in such as way as to be replication incompetent, including biosafety features such as splitting the viral genome over three plasmids during production to minimise the risk of recombination events. Further to this Sigma-Aldrich regulatory QC production for any evidence of recombination/replication competence.

### Origin & function

The genetic material will have originated from Sigma-Aldrich LLC. The genetic material will consist of a lentiviral genome which will be incorporated into a mammalian genome without replication of the lentiviral system. Once incorporated the DNA of lentiviral origin will encode an antibiotic selection marker (such as puromycin or neomycin) to select clones of the transformed cells. The DNA will also encode a shRNA transcript which when expressed will cause knockdown of a targeted gene such as EP300 or CTNS. The shRNA transcript will be under the control of a 3* lac operon, thus in the presence of lactose the shRNA is not expressed, however upon treatment with IPGAL repression of the shRNA is removed and the transcript is freely expressed.

### Evaluation of foreseeable effects

Although the lentiviral vector has the ability to infect humans, and random integration of lentiviral DNA to the human genome may cause cancer, the viral titre to be used in the experiments (10^6 viral particles per vector) is too small to pose a significant risk to the operator.

HIV is a significant human health concern, the viral vectors used in the above project are replication incompetent and have biosafety features built in (see 7: Host/ vector system) and thus would not cause a significant risk to human health.

Lentivirus is easily decontaminated by the use of either alcohol (destroys viral envelope) or Trigene (Destroys viral envelope and inactivates RNA) which are the routine decontamination procedures our labs, thus the risk of residual virus surviving on laboratory surfaces is low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Larger GMOs will not be employed

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The majority of waste will be in liquid form (e.g. spent tissue culture medium, media in microtitre plates), but some solid waste will also be generated (e.g. stripette tips, reagent vials).

**Disinfection Procedure – liquid waste will be fully inactivated by 2% (v:v) Trigene Advance disinfectant used according to the manufacturers recommendations (MediChem International Ltd).**

**Solids:** Solid waste, once inactivated by 2% (v:v) Trigene disinfection overnight will be double bagged in yellow biohazard bags, sealed and will go into the lab solid waste stream. All contaminated plasticware will be immersed in 20% (v:v) Trigene overnight before disposal. Laboratory waste will be collected by an external waste management contractor (PHS Waste Management) for processing off-site. **Liquids:** Liquid waste, following 2% (v:v) Trigene/Chemgene inactivation (overnight), liquid
waste is decanted into 10 litre plastic bottles (labelled ‘Bioscience aqueous Trigene waste’)

Project Ref  3126/18.1

Date Ackn'd 14/12/2018

CU2 Project Title Development of cytopathic effect assays in DF-1 cells for the screening of MVA vaccines.

Class 2
CultureVol Class 2 < 1 Litre
Non-GMM Consent Granted

Withdrawn N
Tick if notifying a connected programme of work N

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Sygnature Discovery intends to perform this work in order to determine the infectivity of vaccine formulations post manufacture and to determine the effect of long term storage on vaccine infectivity. Formulations are expected to have improved infectivity/stability over time compared to current formulations of the vaccine.

The parental organism/GMOs are Modified Vaccinia virus Ankara (MVA) and Sementis Copenhagen Vector (SCV). The recipient will be the DF-1 cell line (chicken embryonic fibroblasts) for the MVA vaccine and ST01 (1438 osteocarcinoma cell line. expressing recombinant D13 from vaccinia virus) for the SCV virus.

The vector system are MVA and SCV, with the host systems as DF-1 (MVA) and ST01 (SCV) cells.

Regarding MVA:
MVA was originally derived from the Chorioallantois Vaccinia virus Ankara (CVA) through serial passage (>570 passages) in chicken embryonic fibroblast (CEF) cells. Due to the high number of passages MVA lost approximately 30 kbp of genetic material, and largely lost its capacity to propagate in mammalian cells. This was done initially to produce a safer alternative to the smallpox vaccine. In 1977 MVA was licensed in Germany, and was administered to over 120000 persons with nominal side effects. Although attenuated, MVA remains able to stimulate the immune system by expressing viral genes. This enables a recombinant MVA expressing genes from a different virus to be used as an effective and safe vaccine. This has been attempted with other diseases such as HIV/AIDS, tuberculosis, malaria, influenza and hepatitis 8.

The MVA to be used here encodes antigens from Makona Ebolavirus. The inserts were created in vitro by gene synthesis and cloned into an expression plasmid before amplification in E. coli. Plasmid DNA was purified and used for recombination with the MVA genome.
MVA will undergo abortive infection in host DF-1 cells, allowing the replication of MVA DNA and expression of the Makona Ebolavirus antigens. Infection in DF-1 cells will enable the quantification of MVA infectivity, enabling the determination of vaccine stability.

Regarding SCV:
SCV was generated by deleting the D13L gene from the Copenhagen strain of vaccinia virus by Sementis. The D13L gene encodes an essential viral assembly protein (D13). Deletion of the D13L gene therefore renders SCV incapable of generating viral progeny in vaccine recipients. As such, SCV undergoes abortive infection when infecting host cells. This gene deletion still enables SCV to infect host cells and preserves genome amplification, allowing expression of antigens to modulate a host immune response. SCV has been previously used to produce a vaccine against chikungunya virus, and was able to immunize mice against chikungunya virus infection. As a modified strain of vaccinia virus, SCV can also act as a vaccine for smallpox. The vaccinia virus has previously been used as a
smallpox vaccine in Denmark and the Netherlands. The SCV to be used here encodes the red fluorescent protein from Discosoma nummiforme (dsRed). The purpose of dsRed expression is to be a marker of virus infection. The inserts were created in vitro by gene synthesis and cloned into an expression plasmid before amplification in E.coli. Plasmid DNA was purified and used for recombination with the SCV genome.

ST01 cells express the D13 protein deleted in SCV. Therefore, infection of ST01 cells with SCV will rescue the replicative capacity of SCV in ST01 cells alone, allowing the assessment and quantification of SCV titer.

Evaluation of foreseeable effects

Regarding MVA:
MVA is considered stable within the environment and has the capacity to infect a broad range of host cells, including human cells. However, in the unlikely event of the genetically modified MVA being unintentionally released there is a low likelihood of infection, as this would be dependent on exposure to mucosal membrane or open wounds. In the event of infection, symptoms of MVA in healthy adults are mild, potentially including a rash or fever. Additionally, the capacity of MVA to replicate is attenuated and any infection would be expected to be rapidly cleared by the host immune response. Expression of the Makonavirus Ebolavirus genes is not anticipated to be harmful, and is intended to elicit a protective immune response. However, the true effects of these antigens are untested in humans.
Evaluation of foreseeable effects includes the intended effect of generating data on the infectivity of the MVA vaccine in DF-1 cells the unintended effect of generating small quantities of biohazardous waste, which will be disposed of appropriately as determined by in-house risk assessments (See section 12).

Regarding SCV:
Vaccinia virus, similarly to MVA, is considered stable within the environment and has a capacity to infect a broad host range, including human cells. However, in the unlikely event of SCV being unintentionally released into the environment, the likelihood of infection is low as SCV requires direct contact with a mucosal membrane or an open wound. If this were to happen, infection of healthy individuals with vaccinia virus may produce mild symptoms including rash or fever. The capacity of SCV to replicate is attenuated due to the deletion of the D13L gene. As a consequence it would be expected that SCV would be quickly removed by the host immune response. However, infection of ST01 cell culture will enable a local replication of SCV, which may increase the likelihood of infection. Expression of dsRed by SCV is not expected to cause harm, as its intention is to act as a marker only. However, the true effect of SCV coupled with dsRed are untested in humans.
Evaluation of foreseeable effects includes the intended effect of generating date on the infectivity of SCV in ST01 cells, and the unintended effect of generating small quantities of biohazardous waste, which will be disposed of appropriately as determined by in-house risk assessments (See section 12).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All operations will be perform by trained personnel within a containment level 2 laboratory. Appropriate signage warning of the biohazard risk will be placed on all doors to the laboratory. All activities involving the vaccine will take place in a Class II microbiological safety cabinet (MSC). All aqueous waste material potentially contaminated with vaccine will be decontaminated with 1 % (v:v) Virkon overnight inside a Class II
MSC before removal into designated Bioscience aqueous waste. Potentially contaminated solid waste (powder, wipes, gloves etc.) is to be deconaminated with 1% (v:v) Virkon and sealed in a clinical waste bin for disposal by an approved waste-handling agent. Potentially contaminated surfaces will be treated 1% (v:v) Virkon, 20% (v:v) Chemgene and 70% (v:v) ethanol before being left to try. Equipment used will similarly be treated with 1% (v:v) Virkon, 20% (v:v) Chemgene and 70% (v:v) ethanol. Before leaving the laboratory all users are to thoroughly wash and dry hands.

The GMO risk assessment has been presented to the genetic modification safety committee. Summary findings: The health and environmental risks associated with the handling of GMOs has been reduced to low, acceptable levels by the use of trained staff, procedural and containment controls and personal protective equipment and as such the committee have endorsed the assessment.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use

Sygnature Discovery intends to perform this work in order to identify novel molecules that block RSV infectivity. Human respiratory syncytial virus (RSV) is an enveloped, nonsegmented, negative-sense, single-stranded RNA virus belonging to the Pneumovirus genus of the subfamily Pneumovirinae, the family Paramyxoviridae. RSV is the most common virus responsible for acute and severe lower airway disease in infants and young children worldwide. Despite the enormous burden of RSV disease, there is no efficacious vaccine or antiviral drug therapy yet available.

Recipient or parental organism

The parental organism/GMOs is the RSV A2 strain. The RSV genome (15.2 kb) contains 10 mRNAs encoding 11 proteins. The nucleocapsid (N) protein binds the negative-strand RNA genome and associates with the phosphoprotein (P), the large (L) polymerase protein, and the M2-1 protein to form the nucleocapsid. The matrix (M) protein is present between the nucleocapsid and the outer envelope and plays a structural role in virion assembly and budding. There are three envelope glycoproteins: the attachment glycoprotein (G), the fusion (F) protein, and the small hydrophobic (SH) protein. The genome also encodes two nonstructural proteins (NS1, NS2) which suppress the interferon response and M2-2 protein (the second product of the M2 gene) which governs the transition from transcription to replication of genomic RNA.

Host/vector system

The Red Fluorescent Protein (RFP) gene was inserted in front of the NS1 gene (as the first gene). Recombinant, RFP-expressing RSV (RSV-RFP1) was generated from the full-length RSV-GFP1 (ViraTree Product# R121) plasmid, by replacing its first GFP gene with the wild-type Discosoma RFP gene from pDsRed plasmid (Clontech cat. no. 632412). To accomplish this, the BstXI restriction site within the RFP gene was disrupted by PCR mutagenesis, and this modified RFP gene was amplified by PCR with primers that added the gene start and NS1 untranslated region preceding the RFP gene and the L gene end following the RFP gene.

Origin & function

The DsRed fluorophore was isolated from the wild-type Discosoma RFP gene. The RFP protein is expressed by the host cell (HEp-2 cells, ATCC® CCL-23™ or A549 cells, ATCC® CCL-185™) upon successful infection by the virus. The fluorescence readout can be used as a measure of RSV infectivity. RSV-RFP will be be propagated in HEp-2 cells and upon release into the supernatant, frozen down into 1 ml aliquots for anti-viral screening assays. The anti-viral assays will be performed in different formats in HEp-2 cells or A549 cells:
- Cytopathic effect assay: readout of RSV-induced cell death as a measure of infectivity using CellTiter-Glo® Luminescent Cell Viability Assay (Promega). Cells and virus are lysed at the end-point.
- RSV RFP expression from the host cell as a measure of infectivity: infected cells are fixed using 4% paraformaldehyde.
- Plaque assay to determine RSV titer: quantifying RSV-induced plaque formation in cells at different dilutions. Cells and virus are fixed using 10% formaldehyde.
- Plaque assay for anti-viral screening: quantifying RSV-induced plaque formation in cells after 10% formaldehyde fixation.
The insertion of the RFP gene has little or no effect on RSV-A2 host infectivity, and according to the manufacturer, the recovered virus replicates to near-parental RSV-A2 titers.

RSV PATHOGENICITY/TOXICITY: RSV primarily infects human epithelial cells within the nasopharynx; however, it can also infect other types of cells, including cell lines, but with much lower efficacy. Infection may lead to the formation of syncytia within the infected cell. Primary infection with RSV is generally exhibited as lower respiratory tract disease, pneumonia, bronchiolitis, tracheobronchitis, or upper respiratory tract illness. Common clinical symptoms include rhinorrhea, sneezing, cough, pharyngitis, bronchitis, headache, fatigue, and fever. In some cases, otitis media may occur. RSV infections usually begin with upper respiratory tract disease, which has the tendency to progress to lower respiratory tract disease (in ~50% cases). Severe infection (involving pneumonia) may develop among elderly patients with underlying respiratory conditions. Children and immunocompromised individuals are more susceptible to developing severe disease.

RSV EPIDEMIOLOGY: RSV occurs worldwide and is the most common cause of bronchiolitis and pneumonia among infants and young children. Within USA, 100,000 hospitalizations and 4,500 deaths annually are attributed to RSV infections. RSV is also a major cause of nosocomial infections. Morbidity and mortality is highest among children with underlying illness and individuals with immunodeficiency or immunosuppression. Virtually all children are infected by age 2 to 3. Repeated infections are common, particularly in young children with up to 5 or 6 infections per year. Although all individuals can be infected with RSV, those at high risk include premature infants, young children, elderly, immunocompromised, and children under age 2 with chronic lung conditions. Other factors that may predispose to RSV infection include: crowding (schools and day care centers), exposure to tobacco and smoke, low socioeconomic status, and family history of atopy and asthma. Infection among healthy and immunocompetent individuals tends to be less severe. RSV follows a seasonal pattern. Annual outbreaks occur during fall, winter, and early spring among urban centers. In the Northern hemisphere, epidemics peak in February and March, and may last up to 5 months. In tropical and subtropical regions, most outbreaks occur during the rainy season. RSV outbreaks involving lower respiratory illness have been reported in nursing homes and institutions.

HOST RANGE: Humans; however, various animal species can be experimentally infected with RSV including cotton rats, mice, ferrets, guinea pigs, hamsters, marmosets, lambs, and nonhuman primates.

INFECTIOUS DOSE: The infectious dose for RSV is > 160 - 640 viral units, administered through intranasal spray, as listed by the National Institutes of Health.

MODE OF TRANSMISSION: RSV is most likely transmitted through direct contact with infectious secretions (via fomites) and/or large-particle aerosols; however, close contact with infected individuals, or significant exposure of nasal or conjunctival mucosa with contaminated hands is required for transmission. Transmission via small-particle aerosols is less likely.

INCUBATION PERIOD: Incubation period for RSV infection ranges from 2 to 8 days.

COMMUNICABILITY: Communicable during the period of active disease. The disease is likely not readily transmitted from person-to-person, since significant and prolonged contact is required with infected individuals. Children are known to shed virus for long periods (up to weeks) even after clinical recovery.

DRUG SUSCEPTIBILITY: RSV has been shown to be susceptible to ribavirin, which has been used to treat severe RSV infections; however, recent studies suggest that its use produces no significant benefit.

SUSCEPTIBILITY TO DISINFECTANTS: RSV has been shown to be susceptible to ether, chloroform, and a variety of detergents, including 0.1% sodium deoxycholate, sodium dodecyl sulphate, and Triton X100. It may also be sensitive to hypochlorites (1% sodium hypochlorite), formaldehyde (18.5 g/L; 5% formalin in water), 2% glutaraldehyde, and iodophores (1% iodine). The broad spectrum disinfectant Rely+On Virkon is reported by the manufacturer to be effective against RSV.

PHYSICAL INACTIVATION: RSV is sensitive to heating above 55°C for 5 minutes (up to 90% decrease in infectivity). It is also sensitive to freezing and thawing (~90% loss in infectivity following each freeze-thaw cycle). It is also sensitive to acidic media (pH<7).
SURVIVAL OUTSIDE HOST: RSV is generally very vulnerable to environmental changes, particularly temperature and humidity. It is sensitive to high and low temperature, and to drying; i.e., low humidity levels. It loses up to 90% infectivity at room temperature after 48 hours and up to 99% at 1°C after 7 days. The optimal pH is 7.5. It may survive for about 3 to 30 hours on nonporous surfaces at room temperature.

SURVEILLANCE: Monitor for symptoms. Other than monitoring for symptoms, there are four main techniques for diagnosing RSV, including virus cultures, serology, immunofluorescence and/or antigen detection, and nucleic acid based tests. Being labor-intensive and time consuming, the first two techniques are rarely employed for diagnostic purposes in epidemiological studies. Rapid diagnostic techniques for viral antigen detection, including immunofluorescent-antibody assay, optical immunoassay, enzyme immunoassay, and chromatographic immunoassay are preferred. Most are commercially available, easy to perform and produce rapid results. Nucleic acid tests (such as RT-PCR) are generally more sensitive.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All operations will be performed by trained personnel within a containment level 2 laboratory. Appropriate signage warning of the biohazard risk will be placed on all doors to the laboratory.

All activities involving RSV will take place in a Class II microbiological safety cabinet (MSC).

All aqueous waste material potentially contaminated with RSV will be decontaminated with 1% (v:v) Rely+On Virkon overnight inside a Class II MSC before disposal into a liquid waste container within the containment level 2 suite. Before final disposal, the liquid waste container will be placed inside a 30 litre clinical sealed unit waste bin.

Potentially contaminated solid waste (wipes, gloves etc.) will be decontaminated with 1% (v:v) Rely+On Virkon and sealed in a 50 litre clinical sealed unit waste bin.

Both liquid and solid waste will be packaged as clinical waste in their respective sealed unit waste bins, collected and incinerated by an approved waste contractor.

Potentially contaminated surfaces will be treated 1% (v:v) Rely+On Virkon, 20% (v:v) Chemgene and 70% (v:v) ethanol before being left to try. Equipment used will similarly be treated with 1% (v:v) Virkon, 20% (v:v) Chemgene and 70% (v:v) ethanol. Before leaving the laboratory all users will thoroughly wash and dry hands.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All operations will be performed by trained personnel within a containment level 2 laboratory. Appropriate signage warning of the biohazard risk will be placed on all doors to the laboratory.

Historical Significant Changes
Selected reporter genes will be introduced in the human NK cell line NK92 and the resulting cell lines will be cultured for use in various in vitro cell signalling assays to research candidate molecules’ activity against selected cellular targets. Reporter genes can include CD16-EGFP (Enhanced Green Fluorescent protein), destabilised luciferase gene and other fluorescent reporter genes under the control of CARE.

The parental NK-like cell line NK-92 was discovered in the blood of a Male 50YO subject suffering from a non-Hodgkins lymphoma. NK-92 is a NK-like cell line that was initially isolated from the blood of a Subject suffering from a large granular lymphoma and subsequently propagated in cell culture. The NK-92 cell line has been described (Gong et al., 1994; Klingemann, 2002). NK-92 cells have a CD3-/CD56+ phenotype that is characteristic of NK cells. They express all of the known NK cell-activating receptors except CD16, but lack all of the known NK cell inhibitory receptors except NKG2A1/CD94 and IL T2/L1R1, which are expressed at low levels. Furthermore, NK-92 is a clonal cell line that, unlike the polyclonal NK cells isolated from blood, expresses these receptors in a consistent manner with respect to both type and cell surface concentration. Similarly, NK-92 cells are not immunogenic and do not elicit an immune rejection response.

CD16 was introduced into NK-92 cells by means of retroviral transduction in the following manner. Complementary DNA encoding the gene for either the low or high affinity form of CD16 was sub-cloned into a bi-cistronic retroviral expression vector, pBMN-IRES-EGFP (obtained from G. Nolan, Stanford University, Stanford, Calif.) using the BamHI and Not restriction sites in accordance with standard methods (e.g., (Ausubel, 2002; Sambrook and Russell, 2001)). This expression vector was then transfected into the Phoenix-Amphotropic retroviral packaging cell line and the resulting virus-containing supernate was used to transduce NK-92 cell ls. Transduced NK-92 cells expressing CD16 on their surface (NK-92-CD16, also known as CD16/FcεRIy-NK-92) were separated from the residual non-transduced NK-92 cells using a fluorescence activated cell sorter (FACS). When appropriate to the intended use, the NK-92-CD16 cells were further sub-sorted on the basis of CD16 expression level using a FACS, based upon coordinate expression of Enhanced Green Fluorescent Protein (EGFP). The resulting NK-92 CD16 cells stably express CD16 in cell culture without the need for periodic antibiotic selection.

Characterization of the parental NK-92 cell line (Gong et al., 1994; Van et al., 1998) revealed that NK-92 cells are cytotoxic to a significantly broader spectrum of tumour and infected cell types than NK cells, and further that they often exhibit higher levels of cytotoxicity toward these targets. NK-92 cells do not, however, attack normal cells nor do they elicit an immune rejection response.
Since the NK-92 cell line was isolated from a large granular lymphoma subject, the cells have the potential to establish tumors in recipient Subjects. However, no evidence of tumorigenicity has been reported so far. Hazards include: percutaneous injury, ingestion, mucous membrane exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All operations will be performed by trained personnel within a containment level 2 laboratory. Appropriate signage warning of the biohazard risk will be placed on all doors to the laboratory.

All activities will take place in a Class II microbiological safety cabinet (MSC).

Cells will be manipulated in a Class II cabinet - manipulations outside of the cabinet should be avoided.

Users will change gloves regularly to minimise risks of any breach of containment Any contaminated gloves must be disposed of via the clinical waste route

Centrifugation will be performed with the cells contained in screw capped tubes or sealed plates to prevent spillages and aerosol formation. Centrifuge caps will be employed for all centrifugations to provide double containment Pipette boys & multichannel pipettes will be decontaminated with 2% (v:v) Chemgene, followed by 70% (v:v) ethanol before removal from the cabinet.

All aqueous waste material potentially contaminated with RSV will be decontaminated with 2% (v:v) Chemgene overnight inside a Class II MSC before disposal into a liquid waste container within the containment level 2 suite. Before final disposal, the liquid waste container will be placed inside a 30 litre clinical sealed unit waste bin.

Potentially contaminated solid waste (wipes, gloves etc.) will be decontaminated with 2% (v:v) Chemgene and sealed in a 50 litre clinical sealed unit waste bin.

Both liquid and solid waste will be packaged as clinical waste in their respective sealed unit waste bins, collected and incinerated by an approved waste contractor.

Potentially contaminated surfaces will be treated with 2% (v:v) Chemgene and 70% (v:v) ethanol before being left to dry. Equipment used will similarly be treated with 2% (v:v) Chemgene and 70% (v:v) ethanol. Before leaving the laboratory all users will thoroughly wash and dry hands.

#### Project Ref 3126/21.2

- **Date Ackn’d**: 25/08/2021
- **CU2 Project Title**: Class 2 genetic modification of eukaryotic cells using viral vectors
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Project notified under transitional arrangements**: N

#### Purposes of the contained use

This contained use notification covers a range of activities utilising lentiviral, retroviral and adenoviral vectors to genetically modify cells of human or animal origin. The genetic modification in question may include, but is not limited to: expression of known and putative oncogenes, growth factors and other proteins, with or without tags to
facilitate identification and/or purification. Modification of expression levels of endogenous proteins using methods such as shRNA or CRISPR-Cas9. Transformation and/or immortalisation of non-cancerous cells. Induction of pluripotency in cells. Use of packaging cells to generate replication-incompetent viral particles for research.

Recipient or parental organism

Lentiviral, retroviral and adenoviral vectors based on a range of human and animal viruses, such as HIV, EIAV, MMLV, AAV, MMTV and MSCV. To ensure safety of users and public, all viral vectors will be generated using a split-vector system of second generation design or later. Resulting viral particles will be demonstrably incapable of replication outside of a compatible packaging cell line and will be incapable of dissemination in the environment. Vectors may be modified to have wider tropisms through expression of ecotropic and amphotropic envelope proteins, including VSV-G, and may include either wild-type or mutated forms of the Woodchuck Hepatitis Virus Post-transcriptional Response Element (WPRE).

Host/vector system

All viral vectors will be produced using a split-vector system, where components of the viral genome are separated on different plasmids to preclude viral replication outside of their packaging cell lines. Packing cell lines such as HEK293 (or other validated packing cell lines) will be transfected with the relevant packaging plasmids and the vector carrying the genetic cassette of interest. Viral particles will be harvested from the culture medium of the packaging cell line and used to transduce human or animal cells not exceeding Hazard Group 2. Example cell lines include cancer cell lines derived from human tissue, primary human cells, mouse embryonic fibroblasts, among others.

Origin & function

Genetic material in question will be from a wide variety of origins and have a range of functions, some unknown. Example genes include hTERT for immortalisation of primary cells. p53DD for transformation of primary cells. Activated oncogenes for study of oncogenesis. Introduction of genes involved in metabolism, cell cycle regulation, or other functions, to elucidate disease mechanisms. These genes may be fused with tags and proteins such as GFP or luciferase to aid in detection and analysis. CRISPR-Cas9 may be introduced into cells to facilitate manipulation of gene expression, or insertion of identifying tags into the genome. Similarly shRNA constructs may be introduced to modulate expression of endogenous genes. Genetic material known to encode toxins or pathogenic factors which could enable infection or dissemination, is explicitly excluded from this notification.

Evaluation of foreseeable effects

All vector systems in this contained use will use split-packaging to eliminate the possibility of self-replication or dissemination into the environment. Gag, pol, env and rev genes are provided in trans (either on separate plasmids or expressed in the packaging cell lines), meaning that viral particles generated using these systems are not capable of producing new virus themselves. No credible evidence exists of replication competent virus arising from third-generation systems. From this information the risk of these viruses creating systemic disease in an individual, or disseminating amongst a population, are considered negligible.

Insertional mutagenesis resulting in cell transformation is a highly unlikely, but theoretically possible outcome of self-inoculation with these viruses. Contemporary viral vectors incorporate self-inactivating motifs to prevent activation of genes proximal to the insertion site, by removing enhancer and promoter sequences from long terminal repeats (LTRs). However, inactivation of tumor suppressor genes by insertion is a remote possibility. Special consideration will be given to viruses carrying known oncogenes, or cassettes (shRNA, CRISPR-Cas9 etc) which disrupt endogenous expression of tumour suppressor genes.

Viral titre during transduction is unlikely to exceed \(10^{E+7}\) particles / ml. Cells will be transduced sequentially with each plasmid. These factors together mean that even in the event of self-inoculation, it is highly improbable that the correct combination of genetic events would occur to induce a cancerous cell.

All work described in this notification will be subject to local risk assessment and appropriate remediations put in place. These will include, but are not limited to; elimination of sharps in cell culture experiments, adherence to Containment Level 2 procedures, provision of sleeve-covers, isolation of experiments using virus from non-virus activities in the lab, visual indicators that viral activities are being carried out on relevant communal equipment and lab areas.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This notification only applies to cells. Whole organisms are not covered.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The majority of waste will be in liquid form. A small amount of solid waste will also be generated (e.g. stripette tips, reagent vials). Our procedures for both sites is detailed below.

Nottingham BioCity procedures:
Liquid waste: All liquid waste will be decontaminated with 20% chemgene. Chemgene inactivates a broad spectrum of viruses, including those listed here. Following this, waste will be decanted into 20 litre bottles (labelled bioscience aqueous waste, with biohazard symbol) and when full this can be decanted into the chemistry non-halogenated (non-chlorinated) waste stream for disposal by an approved contractor (Stericycle).
Solid waste: Solid waste will be soaked in 20% v/v Chemgene overnight. After soaking, liquid waste will be transferred to the liquid waste stream (see above). Solid waste will be disposed of in 24L or 60L sharps bins labelled biohazard and disposed of by an approved contractor (Stericycle).

Alderley Park Procedures:
Liquid waste: All liquid waste will be decontaminated with 1% w/v Virkon. Virkon inactivates a broad spectrum of viruses, including those listed here. Following decontamination, liquid waste will be disposed of down the sink with copious amounts of water.
Solid waste: Solid waste will be soaked in 1% w/v Virkon overnight. After soaking, liquid waste will be disposed of down the sink with copious amounts of water. Solid waste will be disposed of in 24L or 60L sharps bins labelled biohazard and disposed of by an approved contractor (Stericycle).

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Extensive discussion was conducted with the Bioscience Safety Health and Environment (SHE) team, which has responsibility for reviewing risk assessments in the department. This includes work involving genetic modification, with the SHE team constituting our Genetic Modification Safety Committee (GMSC). Our team has considerable expertise in the biology and handling of viral vectors and transduced cell lines. It was decided unanimously that these activities should be assigned contained use Class 2.

02/03/2022
All waste generated to GMMs is to be disposed of by incineration by a licenced contactor. Before leaving the laboratory itself, the waste will be disinfected using a Rodwell Monach 50 autoclave. Samples will be heated for 15 minutes at 121°C under pressure with steam. The temperature profile within the autoclave will be monitored by the integral data logging system, which takes readings of the vessel temperature and load temperature by means of a probe. If larger volumes of liquid are to be sterilised, a matched volume of water in an identical container will be used for monitoring the temperature of the load. Confirmation that the correct temperature has been reached will be obtained firstly using the confirmation display of the autoclave. To provide a backup to this message, temperature sensitive indicator strips (Browne TST or similar), and temperature sensitive autoclave tape (3M or similar), will be used. Only when positive confirmation has been supplied by both the autoclave and by temperature sensitive indicators will the load be considered safe to leave the laboratory. Periodically the activity of temperature indicators will be tested using a biological indicator (Attest, 3M, or similar).

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Overall the risk assessment covers the necessary procedures well. Include the use of a biological indicator periodically to ensure that the effectiveness of the multiple overlapping sterilisation measures is confirmed.

**Purposes of the contained use**

To prevent release of genetic material coding for antibiotic resistance genes and fluorescent proteins into the environment

**Recipient or parental organism**

Streptococcus mutans UA159

**Host/vector system**

pDM15

**Origin & function**

The plasmid pDM15 (Deng et al. 2009), is to be used to constitutively produce protein fluorophores such as GFP to allow visualisation of bacteria by microscopy. pDM15 is a derivative of pVA838, a non-mobilisable Escherichia coli-Streptococcus shuttle vector. The genetic material carried by this plasmid is the gene coding for green fluorescent protein from Aequoria victoria. In addition, the vector is to be used for carrying derivatives of the fluorescent protein dsRed from Discosoma sp.

**Evaluation of foreseeable effects**

The encoded genes within the pDM15 vector encode non-toxic fluorescent proteins which would have no selective benefit in human, animal or plant pathogens. It is not foreseeable that these carry any risk to the wider environment. The vectors are non-mobilisable, reducing the likelihood of the spread of genetic material from the plasmid. The vectors encode antibiotic resistance genes for erythromycin and cloramphenicol, which have both been in use for a significant amount of time, meaning resistance is likely to be widespread and easily acquired. Release of these sequences should however be minimised at all times so as to reduce the prevalence of these determinants in the environment. The plasmids have previously been found to be lost after a short time without antibiotic selection (Macrina et al. 1982), and as such would be expected to be poorly maintained in the environment if accidentally released. Streptococcus mutans UA159 is a category 2 microorganism, and causes disease in the mouth only through production of organic acids from sugar provided in the diet. It is not known to have specialist virulence determinants such as secreted toxins.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste generated related to GMMs is to be disposed of by incineration by a licensed contractor. Before leaving the laboratory itself, the waste will be disinfected using a Rodwell Monarch 50 autoclave. Samples will be heated for 15 minutes at 121°C under pressure with steam. The temperature profile within the autoclave will be monitored.
by the integral data logging system, which takes readings of the vessel temperature and load temperature by means of a probe. If larger volumes of liquid are to be sterilised, a matched volume of water in an identical container will be used for monitoring the temperature of the load. Confirmation that the correct temperature has been reached will be obtained firstly using the confirmation display of the autoclave. To provide a backup to this message, temperature sensitive indicator strips (Browne TST or similar), or temperature sensitive autoclave tape (3M or similar), will be used. Only when positive confirmation has been supplied by both the autoclave and by temperature sensitive indicators will the load be considered safe to leave the laboratory. Periodically the ativity of temperature indicators will be tested using a biological indicator (Attest, 3M, or similar).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Overall the risk assessment covers the necessary procedures well. Include the use of biological indicator periodically to ensure that the effectiveness of the multiple overlapping sterilisation measures is confirmed.

Give brief details of the genetic modification safety committee

IMSL's Genetic Modification Safety has three (total number of employees is currently four) and comprises the laboratory Manager (convenor), Chief Operations Officer (member) and chief Scientific Officer (member). The committee meets quarterly, or more frequently as needed. The committee members also communicate regularly by email and face to face discussions.

| Scientist (1) |
| Scientist (2) |
| Quality/Lay member |

The Genetic Modification Safety Committee (GMSC) will consist of at least four members to be quorate and must include an EHS representative and the BSO. Where it is not possible for all designated persons to attend a committee meeting, comments should be provided in advance of the meeting on any documents under review or an appropriate deputy appointed. A deputy will be selected on the basis of their experience; however the proposers of the activity under discussion will be excluded from consideration. Invites will also be extended to risk assessment authors and/or area Responsible Persons as appropriate. The frequency of meeting will be biannual at minimum, with committee meetings arranged as and when is necessary to ensure that risk assessment are reviewed within a timely manner. The role of Chairperson and Secretary will be assigned to the aforementioned members as appropriate and meeting minutes will be kept. The remit of the committee is to advise management on the adequacy of GMO risk assessments, to provide a beneficial influence on ensuring good practice on safety, training and laboratory discipline for the GMOs, to help with the formation of local GMO rules, to review risk assessments at least every two years and to review any accidents and near misses involving GMOs.

Give brief details of the genetic modification safety committee

Cangenix will utilise the existing biology safety committee in place in the Biosciences department at the University of Kent at Canterbury, currently consisting of the BSO, a representative of the academic staff and a post-doctoral researcher. Meetings of the committee are held on an ad hoc basis several times during the year. It is envisaged that a Cangenix representative will be present at all appropriate meetings of the committee.
To minimise the risk of escape of GMOs to the environment, all contaminated waste streams generated during the course of the work will be decontaminated within the laboratory within the laboratory buildings. Cultures will be grown within leak proof vessels. Fermenters be set up in such a way that accidental spillage will be contained. Solid and liquid waste will be autoclaved within the laboratory block prior to incineration. Autoclaves are maintained and tested as part of the wider university safety policies. All laboratory work surfaces will be regularly cleaned using Virkon disinfectant. Spillages will be treated with Virkon and any associated waste (paper towels, etc) will be treated as per solid waste streams. No live GMOs will be present at the end of the decontamination procedures.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

There were no comments made by the Biology Safety Officer with respect to the assessments. All such assessments had previously been approved by the full GM Safety Committee at Pfizer in Sandwich where the work was previously undertaken.

Project Ref 3130/19.1

Date Ackn'd CU2 Project Title
09/01/2019 Purification of recombinant human myosin protein from adenovirus-infected murine

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 1-50 Litres

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Generation of human recombinant myosin protein for structural biological studies. Cell pellet derived from this process will be supplied to Charles River Discovery Services at Sandwich from an external client. No expression work will be undertaken at the Sandwich location, only the recombinant myosin protein purification which is the purpose of this notification.

**Recipient or parental organism**

The GMO in question will be the adenovirus vector used for gene delivery into mouse myoblasts for the purposes of over-expression of myosin protein.

**Host/vector system**

Commercial adenovirus gene delivery system (pAdEasy) from Qbiogene.

**Origin & function**

Gene encoding human myosin IIa protein. This is a cytoskeletal protein widely expressed in human muscles.

**Evaluation of foreseeable effects**

There is the potential for residual infectious/non-replicative adenoviruses to be present in the cells that will be provided. Whilst these viruses are nonreplicative, they can technically still be infectious to human cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Any liquid waste derived from lysis of the cell pellets will be treated with Virkon disinfectant (2%) or bleach (10%) for a minimum of 2 hours before disposal to drainage. Glassware will similarly be treated with Virkon disinfectant (2%) before washing. Any solid waste will be kept to a minimum and autoclaved within the laboratory where the work is being conducted before disposal into site waste streams. 1% Virkon has been determined to be 100% effective against similar viruses in external manufacturer's testing.

Is an emergency plan required according to regulation 20?

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

A four member GM safety committee led by a chair has been established to advise on risk assessments of contained use of genetic modification research activities.

Members of the committee are experienced researchers who have previously led active research programmes and supervised and trained research students and staff and have widely published in biological and biomedical areas using microbiological and mammalian cell culture systems. Members of the committee have experience in research at Class I and Class II levels and also in compliance of HSE and Defra regulations.

The committee meets periodically at one to three month intervals as per the requirements of the departmental activities. GM safety committee members also sit on the Departmental H & S committee and the Chair of the GM committee also sits on the University H & S committee. These arrangements ensure coordination of the general H & S and COSHH/GM safety requirements.

Minutes of the committee proceedings approved by members are available on BREO, the University electronic resources system accessed by staff and students, based on appropriate levels of access set.

GM safety committee approved form for Risk Assessment of Work with Genetically Modified Organisms with relevant guidelines as well as appropriate HSE guidelines documents are available to academics and members of the research groups via BREO.

02/03/2022
Liquid waste will be decontaminated by disinfecting with 1% Virkon overnight. Waste will then be disposed of down the sink with running water.

Glassware will be decontaminated by disinfecting with 1% Virkon overnight. Glassware will then be rinsed thoroughly with water, washed in the glass washer and autoclaved.

Solid waste will be placed into clear waste bags which will be tied and autoclaved on site, prior to disposal in yellow waste bags for incineration.

Virkon treatment and autoclaving are both routine methods of inactivating biological material with very high efficacy, and these methods have been standardly used in most laboratories for many years and are in accordance with the waste management policy document on the Division's BREO site.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The GM safety committee reviewed the GM-Risk assessment forms completed by the academics for each of the project areas described in the attached document.

For each project, forms including the description of 1) research and methodology; 2) donor, vector and host and their characteristics; 3) characteristics of any GMO produced including any protein expression, effects and risk to human health, quantity of organism used; 4) containment conditions and level including use of PPE, disinfection, inactivation, transport and storage; 5) monitoring of containment and control methods and 6) Table of control measures and containment levels were scrutinised by the members individually ahead of the committee meetings and collectively during the committee meetings.

Any clarifications and amendments required were communicated to individual academics and the revised forms were scrutinised by the committee, as above.

Following the amendments, it was confirmed by the UoB-DoS-GM safety committee that all approved submissions included in the current CU1 are deemed appropriate for Class 1/CU1 classification.

Purposes of the contained use

E.coli strains will be used to amplify cDNA vectors and plasmid constructs. This will be achieved by heat shock and overnight culture, selection of colonies and their subsequent amplification. Glycerol stocks will be kept at -80oC. cDNA vectors and constructs will be transfected and amplified in this way. This includes all cDNA described below. Escherichia coli will also be transformed with cDNA plasmids to express recombinant fusion proteins. Typically these will be glutathione S-transferase (GST) fusions and a commercial pGex2T vector used (GE Healthcare). Finally, Escherichia coli will be used to propagate lentiviral plasmids, each plasmid will be generated separately and no single plasmid will carry sufficient genetic information to produce a complete lentiviral particle.
Mammalian cell lines will be produced that express recombinant protein or have specific gene expression attenuated using silencing shRNA. Again a wide variety of mammalian cell lines (typically) will be used. This will be achieved in several ways that allow direct introduction of cDNA plasmids or oligos. For this purpose inorganic (calcium phosphate), physical (electroporation) and lipid based approaches (Lipofectamine Invitrogen) will be used. cDNA of interest will be sub-cloned into mammalian expression vectors that include pcDNA3.1 and pEGFP. Mammalian cells will be used to generate lentiviral particles that will be used to introduce shRNA for the purpose of gene silencing. The use of such packaging cells confers additional biosafety by reducing the possibility of a recombination event that may generate lentiviral particles capable of self replication.

Recipient or parental organism

| Disabled E.coli strains | XL1- Blue, DH5a, DH5aT1R, STBL-3, BL21, JM109 |
| Mammalian cells including Murine: Swiss 3T3, NIH3T3, WT-M8+13 & Human: A wide variety of cell lines that include A431, Human embryonic kidney (HEK293), HMT3522, HeLa, ABB/13 |

Host/vector system

| pBluescript family to allow amplification and sub-cloning of cDNA sequences |
| pGex family and others to express recombinant proteins in bacteria |
| pcDNA, TOPo, pMT2, pEGFP and others to express recombinant proteins in mammalian cells |
| Lentivirus plasmid vector, pLKO.1-puro5 or TRC2- pLKO-puro for transduction of shRNA sequences into mammalian cells. |

Origin & function

Gene sequences used are primarily mammalian – human or mouse but possibly zebrafish.
Platelet derived growth factor receptor (PDGFR), epidermal growth factor receptor (EGFR), hepatocyte growth factor receptor, (MET), GM-CSF receptor (FMS), Insulin receptor, Adaptors and Scaffold proteins: p85, nck, grb-2 , Linker of activated T-cells (LAT), intersectin
Phospholipases and kinases: Phosphoinositide 3-kinase enzymes p110a, p110b, p110d, p110g, PI3K-C2a, PI3K-C2b, PI3K-C2g and vps34, Phospholipase A2; Phospholipase C; Phospholipase D
Non-receptor tyrosine kinases: Src, Fyn, ZAP70
It is important to stress that although oncogenic forms of some proteins above exist (ie. src, PDGFR, EGFR), the cDNAs we will use do not encode oncogenes and the products are non-toxic.
Protein expression in E.coli is typically at a 1- 20 mg / l level under a T7 / lac promotor. All cloned inserts are intron-free to allow expression in a prokaryotic system and have ampicillin resistance to allow for selection. Mammalian expression vectors primarily employ the CMV promoter for the expression of recombinant protein. Puromycin, kanamycin, or hygromycin resistance genes are the selectable markers typically used in mammalian expression vectors.
Lentiviral expression vectors primarily employ the U6 or Human phosphoglycerate kinase eukaryotic promoter (TRC2 only) and have puromycin and ampicillin resistance genes to allow selection. Lentiviral work will be used for downregulation of gene expression in host cells.

Evaluation of foreseeable effects

The highest containment level required for this risk assessment is level 2, which corresponds to class 2 GMO to cover the lentiviral work. The host systems used are either non-pathogenic or disabled, and host systems have been routinely used in containment 1 / 2 laboratories safely for many years. The bacterial strains to be used are mobilisation-deficient (Mob-) and recombination deficient. Protein sequences are non-toxic. The generation of separate lentiviral DNA plasmids at different times (envelope vector, shRNA transfer vector and the packaging vector) in E.coli minimises the risk of recombination events. Modification of mammalian host systems with shRNA does have the potential to increase the hazard level. However, recombinant lentiviruses produced with the MISSION
third generation lentiviral system have been shown to produce replication incompetent viral particles because of the designed safety features:
The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping. The shRNA transfer vector, which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging. The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus. The resulting particles are replication-incompetent and deletion in the U3 portion of the 3’ LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for shRNA packaging. These features combined have improved biosafety and handling. There are no known incidents of third generation systems producing infectious, replication competent virus, but replication competency will be monitored (see below). NIH guidelines recommend replication-incompetent lentiviral particles be handled as Risk Group-Level 2 (RGL2). A packaging cell (HEK293) will be used to generate the lentiviral particles, the cells will be destroyed (see disinfection and inactivation) within 72 hours as an additional containment measure. All work will be carried out in a restricted access area using a designated class II laminar flow hood. Routine monitoring will be conducted to ensure that the viral vector remains replication incompetent. This will be achieved using PCR to detect the presence of deleted sequences in transduced target cells.

Work with lentivirus will not be permitted without prior training by the Principal Investigator who will supervise work (or their designated technical expert). The worker should demonstrate good microbiological and tissue culture technique and an understanding of this risk assessment prior to being permitted to work with lentivirus. Risk assessments will be provided for all areas of work.

The only procedure involved in these experiments that might produce aerosols is the centrifugation of cells, where a spillage may result in aerosols. Sealed tubes/containers holding up to 50ml of resuspended transfected mammalian cell lines or 250ml E.coli cultures will be centrifuged in sealed buckets to contain aerosols. If a spillage should occur in the centrifuge, we will allow time for aerosols to settle, and then buckets will be opened in a class II hood (transfected mammalian cells) or a microbiological class II hood (E.coli cultures). Spillage will be absorbed with tissues and placed in clear waste bags for autoclaving prior to incineration. Rotor and buckets will be removed and washed with 3% Virkon/ 10% bleach (in the appropriate Class II hood), and then rinsed clean with distilled water and allowed to dry. Inside of the centrifuge will be wiped with tissues soaked in 3% Virkon or 10% bleach, and then sprayed with 70% ethanol and wiped dry. Laboratory coats and nitrile gloves will be worn for all work. The following PPE will be worn when working with lentiviral vectors: gloves; lab coat. A surgical mask and eye protection (goggles) or face shield will be worn any time that there is a risk of a ‘splash’ of lentiviral particles to the face (such as clearing up a spillage).

E. coli has the potential to be a gastrointestinal pathogen, and although the strains we are using are non pathogenic, good microbiological practice and good occupational hygiene will be observed at all times. A single Class 2 microbiological hood will be designated for GMO work to minimise the risk of creating pathogenic strains by cross contamination. Additionally, propagation of separate lentiviral DNA plasmids (envelope vector, shRNA transfer vector and the packaging vector) in E.coli minimises the risk of a recombinant event.

Transfected mammalian cells may be viable if ingested or taken through broken skin. shRNA has the potential to inhibit expression of a tumourogenic regulator, however this risk is deemed to be very low. To minimise risks, eating or drinking is strictly prohibited in all laboratory spaces. PPE; wearing gloves and a labcoat, while working with GMOs should prevent any direct contact of the GMO with the workers skin, greatly reducing the risk of GMOs entering the worker via broken skin. The use of a surgical mask and eye protection (goggles) or face shield (if there is a risk of a ‘splash’ to the face, such as clearing up a spillage), will reduce the risk of inhalation, or contact with mucosal membranes. All work will be carried out in a restricted access area using a designated class II cabinet. Sharps will not be used.

The lentival system is an HIV based plasmid and is used because of its efficacy at infecting mammalian cells, giving it the potential to infect the worker through broken skin, aerosols or ingestion. To minimise this risk, we will use a third generation lentiviral system which has been developed with enhanced safety features: The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping. The shRNA transfer vector, which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging. The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus. The resulting particles are replication-incompetent and a deletion in the U3 portion of the 3’ LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for shRNA packaging. These features combined have improved biosafety and handling. There are no known incidents of third generation systems producing infectious, replication competent virus, but, replication

The GM safety committee reviewed the GM-Risk assessment form completed by the academic responsible for the project area described.

Description of 1) research and methodology; 2) donor, vector and host and their characteristics; 3) characteristics of any GMO produced including any protein expression, effects and risk to human health, quantity of organism used; 4) containment conditions and level including use of PPE, disinfection, inactivation, transport and storage; 5) monitoring of containment and control methods and 6) Table of control measures and containment levels were scrutinised by the members individually ahead of the committee meetings and collectively during the committee meetings.

Any clarifications and amendments required were communicated to the concerned academic and the revised form was scrutinised by the committee, as above.

Following the amendments, it was confirmed by the UoB-DLS-GM safety committee that the approved submission included in the current CU2 is deemed appropriate for Class 2/CU2 classification.

Before taking receipt of any GMO product, the Genetically Modified Safety Committee at Biotec will identify a suitable chemical disinfectant for inactivating the GMO and the exposure time to the disinfectant required for inactivation. Biotec will be handling primary packed GMOs and the only time in which waste management methods will be employed is if a GMO's primary packaging is damaged. At this point, Biotec's Standard Operating Spill Procedure will be activated. Spilled material will be covered and contained with absorbent pads from a SPC Spillage Kit; the selected disinfectant will be applied to the spillage area. The spillage area will be in contact with the disinfectant for a predetermined time, and then all items associated with the spill will be placed into a biohazard bag. The biohazard bag will be labelled with the date of spill, GMO, number of damaged items, cause of breakage, and names of persons involved in cleaning the spill. The biohazard bag will be placed in a designated location ready for destruction and the spillage clearance record will be completed and handed to the Biological Safety Officer for review. The Biohazard bag will be sent for incineration; incineration will be undertaken by a company licensed to handle GMOs.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

The only risk of exposure to material would be if there is an accidental spill because no primary manufacturing takes place on Biotec's premises. The type of illness caused by exposure will be described in each GMO's risk assessment. Generally, Containment Level 2 GMOs could cause human disease but this is unlikely and treatment is available.

**Project Additional Information**

**Purposes of the contained use**

Long term storage of virus at -80 degrees.

**Recipient or parental organism**

ORCA-1010 is a CRAd (serotype 5) vector containing a distinct mutation in the adenoviral E1A proteins (called "Delta" or dl922-947") enabling selective virus replication in pRb-(Retinoblastoma protein)-deregulated tumour cells and the incorporation of an Arg-Gly-Asp (RGD) sequence, known to interact with αV integrins, into the adenovirus fiber to enhance tumour infection. Further, a mutation within the adenoviral E3/19K protein allows for more efficient virus release and spread within permissive tumour tissue.

**Host/vector system**

Not applicable, only virus stored on site.

**Origin & function**

The ORCA-010 virus is based on human Adenovirus serotype 5 (Ad5).

ORCA-010 comprises the following genetic modifications:

1. Deletion of bp 922-947 of the adenoviral genome. This causes an eight amino-acid deletion in the conserved region-2 (CR2) of adenoviral E1A proteins. This mutation provides tumour-selective virus replication in pRB-deregulated tumour tissue /cells.
2. Insertion of one adenine nucleotide at position bp 29174 equivalent to bp 445 of the adenoviral E3/19K protein. This insertion causes a shift in the open reading frame (ORF) of E3/19K that changes the amino acid sequence from position 149 onwards and generates a stop-codon at position 154 resulting in a truncated version of E3/19K. Whereby wild-type E3/19K is retained in the endoplasmatic reticulum the mutated E3/19K as expressed from ORCA-010 is re-localised to the plasma membrane (Gros et al., Cancer Research 2008, 68: 8928-8937).
3. The Fiber protein of ORCA-010 contains an RGD sequence in the HI loop of the knob domain. This Arg-Gly-Asp amino acid sequence provides the virus with the capacity to infect cells using αV integrins as a receptor, therby increasing tumour cell infectivity (Suzuki K et al., Clin Cancer Res 2001, 7: 120-126).
Ad5 is transmissible via the mouth, nasopharynx or ocular conjunctiva and has been uniquely recorded as being transmissible via the airborne route in a military setting. Ad5 is most commonly spread in children by the faecal/oral route although other strains may largely spread via contaminated water (Fields, Virology (1996): page 2153). Whilst adenoviruses can transform rodent cells numerous screens have failed to correlate the presence of adenoviruses with oncogenesis in humans. Wild-type Ad5 is classified as ACDP class 2 biologic according to UK HSE standards. The infection with Ad5 is very common within populations and within the Western world over 90% of individuals are sero-positive for Ad5 resulting in lifelong immunity.

The virus may be transmitted by inhalation, ingestion, skin absorption or via needle stick injury. The determination of toxicity of replicating adenoviruses in animal models is difficult as human Ad5 does not replicate in mice. Semi-permissive animal models for replication of human Ads are the Syrian hamster and the cotton rat.

In case of accidental inoculation of an operator with ORCA-010 it is expected that the infection is cleared efficiently in sero-positive individuals. Additionally, the capacity to replicate in normal, non-dividing tissue should be decreased compared to wild-type Ad5. However, it is expected to replicate in normal, non-dividing tissue should be decreased compared to wild-type Ad5. However, it is expected that the level of cancer-specific virus replication is not complete and some leaky, residual replication in normal cells might be present (see also Sauthoff et al., Mol Ther 2004, 10: 749-757). The level of residual replication in normal cells seems to be dependent on the cell type used. For example Fueyo et al. reported resistance of normal fibroblasts to the dl922-947 virus replication.

Virus replication/propagation could happen if ORCA-010 does infect cells that are actively dividing. However, again this event should be controlled by the operator's immunity against Ad5.

Further, at least two clinical studies (US-624 and US-625) have been initiated with the Ad5 dl922-947 virus (also called Delta24 deletion). (http://www.wiley.co.uk/genetherapy/clinical). One clinical trial has been performed with Ad5 dl922-947 RGD in ovarian cancer and one clinical study with the same virus is ongoing in glioma. The Phase III data in ovarian cancer indicated that the virus was safe and well tolerated up to dosages of 1x10^12 virus particles per day over three consecutive days (KJ Kimball et al., Clin Cancer Res 2010, 16(21): 5277-5827).

Expected effects of mutations on the virus phenotype/properties:

1. The Retinoblastoma protein (pRb) is a key cell-cycle regulator by controlling the transcriptional activity of the transcription factor family E2F. The dissociation of pRB from promoter-bound E2F protein allows the entry of the cell into the S-phase of the cell cycle. The interaction of pRB with E2F is regulated by phosphorylation within the cell. This pathway is deregulated in many tumour types and as a consequence pRB can not interact with E2F anymore leading to uncontrolled entry into S-phase and therefore cell proliferation. Viral replication within the host cell also requires the entry of the host cell into S-phase and this is enabled by the binding of viral E1A proteins to the cellular pRb protein thereby releasing it from promoter-bound E2F protein. Therefore, the dl922-947 deletion in E1A enables selective virus replication in pRB-deregulated tumour cells, which are constitutively deregulated for the E2F pathway. On the other hand, if ORCA-010 infects a non-tumour host cell, it can not dissociate pRB from E2F and therefore not drive the cell into the S-phase of the cell cycle. In this situation the cell will go into apoptosis or cell growth arrest dependent on the cellular background of the infected cell.

2. The re-localisation of the truncated E3/19K protein, lacking the intra-cellular domain, causes an increase in influx of Ca2+ and this leads to an increase in cell permeability leading to an earlier release of viral progeny during the replication cycle. Therefore ORCA-010 does spread more efficiently through permissive tumour tissue compared to wild-type Ad5 virus.

3. The endogenous receptor for Ad5 viruses, the CAR receptor, is often downregulated or not present at all at the surface of cancer cells. Integrins however, are widely present on many different types of cancer cells and thus the integration of the RGD sequence into the receptor binding domain of the Fiber protein increases the infectivity of ORCA-010 significantly. It should be noted however, that the TGD modification applied to ORCA-010 does not preclude the binding of the fiber to CAR, and the modified virus can enter the cells through αv integrins and CAR.

In summary, it is expected that ORCA-010 is less cytotoxic after accidental inoculation than wild-type Ad5. The presence of the RGD insertion and of the E3/19k mutation are not expected to increase the pathogenicity of the virus in both sero-positive and sero-negative operators. The potential increase in viral spread caused by the E3/19K mutation and the RGD insertion should be counter-balanced by the reduced replication potential caused by the E1A mutation.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No autoclave in the building: Only storage of material is performed at the site. Therefore contamination will only occur if there is the breakage of a bottle. Spill procedures are in place for spills, all material in contact with the spill is collected, treated with 10% sodium hypochlorite and sent off site for incineration with a registered waste management company. There is no equipment used during storage that would come into contact with the virus and require autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus

Spills of the GMO will be inactivated by treatment with 10% sodium hypochlorite solution (1.2% available chloride) for a minimum of 5 minutes, the inactivated spill will then be absorbed with spill kits (kept in the storage area) and all material disposed of as class II solid waste or placed in a biohazard waste bin and treated with 10% sodium hypochlorite for 1hr to inactivate and then dispose of via incineration by an approved contractor.

Is an emergency plan required according to regulation 20? [N]

Project Ref 3136/14.1

Date Ackn'd 12/11/2014

CU2 Project Title Storage, labelling and distribution of TM1050 for Clinical Trial

Class 2

Culture Vol Class 2 Not Applicable

Consent Granted

02/03/2022
Project Additional Information

Purposes of the contained use
Supply of clinical sites with the investigational medicinal product (GMO base product) and the placebo (salt buffer) in the context of the clinical study TG1050.02. The clinical study is to study a HBV therapeutic vaccine candidate able to induce strong and multispecific T cell responses in order to prime or recall T cells in HBV chronically infected patients.

Recipient or parental organism
The parental organism is the wild type Adenovirus type 5 (GENBANK access of hAd5 sequence: AY339865). Adenovirus is a non enveloped, double-stranded DNA virus.

Host/vector system
The transfer system used is a viral transfer system with a human adenovirus vector of group C and serotype 5 (Ad5) deleted of several regions of its genome (E1 and E3). Adenoviral vectors of this type are commonly used in humans (Vorburger S.A. and Hunt K.K., 2002). There is no use of transposons for the construction of the GMM. The genome of the vector Ad5 E1° E3° is assembled in a plasmid with gene of interest and sequences for functional expression. The plasmid genome, used to generate the viral vector, was obtained by homologous recombination (Chartier C. et al., 1996) (Degryse E., 1996) between two plasmids, one carrying the backbone of the Ad5 viral vector body and the other the expression cassette with the sequence coding for HBV. The transfer system used is a viral transfer system with a human adenovirus vector of group C and serotype 5 (Ad5) deleted of several regions of its genome (E1 and E3). Adenoviral vectors of this type are commonly used in humans (Vorburger S.A. and Hunt K.K., 2002). There is no use of transposons for the construction of the GMM. The genome of the vector Ad5 E1° E3° is assembled in a plasmid with gene of interest and sequences for functional expression. The plasmid genome, used to generate the viral vector, was obtained by homologous recombination (Chartier C. et al., 1996) (Degryse E., 1996) between two plasmids, one carrying the backbone of the Ad5 viral vector body and the other the expression cassette with the sequence coding for HBV Pol, Env and Core antigens and the regulation genetic elements.
Hepatitis B virus (HBV)
Orthohepadnavirus
Hepadnaviridae family.
Accession number Y07587 described by Stoll-Becker (Stoll-Becker S. et al., 1997)
Genotype D, serotype ayw
The three following genes are encoded in the Adenovirus vector:
Core protein: has been demonstrated as being the target of T cell responses in patients resolving their HBV infection spontaneously or under treatment (Ferrari C. et al., 1990) (Penna A. et al., 1997), with 2 epitopes described to be associated with resolution (Rossol S. et al., 1997; Tsai S.L. et al., 1992) (Bertoni R. et al., 1997; Webster G.J. et al., 2004). The Core protein was considered as the key antigen of the vaccine.
Polymerase protein: has been demonstrated as being rich in T cell epitopes, including one epitope described to be associated with resolution (Webster G.J. et al., 2004) even if less studied than the Core protein.
HBsAg protein or Envelope protein: has also been demonstrated as being rich in T cell epitopes, including 2 epitopes described to be associated with resolution (Webster G.J. et al., 2004).
The original HBV design encoded by the vaccine candidate is a fusion protein Core-Pol-Env being composed of a truncated Core protein (aa 1-148) fused to a polymerase protein deleted of the amino acid residues involved in pol-associated polymerase and RNase H enzymatic activities and mutated at 4 amino acid positions to further abolish RNaseH activity with 2 HBsAg domain inserted in Pol deletion sites, Env1 corresponding to amino acids 14 to 51 of the small HBsAg inserted in the polymerase-abolishing deletion site and Env2 corresponding to amino acids 165 to 194 of the small HBsAg inserted in the RNaseH-abolishing deletion site.

Origin & function
The strain Ad5 E1° and E3° is non replicative on mammalian normal cells. It need for its propagation, a complementation cell line which bring it up missing functions, that are, at minimum, proteins coded by E1A and E1B genes.
The absence of sequence homology between the vector and the complementation cell line genomes should eliminate the occurrence of Replication Competent Adenovirus (RCA), during the production process.
The genome of the GMM contains no gene for antibiotic resistance. Ampicillin resistance gene used as a selection marker in the plasmid is completely deleted during the transfection to produce the GMM (plasmid digested by Pac I prior to the transfection).
One cannot exclude that the missing E1 function, necessary for viral replication, could be complemented during coinfection of the vector with a wild type (Ad5) adenovirus. However, our assessment of this risk concludes that this event is not likely to cause any significant harm in anyone, for the following reasons:
- This complementation will not extend beyond the viremia of Ad5, which is known to be limited. The vector will be complemented only as long as the parental virus propagates.
- This complementation will be limited to areas where both types of viral particles are numerous enough to simultaneously infect the same cell. Consequently, only a fraction of the recombinant vector will be amplified, and this amplification will be less efficient than the amplification of the wild type parental virus (Ad5).

Evaluation of foreseeable effects
The strain Ad5 E1° and E3° is non replicative on mammalian normal cells. It need for its propagation, a complementation cell line which bring it up missing functions, that are, at minimum, proteins coded by E1A and E1B genes.
The absence of sequence homology between the vector and the complementation cell line genomes should eliminate the occurrence of Replication Competent Adenovirus (RCA), during the production process.
The genome of the GMM contains no gene for antibiotic resistance. Ampicillin resistance gene used as a selection marker in the plasmid is completely deleted during the transfection to produce the GMM (plasmid digested by Pac I prior to the transfection).
One cannot exclude that the missing E1 function, necessary for viral replication, could be complemented during coinfection of the vector with a wild type (Ad5) adenovirus. However, our assessment of this risk concludes that this event is not likely to cause any significant harm in anyone, for the following reasons:
- This complementation will not extend beyond the viremia of Ad5, which is known to be limited. The vector will be complemented only as long as the parental virus propagates.
- This complementation will be limited to areas where both types of viral particles are numerous enough to simultaneously infect the same cell. Consequently, only a fraction of the recombinant vector will be amplified, and this amplification will be less efficient than the amplification of the wild type parental virus (Ad5).
• The most likely recombination event which could have occurred is the homologous recombination, that could lead to the generation of either a recombinant vector AdE1+ E3+ competent for replication but having lost the transgene or the recombinant vector TG1050 E1+E3+, deficient for the replication. Thus, these recombinants do not present higher risk than the recombinant vector TG1050. Much more unlikely, illegitimate recombination events (TG1050 E1+E3+) only remain theoretical and thus undetectable since there are so rare.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All material will remain frozen whilst at Biotec. Therefore the main risk is to staff handling the material and exposed to spillage of a vial. The material is non-replicating, therefore the risk to staff is minimal. All staff handling the material are trained in the required spillage procedures for class 2 organisms. There is minimal risk to the environment as the material will remain within controlled storage areas.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any unopened material will be sent to a waste company licensed for GMO incineration. Any waste from spills (including all materials used to clean the spill) will be treated with 2% virkon for 1 hr prior to being sent for incineration. Any contaminated surfaces will have 2% virkon in contact for 30 minutes prior to cleaning.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The client has provided all the information for the completion of the form and MSDS. A risk assessment from the client has not been supplied. The risk assessment for handling the material at Biotec has been supplied.

Purposes of the contained use

Oncolytic viral vaccine for human use in Phase 1-3 Clinical Trials

Recipient or parental organism

Human

Host/vector system

Vaccinia Virus (Wyeth strain, New York Board of Health)

Origin & function

1. Thymidine kinase (TK) gene deactivation
   Origin: see #3 below
   Function: to enhance vaccinia virus selection to cancer cells

2. human GM-CSF insert (human granulocyte-macrophage colony stimulating factor)
   Origin: human
   Function: stimulate the immune system against tumor cells

8. Containment and control measures for larger GMOs (e.g. GM animals and plants) - Public
Register
9. Maximum culture volumes per experiment - for GMMs only - Public Register
10. For GMMs only - the level of containment that will be applied - Public Register
Level 2 - Laboratory contained use
11. For GMMs only - Application for any derogation from full containment for the class of contained use (measures and justification) - Public Register
I would like to request derogation from full containment measures
12. Description of waste management measures - Public Register
3. Beta-galactosidase insert
Origin: E. coli
Function: to disrupt and deactivate the TK gene and to provide a marker.

Evaluation of foreseeable effects

General vaccinia virus information:
Based on use of the vaccine (wild type vaccinia): As a vaccine, wild-type vaccinia has been intentionally given to hundreds of millions of people, many of whom were young children; Serious toxicities occurred rare; At risk populations are now well defined; No new, dangerous virus arose
Transmission very rare and only with direct inoculation and touching of infectious material – open pustule, contaminated dressings (i.e. NOT airborne).
Complications are very rare with wild-type vaccinia: Vaccine overall effective and safe in people with healthy immune systems
Per CDC:
~1,000 of 1 million 1st time vaccinees → serious, non-life threatening side effects
14-52 of 1 million 1st time vaccinees → potentially life-threatening reactions
1-2 of 1 million: life-threatening reactions result in death
Rare side effects include: Eczema vaccinatum, progressive vaccinia, postvaccinal encephalitis myopericarditis
“At Risk” populations who should not receive the vaccine have been identified
Pexa-Vec (GMO):
is an attenuated vaccinia vaccine being investigeted for treatment of multiple types of solid cancers. To date, over 300 adult and pediatric patients with advanced, refractory cancer have been treated with over 1100 doses of Pexa-Vec. Treatment with Pexa-Vec has been well-tolerated, and no transmission to patient contacts for health care workers has been reported.
The GM-CSF and beta-galactosidase are well characterized that do not induce any negative reactions in humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
I would like to request derogation from full containment measures.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Only closed vials of material will be handled therefore contamination will only occur if there is a spill. Self contained biological spill kits are held in the areas where the material is stored. These contain all PPE required and absorbent materials. Spills are cleaned and all contaminated material and PPE is treated with 1% sodium hypochloride for 1 hour prior to sending for incineration by our licensed provider.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The material is in line with our current storage capability and no additional activities are required prior to receipt.

Date Project Ceased

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Storage below -70 and distribution in dry ice of SFG.iCasp9.2A.dCD19 retroviral supernatent.

**Recipient or parental organism**

Murine origin, PG13 cells ATCC #CRL-10686 base on NIH 3T3

**Host/vector system**

The infectious agent is attenuated (see vector map in attached risk assessment)

The infectious agent is replication incompetent

The producer cell system used to generate the vector supernatant is safety optimised by deletion of packaging signals from viral genes expressed in the packaging cell line. There is no RCR formation reported so far for this host.

**Origin & function**

The BPZ-1001 (SFG.iCasp9.2A.dCD19) retroviral vector was constructed at the Baylor College of Medicine, Cell and Gene Therapy (CAGT) Translational Research Laboratory in a GLP environment. The SFG backbone uses a Moloney murine leukemia virus (MoMLV)–based retroviral vector. All of env and most of gag/pol except the segment constituting the packaging sequence (psi) have been removed from the SFG backbone. As a result, the vector is replication incompetent.

The intended function is the expression of CD19 after transduction in T cells

**Evaluation of foreseeable effects**

Replication deficient retroviral vectors pseudotyped with GALV env are able to infect a broad range of mammalian cells including human cells during their cell division. But they require MLV gag/pol as well as the envelope protein, both provided by the helper cell line, for replication. For this reason uncontrolled spread is not expected.
Material is stored on site and distributed frozen

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No autoclave in the building: Only storage of material is performed at the site. Therefore contamination will only occur if there is the breakage of a bottle. Spill procedures are in place for spills, all material in contact with the spill is collected, treated with 2% Virkon and sent off site for incineration with a registered waste management company. There is no equipment used during storage that would come into contact with the virus and require autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Secondary storage only on site. All materials would be sent off site to a licensed facility for incineration. In the event of a spill all materials/surfaces would be treated with 2% virkon for 1 hour. All contaminated materials would be sent for incineration following decontamination in virkon.

Project Ref 3136/16.2
**Project Additional Information**

**Purposes of the contained use**

Storage and distribution of material for clinical trials.

**Recipient or parental organism**

The recipient organism is the 293 HEK cell line which was derived from human embryonic kidney (HEK) cells transfected with fragments of mechanically sheared adenovirus S DNA (Ad5) by selection for cells that exhibited many of the characteristics of Ad transformation.

**Host/vector system**

Recombinant AAV vector serotype 2 containing the human mitochondrial ND4 gene (rAAV2-ND4 vector)

**Origin & function**

Human derived:

Insert 1.1:
- Name: NADH deshydrogenase type 4 gene.
- Characterization/nature of the sequence: cDNA encoding for the mitochondrial enzyme ND4 gene. This sequence has been codon optimized for an optimal gene expression in humans.
- Activity: the ND4 protein is involved in the mitochondrial respiratory chain, in particularly in the ATP synthesis used as a source of chemical energy for cell.

Insert 1.2:
- Name: HBB2, human beta globin intron
- Characterization/nature of the sequence: intronic sequence derived from the human beat globin human gene.
The material will be used for an in vivo gene therapy approach based on a recombinant AAV2 (rAAV2) viral vector expressing the human mitochondrial NADH deshydrogenase type 4 gene. The final GMO is the recombinant vector rAAV2/2-ND4 produced by tri-transfection of plasmids into adherent HEK293 cells. The final GMO will be administered by single intravitreal (IVT) injection into LHON patients bearing a mutation into their ND4 gene. Activity this sequence is used to enhance gene expression by facilitating the transport of mRNA from nucleus to cytoplasm.

Insert 1.3:
- **Name**: COX10 MTS
- **Characterization/nature of the sequence**: mitochondrial targeting sequence (MTS) derived from the COX10 mitochondrial gene (cytochrome c oxidase assembly homolog 10), gene which belongs to the mitochondrial respiratory chain complex assembly factors
- **Activity**: this sequence is used to translocate the mRNA into the mitochondria.

Insert 1.4:
- **Name**: COX10 UTR
- **Characterization/nature of the sequence**: Untranslated region (UTR) of the COX10 mitochondrial gene (cytochrome c oxidase assembly homolog 10), gene which belongs to the mitochondrial respiratory chain complex assembly factors
- **Activity**: this sequence is used to stabilize ND4 mRNA.

Cytomegalovirus derived:

Insert 2.1:
- **Name**: CMV promoter
- **Characterization/nature of the sequence**: Non coding sequence, promoter sequence.
- **Activity**: Used as binding DNA sequence for transcriptional factors. Allow the transcription of the cDNA ND4.

**DONOR 3: VIRUS**

1. **Scientific Name**: Adeno-associated virus
2. **Taxonomy**:
   (i) **order and/or higher taxon**: Parvoviriidae
   (ii) **genus**: Dependovirus
   (iii) **species**: Adeno-associated virus
   (v) **strain**: serotype 2
3. **Other names (usual name, strain name, etc.)**: The common name is AAV2
4. **Phenotypic and genetic markers**: NA
5. **Pathogenicity**: No

**Evaluation of foreseeable effects**

No pathological, ecological and physiological traits are present. In natural conditions, wild type AAV2 in the presence of a helper virus (adenovirus) is found to transmit to humans or non human primates only and is not known to colonize other species.

Wt AAV does not appear to cause any diseases in humans, and none of its close zootropic relatives cause any known diseases in animals.

Wt AAV2 as well as GS010 viral vector are non pathogenic.

When documented, the pathogenicity of parvoviruses is related to the Rep proteins. rAAV vectors contain no viral coding sequence, more especially they do not express Rep proteins which play a key role not only for DNA replication but also for site-specific integration and cellular growth inhibitory effects. Recently accumulated data enlighten the specific biological properties of rAAV such as integration specificity and efficiency.

Because they lack all viral encoded proteins (especially the Rep proteins), rAAV are doubly defective in comparison to
their wild type counterpart.
Most of the in vivo studies of rAAV mediated gene transfer have led to the conclusion that the vector is maintained into the transduced cells essentially as extrachromosomal episomes. However depending on the cell type, maintenance of the AAV genome occurs under multiple forms. In muscle, episomal forms appear to be almost the exclusive mode of persistence whereas, in liver cells, integrated DNA forms up to 5% have been reported. Accidental insertional mutagenesis and subsequently adverse effects such as gene disruption or oncogene activation associated with the use of AAV vectors is seen currently as a very infrequent possibility. It should be emphasize that no real and unambiguous adverse effect attributable to rAAV as been reported in the literature so far, notably in animals that have been followed over long period. [7]. Clinical trials performed up to now with AAV vectors has not raised this issue.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No Autoclave in the building. Only labelling, storage and distribution of primary packaged material being performed. Any contaminated material on site will be sent for incineration by licenced waste company. The only exposure on site will be if there is a spill, procedures are inplace to ensure all spilled material is decontaminated with 2% virkon prior to sending for incineration. No equipment is used on site that would require autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

**Purposes of the contained use**

Storage and distribution of 5 retroviral supernatants material.

**Recipient or parental organism**

Human cells

**Host/vector system**

*murine gamma Retroviral SIN vector*

**Origin & function**

*synthetic therapeutic gene of Human origin*

The intended function is chimeric antigen receptor (CAR) like protein.

The 4 retroviral vectors and inserts are named as follows:

- CG_CAR_001.1 (HE-DN35)
- NCARGD2MP10413
the full vector map for each insert is shown on each risk assessment

**Evaluation of foreseeable effects**

The supernatent contains replication deficient, recombinant gamma-retroviral SIN vector particles pseudotyped with Gibbon Ape Leukimia virus (GALV) envelope, thus are infectious for human but not mouse (xenotropic). Infection requires cell division. Accidental uptake (wounding) of vectors will result in rapid degradation by the host immune system.

The vectors do not encode any toxin and are unable to pread in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No Autoclave in the building. Only storage and distribution of primary packaged material being performed.

Any contaminated material on site will be sent for incineration by licenced waste company. The only exposure on site will be if there is a spill, procedures are inplace to ensure all spilled material is decontaminated with 2% virkon prior to sending for incineration. No equipment is used on site that would require autoclaving.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The only exposure on site will be if there is a spill, procedures are inplace to ensure all spilled material is decontaminated with 2% virkon prior to sending for incineration. All contaminated material is sent for incineration by a licenced waste company. Any material at the end of the project is sent for incineration by a licenced waste company. Material is kept frozen whilst on site and during distribution so there is minimal risk of aerosols from vial breakage.

**Project Additional Information**

**Purposes of the contained use**

The material may be for storage only, or for labelling and distribution to clinical trial sites. PCI Bridgend is a clinical trial cold chain storage and distribution specialist.

**Recipient or parental organism**

The majority of materials are for use in Humans as various therapies in clinical trial. Influenza is for use in testing of flu vaccines.

**Host/vector system**

- murine, human or avian

**Origin & function**

Various genetic inserts are inserted into the recombinant vectors. These are all identified on individual risk assessments held by PCI. Consideration of the effect of the vector insert and position of the insert is made when assessing the class of the
GMO. Only class 1 and 2 materials are handled at the site. These remain fully closed at all times and held with appropriate containment measures (frozen, doubly contained with absorbant materials within each box).

**Evaluation of foreseeable effects**

Materials held at site are generally replication deficient or altered to ensure they are unable to infect and spread between hosts. An assessment of the effect of each individual GMO held at PCI Bridgend is completed on the individual risk assessments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No Autoclave is present in the building. Only storage, distribution and occasional labelling of primary packaged material being performed. Any contaminated material on site will be sent for incineration by a licenced waste company. The only exposure on site will be if there is a spill, procedures are in place to ensure all spilled material is decontaminated with 2% virkon prior to sending for incineration. No equipment is used on site that would require autoclaving. All staff handling influenza material are vaccinated with the annual flu vaccine.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Please enter comments on the GM safety committee on the risk assessment

This is a generic application to cover the contained use performed at the site for the range of materials we currently handle. All the material types listed have already been accepted by the HSE for handling at PCI Bridgend. This would allow us to bring in new genetic inserts for the current organism types and activities without completing individual CU2’s. However every GMO brought into the PCI Bridgend facility would undergo full risk assessment and if it did not meet the criteria covered within this notification for organism type or activity a separate notification would be made. No new influenza strains would be brought onto the site without discussing with the HSE to determine whether the current notification and precautions are sufficient.

Give brief details of the genetic modification safety committee

Committee is comprised of the following - VP Pharmaceutical Sciences (senior management), Health & Safety Manager, Clinical Research Physician, Scientists with relevant microbiology background and experience.

As we do not routinely perform GMM work, the committee will meet on an as required basis, prior to each program of work. The committee will be responsible for ensuring a suitable and sufficient risk assessment of all work is performed as required by the Regulations. The H & S Manager will be responsible for ensuring employees handling GMMs are trained appropriately and are made aware of the outcome of risk assessments.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The members of the safety committee are ex officio members of the GM committee. They comprise the owner and the Principal Scientist. Both of them have extensive prior experience of working with the type of GMMs to be used. Both members are based at the laboratory where the work will be carried out. Meetings are held whenever a new project is to be initiated and at least once a year to review all projects.

#### Laboratory
- Level 1 (GMMs): Yes

- Transgenic Animals
- Gene Therapy

02/03/2022
All waste material containing GMMs or exposed to GMMs will be treated according to the standard operating procedure for biohazardous waste. It will be decontaminated by treatment with a suitable disinfectant prior to being securely bagged, sealed and sent for incineration by an approved contractor. Liquid waste will be decontaminated with disinfectant prior to disposal by a suitable route depending on the nature of the liquid. If these methods are deemed not to be suitable for particular items, they will be made safe by autoclaving in the on site autoclave prior to disposal by incineration. The estimated degree of kill by these combined methods is extremely close to 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Mammalian cell lines will be transfected with gene vectors for research-scale production of recombinant proteins.

Tick to confirm that you are attaching a summary of the risk assessment: Y

Project Ref: 3139/13.1

Date Ackn'd: 28/11/2013
CU2 Project Title: Expression of Fc receptors in human lymphocytes
Date Project Ceased: 27/04/2015
Class: Class 2
Culture Vol: 1-50 Litres
Non-GMM: Consent Granted

Project notified under transitional arrangements: N

Tick if notifying a connected programme of work: N

Historical Significant Changes: CM3139 closed. Class work transferred to GM3007 class 2 project closed

Historical Date of Additional Info: 02/03/2022
### Purposes of the contained use

The purpose of the project is to develop human lymphocyte cell lines which express immunoglobulin Fc receptors and are able to kill antibody-coated target cells. The cell lines will be used in research and quality control of antibodies.

### Recipient or parental organism

The recipient cells will be human lymphocyte cell lines with characteristics of natural killer cells, such as NK-92 and/or KHYG-1. NK-92 was established in 1992 from the blood of a 50-year-old man with non-Hodgkin lymphoma. The cell line has been routinely used by others for the planned purpose. The cell line is EBV positive, with a latent infection, and is classified Level 1.

KHYG-1 was established in 1970 from the pleural effusion of a 53-year-old woman with chronic myeloid leukemia. The cell line is commonly used in laboratories for cytotoxicity assays. The cell line is classified Level 1.

The intermediate host cell line for packaging of the retroviral vector will be HEK-293T. This is a very widely used human embryonic kidney cell line which has been transformed with adenovirus E1a and carries a temperature sensitive T antigen co-selected with neomycin. The cell line is classified Level 1.

### Host/vector system

The Gryphon expression vector pCHAC is a standard vector based on murine moloney leukaemia virus (MMLV). Such viruses can potentially cause cell transformation and tumour formation. The vector has been rendered replication-incompetent by deletion of its envelope (env) genes and therefore needs to be produced in a packaging cell which can complement the env gene in order to produce infectious virus. The host range depends on the specificity of the viral envelope. We will be using an amphitropic env gene to allow infection of murine and non-murine, including human cells.

Following transduction, the virus integrates into the host genome and is present in the infected cells as a DNA provirus. The main safety concern is the possibility of recombination between the provirus and an endogenous helper virus which might theoretically result in the production of replication competent virus.

Gryphon is an upgraded version of the Phoenix retroviral transduction system which has an excellent safety record over many years of use with a wide variety of host cells, including NK cells such as those proposed in this project. Gryphon includes a gene encoding a green fluorescent protein (mWasabi) for easy visualisation of transfectants and to prevent potential recombination, different non-Moloney promoters for the gag-pol and env genes are used. Nevertheless, due to the theoretical possibility of producing replication competent viruses, the genetically modified cell lines resulting from this project will be classified Class 2 unless and until the absence of replication-competent virus is proved.

### Origin & function

There are several types of immunoglobulin Fc receptors (FcR) which are naturally found on the surface of various human white blood cells. They include CD16, CD32 and CD64. We propose to use CD16 which is a low affinity receptor found on the surface of natural killer cells. It is involved in antibody-dependent cell-mediated cytotoxicity (ADCC). Natural killer cell lines such as NK-92 and KHYG-1 do not express CD16. By transfecting them with a vector which contains the CD16 gene, we expect that the CD16 Fc receptor will be expressed on their surface and they will be enabled to carry out ADCC in a similar fashion to normal natural killer cells.

The CD16 gene to be used in these experiments will be designed to code for the published protein sequence of human CD16 protein. The natural protein consists of two subunits. It has been shown that the corresponding genes may be fused together to code for a single protein chain. This may increase the chance of success of the transfection and improve the expression levels. The codon usage of the synthetic CD16 gene will be optimised for expression in human cells.

### Evaluation of foreseeable effects

This project includes in-frame insertion of expressible DNA downstream of a promoter with the intention of expressing Fc receptors (e.g. CD16) on the surface of mammalian cells. Therefore, it is possible that biologically active proteins will be produced. However, the quantities will be extremely small (micrograms) and it is not...
suspected or known that these molecules are toxic, oncogenic or would be detrimental if administered to a target tissue. No adverse effects are expected to be associated with the genetic insert.

The vectors used in this project will be well-characterised replication-incompetent retrovirus. The vectors will contain only selective markers (ampicillin resistance) that are already in routine use in standard cloning vectors and will contain no recognisable harmful sequences. This specifically excludes cloning any sequences that are known or suspected to be oncogenic, encode a toxin or allergen or encode a product that could be detrimental if delivered to a target tissue. No adverse effects are expected to be associated with the vector per se.

The final engineered cells will contain the stably integrated vector as a DNA provirus. A theoretical safety concern is the possibility of recombination between the provirus and an endogenous helper virus (if such exists in the host cells) which might theoretically result in the production of replication competent virus. We are not aware of any reports of such recombination events associated with the cell lines or vector system to be used. Nevertheless, as a result of this theoretical concern, the resulting GMM will be treated as Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste material which might be contaminated with the GMM will be disposed as follows:

Cell culture ware, plastic ware etc will be immersed in 10% bleach or 1% Virkon for at least 1 h. Aqueous liquid will be discarded to the laboratory drain, solid waste will be securely bagged and taken for incineration by an approved contractor (Select Environmental Services Limited, Prosper Park • Bennet Road • Reading • Berkshire RG2 0QX)

Culture medium, other liquids will be treated with bleach to final concentration of 10% or Virkon to a final concentration of 1%, for at least 1 h and discarded to the laboratory drain.

Sharps, pipettor tips, broken glass etc will be stored in sealed sharps container and taken for incineration by the approved contractor.

Our risk assessment indicates that these proposed waste management measures are at least as effective, and overall less inherently hazardous than inactivation by autoclaving, and therefore the availability of an autoclave within the facility is not considered necessary.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was approved by the genetic modification safety committee without any objections

Give brief details of the genetic modification safety committee

Committee composed of Biological Safety Officer, Deputy Biological Safety Officer, Associate Director, Anti-Infectives Research. This structure has inputs from three biologists and one chemist. All have extensive experience working in research and biotech drug discovery environments and previous involvement with health and safety, COSHH assessments and/or GMO safety committees. Any new planned GM work requires preparation of a GM risk assessment, which is reviewed by the GMO safety committee. GMO Safety Committee will meet ahead of new planned GMO activities to ensure procedures, safeguards and compliance to regulations are in place in advance of initiation of those projects. These meetings will be minuted and records of these meeting retained.

02/03/2022
Solid waste that is contaminated with bacteria (including the parent strain and the GMO) will be autoclaved (heating with steam under pressure at 121°C for 30 minutes) to achieve 100% kill before removal from the containment facility. This will be monitored by taking samples from the autoclaved waste (e.g., from small liquid cultures) onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals.

Liquid waste that is contaminated will be treated with "Virkon" disinfectant according to the manufacturer's instructions to achieve 100% kill. This will be monitored by taking samples from treated waste onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals.

The safety committee discussed the potential for modulation of pathogenicity determinants by transposon insertion, but agreed that the number of endogenous genes so modulated would be limited and would therefore not confer a pathogenic advantage. Moreover, the experimental process does not specifically select for any pathogenic derivatives.
**Project Additional Information**

**Purposes of the contained use**
- To identify essential genes of bacteria that may indicate targets for the development of new antibiotics.
- To identify as yet unknown mechanisms of bacterial resistance to antibiotics.
- To assist in the identification of the bacterial targets for newly identified antibiotics.
- These results will be obtained for clinically relevant bacteria, as indicated above and below.

**Recipient or parental organism**
- Pseudomonas aeruginosa, Acinetobacter baumanii and Klebsiella pneumoniae that do not normally cause disease in healthy individuals but are associated with infection of patients in hospitals.
- Uropathogenic Escherichia coli that causes infection of the urogenital tract, both in hospitals and in the community, and like Klebsiella pneumoniae is transmitted in contaminated water and food. Neisseria gonorrhoeae which causes gonorrhoea and is transmitted by sexual contact.

**Host/vector system**
- The transposon mutagenesis procedure involves the introduction of a short DNA fragment of 1 to 2 kb (the transposon) directly into the bacterial cell without the need for an additional bacterial or DNA host or vector.

**Origin & function**
- The transposon used in the mutagenesis procedure consists of components of a naturally occurring transposon (Tn5) originally identified in an antibiotic resistance strain of a bacterium called Klebsiella. However, the transposon is modified to include only the minimal components required for the experiment. The functional components of the modified transposon consist only of a chosen antibiotic resistance gene and the short 19bp transposon ends which are recognised by the transposase enzyme during the transposition process. The antibiotic resistance gene of the transposon allows the selection of the GMO from the parental strain. The modified transposon does not include the gene coding for transposase which is present in the naturally occurring transposon. Instead, the transposase enzyme is bought commercially and mixed with the minimal transposon to generate the active transposition bodies. Thus, once the mutagenesis procedure is finished the minimal transposon is fixed in the bacterial genome, no longer able to insert anywhere else, as it does not possess the necessary transposase gene. The locations in the genome of the sites of transposon insertion can then be determined and used to identify targets for new antibiotics.

**Evaluation of foreseeable effects**
- The GMOs will become resistant to the antibiotic against which the resistance gene encoded by the transposon is active. These resistance genes will be chosen against...
antibiotics that would not normally be used in therapy, so that should any of the GMOs escape into the environment, or be transmitted inadvertantly to susceptible individuals, they will possess no selective advantage over non-GM bacteria and so would be unlikely to spread. The inserted DNA (transposon) does NOT possess any additional traits that would be expected to increase the GMM's ability to cause disease or survive in it's natural habitat. The transposon mutagenesis procedure will result in the modulation of genes in the genome as a result of the insertion of the transposon, most likely resulting in attenuation of the bacteria or reduced ability to survive in the environments normally inhabited.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation of containment level is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste that is contaminated with bacteria (including the parent strain and the GMO) will be autoclaved (heating with steam under pressure at 121C for 30 minutes) to achieve 100% kill before removal from the containment facility. This will be monitored by taking samples from the autoclaved waste (eg. From small liquid cultures) onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee or quarterly intervals.

Liquid waste that is contaminated will be treated with "Virkon" disinfectant according to the manufacturers instructions to achieve 100% kill. This will be monitored by taking samples from treated waste onto solid growth medium with incubated to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals.

02/03/2022
Manipulation of HG2 pathogen genomes to aid antibiotic target identification and reveal resistance mechanisms by overexpression (complementation) or gene product downregulation of endogenous proteins

Purposes of the contained use
To elucidate mechanisms of resistance and sensitivity to known and new antibiotic compounds with the aim of revealing their modes of action and potential intracellular targets, and so aid in the development of new compounds as therapeutic antibiotics

Recipient or parental organism
Discova programs involve research using the following HG2 microorganisms:
Pseudomonas aeruginosa, Acinetobacter baumanii and Klebsiella pneumoniae that do not normally cause disease in healthy individuals, but are associated with infection of patients in hospitals.
Uropathogenic escherichia coli that causes infection of the urogenital tract, both in hospitals and in the community, and like Klebsiella pneumoniae is transmitted in contaminated water and food. Neisseria gonorrhoeae which causes gonorrhoea and is transmitted by sexual contact. Non-pathogenic E. coli K12.

Host/vector system
Laboratory strains of E. coli will be the host for the DNA vectors.
Bacterial plasmid DNA vectors will be used, and will include standard cloning vector plasmids, which are often commercially available. Suicide vectors will also be utilised which do not normally replicate in bacteria other than specific laboratory strains of E. coli.

Origin & function
Plasmid vectors to be used will be constructed from components that occur naturally in the bacteria being used in the studies. These components include a replication origin to maintain the plasmid through replication cycles and an antibiotic resistance determinant to allow for selection of bacteria harbouring the plasmid vector. Some of the plasmid vectors may also include bacterial gene transcriptional promoters, such as the araBAD promoter from E. coli, which function to promote expression of genes inserted into the plasmid, and genes such as sacB from Bacillus subtilis that codes for levansucrase and which allows counter-selection against the plasmid in the presence of sucrose. None of the plasmid vectors to be used are self-transmissible, unlike the many naturally occurring plasmids from which the plasmid vector components are derived.

The chromosomally-inserted DNA will normally code for a gene, or genes, of interest from the HG2 micro-organism, and may include the gene's native promoter, or potentially a heterologous inducible promoter (such as araBAD). The inserted DNA functions to complement existing gene function, or to mediate homologous recombination with the existing gene in the HG2 recipient in order to specifically replace, mutate, or knockout the gene or promoter of interest. Such mutations may serve to specifically inactivate the gene, or in some cases to specifically regulate expression of the gene.

**Evaluation of foreseeable effects**

The modern DNA manipulation techniques to be employed allow the precise construction of DNA molecules, thus unforeseeable effects due to the presence of DNA not necessary for the experiment can be avoided.

Some GMOs will become resistant to the antibiotics to which the resistance gene encoded by the plasmid vector is active. However, only one or two antibiotics to which the resistance gene encoded by the plasmid vector is active. However, only one or two antibiotic resistance determinants are used at a time, so the generation of multiple resistance GMOs will normally be avoided. In the case of chromosomally-inserted sequences, the ultimate GMO will not possess a selectable resistance gene.

Any resistance genes are chosen against antibiotics that would not normally be used in therapy, so they will possess no selective advantage over non-GM bacteria, would be expected to respond to treatment, and would be unlikely to spread.

The inserted DNA does NOT possess any additional traits that would be expected to increase the GMO's ability to cause disease or survive in its natural habitat, or any other environment. The inserted DNA would normally code for genes that have been identified as modulators of sensitivity to antibacterial agents (novel antibiotics). As such, some GMOs will possess reduced susceptibility to these agents, while others will demonstrate increased susceptibility. This reduced susceptibility is unlikely to be sufficient to cause the GMO to show clinical (high levels of) resistance to those agents, and is unlikely to persist in the absence of continued selection pressure.

The work does not involve specifically the modulation or investigation of genes coding for pathogenicity determinants; rather, it involves those that may be involved in the modulation action of resistance to known and new antimicrobial compounds, which would be expected to be genes important for growth under the laboratory conditions which are used to study antibiotic resistance.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- The work does not involve any non-micro-organisms.

- **For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
  - No derogation of containment level is requested

- **Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
  - Solid waste that is contaminated with bacteria (including the parent strain and the GMO) will be autoclaved (heating with steam under pressure at 125°C for 30 minutes) to achieve 100% kill before removal from the containment facility. This will be monitored by taking samples from the autoclaved waste (e.g. From small liquid cultures) onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals. The autoclave used for processing is validated annually. All processed solid waste will be transferred to an authorised Waste Management provider where waste will be processed via incineration.
Liquid wasr that is contaminated will be treated with "Virkon" disinfectant according to the manufacturer's instructions to achieve 100% kill. This will be monitored by taking samples from treated waste onto solid growth medium with incubated to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The safety committee discussed the potential for modulation of pathogenicity by genetic manipulation procedures, but agreed that such modulation would most likely result in no change or reduced pathogenicity, although scientists will be vigilant for changes to pathogen characteristics. In addition, current working practices are sufficient to prevent exposure. The safety committee concluded that the work involved is no more risk than a microbiology lab handling different strains of HG2 pathogens which themselves will vary in their levels of virulence.

Moreover, the experimental process does not specifically select for any derivatives with increased pathogenicity.

Please enter comments on the GM safety committee on the risk assessment

Give brief details of the genetic modification safety committee:

Biological Safety Officer attends monthly safety meetings to raise any biological safety issues. All lab stewards attend and disseminate information to lab users. Risk assessments are created in an electronic registration system and are circulated to registered Gmusers with appropriate expertise and experience, before final approval by BSO and discussion at safety meeting.

Please see the attached documents 'Lentivirus notification' and Significant Change to risk GM331/08.1 - GMSC approved document'

Neusentis was originally covered under GM centre GM331 and the attached assessment was originally notified at Sandwich. The significant change was submitted to include Neusentis work. This activity will be transferring entirely to Neusentis and to the new GM centre reference ie Neusentis will carry out class 1 activities exactly as previously notified at Sandwich, but now independently of Sandwich and class 2 activity only in terms of in vivo use of lentivirus, where the use of sharps increases risk to human health.

**Date Project Ceased**
**Project Additional Information**

**Purposes of the contained use**

The lentivirus vector system will be used for the following experimental purposes:

1. To evaluate gene function in normal body cell biology and disease by overexpression or RNAi-mediated knockdown of the relevant gene function in primary cultured cells from normal and diseased tissues.

2. To generate stable cell lines expressing genes of interest to be used in the development of cell-based screening assays and disease-relevant in vitro cell models. These assays will be used to explore gene function and to screen compounds for activity at drug targets.

**Recipient or parental organism**

Recipient organisms will be cultured mammalian cells.

**Host/vector system**

The lentiviral vector systems used for these studies will be third generation replication-defective lentiviral vector systems. Only gag, pol and rev genes from HIV will be employed and these will be supplied in trans to facilitate virus packaging. All other HIV genes have been deleted. Examples of commercially available vectors with these properties include invitrogen’s ViraPower (pLenti vectors), and Stigma’s pLKO.1 vector systems. High litre virus stocks will be generated by cotransfecting a 293FT packaging cell line with transfer and packaging vectors.

**Origin & function**

Genes to be overexpressed will be derived from human or other relevant mammalian species (e.g. rodent, dog, non-human primate). Genes will be those considered to be of potential relevance in disease processes and will be overexpressed in cultured cells to determine their functional activity and to enable discovery of novel drugs targeting the gene product. Genes will include those encoding cell receptors, ion channels, enzymes and regulatory proteins from cellular signalling pathways. Genes will be derived from in-house cloning efforts or from academic or commercial sources.

Inhibitory RNA sequences will be targetted to genes considered to be of potential relevance in disease processes. Targetted genes will include those encoding cell receptors, ion channels, enzymes and regulatory proteins from cellular signalling pathways. Inhibitory RNA sequences will be obtained from commercial sources.

**Evaluation of foreseeable effects**

The risk associated with overexpression or knockdown of individual genes will be considered on a case by case basis and reviewed locally by the GM safety committee prior to work being started. Particular consideration will be given to genes that may be oncogenic or immunomodulatory.

VSV-G pseudotyped lentivirus strains will be used and these strains will have the ability to infect human cells and cells from other mammalian species. However, because these strains are replication defective, the virus can only carry out a single round of infection. Structural genes and other components required for packaging the viral
genome are separated onto three plasmids and have been engineered so as not to contain any homologous sequences to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. Cells that may contain virus sequences able to mobilise the lentivirus vectors by providing structural genes in trans will be excluded from these experiments. Provirus insertion into the host genome will occur with high frequency and while this is unlikely to generate a harmful phenotype in the cultured mammalian cell (host cells from workers will not be used), there is a low probability of infection of a worker e.g. through accidental inoculation with packaged virus. Integration and long term expression of the recombinant gene or cDNA encoding inhibitory RNA could occur. There is a theoretical risk of transformation of cells by insertion of oncogenes or by knock-down of tumour suppressor genes. Because of the replication-defective nature of these vectors, this could only occur at low frequency and therefore unlikely to have a detrimental effect as a single event is unlikely to result in cellular transformation. Lentiviruses can also act as insertional mutagens. The likelihood of this occurring is reduced by the use of a self-inactivating vector which disables the LTR regions in the integrated vector and thus reduces the risk of oncogene activation at the site of insertion. Additionally, because the vector is replication-defective, the level of exposure that might occur following accidental introduction of the virus will be low and thus reduces the probability of virus insertion at a site likely to promote tumourigenesis. However, because these vectors incorporate strong heterologous promoters and because provirus insertion is a feature of retrovirus biology, work with these vectors is assessed as a class 2 activity and the use of appropriate containment is used to minimise exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk of escape of GMO's to the environment, all work will be performed in containment level 2 biology laboratory. Cultures will be grown within leakproof vessels. All contaminated waste streams generated during the course of this work will be decontaminated on site. Virkon disinfectant will be added to liquid waste and left for a defined contact period prior to disposal. Solid waste will be autoclaved and subsequently incinerated prior to disposal. Additional information on disinfection procedures is included in departmental safety manuals. The only foreseeable release of viable waste from our facility is in the form of aqueous waste that has been inadequately treated, possibly in the event of an accidental spill to a sink. Such waste is emitted via our Waste Water Treatment Facility (WWTF) before final discharge to the River Stour. Processing via the WWTF is such that the virus concentration will be massively diluted and will not reach the river Stour for approximately 5 days after leaving the laboratory. The treatment regimen in the WWTF includes a 24hr disinfection step. Thus the risk of viable organisms entering the local environment is effectively zero.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
This project was discussed with the HSE during a routine inspection by the Biological Agents Unit of the Pfizer facilities in April 2007. Under the new guidance from SACGM the Lentivirus work could be assigned as a class 2 activity. The HSE recommended that a generic notification and risk assessment should be submitted as a broad connected programme of work covering all Lentiviral vector work when the next Lentivirus project was proposed. Individual assessments would then be written at Pfizer for each proposed project but there would be no need to notify HSE of any future projects unless they fell outside the connected programme.
A copy of the risk assessment was circulated to the full GMSC membership who gave their approval.

Research
Waste management is controlled by SOP.

Contaminated microbiology consumables will be immediately discarded into liquid disinfectant (10% Trigene) and left for a minimum of 12 hours. Preparation of liquid disinfectant will be controlled by training and SOP.

Contaminated liquid, solid media and glassware will be sterilised by autoclave (121C for 15 mins). Autoclave usage will be controlled by training and SOP. Autoclave waste cycles will be validated and users will record confirmation that cycling has reached correct temperature and time before disposing of autoclaved waste via the clinical waste (yellow bag) route.

Contaminated surfaces will be wiped with liquid disinfectant before and after each use.

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC) is comprised of the Chief Scientific Officer, Science Director and the Managing Director of the company. These three individuals have greater than 70 years combined experience of working within the research environment of the pharmaceutical industry. The CSO has previously held the role of Safety Officer for a group of 30 individuals. The Science Director has trained and supervised other members of staff in working with GMO's. The Managing Director has a background in Molecular Biology has served on GMO committees in the past and was chair of a cross-functional safety committee in previous employment.

All members of the GMSC have formal qualifications at postgraduate level in the form of a PhD or an MSc.

The committee meets as required due to the size of the company but at least once every 3 months to review risk assessments and to discuss proposals for new GMO work.

</table>
The spent culture material from plastic culture ware will be inactivated using the disinfectant Trigene as per the manufacturer's recommendations. This will involve inactivation overnight using a 2% solution (final concentration) of the disinfectant Trigene. Following overnight treatment the inactivated liquid waste will be flushed down the sink. The disinfected plastic ware will then be bagged as biohazard waste and disposed of by a contractor (e.g. SRCL) via incineration. Contaminated sharps including pipette tips are disposed of in “sharps bins” that once full are sealed and sent for incineration by waste contractor. Monitoring and checks will be made on a weekly basis to ensure that liquid waste is being inactivated correctly and that the plastic waste is correctly bagged. Standard Operating Procedures will be used to ensure compliance.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Following overnight treatment the inactivated liquid waste will be flushed down the sink. The disinfected plastic ware will then be bagged as biohazard waste and disposed of by a contractor (e.g. SRCL) via incineration. Contaminated sharps including pipette tips are disposed of in "sharps bins" that once full are sealed and sent for incineration by waste contractor. Monitoring and checks will be made on a weekly basis to ensure that liquid waste is being inactivated correctly and that the plastic waste is correctly bagged. Standard Operating Procedures will be used to ensure compliance.

Other(s)

Use of immortal cell lines (e.g. HEK293 or CHO-K1) that have been transfected with human or animal D

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMSC discussed the operational plans and the remit of Aurelia Biosciences service offerings with respect to GMO's. The summary risk assessment represents the current scope of Aurelia Bioscience services. A decision was reached that the work to be conducted would be restricted to Class I GMO's at this time. The GMSC acknowledged that this policy would be reviewed in the future as the business need required.

Give brief details of the genetic modification safety committee

The committee is composed of four members including the biosafety officer, a technician (providing staff representation) and an executive director of the company along with a University Academic, with extensive experience in human and environmental safety, acting as an expert advisor. The Safety Committee fulfils the responsibilities under GMO Contained Use Regulations to approve risk assessments and provides guidance and direction on good bio-safety at the laboratory. The Safety Committee is representative of all people having access to the laboratory and will encourage discussion to ensure the views of all members are taken into account. Risk assessments will be circulated amongst the committee for scrutiny and commented on electronically & revisions will be made as necessary. The committee will meet at minimum twice a year with the ability to additionally meet promptly as and when needed.

Waste disposal

The only waste that should be produced will be that arising from any breakages or rejected stock. As the material is supplied in vials and will be maintained frozen at all times while on site. It is not anticipated that significant quantities of waste will be produced. Any waste that is generated will be consigned as genetically modified clinical waste for incineration at a site notified to the HSE under the GMO (Contained Use) Regulations. Such waste will be transported in UN approved sealed waste units.

Spillage

Any spillage of HSV1716 will be inactivated by immersion in Virkon or Chloros overnight. Non-disposable items will also be immersed in Virkon or Chloros overnight prior to normal cleaning. Manufacturer's data on the disinfectant and its methods of use will be kept in the area spillage kits.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

The work covers the receipt, storage, labelling and distribution of pre-packaged vials (within a clinical supplies facility). A full assessment has been carried out and through the GMSC has been assigned Containment Level 1 and Activity Class 1.
### Project Additional Information

**Purposes of the contained use**

Storage and Distribution

**Recipient or parental organism**

The recipient organism is Adenovirus type 5; the taxonomy of which is detailed below:
- **Scientific Name:** Adenovirus Type 5 (Ad5)
- **Group:** Group III, Subgroup C
- **Family:** Adenoviridae
- **Genus:** Mastadenovirus
- **Species:** Human adenovirus
- **Strain name:** Serotype 5

**Host/vector system**

The gene transfer vector is a recombinant type 5 adenovirus vector containing the human interferon α2b (IFNα2b) gene. The vector was generated by recombination between an IFN-α2b-containing plasmid and a derivative of adenovirus type 5.

**Origin & function**

Replication deficiency: the final vector is replication deficient, as a consequence of removing the adenovirus E1a and E1b regions.
- Transfer of human IFN-α2b complementary DNA (cDNA): when administered locally to the pleural space, the vector transfects both normal mesothelial and malignant mesothelioma cells, resulting in the production of high and sustained local concentrations of IFN-α2b protein within the pleural space and tumor.

**Evaluation of foreseeable effects**

Expression is measured for each batch of rAd-IFN clinical material.
- Expression of IFNα2b is determined using a limit assay which is reported qualitatively (expresses/does not express IFN). The assay is complementary to the infectivity and potency assays.
- rAd-IFN has been engineered to be replication-incompetent and is naturally integration deficient. Therefore infection leading to replication of the GMO (and therefore potential for dispersal) is not possible under normal circumstances.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A - Bathate facility is Storage and Distribution only

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

If a spill occurs on site the waste will be processed as follows:
Disposable items should be placed in biohazard bags (or other appropriate designated containers) and incinerated (rAd-IFN is sensitive to heat; 1 hour at 56°C is used to inactivate the virus, or autoclaving at 121°C for a minimum of 15 minutes). Autoclaving will be carried out via an approved contractor. Once the GMO has been autoclaved it will be sent for incineration via an approved contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Storage and Distribution Only, recipient sites will access the risk to there operations/ people/ environment and consult with their own site GMO Safety Committee.

Project Ref 3150/21.2

Date Ackn'd: 16/06/2021
CU2 Project Title: Secondary Packaging, Storage and Distribution at the Catalent Bathgate facility
Class: Class 2
CultureVolClass2: Not Applicable
CultureVolumeClass3-4: Not Applicable
### Project Additional Information

#### Purposes of the contained use
Secondary Packaging (labelling vials), Storage and Distribution of Clinical Trial material.

#### Recipient or parental organism
No hazard identified from 293 or 293TR cells

#### Host/vector system
293 cells (human cells with part of the adenovirus genome integrated, so that adeno protein E1 is expressed). 293TR cells (293 cells expressing TetR repressor protein)

The recombinant adenoviral vector is replication incompetent, and can only form infectious particles in 293 cells, not in other human or animal cells, and cannot therefore cause a disseminated infection or disease.

#### Origin & function
Antigen to be used are targets of immune response. MAGEA3-NYESO is not allergenic or toxic but could potentially be oncogenic or unknown function.

Transfection of 293 cells with the recombinant adeno genome and production of adeno particles for animal immunisations and pre-Master Virus Seed intended for clinical manufacture. Max volume 10 x 500 ml

#### Evaluation of foreseeable effects
The resulting genetically modified virus will be infectious but will be replication defective. Expression of the inserted MAGEA3-NYESO may increase the hazard of the virus.

The vector is therefore assigned to hazard group 2.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A - Bathgate facility is Secondary Packaging (labelling of vials), Storage and Distribution only

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from autoclave on site. As per client information the use of Virkon solution is sufficient to deactivate the material.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
If a spill occurs on site the waste will be processed as follows:
Area will be evacuated and a Risk Assessment completed. Disposable items should be placed in biohazard bags (or other appropriate designated containers) and incinerated. The material will be sent for incineration via an approved contractor.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment
Secondary packaging (labelling of vials), Storage and Distribution, recipient sites will access the risk to there operations/people/environment and consult with their own site GMO Safety Committee.

CU2 Project Title Secondary Packaging, Storage and Distribution at the Catalent Bathgate facility (MVA-NYESO)

Class 2

CultureVolClass2 Not Applicable

CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements [N]

Tick if notifying a connected programme of work [N]

Historical Significant Changes [N]

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Secondary Packaging (labelling vials), Storage and Distribution of Clinical Trial material.

**Recipient or parental organism**

NONE: Primary chicken embryo fibroblasts from an SPF flock may be handled at containment level 1. Hazard Group 1 for all mammalian cell lines. Cell lines have been screened for the presence of contaminating agents.

**Host/vector system**

NONE: The recombinant MVA vector can only form infectious particles in the relevant permissive cells, not in other human or animal cells, and cannot therefore cause a disseminated infection or disease.

**Origin & function**

NONE: The resulting genetically modified virus will be infectious but will be replication defective. The inserted NYESO gene may increase the overall hazard group, as the function of the antigen is not fully known.

The NYESO gene is synthetically produced and cloned and will be derived from plasmids for this work.

NYESO is not allergenic or toxic and not known to be oncogenic. However, the function is not fully known.

Infection of CEF cells with the recombinant MVA and production of recombinant MVA particles. Maximum cell culture volume 2 x 1.3 litres ml in Vaccitech laboratories.

**Evaluation of foreseeable effects**

The recombinant MVA-NYESO particles generated in the permissive cells will transduce animal cells and express the NYESO transgene. The proteins will then be processed by the normal cellular machinery. If injected into animals, an immune response will be generated against the recombinant protein. However no further infectious particles can be formed.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A - Bathgate facility is Secondary Packaging (labelling of vials), Storage and Distribution only.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Derogation from autoclave on site. As per client information the use of Virkon solution is sufficient to deactivate the material.

## Project Additional Information

### Purposes of the contained use

Secondary Packaging (labelling vials), Storage and Distribution of Clinical Trial material.

### Recipient or parental organism

Primary chicken embryo fibroblasts from an SPF flock may be handled at containment level 1. Hazard group 1 for all mammalian cell lines. Cell lines have been screened for the presence of contaminating agents. CEF can be considered as especially disabled hosts and are unable to survive outside of the laboratory environment. CEF are primary cell cultures with a limited passage capability and no tumorigenic potential.

### Host/vector system

The recombinant MVA vector can only form infectious particles in the relevant permissive cells, not in other human or animal cells, and cannot therefore cause a disseminated infection or disease.

### Origin & function

MAGE-A3 is one of the melanoma antigen gene (MAGE-A3)-type antigens. This protein is expressed in various tumour cells but not expressed in normal tissues except in male-germline cells that lack MHC class I molecules. Since the MAGE-A3 protein is restricted to germ cell of testis and trophoblast of placenta which are immune privileged tissues, the protein is highly immunogenic and recognized by CTLs when expressed elsewhere. MAGE-A3 is the most frequently expressed MAGE-A3-type antigen in human cancers.

Infection of CEF cells with the recombinant MVA and production of recombinant MVA particles. Maximum cell culture volume 2 x 1.3 litres ml in Vaccitech laboratories.

### Evaluation of foreseeable effects

Negligible. MVA-MAGE-A3 this poses no environmental impact as the recombinant vector cannot disseminate. In additional, all waste is inactivated, and any transported materials are suitably packaged according to UN3373. The resulting genetically modified virus (MVA-MAGEA3) will be infectious but will be replication defective. There potential tumorigenic nature of the MAGE-A3 inserted gene increases the potentially hazardous nature of the recombinant MVA. MVA-MAGEA3 is therefore classified as Hazard Group 2.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A - Bathgate facility is Secondary Packaging (labelling of vials), Storage and Distribution only

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from autoclave on site. As per client information the use of Virkon solution is sufficient to deactivate the material.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

If a spill occurs on site the waste will be processed as follows:

Area will be evacuated and a Risk Assessment completed. Disposable items should be placed in biohazard bags (or other appropriate designated containers) and incinerated. The material will be sent for incineration via an approved contractor.
Secondary packaging (labelling of vials), Storage and Distribution, recipient sites will assess the risk to their operations/ people/ environment and consult with their own site GMO Safety Committee.

Please enter comments on the GM safety committee on the risk assessment

Secondary packaging (labelling of vials), Storage and Distribution, recipient sites will assess the risk to their operations/ people/ environment and consult with their own site GMO Safety Committee.

**Premises Conditions**

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  
Y

Give brief details of the genetic modification safety committee

Oxford Genetics GM Risk Assessments are reviewed and approved by the Biological Safety Committee that we have established within the company. This committee provides guidance on all safety aspects of projects that are proposed within the company. It attempts to identify possible hazards associated with the proposed work that could compromise the safety to the general public, the risk of cross contamination or recombination, the risk of release into the community of GMOs, and any ethical considerations that may be relevant. Its members are drawn from a variety of scientific backgrounds and bring a diverse range of expertise, both within and outside, of the company itself, from University lecturers to MDs. The Committee conducts its business both electronically and in meetings on an ad hoc basis whenever new GMO projects are proposed.

02/03/2022
Any Solid GMM Biological Waste (including flasks, pipettes, tips etc) is to be sterilised in an autoclave that has been validated to ensure the sterility of autoclaved waste. After autoclaving, bags will be transferred to yellow clinical waste bags no more than 3/4 full and closed with a black cable tie. Full clinical waste bags are put in a locked cabinet for collection by the waste disposal service where they will be incinerated.

Liquid GMM Biological Waste is to have sufficient Virkon powder added to it to make it at least 1% overall and left for a minimum of 24 hours to inactivate any viable pathogenic material. Thereafter it is to be disposed of down the sink with plenty of water.

Contaminated sharps such as needles used in banding should be soaked in 1% Virkon for 24 hours then disposed of in the sharps bins provided. Full sharps bins are collected by the waste disposal contractors and incinerated off site. The process of disinfecting with Virkon has been demonstrated to completely destroy any infectivity or viability of every microorganism used by our own staff by the manufacturere of the powder. Susceptibility of any new GMO to killing in this way will be validated prior to use.

**Please enter comments of the GM safety committee on the risk assessment**
The GMO Biological Safety Committee reported that the genetic engineering conducted at Oxford Genetics poses little to no risk to any of the companies' members, the environment, or the general public. It is of a non-infectious, non-hazardous nature and the genes that are being encoded within their genetic material have no inherent biological toxicity. It was noted that a Risk Assessment number should be used to help track Risk Assessments (this has now been added), and the committee wanted to remind the company to keep all manufacturer's literature and product information for any vectors, organisms or cells that are being purchased, to add to the background safety information. The committee also noted that every risk assessment should be reviewed on a regular basis to ensure they are still accurate and applicable.

**Project Additional Information**

**Purposes of the contained use**

To improve the production processes for replication incompetent retrovirus and lentivirus particles in terms of viral titres, safety and infectivity in a range of different cell types.

**Recipient or parental organism**

The parental organism of retroviral vectors are Moloney Murine Leukemia Virus (MoMLV) and/or Murine Stem Cell Virus (MSCV) belonging to the gammaretroviral genus of the Retroviridae family. The parental organism of lentiviral vectors is Human immunodeficiency virus (HIV) belonging to the lentiviral genus of the same family of viruses. Following infection with retroviruses/lentiviruses, the viral genome stably integrates into the genome.
of the host cell whereby it uses the host cell replication machinery to replicate, giving rise to a persistent infection. Particularly the gammaretroviruses have a bias for integration near proliferation-associated genes or transcriptional start sites endowing them with a high potential for oncogenesis through insertional mutagenesis. Lentiviruses on the other hand show a stronger preference for integrating within active transcription units with no such bias and so are generally considered nononcogenic. Gammaretroviruses can infect only actively dividing cells whereas lentiviruses can also target nondividing cells.

Wild-type MoMLV can infect only mice and is oncogenic as chronic productive retroviral infection allows insertional mutagenesis leading to cell transformation and tumor formation. However, amphotrophic envelope MoMLV or recombinant viral particles pseudotyped with non-native envelope can have a wider host range which might include humans and other vertebrates. Therefore, infection of humans can occur only with such amphotrophic or pseudotyped viruses following direct injection or exposure of mucosal membranes. However, as highlighted, MoMLV derived vectors can infect only actively dividing cells, though, following cell entry they are unstable and lose their ability to integrate with a half-life in the range of 5.5 to 7.5 h.

MSCV is a recombinant virus, derived from PCC4-cell-passaged myeloproliferative sarcoma virus (PCMV) with further mutations in the 5’ untranslated region, with the ability to infect mouse embryonal carcinoma and embryonal stem cells. Once again, only viral vectors derived from this virus pseudotyped with a glycoprotein targeting human cells can pose a potential risk to humans following direct exposure.

Wild-type HIV infects vital cells in the human immune system such as helper T cells (specifically CD4+ T cells), macrophages, and dendritic cells. Transmission occurs via blood, semen, vaginal fluid, pre-ejaculate, or breast milk. It causes life-long infection through integration into the host genome as well as host immunity evasion. Within 2-4 weeks of infection follows the acute infection stage which most often manifests with flu-like symptoms which include fever, swollen glands, sore throat, rash, muscle and joint aches and pains, and headache. During this time the virus replicates in large amounts, destroying CD4+ T cells in the process. This is followed by a response from the immune system which lowers the level of virus in the body, bringing up the number of CD4+ T cells again. The disease is then in a mostly asymptomatic clinical latency stage whereby the virus replicates at very low levels. Eventually, the disease progresses to AIDS whereby the number of CD4+ T cells falls below a defined threshold, whereby the infected person becomes vulnerable to dangerous opportunistic infections.

**Host/vector system**

The vector system is lentiviral or retroviral delivery of transgenes into mammalian cells. The most common cell type used for production will be
either adherent HEK 293/HEK 293T cells or suspension 293 cells. These cells are derived from human embryonic kidney cells and are widely used as they are easily maintained in culture and are very amenable to transfection. They differ from normal embryonic kidney cells as they have been transformed with adenovirus 5 DNA. Specifically, a 4.5 kb insert from the left arm of the viral genome is found in human chromosome 19 which includes the E1 genes, which normally function in replication of the wild-type adenovirus. The E1 proteins, originally described as immortalising oncproteins, can induce mitogenic activity and allow the HEK293 to proliferate indefinitely. Suspension 293 cells are HEK293 cells that have been adapted to growth in high-density suspensions in serum-free chemically defined medium. HEK 293T cells have an additional insertion of the SV40 Large T-antigen, another viral oncogene which acts by suppressing the tumour suppressor Retinoblastoma protein, enabling the by-pass of the G1/S checkpoint and entry into the S-phase of the cell cycle. Additionally, it allows episomal DNA replication from SV40 ORIs providing extra plasmid amplification within the cells.

The viral transfer and packaging plasmids will be transfected into HEK 293/293T or 293 cells either for transient expression or transfected linearised to allow stable integration into the cell genome to generate stable virus producer cell lines. This should not alter the characteristics of the cell line beyond the ability to produce recombinant retroviral or lentiviral particles. Target cells that will be subsequently transduced with such generated retroviral/lentiviral particles will stably integrate the delivered DNA into their genome. It will be ensured that the transgenes used will not be oncogenic (or potentially oncogenic) or any known cytotoxins. The intended effect of the vector in the host is that the transgene is permanently expressed. This will change the characteristics of the transduced cell at the level of gene and protein expression. In a therapeutic system, such change would constitute for example restoring the function of a defective gene or adding an additional functionality to the cell such as for example expression of a chimeric antigen receptor in a T-cell enabling such altered T-cell to target cancer cells for destruction, and as such this change will be desirable.

The plasmid backbones used will be designed at Oxford Genetics, whereas the viral sequences will be taken from NCBI records and synthesized externally as required. The work to be undertaken will involve engineering or modification of pre-existing retroviral and lentiviral packaging and transfer plasmids to improve the production of replication incompetent retrovirus and lentivirus particles in terms of viral titres, safety and infectivity in a range of different cell types. Genetic inserts for the transgenes will be predominantly human genes, either wild-type or various fusion/truncated genes, reporter genes and tags. Inserts will not include known protein encoded toxins, superantigens or oncogenes and so should not confer potentially harmful
biological activity. Transgenes delivered by the recombinant virus are intended to be stably integrated and so permanently expressed in transduced cells. In some cases, the transgenes may be intended for therapeutic use to supply defective function or provide an additional functionality of therapeutic benefit. In the case of reporter genes, the intended function of the insert is likely to be assessment of the viral titre and as a measure of infectivity and level of gene expression during optimisation of the transient and stable cell production methods.

Evaluation of foreseeable effects

The generated recombinant retroviral/lentiviral particles will only contain the gene of interest flanked by viral packaging signals in terms of genetic information and so will lack the ability to self-propagate. Yet such particles will still be able to infect target cells, effectively delivering the gene of interest which subsequently becomes stably integrated into the genome. The major risks to be considered are potential for generation of replication-competent viral particles (RCP) via homologous recombination and the potential for oncogenesis or other deleterious effect through insertional mutagenesis. The risk of generation of RCP during virus manufacture is very low due to employing a plasmid system where essential viral genes will be separated onto different plasmids with very low homology. Reconstitution of a replication-competent retrovirus or lentivirus particles would require multiple specific recombination events to take place in the presence of a wild-type virus and is thus, highly unlikely. Similarly, this holds true for transduction of target cells where no prior viral sequences should be present precluding any recombination events.

As the vectors will stably integrate into the genome of transduced cells, if the site of integration is near protooncogenes or tumour-suppressor genes, their expression pattern could be altered such that cell transformation will follow. This risk is higher with retroviral rather than lentiviral vectors given the bias of the parental organisms towards such sites. Additionally, there is a risk of insertion within endogenous gene sequences, potentially disrupting their function.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from containment level 2 measure (schedule 8 table 1a) are not needed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid biological hazardous waste and contaminated consumables shall be generated. Liquid waste is to be treated with 1% Virkon for at least 30 mins before being flushed down the sink with plenty of water.
Any consumables that come into contact with viral material are to be packaged appropriately and sent for incineration by a licenced third party contractor as biological hazardous waste. Virkon is a disinfectant shown to be active against all families of virus as well as large numbers of bacteria and fungi. The comprehensive range of biocides within virkon target the virus in varying ways, this means that resistance against disinfection can not occur and the virus is at minimum deactivated but most likely destroyed. The efficacy of virkon has been sufficiently validated through testing by the manufacturer and its users. Using incineration by a third party is the only way to ensure a 100% kill of all biological materials on contaminated consumables.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment has been reviewed to have been carried out correctly and sufficiently with control measures in place that are appropriate to minimise personnel and environmental risks associated as well as being in line with the regulatory requirements. The genetic modification safety committee acknowledges that this contained use excludes the use of working with any sharps or harmful genetic inserts. If the stated project needs change with regards to these exclusions then it is acknowledged that a full review of the contained use be carried out. The information outlined in this notification is in-line with the risk assessment carried out for the generation and production of retroviral and lentiviral vectors and particles.

Project Ref 3151/19.1

02/03/2022
Production of human Adenovirus particles (Adenovirus type 5)

To improve and carry out the production, purification and concentration processes for type 5 Adenovirus and to assist in the titration of Adeno-associated virus. Additional ly, further modifications to the Ad5 GMO may include encoding reporter (fluorescent and luminescent) transgenes to enable tracking of viral infection in vitro and in vivo.

The Ad5 GMO in question is a replication-competent form that resembles wildtype-adenovirus infection with some modification causing a reduction in pathogenicity. Wild type adenovirus infection varies in clinical manifestation and severity; symptoms include fever, rhinitis, pharyngitis, tonsillitis, cough and conjunctivitis; common cause of nonstreptococcal exudative pharyngitis among children under 3 years; more severe diseases include laryngitis, croup, bronchiolitis, or severe pneumonia; a syndrome of pharyngitis and conjunctivitis (pharyngoconjunctival fever). Most of the general population harbour neutralising antibodies to Ad5 and infections are generally self-resolved. Incubation period: 1-10 days. The virus is stable at temperatures of 4°C or less and cannot infect organisms other than humans and some primates.

The vector system in question is a replication-competent Ad5 vector transgene delivery into mammalian cells. The genome of the vector is encoded in a plasmid DNA vector to allow propagation of the DNA in bacterial cells and the viral vector is produced by transfection into mammalian cell lines. The most common cell type used for production of the viral vector will be either adherent HEK 293/HEK 293T cells or suspension 293 cells. These cells are derived from human embryonic kidney cells and are widely used as they are easily maintained in culture and are very amenable to transfection. They differ from normal embryonic kidney cells as they have been transformed with adenovirus 5 DNA. Specifically, a 4.5 kb insert from the left arm of the viral genome is found in human chromosome 19 which includes the E1 genes, which normally function in replication of the wild-type adenovirus. The E1 proteins, originally described...
as immortalising oncoproteins, can induce mitogenic activity and allow the HEK293 to proliferate indefinitely. Suspension 293 cells are HEK293 cells that have been adapted to growth in high-density suspensions in serum-free chemically defined medium. HEK 293T cells have an additional insertion of the SV40 Large T-antigen, another viral oncogene which acts by suppressing the tumour suppressor Retinoblastoma protein, enabling the by-pass of the G1/S checkpoint and entry into the S-phase of the cell cycle. Additionally, it allows episomal DNA replication from SV40 ORIs providing extra plasmid amplification within the cells.

**Origin & function**

The Ad5 GMO will be constructed by de novo DNA synthesis encoding the full (or partial) genome of human adenoviruses. Viral particles will be produced by transfection into producer cells (HEK293, HELA) for production of viral particles. Viral particles recovered from plasmid DNA constructs will be further amplified in producer cells at midscale (HYPERflask) and purified using caesium chloride density centrifugation. Adenoviruses will be used as a helper virus to induce replication of recombinant adenov-associated viruses (rAAV) in producer cell lines. rAAV are replication deficient AAV that need factors provided in trans for replication. Adenovirus will be used to infect the cells to provide factors necessary for rAAV replication. Another potential use is to produce recombinant proteins - native, bacterial and viral antigens, structural proteins, reporter proteins, antibodies and single-chain antibody molecules. Proteins associated with tumorigenesis or toxins will not be produced and are not in the remit of this notification.

**Evaluation of foreseeable effects**

The Ad5 GMO in question is a replication-competent form that resembles wildtype-adenovirus type 5 infection that can cause a self-limiting infection of the upper respiratory tract and the common cold in humans. This form of Ad5 is only able to infect humans and some primates so poses little risk to the environment and most of the general population harbour neutralising antibodies to Ad5 and infections so would generally be self-resolved with little effect to human health if infection were to occur. The specific modifications to this vector will include the addition of encoding reporter (fluorescent and luminescent) transgenes to enable tracking of viral infection in vitro and in vivo, which will pose no additional effects to human health or the environment compared to the wild-type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Derogation from containment level 2 measure (schedule 8 table 1a) are not needed.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid biological hazardous waste and contaminated consumables shall be generated. Liquid waste is to be treated with 5% Chemgene for at least 30 minutes before being flushed down the sink with plenty of water. Any consumables that come into contact with viral material are to be packaged appropriately and sent for incineration by a licenced third party contractor as biological hazardous waste or autoclaved using a validated method before disposal. Chemgene is a disinfectant shown to be active against all families of virus as well as large numbers of bacteria and fungi. The comprehensive range of biocides within Chemgene target the virus in varying ways, this means that
resistance against disinfection can not occur and the virus is at minimum deactivated but most likely destroyed. The efficiency of Chemgene has been sufficiently validated through testing by the manufacturer and its users.

The risk assessment has been reviewed to have been carried out correctly and sufficiently with control measures in place that are appropriate to minimise personal and environmental risks associated as well as being in line with the regulatory requirements. The genetic modification safety committee acknowledges that this contained use excludes the use of any harmful genetic inserts. If the stated project needs change with regards to these exclusions then it is acknowledged that a full review of the contained use be carried out. The information outlined in this notification is in-line with the risk assessment carried out for the production of human adenovirus type 5.

Give brief details of the genetic modification safety committee

The genetic modification safety committee is a sub-group of the Biological Safety Committee, which has members from the Life Sciences Department, the Life Sciences Technician Team and from the central University Health and Safety and the Environmental Sustainability Departments.

The genetic modification safety committee has received advice and guidance from a biological safety officer from the neighboring, University of Birmingham

Liquid cultures and contaminated laboratory glassware will be disinfected by submersion and soaked in 1% Virkon solution for at least 4 hours. Samples will be regularly tested by plating on agar plates to assess killing efficiency.

Larger culture volumes may be sterilised by autoclave, at 126°C for 15 minutes, as an alternative.

GMMs contained on solid agar media will be sterilised by autoclave, at 126°C for 15 minutes.

Contaminated tissues, gloves, wipes etc will be sterilised by autoclave, at 126°C for 15 minutes.

All autoclaved waste will be disposed of to landfill in black bags.

Pipette tips, cuvettes, centrifuge tubes and other laboratory plastics contaminated with GMMs will be sterilised by autoclave, at 126°C for 15 minutes.

Sterilisation by autoclave will be done in the two large capacity autoclaves that are present in the technical preparation room adjacent to the research laboratories. All autoclaved waste will be disposed of to landfill in black bag waste.

The waste stream described above is supplemented through a contract for sharps collection through Cannon Hygene. This contract is currently being extended to include yellow bag waste - which will alleviate the requirement to autoclave tissues, gloves, wipes etc.

Contaminated spills will be sterilised locally by wiping with 1% Virkon solution.

Give brief details of the genetic modification safety committee

The genetic modification committee at MISSION Therapeutics is composed of the chief operating officer of the company acting as head of health and safety, the biological safety officer (head of biology) and a health and safety laboratory manager (senior scientist).

The health and safety committee meets approximately every month and all aspects of the company health and safety are reviewed, including matters related to genetic modifications.

Risk assessments related to genetic modifications are established by scientists planning on performing the procedures and reviewed by the biological safety officer as well as the head of health and safety.

Please enter comments of the GM safety committee on the risk assessment

The MISSION Therapeutics genetic safety committee has evaluated the risk assessment for the proposed GMM procedures and has agreed that the proposed activities will fall into level 1 and the committee supports the CU1 application.
To enable the generation and use of recombinant self-inactivating second or third generation lentiviral particles (by commercial research organisations or in house using commercially available 3rd generation lentivirus systems) encoding:

1) Open Reading Frames (ORFs), cDNAs, peptides
2) Specific gene sequences
3) Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro)

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues.

The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which plasmids containing lentiviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

The lentiviral vectors which will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent.

However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences.

For example, second and third generation Lentiviral Expression Systems include the following key safety features:

In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and nef) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.

In addition to this in the third generation lentiviral vectors:
• The Lenti expression vectors contain a deletion in the 3' LTR (boU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Vee et al., 1987; Vu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
• The number of genes from HIV-1 that are used in the system has been reduced to three (Le. gag, pol, and rev).
• Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
• Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them containLTRs or the 4J packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced. Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphoteric 'helper' cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

Origin & function

Selectable markers - examples (but not restricted to);
D Ampicillin resistance: E.coli derived
D Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
D Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to);
D Fluorescent proteins as reporters;
• GFP derived from the jellyfish Aequorea victoria and variants of this
D Luciferase - class of oxidative enzymes used in bioluminescence
• renilla luciferase derived from the Sea pansy (Renilla reniformis)
• firefly luciferase derived from the firefly Photinus pyralis.

Open reading frames, cDNAs and gene sequences encoding GFP or Luciferase proteins and I or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding GFP or Luciferase proteins).

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and I or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) - all human derived.
This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in third generation SIN lentiviral vectors. Any use of lentiviral particles encoding oncogenic inserts will require appropriate controls and operator training.
The lentiviruses are, at worst, amphotropic or pseudo typed with VSV G protein, either of which confers a broad host tropism including human cells. However, the lentivirus is self inactivating and there is thus no possibility of it multiplying further.

Since some of the inserted DNA could code for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance (Part 2, section 2.11 "Retroviruses", para. 18-20).

Even for the non oncogenic inserted DNA, there is a slight but non negligible risk due to the presence in the lentiviral vector of the Woodchuck Post-transcriptional Regulatory Element. The WPRE containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance (Part 2, section 2.11 "Retroviruses", para.13)).

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus. But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

Second or third generation lentivirus vectors will be used in all experiments.

Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance (Part 2, section 2.11 "Retroviruses", para.30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. our 2nd or 3rd generation lentivirus vector systems), gloves should be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits invasion of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
  1. We do not have access to an autoclave within our area of the building
  2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

  All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM1 05/4.1.
  
  Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21 Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled “Eurobins”. Contents of the bin are recorded and collections by the local
registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor’s facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major road traffic accident, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM1 05/4.1.

Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21 Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled “Eurobins”. Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor’s facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major road traffic accident, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Give brief details of the genetic modification safety committee

The committee consists of: Biological Safety Officer (BSO), Genetic Modifications Safety Officer (GMSO), SHE Officer, Head of Medicinal Chemistry (Senior Management Representative), Scientist from Pharmacology lab (representative of technical staff), a representative from the University of Liverpool (UoL Biological Safety officer), and a project manager (Management Representative). The Committee meets every two months, or more often if required. Risk Assessments and background reading is circulated to committee members by the GMSO a minimum of two weeks in advance of a committee meeting. The meeting is chaired by the GMSO. Risk Assessments are discussed, and either passed with comments or further information may be requested and risk assessment is put back for discussion at the next committee meeting. The Minutes are circulated after the meeting and should be agreed upon, sent to senior management and stored.

Oncology research will be carried out.

Solid Waste will be bagged and autoclaved at 126°C for approximately 1hr, it will then go through a drying process in the autoclave for approximately 1hr, for 100% kill. The autoclave will give a print out which shows the temperature it reaches and the duration it is at temperature for, printouts will be checked to ensure temperature is reached and to ensure temperature is maintained for required length of time, printouts will be retained & logged. Autoclaved waste will then be sent for incineration with SRCL waste disposal company. Waste will be incinerated at one of three incineration sites (at Speke, Crewe or Bolton), used by SRCL. Liquid waste will be handled in the same way. If the autoclave is unavailable or breaks down, Redx Oncology has access to an autoclave on the 5th floor of the Duncan Building. If both autoclaves are broken/inaccessible liquid waste will be mixed with Virkon (final concentration of Virkon 1.25%), for 24 hrs to inactivate (99.99% kill).

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment Y

Please enter comments of the GM safety committee on the risk assessment

The Genetic Modifications Safety Committee (GMSC), agreed with the classification of the Risk Assessment as Class I. The genetic modification of the cells does not make the original parental cell line any more dangerous/infective. The technical representative on the GMSC indicated that they had worked with this commercially available Gli-bla 22 Rv1 cell line before and had no concerns relating to the safety classification.

Project Ref 3158/12.1

Date Ackn'd 20/06/2012 CU2 Project Title Smoothened HEK293/D473H Smoothened HEK293 Class 2 CultureVolClass2 1-50 Litres
Project Additional Information

Purposes of the contained use

Please See Section 17
These stably transfected cell lines will be used to assess the efficacy of novel compounds ability to inhibit signalling in the Hedgehog signaling pathway, via inhibition of the Smoothened receptor. We will use these stably transfected cell lines to assess the efficacy of novel Smo Inhibitors at inhibiting both WT Smo and D473H Smo receptors, in functional assays and in binding assays.
Aberrant activation of the Hedgehog signalling pathway (of which smoothened is an integral part), is present in 25% of all cancers.

Recipient or parental organism

Please See Section 17
HEK 293 (human embryonic kidney) cells will be purchased from ATCC and contain Adenovirus and are classified as biosafety level 2.

Host/vector system

Please See Section 17
MMLV-derived retroviral vector, will be used to transfect HEK293 cells with our gene of interest (human wild type smoothened of human D473H smoothened). There are no known hazards associated with the use of the MMLV-derived retroviral vector, a marker rescue assay has been done on this vector virus showing there is no replication competent virus left.

Origin & function

Please See Section 17
Smo (Smoothened) is a protein involved in signalling in the Hedgehog pathway. Hedgehog pathway activation is initiated when Hedgehog ligand binds Patched receptor and relieves its inhibition of Smoothened. This allows Smoothened to move into the cilia of cells and interact with complex of proteins resulting in activation of the Glioma associated family of zinc finger transcription factors which translocate to the nucleus, and result in transcription of Hedgehog target genes. Tumours in about 25% of all cancer deaths are estimated to involve aberrant Hh pathway activation. The Hh pathway is also thought to be important for driving self-renewal of cancer stem cells.

Evaluation of foreseeable effects

Please See Section 17
The inserted gene does not encode a pathogenicity determinant, such as an adhesin, a penetration factor or a surface component providing resistance to host defence.
mechanisms. The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by the recipient microorganism. Thus it is unlikely to have any indirect effects. Gene transfer or recombination of the GMM with a wild-type microorganism, is unlikely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to survive in the environment for long enough for any such gene transfer to take place. If gene transfer did take place it could result in expression of WT Smo or D473H Smo in cell. Overexpression of Smo could result in aberrant signalling in the Hh pathway, giving rise to an oncogenic phenotype. D473H Smo, gives rise to Smo resistant to inhibition by several Smo antagonists.

02/03/2022
pcDNA3.1-ABCB1 will be stably transfected into He La cells to generate the cell line HeLa-ABCB1.

The generated stably transfected cell line will be used to assess a variety of in-house generated compounds if they are substrates for ABCB1. To be more specific, a clone will be chosen with ABCB1 expression levels similar to that of human tumours. This will then be used in comparison to the parental cells to determine the susceptibility of compounds towards ABCB1 using a proliferation assay.

He La cells will be purchased from ECACC and are classified as BioSafety level 2.

A pcDNA3.1-derived vector will be used to transfect HeLa cells with ABCB1. As this vector has a non-viral backbone and gene expression is driven by a CMV promoter there is no interaction between the vector and HPV-18 (which is present in HeLa cells) possible.

In cancer, multiple mechanisms can contribute to tumour resistance, and one implicated in causing multidrug resistance (MDR), whereby resistance is acquired against mechanistically and structurally distinct drugs, is the P-glycoprotein pump (Pgp); also known as multidrug resistance protein 1 (MDR1) or ATP-binding cassette (ABC).
sub-family B member 1 (ABCB1)]. This is a 170 kDa membrane integrated transporter encoded by the ABCB1 gene which is responsible for the efflux of xenobiotics from cells and controlling their absorption across the intestinal and blood brain barriers. Known substrates of Pgp include chemotherapy drugs from the taxane, vinca alkaloid and anthracycline families, which are rapidly effluxed in vitro by certain tumour cell lines over-expressing Pgp. Although the physiological relevance of Pgp to MDR in patients remains to be fully discerned, clear correlations between levels of Pgp expression and the overall efficacy of chemotherapy treatments have been found in breast cancer and certain leukaemias.

**Evaluation of foreseeable effects**

The inserted gene does not encode a pathogenecity determinant, such as an adhesin, a penetration factor or a surface component providing resistance to host defence mechanisms. The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by the recipient microorganism. Gene transfer or recombination of the GMM with a wild-type microorganism, is unlikely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to survive in the environment for long enough for any such gene transfer to take place. If Gene transfer did take place it could result in expression of ABCB1 in a cell. Overexpression of ABCB1 results in a reduced sensitivity to a large number of approved drugs. Still, there are a large number of compounds not affected by this transporter protein.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The Genomic Modification Safety Committee (GMSG), agreed with the classification of the cell line as Class II. This is due to the fact that insertion of ABCB1 into HeLa cells (the parental cell line is already biosafety level 2) makes them less susceptible to a number of drugs, but a large number of drugs are still efficacious on them.
The assay represents an invaluable system for testing the inhibitory activities of small molecules against a specific kinase of interest in the context of human cells. Cell based compound potency measurements are important components of the drug discovery process, since biochemical potency values often do not translate to cellular activity for a number of reasons, including compound membrane permeability, cellular ATP concentration, compound localisation etc.

Recipient or parental organism

HEK 293 (human embryonic kidney) cells transiently expressing either full length Human BTK WT or Mutant contain Adenovirus and are classified as biosafety level 2.
pCMV vector will be used. pCMV is a eukaryotic vector in which gene of interest is expressed under the control of CMV promoter. Vector pCMV, there is no known hazards associated with use of this vector; the vector has been commonly used to express gene of interest in mammalian cells. pCMV is a eukaryotic vector in which gene of interest is expressed under the control of CMV promoter. There is no evidence that the vector could potentially mobilize.

Origin & function

BTK is a member of the Tee family of protein tyrosine kinases and plays an important role in regulation of B-Cell receptor development & signaling. Targeted therapies that suppress B-cell receptor signalling have emerged as promising agents in the treatment of several B-cell malignancies and autoimmune disease. We have developed a number of small molecules capable of inhibiting BTK, as potential treatments for B-cell malignancies.

The activity of BTK is regulated by a variety of mechanisms, including membrane translocation & phosphorylation. LYN is usually associated with CD79B in unstimulated B cells. Upon antigen activation CD79A and CD79B are phosphorylated on their ITAMs by Tyrosine Kinases Lyn & Fyn. This results in recruitment of Syk & activation of Syk. Multiple proteins including PI3K, BLNK and BTK are also recruited to the PM. PI3K phosphorylates PIP2 to PIP3 which accumulates on inner surface of the PM and acts as a docking site for BTK recruited to the PM upon antigen activation. In unstimulated cells a very small proportion of BTK is localised to the PM. During BCR ligiation- 30% of BTK is transported to PM, through interactions of its PH domain with PIP3, generated by PI3K. Here BTK comes into close proximity of an array of proteins including cell surface receptors, Src family protein tyrosine kinases & PI3-K. Membrane targeting of BTK is a prerequisite for its phosphorylation and activation. BTK is first phosphorylated by SYK or LYN at tyrosine 551 (in its catalytic domain) and later is autophosphorylated at tyrosine 223 in SH3 domain. There are two possibilities about how BTK autophosphorylates through an intramolecular interaction involving catalytic & SH2 domains, BTK could autophosphorylate itself at tyrosine 223 autophosphorylation at tyr 223 could take place via dimerization.

Evaluation of foreseeable effects

Direct Effects: The sequence inserted does not encode an insect or animal toxin or a product which can cause silencing of a gene encoding a crucial metabolic enzyme in susceptible hosts. Overexpression of BTK could result in aberrant signalling in the BCR pathway, giving rise to an oncogenic phenotype. Mutant BTK, gives rise toibrutinib acquired resistance.

Indirect Effects: The inserted sequence does not encode a pathogenicity determinant, such as an adhesin, a penetration factor or a surface component providing resistance to host defence mechanisms. The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by recipient microorganism.

Gene transfer or recombination of the GMM with a wild-type micro-organism, is unlikely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to survive in the environment for long enough for any such gene transfer to take place. If Gene transfer did take place it could result in expression of WT BTK or mutated BTK in a cell.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste will be bagged and autoclaved at 126°C for approximately 1hr, it will then go through a drying process in the autoclave for approximately 1hr, for 100% kill. ## Project Additional Information

### Purposes of the contained use

In order to study pancreatic adenocarcinoma we aim to create 3D co-culture system to study the interaction of cancer cells with stellate cells and eventually to test the effect of compounds on this interaction. The transfection of fluorescent proteins will allow us to distinguish the two cell types from each other. This model would be a useful tool to test compounds taking into account the effect of the tumour microenvironment and an extracellular matric on the efficacy of the compounds.

### Recipient or parental organism

- **Panc-1 cells** are available from the ATCC and are classified as biosafety level 1.
- Human primary stellate cells isolated from samples collected at the Royal Liverpool University hospital. (Primary Cells: Biosafety level 2)

### Host/vector system

Pre-made lentiviral particles (from pPACKH1) will be used to transfect cells with our genes of interest. Replication-defective lentiviral vectors, such as the 3rd Generation vector provided in this product, are not known to cause any diseases in humans or animals. However, lentiviruses can integrate into the host cell genome and thus pose some risk of insertional mutagenesis. Material is a Risk Group 2 and should be handled under BSL2 controls.

### Origin & function

Both β-actin and Vimentin are housekeeping genes and have no oncogenic role. Their insertion in the proposed procedures is to allow the monitoring of different cell types within the same co-culture. Links to the products are provided below:

2. [https://www.millipore.com/catalogue/item/17-10203](https://www.millipore.com/catalogue/item/17-10203)

### Evaluation of foreseeable effects

The inserted gene does not encode a pathogenicity determinant, such as an adhesion, a penetration factor or a surface component providing resistance to host defence mechanisms. The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by the recipient microorganism.

Though highly unlikely, recombination could occur between vector coding sequences and the helper packaging sequences of any virus contained in the primary cells which will not have been screened for viruses, however its not expected to result in the formation of functional and replication competent recombinant viruses. Gene transfer or recombination of the GMM with a wild-type microorganism, is unlikely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to survive in the environment for long enough for any such gene transfer to take place. If Gene transfer did take place it could result in expression of full-length human b-actin-RFP or Human Vimentin-GFP

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid Waste will be autoclaved using an autoclave cycle for solids (>120C for 1 hour followed by a drying process for 1hr to give 100% kill). This inactivated waste will then be sent for incineration by Initial Medical Services. Liquid Waste will be autoclaved using an autoclave cycle for decontamination before being sent for incineration by Avanti.
parent company SRCL. If not possible to autoclave, liquid waste will be mixed with Vircon (final conc 10%), for 2 hrs (99.99% kill) before being sent for incineration by Initial Medical Services

The Genetic Modification Safety Committee (GMSC), agreed with the classification of the proposed GMO work as Class II. The GMSC felt that due to the proposed use of primary cells that this work warranted a Class II Classification. The GMSC recommended that secondary containment should be used when plates and cultures are in the incubator, to transport plates and flasks, and to store viruses in the freezer. The GMSC also suggested that waste should be sealed within the tissue culture hood.

Please enter comments on the GM safety committee on the risk assessment

### Project Additional Information

**Purposes of the contained use**

Reproducible 3D systems for the exploration of the interactions between the stroma and pancreatic cancer cells are not readily available. Immortalized stellate cell lines in combination with our 3D co-culture system will allow us to study the tumour-stoma interaction of pancreatic adenocarcinoma for an extended period of time.

**Recipient or parental organism**

Human primary stellate cells isolated from samples collected at the Royal Liverpool University hospital (Primary Cells: Biosafety level 2)

**Host/vector system**

The lentiviral particles used will be the following:
- Vector Name: pLenti-hTERT, pLenti-EF1α-hTERT-RFP
- Vector Type: Lentiviral Vector
- Antibiotic Information: Puromycin

**Origin & function**

Reproducible 3D systems for the investigation stroma-pancreatic cancer cell interaction are not readily available. We therefore aim to create immortalized stellate cell lines to use in 3D co-culture system. We will create immortalized stellate cell lines isolated from a normal, chronic pancreatitis and cancer by inserting human telomerase reverse transcriptase protein (hTERT) when this protein is exogenously expressed the cells are able to maintain sufficient telomere lengths to avoid replicative senescence.

**Evaluation of foreseeable effects**

The direct effect is that the human telomerase reverse transcriptase protein is an oncogene and has the capacity to immortalize any human cell which is inoculated with the virus.

With regards to indirect effects, they inserted gene does not encode a pathogenicity determinant, (e.g. and adhesin). The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by the recipient microorganism. An enhancer deletion in the U3 region of 3'ΔLTR ensures self-inactivation of the lentiviral vector following transduction and integration into genomic DNA of the target cells. The number of lentiviral genes necessary for packaging, replication and transduction is limited to three (gag, pol, rev), and their expression is derived from different plasmids, which all lack packaging signals. These plasmids share no significant homology to the expression vector, preventing the generation of replication-competent virus. None of the gag, pol, or rev genes will be present in the packaged viral genome, thus making the mature virus replication-incompetent.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

**Purposes of the contained use**

Stably transfected cell lines will be used to assess the efficacy of novel compounds ability to stimulate signalling of target receptors

**Recipient or parental organism**

Commercially available HEK293 cells. Classified as Biosafety Level 2

**Host/vector system**

Prior to purchase of the HEK293 cells they have been co-transfected with the human target receptor genes of interest and an inducible secreted embryonic alkaline phosphatase (SEAP) reporter gene. The SEAP reporter gene is placed under the control of a transcription factor. Stimulation with receptor ligands activated the transcription factor which induces the production of SEAP

**Origin & function**

The inserted sequence does not encode a pathogenicity determinant, such as an adhesin, a penetration factor or a surface component providing resistance to host defence mechanisms. The inserted gene does not encode a surface component, envelope protein or capsid protein that might bind to a different receptor to that used by recipient microorganism. Gene transfer or recombination of the GMM with a wild-type microorganism, is not likely to be a matter of concern. In the event of a breach of containment the GMM is unlikely to survive in the environment for long enough for any such gene transfer to take place. Overexpression of target receptor could result in over-stimulation of pro-inflammatory signalling pathways. HEK293 cells are tumorigenic

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be disinfected with a suitable detergent (e.g. 10% Distel or Chemgene) then autoclaved using an autoclave cycle (held at a minimum of 125 degrees C for at least 15 minutes). The inactivated waste will then be sent for incineration by a waste management contractor.
Liquid Waste will be disinfected by incubating with equal volume of suitable detergent (e.g. Distel or Chemgene) for a minimum of 2 hours before disposing to drain.

Autoclave monitoring and validation:
1. Daily Efficacy Monitoring is achieved by Chemical Indicator strips used in each cycle every day and each container of waste is sealed with colour reactive autoclave tape.
2. Alongside this are printout report checks which are used to determine if a successful cycle has been achieved in terms of temperatures and times. The printer report will also be checked to see if any alarms have been recorded thereafter.
4. Servicing is to be completed twice a year and Validation Testing annually by an authorised, competent recognised 3rd party contractor.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The Risk assessment was circulated on the 19th May 2014.

The risk assessment was discussed by the GMSC on 22nd May 2014. All committee members agreed that Class 2 is the appropriate classification for this work and that GMM_RA_A1001 is approved subject to the following actions, which have been undertaken.

Actions from meeting:

- Safety procedure documents "REDXAI PSP_002 Tissue Culture" and "REDX AI PSP_003 Waste Disposal" have been referenced in the document.
- Autoclave operating and validation procedures have been sourced from third party contractor and relevant information included in risk assessment.
- Clarification sought on Biological Safety Officer and Team Leader being one and same - agreed this is ok since on other signatory still required for approval.
- Reference made to all disinfectants currently or previously used in laboratory.
- Wording in Section 4.5.2 revised to ensure all staff working on this project have had or will be offered HBV immunisation
- Question raised as to whether cells to be segregated in cell culture incubator and liquid nitrogen store. Incubators in cell culture laboratory can be designated according to cell type/risk. Cells can be segregated into separate racks within liquid nitrogen store.
- Added comment to risk assessment confirming that no genetic modifications will be performed on Redx premises, the cell lines are commercially available with modifications in place.
- Volumetric estimates of cell usage added to risk assessment
- Wording in Section 4.6.1 amended to ensure that employees known to be immunocompromised refrain from working with these cells

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  Y

Give brief details of the genetic modification safety committee

The committee contains the following members:

- Oxford Therapeutics safety officer
- Scientific staff involved in GMM (Junior and Senior Scientist)
- Manager involved in initiating and supervising the GMM work (Director of Proteomic Discovery)

The committee will meet quarterly. An approved form detailing all the work in a project will be generated. The decisions of the committee with regard to a project and its risk assessment will be minuted.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All solid waste must be soaked in a final concentration of 1% Virkon overnight and disposed of in the grey autoclave box. Autoclave all waste by the end of the week.

All liquid waste must be made up to at least a final concentration of 1% Virkon overnight. Discard down the sink with excess water the following day.

All glassware and plastics must be soaked in at least a final concentration of 1% Virkon for at least 1 hour. Rinse thoroughly and place into the washing-up bowls or yellow bins as appropriate.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The committee reviewed the risk assessment and were satisfied that all the safety issues associated with the work had been fully addressed

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Y
Role of the Genetic Modification Safety Committee
● To advise on and review new and amended GM research activities within the Trust
● Ensure the risk assessment has been completed in accordance with the GMO (Contained Use) Regulations and Advisory Committee on Genetic Modification Compendium of Guidance (ACGM).
● Advise on the genetic modification safety training requirements needed to carry out the work of the Constitution of the Committee
The Committee should be composed of:
● Chairperson
● Secretary
● Representative from the Pharmacy Clinical Trials Research Management
● The Principal Investigator or a representative from the project group intending to carry out a particular GM activity can be invited.
● The Committee also has the right to co-opt members to serve for a period specified by the Chair of the Committee
Role of the GM Chair
The GM Chairperson should be a member of the Trusts staff. They must be nominated by the R & D Committee and formally appointed by the Trust's Associate Medical Director of Research. Their appointment must be ratified by the Medical Director on behalf of the Trust.
The GM chair must:
● Be familiar with the GMO (Contained Use) Regulations & GMO (deliberate release) Regulations
● Ensure that each application is dealt with in an unbiased manner.
● Provide advice regarding proposed GM projects.
● Give Trust approval for the project if they meet all regulatroy and local requirements.
● If approval is conditional, ensure that the risk assessment form has been amended as requested.
Role of the GM Secretary
● Be familiar with the GMO (Contained Use) Regulation & GMO (deliberate release) Regulations.
● Issue an acknowledgement to the Principal Investigator following the successful submission of a GM risk assessment form to the GMSC.
● Issue formal approval or rejection to the Principal Investigator following a GMSC meeting
● Ensure minutes of meetings are recorded and distributed as required
Duty/Role of GMSC Members
The GMSC members must be familiar with the following:
● GMO (Contained Use) Regulation & GMO (deliberate release) Regulations
● ACGM Compendium of Guidance.
● Advisory Committee on Dangerous Pathogens (ACDP) "The management, design and operation of microbiological containment laboratories" ISBN 0 71762034 4.
● Control of Substances Hazardous to Health Regulations (COSHH).
● Other relevant publications.
The chair members should:
● The Committee can seek confidential technical advice from sources outside the committee as required.
● Have an understanding of the risks to both human health and the environment that may arise from the proposed GM activity.
● Review the accuracy and detail of GM risk assessments presented to the Committee and advise accordingly.
● Ensure the risk assessment has been completed in accordance with the GMO (Contained Use) Regulations and ACGM guidance.
● Advise on the genetic modification safety training requirements needed to carry out the work.
● Consider wether the appropriate containment facilities, as indicated by the risk assessment, are available.
Meetings of the Genetic Modification Safety Committee:
The committee will only meet as required. Dates of the meetings will be fixed in advance; notice of the meetings will be circulated one week in advance and
accompanied by a meeting agenda, minutes of the last meeting and papers for discussion. The Minutes of the Committee must be issued within the two weeks of the
date of the meeting and should be reported to the R & D Committee.

An accurate record of the meeting must be kept of:
- Date of meeting.
- Attendees.
- Apologies/absences.
- Title of the projects submitted to the Committee, principal Investigator, directorate and location of work to be carried out in.
- R & D number assigned to the project.
- Agreed classification of the project and whether the notification to the HSE is required.
- Containment level required.
- Any further control measures to be taken by the personnel involved with the project.
- Amendments to be added to the risk assessment form.
- Comments and concerns raised by the GMSC members regarding the project.
- Dissenting opinion and agreed outcome.
- Actions to be taken and the named responsible person
- Minutes must be distributed to the GMSC and R & D Committee members

For activities involving GMMs, describe the waste management measures which will apply to the activity

All wastes resulting from the IMP handling are treated according to regular hospital procedure for infectious wastes. Work area must be disinfected according to the standard hospital procedure. Standard methods of waste treatment will be used, such as off the shelf disinfectants, standard heat treatment and incineration.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
TG4010 is a viral suspension of the recombinant vector MVATG9931. The recombinant vector MVATG9931 is a recombinant vaccinia virus carrying sequences coding for human mucin 1 (MUC1) antigen and interleukin-2 (IL2). MVATG9931 was generated by homologous recombination between a transfer plasmid (pTG9931) which carries a gene coding for MUC1 flanked by sequences surrounding the deletion II of Modified Vaccinia Virus Ankara (MVA) and a subclone of MVA, named N33.1, isolated in Transgene laboratory.

Recipient strain: Modified Vaccinia virus Ankara (MVA)
MVA is a substrain of the vaccinia virus, belonging to the Poxviridae family and attenuated after several passages on primary chicken embryo fibroblasts (CEF). It has been developed by Mayr and Stickl during the course of the smallpox eradication campaign. The MVA strain was obtained after 570 passages of the Chorioallantois vaccinia virus Ankara (CVA) on primary CEF. Since the 516th passage in CEF, due to the stability of its new properties described below, the attenuated virus was re-named MVA.

Human mucin-1 (MUC1) antigen
The main function of mucin, normally found at the apical surface of mucin-secreting epithelial cells in many types of tissue, is to lubricate and protect epithelial cells from the harsh environment of the lumen. The MUC1 protein is over-expressed by tumor cells and less glycosylated than the normal form of the MUC1, revealing new peptide and carbohydrate antigenic epitopes. These immunological differences between MUC1 in normal cells and in tumors make it a target for immunotherapy.

Human interleukin-2 (IL2)
IL2 cytokine is included to act as an adjuvant in the immune response as IL2 is naturally secreted by antigen-stimulated T lymphocytes and is capable of stimulating the proliferation and differentiation of lymphoid cells by binding to specific surface cell receptors. The presence of IL2 is essential for the manifestation of cell-mediated and humoral immunity as well as for primary and secondary immune responses.

The MVA strain is not found in natural ecosystems and is a highly attenuated vaccinia virus. The clinical drug product TG4010 is provided in single dose 4-mL glass vials. Each vial contains the GMO in suspension in the formulation buffer named S 08. Active chlorine at 0.6% and some chemical disinfectants like aldehydes, alcohols (e.g., isopropyl alcohol 30% or ethyl alcohol 40%), hydrogen peroxide, phenols and quaternary ammonium compounds have been established to be active on the GMO.

GMO preparation is performed in advance by the sponsor which supplies all participating clinical sites with clinical drug product individual glass vials. Then, the most hazardous procedure is the preparation of a clinical drug product dose to be administered to the patient.

Wild-type vaccinia virus may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination to smallpox.

There is no established pre-existing medical condition that increase the risk associated with this agent. In addition, to be on the safe side in any case:
Healthcare personnel: Individuals who are pregnant, who are breast feeding, who have eczema or other exfoliative skin conditions or are immunocompromised should not handle the clinical drug product or come in contact with contaminated dressings.
Patients: Individuals who are pregnant, who are breast feeding, who are under chronic treatment with any immunosuppressive drug are not allowed to take part to the
The MVA strain is not directly classified by the French biosafety commission (Haut Comite de Biotechnologies). On the other hand, the resulting recombinant MVA (MVATG9931) as well as other recombinant MVA vectors developed by the company Transgene SA have been classified as class 1 Laboratory and other health-care personnel who work with highly attenuated strains of vaccinia virus (e.g., MVA) do not require routine vaccinia vaccination. Furthermore, no reports of transmission to health-care personnel from vaccine recipients have been published. Although no formal surveillance system has been established to monitor laboratory workers, no laboratory-acquired infections resulting from exposure to this highly attenuated strain or recombinant vaccines derived from this strain have been reported in the scientific literature or to Centers for Disease Control and Prevention (CDC). Vaccinia (Smallpox) Vaccine: Recommendations of the Advisory Committee on Immunization Practices (ACIP), June 22, 2001/50(RR10):1-25 (http://www.cdc.gov/mmwr/preview/mmwrhtml/rr5010a1.htm) US National Institutes of Health (NIH): Biosafety Level 1 recommended Swiss classification: Risk Group 1, Biosafety Level 1 recommended German classification: Risk Group 1, Biosafety Level 1 recommended Containment Level 1; Activity Class 1. Notification of HSE required as first GM study at this site.

Give brief details of the genetic modification safety committee

Stratophase is a company with 15 employees. The committee is comprised of 5 members of staff representing a cross section of the stake holders in the company.

The chairman holds a PhD in Physics and has worked within and been responsible for Health and Safety in multidisciplinary (physics, chemistry and biology) laboratories for >13 years including safety policies, risk assessments and COSHH (including Containment Level II facilities).

The Biological Safety Officer and Genetic Modification Safety Officer roles are held by the same employee with >14 years of commercial experience using GM cell lines at containment levels I, II and III and >5 years experience on the Health and Safety Committee (including GM H&S) of a major biopharmaceutical company. Qualified to BSc (Hons) Microbiology.

The Committee is advised by an international expert with >20 years experience in containment level I, II and III environments for Biopharmaceutical production.

The company Health and Safety Officer sits on the committee with >15 years facility management experience and is responsible for the company's integrated pest management activity (IPM).

The committee is completed by a member of technical staff that works daily within the lab.

The scientific goal is the identification and characterisation of the life cycle of a mammalian cell.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

- Liquid waste will be autoclaved.
- All components will be autoclaved.
- The autoclave will be verified through annual thermocouple mapping (and service). Validation of the autoclave cycle will be carried out by the operator using the system controls to verify that the autoclave program was successfully carried out, and in addition Class 6 Time, steam and Temperature test strips will be used every run to verify a successful autoclave run.
- If necessary, whilst awaiting autoclave sterilisation all components will be soaked in 1% Virkon disinfectant.

Give brief details of the genetic modification safety committee

The genetic modification safety committee comprises the safety officer, a member of the sales team, project manager and/or study director. Where further information concerning a particular GMM is required, an external biological safety officer may be consulted.

GMM members will be received from external organisations (the "client") for the purpose of analysis at SGS M-Scan Ltd. All relevant risk assessments, storage requirements and waste procedures pertaining to the GMM will be obtained from the client. On submission of the relevant information, the GMSC will meet to discuss the proposed submission and decide whether to accept the GMM for analysis. Once a submission has been authorised, an internal risk assessment will be completed and circulated to company staff prior to receipt of the GMM on the premises.

Material will be received from various organisations for the purpose of analysis at SGS M-Scan. This may include proteins, viral vectors and/or toxins, all of which may pose a risk of harm to the operator and/or the environment. All material will be submitted from the client to SGS M-Scan Ltd with the relevant risk assessments containing waste management procedures. Internal risk assessments will be produced in relation to the work to be completed as SGS M-Scan Ltd. Such procedures will be adhered to during all work completed with the material at SGS M-Scan Ltd.

Solid waste: Solid waste (e.g. tips, tubes, etc.) where possible, will be decontaminated with 1% [final concentration] virkon for 60 minutes. Virkon will then be drained and washed down the sink with plenty of fresh water. The solid waste will then be placed into orange biobins. Once filtered, orange biobins will be sealed, bagged in an autoclave bag and placed into a rigid waste container (yellow) designated GM waste. Once filtered, rigid waste containers will be sealed and placed ready for collection for incineration by a licensed waste contractor (e.g. Grundon).

Liquid waste: All liquid waste will be decontaminated with 1% [final concentration] virkon for 60 minutes. Inactivated liquid waste will then be washed down the sink with plenty of fresh water.

Y

Give brief details of the genetic modification safety committee:

The Genetically Modified Organisms (Contained Use) Regulations (2000), places a statutory duty on Avacta Group businesses, and specifically on Aptuscan Ltd as an employer intending to carry out genetic modification activities, to establish a Genetic Modification Safety Committee (GMSC) prior to the start of these activities. The role of this Committee is to review all risk assessments relating to the creation, use and disposal of genetically modified organisms. Given the scope of operations in Avacta Animal Health (AAH) and Avacta Analytical (AA), we have extended the role of the Genetic Modification Safety Committee (GMSC) to take account of general biological, chemical and physical safety. As a consequence of the widened roles, the GMSC will be renamed the Laboratory Safety Committee (LSC). The proposed membership of the Committee is as follows:

- Chair: Director of Aptuscan, Head of Discovery Technology, also responsible for Laboratory Safety in Unit 651
- Biological Safety Officer: several years of post-doctoral experience in lab work, quality systems and operations management, mainly in industry; also management representative for AAH
- Staff representative for Aptuscan and lab technician, responsible for safe operations in labs E and F
- Management representative for AAH with responsibility for labs E and B
- Staff representative for AAH and lab B
- Management representative for AA and lab C
- Staff representative for AA and lab C

The combined laboratory experience of this committee exceeds 50 person years in both academic and commercial settings.

</tbody>
</table>

02/03/2022
Waste in labs B, C, E and F falls into 3 categories: non-hazardous eg packing; clinical waste eg from diagnostic assays performed with animal samples in Avacta Animal Health (AAH); and waste potentially contaminated with Class I GMM, such as pipette tips and other disposable plastics; solid microbiological growth media and liquid waste such as biological growth media and waste from the cleaning of glassware.

Liquid waste will be inactivated by incubation and cleansing with a proprietary cleaner such as Virkon, and disposed of via the drain.

Solid waste, including microbiological growth media and plastics, will be inactivated by autoclaving before disposal via incineration by an approved contractor (SRCL). The autoclave will be onsite (to be installed in laboratory E on August 14th) as SRCL are not approved for the transport or storage of GMMs.

E. coli strains and M13 bacteriophage will be used for the creation and screening of libraries of en [Level 4 (GMMs)]

For activities involving GMMs, describe the waste management measures which will apply to the activity

Review of Risk Assessment received
There was a brief discussion of molecular biological (PKF) and veterinary diagnostic (HS, RH, GS) work (ALL). It was agreed that there are potential hazards when handling biological material from animals that will need to be monitored by this committee. PKF noted that as he is also responsible for overall lab safety in 651, he will also be reviewing COSHH assessments, and making sure that we are as "joined up" as possible.

The risk assessment from Avacta Technology entitled "Affimer Arrays" had been circulated on July 12th, and had been read by all. It was agreed that technical and assessment aspects were entirely satisfactory, although the title should be changed to "Affimer Arrays and Assay Development", so as to reflect that work on assay development will also require cat I work. The committee unanimously agreed that the project had correctly been assessed as Class 1, and that the risk assessment should be passed on to AS with a recommendation that he sign off on our notification to the HSE. We remain on course to start work on Monday, September 3rd, as long as the CU1 notification form is received by HSE in the week beginning July 23rd.

[Note - this internal deadline has been missed and we will not be able to start work until September 17th 2012]

Give brief details of the genetic modification safety committee

Shyden Biotechnology Ltd is a small start-up R&D company who are tenants of the newly established Stevenage Bioscience Catalyst (SBC) within the campus site of GlaxoSmithKline (GSK) PLC. The Genetic Modification Safety Committee is made up of 2 representatives from Shyden Biotechnology Ltd, 1 representative from another tenant company, the building manager of the SBC and 1 representative from GSK. All members are experienced in GMM work and are able to assess risk assessments and how to manage projects in the SBC.

Bacteriology Yes Parasitology Transgenic Birds Microbiology Research
All liquid waste containing Class 1 GMMs will be chemically inactivated using 1% Virkon for at least 30 minutes and washed down designated laboratory sinks with copius amounts of cold water. Virkon kills 99.9995% of GMMs in 10 minutes. This will be routinely tested using agar plate colony assays.

All solid waste containing Class I GMMs will be chemically treated as above (if it contains any liquids) and after liquid disposal, the solid material will be autoclaved (124°C for 15 minutes). This effectively kills 100% if the GMMs and will be tested annually as above. The autoclaved material will then be disposed of as laboratory waste by Grundon contractors.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

This risk assessment was reviewed by the committee and after minor modifications and suggestions, it was approved. This risk assessment was also approved by Imperial College when the project was carried out there.

Give brief details of the genetic modification safety committee

The GMSC will be comprised of the Chief Scientific Officer, Biological Safety Officer, two Senior Scientists and the staff health and safety representative. Note that we are a small company, and the Chief Scientific Officer is currently also the Biological Safety Officer. A quorum for the meeting is a minimum of three individuals, to include the CSO, Biological Safety Officer (or deputy), and staff health and safety representative.

The Committee will meet a minimum of once per year to discuss routine matters, review all existing risk assessments and audit the existing procedures. The GMSC will meet more frequently to discuss risk assessments etc. that require more urgent attention

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste, including cell cultures, will be inactivated by aspirating into a concentrated virkon solution, such that the final concentration remains above 2% and disinfected for at least 1 hour. It will then be disposed of down the sink with copious quantities of water.

Contaminated solid waste such as plastic disposables, tissue paper and culture plates, etc will be disposed of into suitable clinical waste disposal bins. Clinical waste disposal bins are sealed by the user and disposed of together with other such material generated on the Babraham Research Campus by incineration offsite.

Sharps materials will be disposed of in yellow sharps containers, which are disposed of by incineration offsite, together with other such material generated on the Babraham Research Campus.

All waste management measures will follow as a minimum the Babraham Research Campus biosafety and guidance policy.

Tick to confirm that you are attaching a summary of the risk assessment  
Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC found that the risk assessment adequately stated the risks of carrying out the activities described, and confirmed the activity class of the work to be 1. The control measures in place were found to be suitable and indeed largely already in place due to the fact that the laboratory in which the work is due to be carried out is already categorised as category 2 for carrying out work on human tissue samples.

Give brief details of the genetic modification safety committee

The Trust Biosafety Committee is chaired by the Trust Medical Director. It has representatives from medical and nursing staff, pharmacy (including Chief Pharmacist and pharmacist responsible for the Trust Pharmacy Aseptic Unit Gene Therapy Facility) microbiology/virology, the Trust Infection Control team, the Trust Infection Control Officer, Trust Research Governance & Development Manager, department of oncology, Health and Safety Representative, Occupational Health, Trust Biological Safety Officer, University of Surrey. Other specialists are seconded ad hoc as required. The committee operates under the Trust's "Guidelines for the use of clinical biological agents (including genetically modified organisms)". It meets as required to assess risk assessments and consider biosafety issues.

2% Virkon used according to manufacturer's guidelines. In validation studies two representatives examples from the poxviridae have been tested, these being vaccinia (the parent of TroVax®) and bovine pseudocowpox virus. For vaccinia, a 10 min exposure to both 0.5% and 1% solutions of Virkon caused 1000-fold reduction in infectious titre, with complete inactivation being demonstrated after 30 minutes. Staff will be trained in the preparation and use of Virkon and monitoring the deactivating efficacy of the solution in use. After inactivation waste will enter the hospital contaminated waste streams for incineration appropriate for sharps or non-sharps.

**Project Ref** 3170/18.1

**Date Ackn'd** 06/09/2018

**CU2 Project Title** Gene therapy product RP1 (Common name rHSV-1 hGM-1-CSF/GALV-GP) for the treatment of solid tumours

**Class** Class 2

**CultureVol Class 2** < 1 Litre

**CultureVolume Class 3-4**

Non-GMM Consent Granted

Project notified under transitional arrangements N

02/03/2022
RP1 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. RP1 has a particular utility in combination with immune co-inhibitory pathway blockade. Intended indications to study include soft tissue sarcoma, breast cancer including triple negative breast cancer (TNBC), lung cancer including non-small cell lung cancer (NSCLC), melanoma, non-melanoma skin cancers, head and neck cancer, primary liver and kidney cancer and colorectal cancer. The initial clinical trial protocol intends to test RP1 in several indications as a monotherapy and in combination with anti-PD-1 therapy.

Recipient or parental organism

RP1 (rHSV:1hGM-CWALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-) [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed Pit-1 receptor for GALV. This results in the death of the cells by membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un.injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Host/vector system

RP1 (rHSV_1 hGM-CSF/GALV-GP) is derived from the RH018A strain of Herpes Simplex Virus-1. RP1 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.

Origin & function

RP1 was constructed using a new strain of HSV-1 (strain RH018A). Replimune obtained and compared 30 clinical strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018A) for further development. RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the Pit1 receptor, which is widely expressed on mammalian cells including human tumour.
cells. PI1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immunemediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un.injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Spills should be treated with 70% isopropanol. All materials contaminated with RP1 must be disposed of in compliance with institutional procedures for the disposal of GMO (genetically modified organism) waste. Used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1 % Virkon solution). As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol (day 1, day 2/3, 015, Day 16/17, Day 29, Day 30/31, Day 43, Day 57, and as part of follow up at 30 day post last dose and 60 day post last dose. 3/7/10, day 14, day 21, day 28, day 35, day 42, day 49, day 56 and as part of the follow up, 30 days after the last dose).

Blood and urine will be collected at the first, second and third RP1 injections at the following timepoints: pre-dose, 6 (+/-2hr) hours, 21 hours (+/-3hr) and 48 hours (+/-6hr) and also immediately prior to dosing at fourth and fifth dose. Samples on injection days will be done prior to any injections and handling of RP1. Samples will also be collected at the 30 day and 60 day follow-up visit.

Saliva/oral mucosa samples will be collected at the first, second and third RP1 injections at the following timepoints: pre-dose, 6 (+/-2hr) hours, 21 hours (+/-3hr) and 48 hours (+/-6hr) and also immediately prior to dosing at fourth and fifth dose. Samples on injection days will be done prior to any injections and handling of RP1. Samples will also be collected at the 30 day and 60 day follow-up visit.

Injection site and exterior of dressing swabs samples will be collected at the first, second and third RP1 injections at the following timepoints: pre-dose (note - no exterior of dressing swab at this time), 6 (+/-2hr) hours, 21 hours (+/-3hr)
and 48 hours (+/-6hr) and also immediately prior to dosing at the fourth and fifth dose. Samples will also be collected at the 30 day and 60 day follow-up visit.

Specimens (swabs) will be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection. Samples should be obtained as soon as possible after symptoms arise to maximize the possibility of detection of virus, optimally within 24 hours, but samples may be collected later if collection within 24hrs is not possible. Subjects will be asked to take swabs at home for the subsequent 7 days after the initial test.

As part of Phase 2 Schedule of Assessments (TNBC, NMSC, NSCLC, melanoma), blood and urine will be collected at the following time points: Day 1, day 2/3, day 22, day 23/34, day 43, day 44/45, day 64, day 85, and as part of follow up, day 60 post last dose. Blood and urine will be collected, pre-dose at the first, second, third and fifth RP1 injections. Additionally, for each of the tumor types enrolled, the first six patients the following additional timepoints will be required: Doses 1, 2 and 3: 6 (+/-2hr) hours, 21 (+/-3hr) and 48 (+/-6hr) hours and also immediately prior to dosing at the fourth and fifth dose. Samples on injection days will be collected prior to any injections and handling of RP1. Samples will also be collected at the 60 day follow-up visit.

Saliva/oral mucosa samples will be collected pre-dose at the first, second, third and fifth RP1 injections. Additionally, for each of the tumor types enrolled, the first six subjects the following additional timepoints will be required: Doses 1, 2 and 3: 6 (+/-2hr) hours, 21 (+/-3hr) and 48 (+/-6hr) hours and also immediately prior to dosing at the fourth and fifth dose. Samples on injection days will be collected prior to any injections and handling of RP1. Samples will also be collected at the 60 day follow-up visit.

Injection site/dressing swabs samples will be collected pre-dose at the first (no exterior of dressing), second, third and fifth RP1 injections. Additionally, for each of the tumor types enrolled, in the first six subjects the following additional timepoints will be required: Doses 1, 2 and 3: 6 (+/-2hr) hours, 21 (+/-3hr) and 48 (+/-6hr) hours and also immediately prior to dosing at the fourth and fifth dose. Samples on injection days will be collected prior to any injections and handling of RP1. Samples will also be collected at the 60 day follow-up visit.

Specimens (swabs) will be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection. Samples should be obtained as soon as possible after symptoms arise to maximize the possibility of detection of virus, optimally within 24 hours, but samples may be collected later if collection within 24hrs is not possible. Subjects will be asked to take swabs at home for the subsequent 7 days after the initial test.

The timepoints for samples have been update for phase I. Risk assessment to include sample information for phase II as this is relevant. Section 6.3 is ticked no autoclaving therefore "NEEDS COMPLETION" in the other boxes can be removed. No further comments made, proceed to submission.

**Purposes of the contained use**

Clinical trial in patients with selected advanced solid tumours.

**Recipient or parental organism**

MEDI5395 is a novel genetically modified recombinant Newcastle Disease Virus (NDV) expressing human granulocyte macrophage colony-stimulating factor (huGM-CSF). NDV has been classified as an avian paramyxovirus that has demonstrated strong oncolytic activity against human tumor cells (Reichard et al, 1992; Amarasinghe et al, 2017). NDV is classified as velogenic, mesogenic, or lentogenic, depending on its virulence in birds. NDV is not a
human pathogen and there is little or no pre-existing immunity against NDV.

**Host/vector system**

MEDI5395 OV is a non-pathogenic (lentogenic) variant of the WT NDV 73T strain. Inserted a huGM CSF transcriptional unit at the phosphoprotein (P) and matrix protein (M) gene junction. The huGMCSF transgene functions to enhance presentation of tumour antigens generated following MEDI5395-induced tumour lysis. MEDI5395 is a rNDV that has been modified to reduce avian virulence (via F-protein cleavage site modification and incorporation of 198 nt intergenic stretch sequence) and to incorporate a human GM-CSF transgene.

**Origin & function**

MEDI5395 is produced in HeLa-S3 cells. MEDI5395 is a systematically administered Oncolytic Virus that selectively replicates, produces GM-CSF, and exerts cytolytic activity in tumour cells. NDV enters cells via cell surface sialic acid, which is ubiquitous; it is selectively cytolytic for tumour cells vs non-tumour cells as a result of defects in the interferon signalling pathway that are common among diverse tumour types. This study will treat subjects with selected advanced solid tumours with Intravenous MEDI5395 in combination with durvalumab. The synergistic activity of this combination is anticipated to provide greater benefit to subjects than either treatment alone with MEDI5395 enhancing durvalumab activity through upregulating PD-L1 on tumour cells and immune cells within the tumour, releasing tumour specific antigens through tumour lysis, triggering both the innate and adaptive immune systems, and in vivo delivery of GM-CSF to the TME enhancing immunologic responsiveness to checkpoint inhibition.

**Evaluation of foreseeable effects**

As described above, MEDI5395 has the potential to enhance durvalumab activity through upregulating PD-L1 on tumour cells and immune cells within the tumour, releasing tumour specific antigens through tumour lysis, triggering both the innate and adaptive immune systems, and in vivo delivery of GM-CSF to the TME enhancing immunologic responsiveness to checkpoint inhibition.

The combination of MEDI5395 (which may induce tumor lysis and prime an antitumor immune response) and durvalumab (which may sustain an effective antitumor immune response) has the potential to provide improved clinical activity versus either monotherapy.

The potential risks for MEDI5395 to the trial subjects are based on the mechanism of action of MEDI5395. Based on nonclinical data and shedding data from human clinical studies with other NDVs it is anticipated that some transient, low-level shedding of MEDI5395 into subject secretions or excretions may occur, however this level of shedding should not constitute a hazard to human health or to birds. Due to its viral attenuation, the Sponsor believes MEDI5395 could be considered biologically contained even if released in the environment and the HSE agreed with the sponsor appraisal of the very low risk of MEDI5395 to human health and the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The Trust received confirmation from the HSE on the 18th October 2018 that the competent authority agreed to the omission of autoclaving at Royal Surrey NHS Foundation Trust due to the delegation of derogation to the GM
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Spills should be treated with Virkon 1% or 10% hypochlorite solution. All materials contaminated with MEDI5395 must be disposed of in compliance with institutional procedures for the disposal of GMO (genetically modified organism) waste. Used and unused vials used in preparation will be destroyed as per institutional policy and procedures. The disposal and moving of the waste will be organised by a delegated member of the contracted estates team. The waste will be tagged ready for SRCL Ltd. to collect, the delegated member of the contracted estates team will inform SRCL Ltd. that the site has GM waste to collect for disposal under the GM waste account. Shedding of infectious viral particles into saliva and urine have been observed following IV administration of nonrecombinant NDVs to mice, non-human primates, and humans. Virus shedding in subjects will be assessed using a quantitative real time-reverse transcription PCR method. The following clinical lab tests will be performed: Serum chemistry, Hematology, Coagulation, Thyroid function tests, Cardiac labs. The genome copies of MEDI5395 will be measured in saliva and urine pre and post dose administration of MED15395, at the end of treatment (within 28 days of the decision) and 90 days (+1- 7 days) post last dose follow-up. Viral infectivity will be determined for the shedding samples which have MEDI5395 genome copies greater than the genome copy cut-point that will be established based on the correlation of genome copies and virus infectivity by an in vitro study.

Give brief details of the genetic modification safety committee

Research Director, Associate Director of Microbiology (Biological Safety Officer), Associate Director of natural Product Chemistry (H&S Chair).

The committee will meet annually to review all risk assessments and HSE notifications. Additional meetings will be held to consider new risk assessments and notification requirements as required. All assessments and notifications will be circulated by email and comments from the committee taken into account prior to any new procedures being adopted. Any assessments which fall outside the expertise of the committee will be sent to external advisors drawn from experienced scientists working in the relevant area.

Bacteriology Yes Parasitology Transgenic Birds Microbiology Research Yes
For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid biological waste will be placed in biological waste bags in plastic bins. When full the waste will be transferred to autoclave and sterilized using a 'killing-off' cycle. This autoclave cycle will include heating the material to at least 121°C, for 30 minutes to ensure 100% kill for all material.

Liquid waste and contaminated glassware will be treated in one of two ways:
1) Autoclaving: The autoclave cycle will include heating the material to at least 121°C, for 30 minutes to ensure 100% kill for all material
2) Presept disinfectant: Presept disinfectant, diluted according to the manufacturer's instructions, overnight at room temperature.

In either case an initial check will be carried out the first time the process is used to check that no culturable cells remain before disposal. This check will be repeated periodically depending on classification of risk and whenever waste from different cell types or quantities of culture are produced to ensure that the procedure results in a 100% kill.

Members of the Genetic Modification Safety Committee have read the attached risk assessment and have agreed with its conclusions.

Give brief details of the genetic modification safety committee

Technical Manager, Laboratory Supervisor, Principal Technologist (Microbiology), 2 x Technologists (both Microbiologists) comprise the committee. Meetings to be held every 6 months to review working practices, advise on the health and safety measures used regarding GMMs, to advise on technical matters.

All solid waste contaminated with GM microorganisms (JM109 competent escherichia coli) will be placed in clear autoclave bags labelled ‘Autoclave Waste Only’. The solid waste (and liquid cultures) will be autoclaved at 121°C for 60 min. Solid waste can then be disposed of in the biohazard waste (although regular waste is acceptable). Liquid cultures will be disposed of down the sink after autoclaving agar will be autoclaved, then bagged and disposed of in regular waste.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Laboratory use of non-commercial and commercially available transfected cell lines. Conduct cell-based assays using genetically modified organisms to evaluate the biological activity of test articles on such cell lines. Genetic modifications may include over-expression of target proteins and/or immortalisation of cell lines using induced (e.g. Viral infection) or un-induced (e.g. Cancerous) Genetic modification will not be carried out.

Solid and liquid waste will be disposed of in biohazard weaver bins (e.g. GRIFF BIN300, Griffiths & Neilsen; ThermoFisher; Rexam, Etc) These are fully lockable and sealable plastic containers. Once locked, the lid has a fluid-tight adhesive seal to prevent any residual fluid leakage after final closure. These bins will be disposed of by full containment followed by incineration. Based on the risk assessment and control measures, on-site autoclaving will not be required.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

A risk assessment and COSHH assessment by the users (Laboratory Scientists) have identified the hazards and who might be harmed and how. Users have evaluated the risks and decided on the precautions. The assessments have been submitted to the appropriate individuals for review and the findings have been recorded ready for implementation pending approval. There is also a review and update procedure should the process require amendment or on a chronological basis.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee comprises three staff members of BioServ UK Ltd. The committee members have worked with genetically modified organisms for many years and are familiar with the SACGM guidance for the containment and control of activities involving genetically modified microorganisms including the risk assessment of such activities. One of the committee members has served on the Genetic Modifications Advisory Group within the University of Sheffield to advise academic researchers on safety considerations for work involving the genetic modification of microorganisms.

All the work will be carried out in designated laboratories suitable for the procedures. Bulk liquid waste will be neutralised by addition of 2% Virkon or autoclaved in designated and validated discard autoclaves. Glassware will be decontaminated by autoclaving or by filling with 2% Virkon solution or 5% hypochlorite. Solid waste will be disposed of by incineration, using the appropriate waste stream as defined by the Biological Safety Committee.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Autoclaving will be performed using validated equipment. Each of these processes shall be tested for effectiveness by time-course sampling followed by determination of degree of kill.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Solids (e.g. plasticware: pipettes, flasks, tubes, culture plates, etc.) Autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 mins, or 126-130°C for at least 10 mins, or 134-138°C for at least 3 mins), or disinfect with freshly prepared Haz-Tabs (2x2.5g tablets/litre water) for 1hr minimum, discharge excess liquids to drains, dispose of solids via clinical waste stream for microwave treatment or via the industrial (landfill) waste stream.

Liquids (e.g. samples, cell culture supernatants, culture media) - Autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 mins, or 126-130°C for at least 10 mins, or 134-138°C for at least 3 mins), or disinfect with freshly prepared 2% Virkon or Haz-Tab (2x2.5g tablets/litre) solution overnight (min 1hr) discharge to drains.

One procedure requires the use of sharps (manipulation of cell colonies with Swemed Stem Cell cutting Tool or 25 gauge needles) Procedures require that sharps are never re-sheathed and placed directly in a sharps bin located within the culture hood after use. Sharps are autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 mins, or 126-130°C for at least 10 mins, or 134-138°C for at least 3 mins), dispose via clinical waste stream for microwave treatment.

Degree of kill:
Autoclaving: Effectively 100% kill (annual qualification using 12 point thermocouple of worst case loads)
Disinfection: A 1% solution of Virkon disinfectant with a contact time of at least 10 minutes gives a >4.25 log reduction of HIV-1 (data from manufacturer).
Heat treatment or incineration: Not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
BACKGROUND FOR COMMITTEE DISCUSSION

The potential methodologies to be used include delivery of gene encoding and non-encoding nucleic acids in vectors that cannot integrate into the Deoxynbonucleic acid (DNA) genome of a cell in its nuclear compartment or replicate. This includes a modified variant Sendai viruses composed of ribonucleic acid (RNA) which does not permit its replication (which would normally only occur in the cytoplasmic compartment of a cell). Replicating sendai have been used safely in the context of gene therapy. We will also use DNA or RNA sequences which cannot replicate and may be unmodified or modified chemically to facilitate their ability to enter into the cytoplasmic or nuclear compartment of stability within the cell. There are eventually destroyed by the cell or diluted out with successive cell divisions.

The Sendai Virus, constitutes as defective mutant clone of the normal cytoplasmic RNA vector which normally resides in a murine host. This mutant clone is non-pathogenic and replication incompetent due to the removal of the M,F and HN genes. The vector includes functional mutations such as temperature sensitivity to aid their safe removal.

Non-integrating, non-replicating gene encoding DNA vectors are composed of "episomal" circular plasmid DNA which contains genes that are expressed by the cell phenotype which is the objective of the reprogramming process.

For purposes of reprogramming to a pluripotent stem cell state, such as manifest by embryonic stem cells, gene encoding vectors may contain genes which promote cell proliferation such as C-myc, that are known tumour promoting oncogenes. As the vectors are replication incompetent, the effect of this gene is transient and the risk of tumour formation is unlikely.

Non-gene encoding nucleic acids may constitute micro RNA or short interfering RNA from 10 to a few hundred nucleotides in length whose effects are to destabilise specific endogenous gene encoding mRNAs, thereby inhibit their expression to facilitate reprogramming of cellular phenotype/identity. They may also include similarly sized anti-sense oligonucleotide DNA which can transiently destabilise endogenous mRNAs or control which variant of a mRNA are expressed from the genome.

The purpose of the research is to reprogram human cells to alternative phenotypes/identities. This may include embryonic or adult derived somatic cells such as for example fibroblasts or blood derived mononuclear cells) to create induced pluripotent (IPS) cell lines, lineage committed stem or progenitor cells or alternative differentiated cells.

CONCLUDING REMARKS

In summary, the committee agreed that the risk posed by the reprogramming vectors should be considered containment level 1, however as the work also involves the culture of human cells and tissues we will be conducting all activities within containment level 2 for COSHH reasons.

The committee also felt it was important to stress that all cellular reprogramming activities will involve the use of vectors which are non-integrating and are gradually removed from the culture over a number of passages. The reprogrammed cells are as such because they will have undergone changes to their gene expression and not due to any actual modification of their genome.

The reprogrammed cell lines are only capable of survival in strictly controlled cell culture conditions within a controlled laboratory. Removal, or even significant variance, from these conditions would cause the cells to perish in a very short time. The reprogramming process will not confer any irreversible survival benefits.

The cells will be non-pathogenic and are expected to pose no additional risk compared to the parental cell line/culture.

Cell culture volumes are expected to be multiples of 4-10mL individual culture volumes. Maximum of 250-500mL at any one time.
The purpose of the research is to reprogram human cells to alternative phenotypes/identities. This may include embryonic or adult derived somatic cells (such as for example fibroblasts or blood derived mononuclear cells) to create induced pluripotent (iPS) cell lines, lineage committed stem or progenitor cells or alternative differentiated cells.

Unmodified or non-genome integrating genetically modified human cells do not survive easily outwith controlled laboratory culture conditions. The genetic modification of the cell is transient and experienced during reprogramming of cellular phenotype/identity, with genetic vectors either being destroyed by the cell or diluted out following successive cell divisions.

The Sendai Virus, constitutes a defective mutant clone of the normal cytoplasmic RNA vector which normally resides in a murine host. This mutant clone is non-pathogenic and replication incompetent due to the removal of the M, F and HN genes. The vector includes functional mutations such as temperature sensitivity to aid their safe removal.
Non-integrating, non-replicating gene encoding DNA vectors are composed of "episomal" circular plasmid DNA which contains genes that are expressed by the cell phenotype which is the objective of the reprogramming process.

For purposes of reprogramming to a pluripotent stem cell state, such as manifest by embryonic stem cells, gene encoding vectors may contain genes which promote cell proliferation such as C-myc, that are known tumour promoting oncogenes. As the vectors are replication incompetent, the effect of this gene is transient and the risk of tumour formation is unlikely.

Non-gene encoding nucleic acids may constitute micro RNA or short interfering RNA form 10 to a few hundred nucleotides in length whose effects are to destabilise specific endogenous gene encoding mRNAs, thereby inhibit their expression to facilitate reprogramming of cellular phenotype/identity. They may also include similarly sized anti-sense oligonucleotide DNA which can transiently destabilise endogenous mRNAs or control which variant of a mRNA are expressed from the genome.

Origin & function
The genetic material in the Sendai and all nucleic acid vectors originate from synthetic manufacture.

Evaluation of foreseeable effects
The reprogrammed cell lines are only capable of survival in strictly controlled cell culture conditions within a controlled laboratory. Removal, or even significant variance, from these conditions would cause the cells to perish in a very short time. The reprogramming process will not confer any irreversible survival benefits.

The cells will be non-pathogenic and are expected to pose no additional risk acompanied to the parental cell line/culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticware: pipettes, flasks, tubes, culture plates, etc): Autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125C for at least 15 mins, or 126-130C for at least 10 mins, or 134-138C for at least 3 mins), or disinfect with freshly prepared Haz- Tabs (2x2.5g tablets/litre of water) for 1 hr minimum, discharge excess liquids to drains, dispose of solids via clinical waste stream for microwave treatment or via the industrial (landfill) waste stream.

Liquids (e.g. samples, cell culture supernatants, culture media) - Autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125C for at least 15 mins, or 126-130C for at least 10 mins, or 134-138C for at least 3 mins), or disinfect with freshly prepared Haz- Tabs (2x2.5g tablets/litre of water) for 1 hr minimum, discharge to drains.

Sharps may be used but there are procedures in place to minimise risk of injury including no re-sheathing of needles and placing of sharps directly into sharps bins within the MSC class II cabinets after use.

Degree of kill:
Autoclaving: Effectively 100% kill (annual qualification using 12 point thermocouple of worst case loads)
Disinfection; A 1% solution of Virkon disinfectant with a contact time of at least 10 mins gives a >4.25 log reduction of HIV-1 (data from manufacturer).
Heat treatment or incineration: Not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.
The vectors are considered low risk as they are non-pathogenic and are replication incompetent. The committee agreed that the vectors would normally be classified as Class 1, however, since some vectors may contain the oncogene C-myc the containment level should be class 2. Therefore any risks considered to be greater than Class 1 requirements are limited to those presented by the presence of this oncogene.

There is no determinable risk to the environment.

Any risk to human health relates to individual operators and is negligible. There is no risk of transmission or dissemination.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the work on the premises is to expand and bank human induced pluripotent (iPS) cell lines. These have not been derived on site, but may still contain reprogramming material on receipt. The potential methodologies that will have been used to generate the iPS cell lines include delivery of gene encoding and non-encoding nucleic acids in different vectors. These include integrating vectors like retro- or lenti-viral or non-integrating vectors such as a modified variant Sendai viruses or nonintegrating, non-replicating gene encoding DNA vectors composed of "episomal" circular plasmid DNA.

**Recipient or parental organism**

Unmodified or non-genome integrating genetically modified human cells perish in a very short time outwith controlled laboratory culture conditions. The genetic modification of the cell is transient and experienced during reprogramming of cellular phenotype/identity, with genetic vectors either being destroyed by the cell or diluted out following successive cell divisions.

**Host/vector system**

The Sendai and episomal vectors are replication incompetent and are not integrated into the genome, rather their genes are expressed in the cytoplasm and resultant transcription factors influence changes in the genome using normal cellular mechanisms. Integrating virus used to generate iPS cells is disabled and unable to replicate in any host and the virions produced are extremely labile and do not persist in the environment. By the time iPS cells generated using retro- or lentiviral stragegies are received, virions will no longer be present.

**Origin & function**

The inserted material includes genes leading to the expression of factors related to cell pluripotency. When expressed, these transcription factors can
induce reprogramming in the host cell genome. By the time iPS cells are received on site, the DNA sequences will no longer be in a gene delivery system and unlikely to cause harm to operators. The genetic material in the viral and all nucleic acid vectors are expected to have originated from synthetic manufacture.

**Evaluation of foreseeable effects**

The reprogrammed cell lines are only capable of survival in strictly controlled cell culture conditions within a controlled laboratory. Removal, or even significant variance, from these conditions would cause the cells to perish in a very short time. The reprogramming process will not confer any irreversible survival benefits. The cells will be non-pathogenic and are expected to pose no additional risk compared to the parental cell line/culture.

## Project Additional Information

### Purposes of the contained use

The objective of this work is transduce differentiated human induced pluripotent stem cell (iPSC) lines with lentivirus from a variety of primary tissue sources and from a variety of reprogramming methodologies and gene editing methodologies to enable disease relevant cellular assay to be developed.

### Recipient or parental organism

Human differentiated induced pluripotent stem cells (iPSCs)

### Host/vector system

Lentivirus. Only virus generated from 3rd generation systems or later systems will be used (Self Inactivation versions.)

### Origin & function

The inserted material includes promoter and reporter genes (fluorescent proteins and luminescent proteins) which lead to expression in mammalian cells. The reporter protein will be used to selectively track biological processes such as proliferation, apoptosis and migration.

### Evaluation of foreseeable effects

Commercially available, self in-activating /replication deficient recombinant HIV based lentiviral will be used. These have been generated from vectors with all viral genes removed and replaced with an expression cassette encoding mammalian promoters such CMV or EF1alpha promoter linked to reporter gene protein (e.g. GFP).

The GMOs generated do not have any growth or selection advantage and should not present any biological advantage or confer any survival benefits. The resulting genetically modified cells require strict culture conditions and skilled operator interventions to ensure their survival. Outside of these carefully controlled laboratory conditions the cells would perish very quickly.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticware: pipettes, flasks, tubes, culture plates, etc.) will be collected in 30 litre Euro bins plastic bins and disposed of according to the Babraham Research Campus -Hazard Group 2 Waste.
disposal stream.
In summary each bin has a unique identifier and the bin labeled with biohazard sticker and the company name an (waste sealed in 30L Euro bins) and sent offsite for incineration by Vetspeed (GM authorisation GM898, notification GM105/4.1) or double bagged in clinical waste bags, placed in locked container and sent offsite for incineration by Healthcare Environmental (GM authorisation GM777).
Liquids (e.g. samples, cell culture supernatants, culture media): Disinfect with freshly prepared 2% Virkon or Haz-Tab (2x2.5g tables/litre) or equivalent chlorine based solution overnight (min 1hr)
Spills will be cleared up using absorbent tissue and discarded as solids. Surfaces are decontaminated using Distel, Microsol 4+ or Chemgene HDL4L, 1% virkon or equivalent.
Degree of kill:
Disinfection: A 1% solution of Virkon disinfectant with a contact time of at least 10 min gives a >4.25 log reduction of HIV-1 (data from manufacturer).
15 min contact time using Distel gives minimum 4-fold log reduction of bacterial, fungi and virus load (data from manufacturer).
15 min contact time using Microsol 4+ gives minimum 3.67-fold log reduction of bacterial, yeast, fungi and virus load. 60min contact time gives a minimum of 3.17-fold log reduction of mycobacterium and spore load (data from manufacturer).
15 min contact time using Chemgene HLD4L gives minimum 3.12-fold log reduction of bacterial, yeast and spore load (data from manufacturer).
Incineration: Effectively 100% kill.

Y

Give brief details of the genetic modification safety committee

The RB&HFT GM Safety Committee (RB&HFT GMSC) is responsible for ensuring that work is conducted in accordance with the study risk assessment and is compliant with Genetically Modified Organism (Contained Use) Regulations.

Represented on the Committee are RB&HFT clinicians, Pharmacy, Infection Control, Quality and Safety Department, R&D (including the Research Governance and Regulatory Compliance Manager and the Associate Director of Research), appropriate Clinical and Research Facility managers, Clinical Trial Manager Representatives and the RB&HFT BSO. Representatives from the Project Team also attend meetings.

RB&HFT GMSC is a subcommittee of the RB&HFT Clinical Trials Oversight Committee (CTOC) which reviews and oversees all clinical trials activities in the organisation.

RB&HFT GMSC receives technical advice from Imperial College GMSC 309 if requested. Responsibility for approval of GM studies rests with RB&HFT CTOC and will be based on the recommendation from RB&HFT GMSC.

Laboratory Animal Unit Growth Room Glass House Large Scale

Level 1 (GMMs) Yes
Level 2 (GMMs)
Level 3 (GMMs)
There are two locations where GM waste is expected to arise: The Royal Marsden Clinical Trials Pharmacy and the Biomedical Research Unit (BRU) Cardiac catheter laboratory.

Waste, pertaining to the Contained Release Regulations, will be generated as a result of preparation of the GM product (Royal Marsden Clinical Trials Pharmacy) and during the cathetization procedure (BRU).

Inactivation of GM product: The GM product for the proposed clinical trial will be inactivated according to the Study Sponsor's guidance, which has provided validation of inactivation by the dilution and mixture of 0.5% sodium hypochlorite solution, with a minimum contact period of 20 minutes.

Royal Marsden Hospital GM waste management system:

Liquid waste: During the preparation of the GM product in the Royal Marsden Hospital Pharmacy, there will be approximately 2ml of undiluted GM product at 3 x 10^{12} DRP/mL as waste and 10mL of 1:15 diluted GM product. The GM product waste will be inactivated by 0.5% sodium hypochlorite as above and then placed in

**Other(s)**
designated bins sealed and marked biohazard materials, for incineration off site.

Solid waste: During preparation of the GM product, one needle and three syringes will come into direct contact with the GM product. These sharps will be placed in designated sharps bins, sealed and marked biohazard materials and destroyed by incineration via the Royal Marsden gene therapy waste stream.

Royal Brompton Hospital Biomedical Research Unit (BRU) Cardiac catheterisation laboratory:

Liquid waste: After administration of the GM product to the patient approximately 10 mls of diluted GM product will remain in the syringe. This will be inactivated (as above) then placed in designated waste bins, sealed and marked biohazard. It will then be sent off site for incineration via the RB&HFT Biohazard Waste stream.

Solid waste: During the catheterisation procedure a high pressure tubing line and a catheter will contact the GM product. This will be inactivated (as above) and then disposed of in designated waste bins, sealed and marked biohazard and which will then be sent off site for incineration via the RB&HFT Biohazard Waste stream.

As patients may shed GM AAV in urine for up to 4 weeks after catheterization and perfusion of the virus, an application for deliberate release has been submitted to DEFRA. Any waste (GM or not) arising from patients post-operatively will be handled in the same way as other clinical waste at RB&HFT.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

A risk assessment has been reviewed by RB&HFT GMSC and Imperial College GMSC 309 in relation to the study:

"CUPID 2 (A Phase 2b, double-blind, placebo-controlled, multinational, multi-centre, randomised study evaluating the safety and efficacy of intracoronary administration of MYDICAR® (AAV1/SERCA2a) in subjects with heart failure.

The risk assessment was undertaken following MHRA (Medicines and Healthcare Products Regulatory Agency) and GTAC (Gene Therapy Advisory Committee) approval of the study.

Imperial College GMSC 309 recommended that the study Sponsor submit to DEFRA for deliberate release approval which it has done. THE Sponsor and Chief Investigator are anticipating a positive response from DEFRA. RB&HFT is fully aware that some aspects of the study would still be regulated by the Contained Use of GMO's Regulation and is therefore submitting notification of premises for its hospital sites.

Following an initial review by Imperial College GMSC 309 and RB&HFT GMSC, the risk assessment was revised and updated to cover:

i) Details of potential needlestick injuries and risk mitigation

ii) Clarification of issues related to viral shedding after leaving the hospital premises (and subsequent DEFRA submission).

iii) Further details on inactivation of the GMO (detailed in section 6) in particular of the use of validated disinfectant.

iv) Clarification on deep clean procedure

v) Development pf plan to mitigate risks of spillsafe either in pharmacy or the catheter laboratories and in the transport of the GM product between facilities.

The revised risk assessment, which was reviewed in conjunction with the Study Manual (detailing local study procedures and the management of the study on-site) has been approved by both Imperial College GMSC 309 and RB&HFT GMSC. Both confirmed this as a Level 1 study.

Due to the relatively small volumes of liquid, waste will not be treated prior to disposal but will be sealed in the original sampling tubes or screw cap tubes to which material has been transferred during the testing processes. The tubes will be placed in clinical waste bin which will be irreversibly sealed before transport by a licensed contractor and incineration. If larger volumes are accumulated then the potentially infected liquid waste will be added to a large volume of disinfectant solution according to the suppliers recommended dosage rates of disinfectant e.g. Virkon 1% w/v solution for 30 mins minimum, then washed away to the public sewer. Accidental spillages will be dealt with by swabbing with disinfectant. Solid waste e.g. culture plates will be placed in a clinical waste bin as above or autoclaved prior to disposal as clinical waste by a licensed contractor.

Commonly used lab strain of E.coli are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1 because they have an established record of safety in the laboratory with no adverse effects on human, animal or plant health or the environment. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

For activities involving GMMs, describe the waste management measures which will apply to the activity

E. coli liquid waste
1 tablet of HazTab per 400ml gives a 2,500ppm of chlorine suitable for killing E. coli with a contact time of at least 1 hour. Alternatively 1 hour contact with a freshly made solution of 2% Virkon diluted 50:50 with liquid waste to give a final w/v of 1% Virkon can also be used. The standard procedure with contact time at least 12 hours effectively kills E. coli 100%. We have not been able to retrieve live E. coli from this solution.

E. coli solid waste
These items (like bacterial agar plates, plasticware etc,) will be placed in autoclave bags which are filled three quarters and tied with a cable tie. Tied bags are placed in a dedicated bin situated in the laboratory and then autoclaved for 30 minutes at 121 degrees centigrade in the service room. Autoclaved waste will be yellow bagged and stored in a dedicated secure area before removal for incineration by contract waste services.

The degree of kill may be monitored by plating aliquots of treated samples on appropriate bacterial growth medium and incubating overnight under appropriate growth conditions for the relevant organism.

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC) is a subpanel of the University of Gloucestershire Research Ethics Committee (REC). The GMSC consists of representatives from across the University, including each school, the Biological Safety officer and an external expert advisor on genetic modification.

Please enter comments of the GM safety committee on the risk assessment

Following initial review by the GMSC, it was highlighted that the risk assessment needed greater clarity in several areas. In particular, because two classes of GMM are produced in this work, the GMSC expressed concern at having a single overarching risk assessment and recommended that two separate risk assessments be formed to cover both GMM classes. All points have now been met and the GMSC has approved this assessment.

Project Additional Information

Purposes of the contained use

The objective of this research is to study commensal and pathogenic bacterial interactions with eukaryotic cells, tissues and whole organisms. Our approach focuses primarily around the study of bacterial genes that are required for bacterial attachment, type three secretion systems and virulence. Type three secretion systems are required for attachment and injection of type three effector proteins into mammalian cells. Genetic modifications in bacteria will include loss-of-function mutation (deletion/insertion/point mutation) as well as introduction of plasmids encoding for fluorescent reporter proteins, wild type alleles (for functional restoration or recombinant protein production), or wild type alleles fused to fluorescent or enzymatic reporters (to generate transcriptional, translational reporters). All strains used will be a maximum of ACDP Cat. 2. Genetically manipulated strains of Escherichia coli (commensal and pathogenic strains, but excluding Shiga-like toxin producing strains), Salmonella typhimurium, Yersinia pseudotuberculosis, Shigella sonnei, Pseudomonas aeruginosa and Klebsellia pneumonia, will either be obtained from ATCC, from other research institutions or will be generated at the University of Gloucestershire by electroporation or conjugation. The project will also include genetic manipulation of Human cell lines, which will include transient transfection of fluorescent or enzymatic reporters (to generate transcriptional, translational and effector delivery reporters). To allow characterization of interaction with human cells, genetically manipulated cell lines (Hela, Caco-2, SW480, RKO) will either be obtained from ATCC, from other research institutions or will be generated at the University of Gloucestershire by transient transfection using electroporation or liposome mediated delivery. In brief, candidate genes in bacteria will be deleted by cloning the open reading frame into a pUC19 or pDM4 suicide vector (or similar), which will then be disrupted by the insertion of a Tetracycline or Gentamycin resistance marker from pSS262 or pSS87, respectively. To effectively introduce the plasmid into the bacterium, morIT will be inserted into the plasmid from pLS214, pLS217 or pSS125 (or similar) and the plasmid mobilised into the bacterium. Wild type alleles will be reintroduced back into mutant strains by cloning the ORF together with the minimal stabilisation fragment (mSF) and morIT cassettes into a plasmid. To generate reporter strains the promoter or ORF of the candidate genes will be cloned into a transcriptional (pSS223) or translational (pSS231) reporter plasmids (or similar) with Lacz, GFP or mCherry as a reporter. Where plasmids are not available, the Lacz reporter will be replaced with GFP or mCherry by standard cloning techniques. For generating human cell lines, fluorescent or enzymatic reporter proteins (CFP, YFP, GFP, mCherry, Luciferase) will be cloned into pDNA3.1 or similar.

Recipient or parental organism

E.coli used as a cloning vector for DNA manipulation, recombinant protein production and to aid for conjugation experiments (Routine laboratory strains DH5alpha, BL21, MM294) that would not survive outside the laboratory and non pathogenic Pathogenic E.coli (Shiga toxin negative or deletion strains) are Gram negative pathogens and can cause GI tract infection. Infections with EPEC or Shiga-toxin negative EHEC cause cramping, vomiting, and diarrhea but are self-limiting in otherwise healthy patients. Salmonella typhimurium is a Gram negative pathogen and can cause GI tract infection or wound infections. Infections are self-limiting in otherwise healthy patients. Yersinia pseudotuberculosis is a Gram negative pathogen and can cause Far East scarlet-like fever in the human host. Symptoms include fever, abdominal pain and, rarely, diarrhoea. Disease can last 1-3 weeks but is self-limiting in otherwise healthy patients. Shigella sonnei is a Gram negative pathogen and can cause GI tract infection. Symptoms include cramping, nausea, and watery or bloody diarrhoea. Infections are self-limiting in otherwise healthy patients but supportive treatment with beta-lactams or quinolones is common and effective. Pseudomonas aeruginosa is a Gram negative, opportunistic, aerobic coccobacillus. P. aeruginosa is commonly found as a skin
commensal, and in the environment on moist surfaces. P. aeruginosa causes infections in burns patients and can cause fatal lung infections in Cystic Fibrosis individuals. Klebsiella pneumoniae is a Gram negative organism commonly isolated from water, soil, the gastrointestinal tract, and skin, and causes nosocomial infections including UTI, pneumonia, sepsis and tissue infections, mainly in immune compromised patients. Human Cell Lines. Are commercially available and are not derived from workers in the department. Human Cell lines will be unable to colonise workers as any inoculation event would provoke a strong immune response by the individual against the cell line due to differences in MHC class I and II types.

Host/vector system

Host species: E.coli (DH5α, Class I) will be used for cloning and propagation of plasmids, E.coli (BL21, Class I) will be used for the production of recombinant protein, E. coli MM294 (Class I) will be used to aid conjugation; Escherichia coli; Only Shiga toxin negative or stx deletion strains will be used (Class II) Salmonella typhimurium (Class II) Yersinia pseudotuberculosis (Class II) Shigella sonnei (Class II) Pseudomonas aeruginosa (Class II) Klebsiella pneumoniae (Class II) Human Cell Lines: To include inclusions such as: Hela, Caco-2, SW480, RKO, HT29, MCF7, PLB985, HLO (Class I) Vector Systems mobilizable and broad host-range vectors, such as: pLS214 contains morT as a HindIII fragment in pUC1918 from E.coli plasmid R4 pLS217 contains morT as an EcoRI fragment in pUC1918 from E.coli plasmid R4 pPS124 contains mSf fragment in pUC1918 from pBR322 E.coli. P. aeruginosa shuttle vector pSS223 conjugative and suicidal lacZ transcriptional fusion plasmid containing morT from E.coli plasmid R4 pPS231 conjugative and suicidal lacZ translational fusion plasmid containing morT from E.coli plasmid R4 pPS262 Tcr cassette in pUC1918 from pBR322 pSS213 contains T7 (A1/04/03) for tight regulation of gene expression pUC19 contains origin of replication, lacZ, ApR and multiple cloning site pm4 contains origin of replication, chiR and multiple cloning site Non mobilisable vectors, to include for example: pGEX4T3, the pET and pCAL vectors, used to express protein, either from T7 promoters or from the gene's native promoter, either in its native form or as part of a his-tagged, MBP or similar fusion to an innocuous protein. Mammalian expression vectors, pCDNA3.1, pSFFV or TCF reporter plasmid or similar. Transient, constitutive expression from CMV, SV40 or native promoter in human cell lines. GentR, NeoR and AmpR. pUC ori for replication in E.coli.

Origin & function

Sequences of candidate genes will be PCR amplified from bacterial genomic DNA isolated from either Escherichia coli (commensal and pathogenic strains, but excluding Shiga-like toxin producing strain), Salmonella typhimurium, Yersinia pseudotuberculosis, Shigella sonnei, Klebsiella pneumoniae, Pseudomonas aeruginosa and cloned into the relevant vector. All donor species are ACDP Cat. 2, with the exception of commensal E. coli, which is ACDP 1. All ACDP II donor species have the potential to cause disease, and are transmitted via the faecal-oral route or via direct contact with infected people, animals or equipment and subsequent ingestion or exposure of open wounds to an infectious dose of the bacterium. Pseudomonas aeruginosa can also be transmitted via aerosols. Sequences will include open reading frames of candidate genes, or promoter regions of candidate genes for expression of reporter genes. Sequences of particular interest include those of virulence factors (e.g., adhesins, effectors, structural components of secretion systems, and secreted lytic enzymes). Reporter genes (i.e., GFP, mCherry, YFP, CFP, Luciferase, lacZ, Tev Protease) will be PCR amplified from E. coli plasmids and cloned into appropriate host plasmids for conjugation, transformation or transfection into the appropriate host species. Antibiotic resistance markers (e.g., ampR, chiR, tetR, strepR, kanR) will be PCR amplified from standard E. coli plasmids and inserted into the open reading frames of candidate genes in pUC19 or pDM4. Mammalian gene ORFs and promoter regions will be PCR amplified either from mammalian cell cultures or from commercially available E.coli plasmids and cloned into appropriate host plasmids for transient transfection into the appropriate cell line.

Evaluation of foreseeable effects

Having considered the nature of the modified organisms, the nature of the transgenes added and the nature of culturing and testing the organisms, we cannot identify any enhanced risk to human health above that normally associated with the culture of these ACDP II organisms. Our approach focuses primarily around deleting genes that are required for type three secretion systems and virulence. Type three secretion systems are required for attachment and injection of type three effector proteins into mammalian cells. Therefore, deletion of the effector proteins, or the secretion machinery itself, will inhibit this mechanism of killing mammalian cells and hence reduce the pathogenicity of the organism. Similarly, deletion of adhesins will decrease the organism's propensity to colonize and cause disease in the human host. Other methods will include tagging functional proteins with fluorescent or enzymatic reporters to enable protein localisation studies, and the reintroduction of genes to complement mutant phenotypes. Where possible and when using ACDP II organisms as hosts, genes will be expressed from native promoters to reduce the chances of over- and ectopic expression. It is possible that in some cases, the nature of the experiment (e.g., expression of constructs from a high copy number plasmid or deletion of repressor genes) may give rise to GMOs with enhanced virulence potential relative to the original strain. However, it is highly unlikely that this enhancement would confer fundamentally new abilities on the strain (such as new host range) or increase virulence to a level that would change the ACDP classification of the organism. Where overexpression is required (to enable chemical/biochemical characterisation of the protein), expression will be performed in a disabled laboratory strain of E.coli (e.g. BL-21 E.coli).
overexpression of bacterial effector proteins, it is worth noting that the catalytic subunit of any toxin cannot exert any effect unless delivered in soluble active from to the appropriate compartment of the appropriate cells within the human body. This cannot happen here as the necessary delivery mechanisms (e.g., a secretion system for getting out of the cell, a binding domain for attaching to cells and mediating entry) will be absent from the cloning host (E. coli BL21). We will never express the binding and toxic domains in the same cell. The selection genes are widely used antibiotic resistance markers. Although our GMO bacteria will be resistant to these antibiotics, we anticipate that the additional risks to human or animal health from these selectable markers will be minimal, as the GMO strains are likely to be attenuated in virulence and have reduced fitness compared to clinical isolates. Additionally, wherever possible, we will use resistance markers that do not give rise to resistance against antibiotics used to commonly treat infections arising from the host species. Reporter genes such as GFP and Lacz, which are used routinely, have not been reported to increase risk to human health.

With regards to the genetic manipulation of human cell lines. These are commercially available and are not derived from workers in the department. The cell will be unable to colonise workers as they do not share the same MHC class I and class II loci and will therefore provoke a host-versus-graft immune response. In addition, the likelihood of colonisation of an operator is extremely low as no sharps (i.e., needles) will be used during handling of the cell lines. The risk of spread to the environment is low as tissue culture cells are unable to survive outside the laboratory environment. The introduction of florescence or enzymatic reporter genes with constructs such as pCDN3.1 is common and will not alter any of these characteristics.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After use, solid media and plastic/glassware that has come into contact with organisms will be autoclaved (50 mins, 121 degrees) and disposed of through the University’s disposal route. Effectiveness of waste autoclave is regularly monitored and all runs are validated with internal temperature monitoring and reporter tape. Liquid waste containing organisms will be inactivated with Virkon (exposed to a final concentration of 1% Virkon for a minimum of 30 minutes). This will result in 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Following initial review by the GMSC, it was highlighted that the risk assessment needed greater clarity in several areas. In particular, because two classes of GMM are produced in this work, the GMSC expressed concern at having a single overarching risk assessment and recommended that two separate risk assessments be formed to cover both GMM classes. Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Under the terms of the agreement between Imperial College London and Imanova the ICL GM safety committee for the Hammersmith Hospital (ICL) site GM31, will review and make comments on risk assessments and related documents received from Imanova. The ICL GMSC will not approve or, in any way, condone the work. The GMSC accepts no responsibility for ensuring that the work is conducted in accordance with the risk assessment or in compliance with the relevant regulations. The GMSC (nor Imperial College Safety Department) accept no responsibility in ensuring that any of the committee's recommendations are complied with. The responsibility for all these matters rest entirely with Imanova.

The Safety Department will only forward the GMSC comments once they have been collated. The ICL Safety Department will not issue any approval forms, no will it administer any notifications required to the HSE. The responsibility for all these matters rest entirely with Imanova.

The committee has representation from Imperial College Academics, Campus Safety Managers, the Hammersmith NHS Trust Safety Manager. The College Biological Safety Officer, post graduate students, and Technical staff. There is currently no formal Union representative but they have been approached.

Reviewer 1
Section 1.1 Typo subsequent and clinical. Please briefly describe which aspects of the work occur in ICL premises and in Imanova.
Section 2.2 Please describe briefly how the Ldtr−/− mouse line created?
Section 7.2 Is the Imanova lab a Home Office designated lab? How is escape prevented in the Imanova facility?

Reviewer
The form looks fine to me apart from 3.3 where they should say that the mice would be incapable of surviving in the wild since they are unused to external pathogens outside the CBS facility.

Reviewer 3
Section 6.3: Please add information relating to injection of PET radioligands into animals for imaging experiments.
Section 9.1: Please confirm decay storage of carcasses injected with PET radioligands before autoclaving. Please confirm what solid waste will be disposed of via the drain. Please describe disposal procedure between autoclaving and incineration.
Section 10.1: Use of holdall bag not required for transport within a laboratory. Please confirm presence of rodent barriers on the lab entrance.

Reviewer 4.
Section 9.1: This section refers to chemical inactivation of waste; although helpful to describe treatment of residues on instruments (this reference can be left in), there is no need to indicate that any solid waste is treated chemically to decontaminate, so the section on chemical treatment of solid waste can be left blank.

Reviewer 5
The main issue I believe is the possible use of radiation (which need to be confirmed). If radiation is used then consideration for its use included in the assessment e.g. listed under section 6.3 (other hazards) and in section 9.2 (autoclaving waste).
Also, section 9.1 under 'solid waste' I am not sure if they need to mention '30 min autoclave'. This is considered under section 9.2

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Liquid waste is treated with freshly made Distel (formerly sold under the name of Trigene Advance) (tristel) at q 1:10 dilution for >12 hours and then sink disposal.

Solid waste is double-bagged in yellow clinical waste bags, placed in a shared large yellow bin and removed by King's College waste-handling services for off-site incineration.

Distel is guaranteed to 100% kill by the manufacturer for a wide range of viruses, bacteria and mycobacteria. Distel has been tested in accordance with BS EN 14347, 14348, 13727, 13624, 13623, 1276, 1675 protocols.

The active constituent of Distel are approved under the European Biocidal Products Directive (ref 98/8/EC) and offer REACH compliance. Distel is manufactured in the United Kingdom to the highest standards of BS EN ISO 9001:2008 and BS EN ISO 13485:2003, for the manufacturer of disinfectant and sterilising solutions for medical, dental and veterinary use.

Spillages of GMMs will be inactivated using DISTEL at a 1:10 dilution for 10 min.

The project titled 'Assay and Process development for CTX0E03 cortex cell therapy product' has been reviewed by the Cell Therapy Catapult GMSC.

The GMSC consider this to be a class 1 because:

1. No virus or other GMO will be constructed.
2. Though the inserted gene is a potential oncogene, the risk to human health is minimised to the lowest level as no sharps will be used.
3. All waste will be handled correctly; there is no risk to the environment.

02/03/2022
All liquid and solid waste (maximum total volume 20 litres) will be deactivated by autoclaving at 125°C for 20 minutes. Deactivation will be monitored by using 3M comply indicator tape for steam. In addition, small amounts of liquid waste may be activated using RBS (final concentration of 5% v/v). There is therefore no possibility that bacteria will escape from the laboratory.

Where possible the use of sharps is avoided and plastic pipettes are used. However, any sharps used are always placed in a Cin-Bin and disposed of through licensed contractors according to the Company's Waste Disposal Procedure.

A kill curve disinfection test versus time is performed on parental organisms.

For activities involving GMMs, describe the waste management measures which will apply to the activity.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

The GMSC has discussed the risk assessments and agree that the hazards and risks have been addressed by the use of appropriate containment.

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Date of Significant Change

Project Additional Information

Purposes of the contained use
Generation of new genetically modified microbial strains to produce novel natural products for research

Recipient or parental organism
Recipient strains are ACDP HG 1 or 2 bacterial or fungal strains.

Host/vector system
Host organisms are ACDP HG 1 or 2 bacterial or fungal strains. Vector systems are based on E.coli and are defective in one or more transfer functions and can only be mobilised by other elements which supply the missing transfer functions

Origin & function
Genetic material is derived from ACDP HG 1 or 2 bacterial or fungal strains, usually from genes coding for natural products of enzymes of medical or commercial benefit

Evaluation of foreseeable effects
Bacterial and fungal strains used are typically naturally occurring bacteria and fungus, frequently isolated from soil and are essentially wild-type. The bacteria are not normally aggressive colonisers and therefore pose minimal risk to humans or the environment

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid and solid waste (maximum total volume 20 litres) will be deactivated by autoclaving at 123°C for 20 minutes. Deactivation will be monitored by using 3M comply indicator tape for steam. In addition, small amounts of liquid waste may be deactivated using Chemgene (1% solution) or sodium hydroxide. There is therefore no possibility that bacteria will escape from the laboratory.

Where possible the use of sharps is avoided and plastic pipettes are used. However, any sharps used are always placed in a Cin-Bin and disposed of through licensed contractors.

Yes

Give brief details of the genetic modification safety committee

The National Waiting Time Centre Board has established a Gene Therapy Safety Committee. The remit of the committee is to:

Review and process risk assessments and Standard Operating Procedures which result from the Board's participation in Gene Therapy trial. This covers all clinical research studies carried out under the Genetically Modified Organisms (contained use) Regulations enforced by HSE and the Genetically Modified Organism (deliberate release) regulations enforced by the Scottish Government's Rural and Environment Directorate GM Policy Unit.

The committee is co-chaired by two consultant cardiologists and includes the Board's Heads of Facilities, Infection Control and Clinical Governance. Also included are the Board's health and safety lead, clinical trials pharmacist, research manager, three external advisors (including scientific expertise) and senior research nurses.

</table>
Pharmacy Department: The GT product (IMP) will arrive by courier to the GJNH Pharmacy in a vial on dry ice. It will be transported in sealed plastic bags in a designated sealed container to the storage location (2-8°C refrigerator) in the GJNH Pharmacy department. The IMP will be held in the Clinical Trial fridge in the Pharmacy Department, GJNH. The Pharmacy Department is alarmed and locked with entry by swipe ID card. When required, each vial will be logged out and the number recorded on the fridge door (and in the Pharmacy File). Each vial is delivered in single units from the GJNH Pharmacy to the Cardiac Catheterisation laboratories, GJNH for assembly into a single syringe. The remaining contents of each vial will be disposed of by autoclaving.

Aerosols and splashes and spillages may be generated during the transfer of material from the vial to the syringe. All personnel will take normal precautions - see Appendix 11 of the National Infection Control Manual - Part 1 Standard Infection Control Precautions: Management of blood and body fluid spillages. Note that, in common with all NHS Boards in Scotland, the disinfectant of choice is Actichlor which is effective against bacteria, spores, yeasts, moulds and viruses including Hepatitis B and HIV.

Cardiac Catheterisation Lab: The GJNH research team will prepare the vector solution in the Cardiac Catheterisation Labs. Staff will wear the PPE normally used for...
Cath Lab procedures. At the end of the session all PPE items will be placed into Clinical Waste and autoclaved prior to disposal as per GJNH procedures for disposal of all Clinicac Waste. All operators will wear gloves as per Appendix 5 of the National Infection Control Manual - Part 1 Standard Infection Control Precautions: Glove use and selection.

Transport: Route 1: Pharmacy to Cardiac Catheterisation labs. This will apply to the vial of GM material as it is received by the pharmacy department. No manipulations of the vial will take place in the pharmacy department. Route 2: Within the Cardiac Catheterisation labs. This will apply to the transfer of GM material from the transport vial to the syringe, the transport of the syringe to patient and the disposal of all GT contaminated material, including PPE, Route 3: From the Cardiac Catheterisation labs to labs (site of autoclave). This will describe the transport of waste material - sharps bins and waste bags - from the Cardiac Catheterisation labs to the autoclave. One SOP will cover all of these routes and will list the responsible personnel, the routes taken and the containment measures in place.

Waste: vials and syringes containing residual GM material, delivery devices, PPE, material used to clean spillages etc - will be stored in a locked room prior to autoclaving using a validated mixed cycle. Waste will then be disposed of through the usual hospital disposal system.

Autoclave: The maintenance/testing regime for the laboratory autoclave (labs department, Level 2, GJNH) is as follows: daily checks (user), weekly tests (CSPD Engineers), quarterly tests (CSPD Engineers), and annual validation tests (Health Facilities Scotland engineers). Maintenance is done on a reactive basis throughout the year based on weekly and quarterly test results, with an annual full service. Twice yearly pressure vessel insurance surveys are carried out using written scheme (CPSD Engineers/Sun Alliance Inspector). Daily and weekly tests are checks to ensure that the machine is performing correctly and that the independent monitoring agrees within the limits set in SHTM2010 with the control devices on the autoclave. Quarterly and annual validation test are carried out with calibrated thermocouples and pressure transducers connected in the same places as control ad independent monitoring devices as well as spread through the various load types to ensure that as well as the autoclave itself, all parts of loads to be processed attain sterilisation temperatures and pressures for at least the stated times required in SHTM2010. If there are any anomalies found calibration can be changed at this time.

The Gene Therapy Safety Committee met on the 29th May 2013 to review the risk assessment for the CUPID 2 trial. Each section was considered and members contributed suggestions and changes as required. The document was redrafted and circulated to the group on the 30th May 2013. One of the Scientific Advisors update a couple of sections - no further updates were requested.

The Risk Assessment was sent to the Gene Therapy Safety Committee Chair on the 5th June for final approval. Note that the GJNH Head of Infection Control has also signed the Risk Assessment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Liquid E. coli waste

1 x 2.5g preSept tablet (containing sodium dichloroisocyanurate, NaDCC) in 560 ml water gives a solution of 2500 ppm available chlorine, suitable for killing E. coli with a contact time of at least 1 hour (99.9% kill with a contact time of 12 hours). All solutions will be freshly prepared to ensure efficacy. Once inactivated, liquid waste will be diluted by flushing down the drain with plenty of water in accordance with MSDS disposal of small quantities of NaDCC waste.

### Solid E. coli waste

Solid waste including agar plates and plastic ware will be collected in autoclave waste bags, closed with a tie, and destroyed by autoclaving at 121° C for 15 minutes in the service room. A service contract is also in place with PHS Wastetech who are authorised to carry and dispose of GM waste.

Efficacy of inactivation methods can be tested by plating samples of the inactivated material onto appropriate bacterial growth media and culturing under suitable conditions. No growth would indicate complete inactivation had been successful.

### Surface spills

Surface spills will be contained with paper towel soaked with 2% Trigene. The area will be thoroughly cleaned with 2% trigene, with paper towels discarded into clinical waste.

Please enter comments of the GM safety committee on the risk assessment
The BioMot genetic modification safety committee (GMSC) met on the 30th May 2013 to discuss the project application and risk assessment. Terms of reference for the committee were agreed.

The use of GMOs in the project was agreed to be an essential part of the proposed work. The project was deemed to be a Class 1 category for GM work, with overall low or negligible risk to both human health and the environment. The risk assessment was deemed suitable for the project, with minor amendments incorporated and circulated to committee members following discussion at the meeting.

Give brief details of the genetic modification safety committee

The GM Safety committee is formed of the Scientific Director and Special Projects Lead. All GM risk assessments will be reviewed and approved by the committee before any work takes place to ensure HSE guideline are met. The role of the committee is to ensure that HSE guidelines regarding the use of GMMs is adhered to and will meet monthly.

All GMMs will be inactivated by immersion in 1% Virkon solution for 30 minutes before disposal. Any material that comes into contact with GMM’s will be disposed of in Biohazard labelled bags or immersion in 1% Virkon solution for >30 minutes and collected for autoclave and incineration by initial Medical Services. Areas where work is conducted with GMMs will be designated according and kept clean before and after work with a 70% ethanol solution.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Bacteriology Parasitology Transgenic Birds Microbiology Research
The notified premises is a dedicated clinical waste incinerator. It is a Part A process regulated by the Environment Agency and have authorisations in place via a permit issued under the Waste Incineration Directive, permit number is WP3836ZF.

The plant is of a Rotary Kiln design and has three main components: A primary combustion chamber, a secondary combustion chamber and a flue gas cooling and cleaning system. The waste is mechanically loaded into the primary combustion chamber where a minimum temperature of 1000 degrees centigrade is maintained for a minimum of two seconds in an oxygen rich atmosphere to completely oxidise the combustable gases. The flue gas is then cooled to around 130 degrees centigrade by means of a steam boiler before being treated with powdered activated carbon and hydrated lime in a baghouse to remove any remaining impurities.

The plant has a designated storage area with separate facilities for the storage of special or hazardous waste. There is a well developed bin bar coding system in place paperwork and written procedures for the handling of the different types of waste and it is intended to extend these systems to include GMO waste. The plant and site is operated around the clock by teams of Shift Leaders and Plant Operators, who are under the management of a Plant Manager and a Senior Site Manager.

To ensure compliance with the CDG regulations the waste will be delivered into site in UN approved packaging such as hermatically sealed containers. These containers are specifically made for the containment of higher risk materials such as human tissue and body parts, microbiological cultures and out of date medicines. They come in a variety of sizes ranging from 30 Litre containers to 120 Litre containers. They are fitted with a lid which when sealed, forms a very strong hermetic seal when pushed into place. The whole container is designed to be incinerated with no manual handling the contents at all.

The site specialises in the collection, transport and disposal of clinical waste in UN Approved 770 Litre containers and it is envisaged that the containers described above will be placed inside these. 770 Litre containers for mechanical loading into the incinerator. In conjunction with the smaller UN Approved containers, this will provide a UN Approved combination package ideal for the transport, storage and disposal of infectious waste.

Each bin has a unique bar code attached which is used to track bin movements from waste producer to final disposal on a computerised system which satisfies the Duty of Care requirements. There are spillage kits containing all the equipment needed to clean up spillage of waste materials and staff are well trained in the spillage procedures. Fortunately because of the mechanical handing systems employed, spillages are extremely rare and the kits and training are more of precautionary measure. In addition, the site has a Safety Representative elected by the workforce who has agreed to be a member of the GMO safety Committee.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The Risk Assessment has been carried out by the Senior Site Manager and Plant Manager and has been reviewed by the Health & Safety Representative.
# Project Additional Information

**Purposes of the contained use**

Disposal of GMO Class 1 and Class 2 waste via High Temperature Incineration

**Recipient or parental organism**

The characteristics and evaluation of foreseeable effects will be determined by the individual waste producer

**Host/vector system**

Determined by the individual waste producers

**Origin & function**

Determined by the individual waste producers

**Evaluation of foreseeable effects**

Determined by the individual waste producers

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Waste must be inactivated, or the waste producer must be able to demonstrate that the waste will pose no threat to human health or the environment.

For only GMOs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

The GMO waste will be packaged in UN Approved sealed packages and mechanically loaded into the incinerator via lockable 770 Litre containers which are also UN Approved. The waste will be incinerated at a minimum temperature of 1000 degrees centigrade and this will kill 100% of the GMO’s. The final product is a sterile ash which then goes onto landfill.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMO waste will be packaged in UN Approved sealed packages and mechanically loaded into the incinerator via lockable 770 Litre containers which are also UN Approved. Yes

Give brief details of the genetic modification safety committee

The GM Safety committee was set up in 2005 when the centre formed part of the MRC Centre Cambridge (GM921). The centre is transferring employment to the University of Cambridge from the MRC; hence requires a new premises centre number.

The current committee, which is intended to remain, consists of a Chair (senior academic), the Biological Safety Officer, two other senior academics and the Lab Manager, health and safety. The committee meets at least annually and communicates face to face and by email at other times; the committee report to the Health and Safety committee and the centre's director.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Liquid Waste:** (Class 1)
Inactivation will either be autoclaving (considered to give 100% kill) or by chemical means; Virkon gives 99.999% kill in 10 mins and is the default disinfectant, used unless a risk assessment indicates otherwise. Deactivated liquid will then be poured down the sink with at least equal volumes of water.

**Solid Waste:** (Class 1)
All bacterial plates are autoclaved (considered to give 100% kill) on site by support staff. They are finally disposed by incineration offsite. We use a reputable disposal company for all our laboratory waste.

Other solid waste is collected in good quality plastic sacks which line rigid plastic bins. When two thirds full they are sealed and taken to internal wheelie bins. At least once per day the wheelie bins are collected by support staff; the sealed sacks are then put into another sack (obtained from our reputable disposal company) these large bins are kept in a secure yard. The large bins are collected by the disposal company and a fresh bin is replaced, therefore all sacks are secure at all times.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The significant GM work in this project was the construction elsewhere of the cell lines to be used and their screening for virus. The work currently planned to be done at the Hutchison is routine transfection of mammalian cells using plasmids that do not lead to expression in the host bacteria.
**Project Additional Information**

**Purposes of the contained use**

To study the pathways regulating differentiation of human cells, in particular how stem cell fate is regulated.

**Recipient or parental organism**

Human and mouse tissue culture cell lines.

**Host/vector system**

Laboratory strains of E. coli K12.

Phoenix-ecotropic and amphotropic retroviral producer cells.

**Origin & function**

Inserts used are all derived from mouse, human and Xenopus cDNA libraries and comprise wild type and mutated forms of Notch ligands, Notch receptors, suppressor of hairless homologues, mastermind homologues, and Notch target genes including the hairy/enhancer of split family of transcription factors. In addition mutant Xenopus beta catenin and mutants of MAP kinase will be expressed to determine how the Notch pathway interacts the wnt and Map kinase signalling pathways. Cell cycle inhibitory proteins such as p21Cip1 and Geminin will also be used.

In addition reporter constructs derived from the pGL3 series of vectors will be used; these consist of Notch and wnt responsive promoter elements, driving expression of the firefly and renilla luciferase genes.

In some experiments green fluorescent protein will be expressed as a reporter.

The intended use is to study how these genetic elements control the cell development.

**Evaluation of foreseeable effects**

The main hazard arises directly from the recombinant retroviruses produced from the packaging cells. These yield both ecotropic and amphotropic retrovirions, depending upon the envelope protein supplied by the cell.
The packaging cell lines used to generate the retrovirus have either ecotropic or amphotropic envelope proteins, and the retrovirus therefore can either infect only mouse cells, or have a wider host range including human cells. Their infectivity is unstable and infection is only obtained by co-cultivation of the packaging cell line with their recipient cells. The retrovirus is self-inactivating and there is thus no possibility of further transfer. With the ecotropic packaging cell line, there is therefore negligible risk to the worker or the environment.

With the amphotropic packaging cell line, the risk of infection of a worker during the packaging/infection step is small, but still not negligible. Although the inserted genes are not known to be oncogenic, they have this potential and it is considered that this part of the work is Class 2. In view of the, at worst, low-oncogenic nature of the inserted genes and also the self-inactivating nature of the retroviruses, there likelihood of any hazardous replication competent virus being generated is negligible and is no need to test for such RCV.

The single non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of some of the inserts. This risk can be controlled if DNA grown up from such clones is handled appropriately; ie gloves should be worn, sharps avoided and allwastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 mins), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

**Project Containment**

This work involved the cloning of some potentially oncogenic genes into disabled retrovirus vectors, with the use of packaging cell lines which have an amphotropic envelope protein.

From the ACGM Compendium of Guidance, Part 2B, Annexe III, particularly para. 30, this requires Class 2 (as already concluded in the risk assessment).

The Committee noted that the risk of the potentially oncogenic DNA had already been considered in the assessment.
Project Additional Information

**Purposes of the contained use**

To functionally silence genes whose inactivation in cancers gives rise to genetic instability, using a recently developed stable RNA interference approach, to ascertain the molecular basis for the abnormal division of cancer cells and their increased genetic instability.

**Recipient or parental organism**

Tissue culture cells of human origin.

**Host/vector system**

Laboratory strains of E. coli K12 derivatives; tissue culture cells of human origin. pUC-based plasmid vectors with RNA polymerase III promoter (eg pSUPER);
Phoenix-amphotropic retroviral producer cells.

Origin & function

The plan is to use vectors based on pSUPER in which an RNA polymerase III promoter drives expression of a short (~25 mer) interfering RNA from a synthetic DNA insert. Details of the categories of interfering RNAs to be inserted are as follows:

A) RNAs which target DNA double-strand break repair pathways: The proteins encoded by BRCA1, BRCA2, RAD51 and its paralogs, Nbs1, ATM, ATR, Ku70, Ku80 and DNA-PK are nuclear molecules which participate in the sensing and repair of DNA double-strand breaks. In mice, homozygosity for null mutations in these genes leads to cell death, embryonal lethality and a DNA repair defect accompanied by genetic instability.

B) RNA which target cell cycle regulators: The proteins encoded by the mammalian cyclin/CDK genes, the mitotic kinases Pik1, nek1, Aurora-A/B/C, Bub1/BubR1 and the chromatid cohesion molecules Scc1, SMC1/3 and Eco1, are required for cell cycle progression and mitosis.

C) RNAs which target regulators of the G1, S and G2/M checkpoints: These inserts will include proteins encoded by checkpoint regulators such as p53, chk1/chk2 and chfr, or proteins involved in the downstream enforcement of these checkpoints (including cdc14, ranGAP, cyclin G, cdc25 or PP1).

Evaluation of foreseeable effects

The inserts encode short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

A non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras 8-10, in which the potential hazard is specifically considered.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing. Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
This work involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNA. The genes targeted in this work are those for sensing and repair of DNA double-stranded breaks, cell cycle progress and mitosis, and checkpoint regulators or downstream enforcement proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled retroviral vectors, which require a helper t.c. line to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse emphotropic cell lines, with the packaging construct in more than one component, to produce the disabled retrovirus with an amphotropic envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras 21-30, it was agreed that Class 2 is appropriate for this work. If cell lines are being maintained for a long time, consideration should be given to testing them for the presence of replication competent virus.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

Historical Significant Changes

- Project transferred from GM921 on 03/09/2013
# Project Additional Information

## Purposes of the contained use

The project aims to determine the molecular basis of the differentiation of human and mouse epithelial cells. Pathways regulating differentiation include Notch, wnt and the MAP kinase signalling cascade. In addition we wish to explore the interaction of Notch with cell cycle regulators such as p21 Cip1 and Geminin.

## Recipient or parental organism

Tissue culture cells of human or murine origin.

## Host/vector system

- Laboratory strains of E. coli K12 derivatives;
- Tissue culture cells of human origin.
- pUC-based plasmid vectors with RNA polymerase III promoter;
- Phoenix-amphotropic retroviral producer cells.

## Origin & function

The expression of inserts encoding siRNAs, consisting of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA, in human primary epidermal keratinocytes, mouse primary keratinocytes and mouse and human cell lines, including squamous carcinoma cells and telomerase immortalised keratinocytes. Once expressed the siRNA oligonucleotides are expected to decrease levels of RNA encoding the target protein by over 70%.

Target genes are those of the pathways regulating epithelial stem cell fate, including Notch receptors, suppressor of hairless homologues, mastermind homologues, and the hairy/enhancer of split family of transcription factors. In addition components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins such as p21 Cip1 and Geminin will also be targeted.

Control siRNAs directed against enhanced green fluorescent protein and luciferase will be required for some experiments.

## Evaluation of foreseeable effects

The inserts encode short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not
enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

A non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10 in which the potential hazard is specifically considered.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

This work involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNA. The genes targeted in this work are those for pathways controlling epithelial stem cell fate, components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled retroviral vectors, which require a helper t.c. line to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse cell lines, with the Phoenix packaging constructs, which give either ecotropic or amphotropic envelopes, to produce the disabled retrovirus with either type of envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras 21-30, it was agreed that Class 1 is appropriate with the ecotropic envelope and Class 2 with the amphotropic. If cell lines from the amphotropic constructs are being maintained for a long time, consideration should be given to testing them for the presence of replication competent virus.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

Historical Significant Changes: Project transferred from GM921 on 03/09/2013

Project Additional Information

**Purposes of the contained use**

The project aims to determine the molecular basis of the differentiation of human and mouse epithelial cells. Pathways regulating differentiation include Notch, wnt and the MAP kinase signalling cascade. In addition we wish to explore the interaction of Notch with cell cycle regulators such as p21 Cip1 and Geminin.

**Recipient or parental organism**

Tissue culture cells of human or murine origin.

**Host/vector system**
Laboratory strains of E. coli K12 derivatives; tissue culture cells of human or mouse origin, including murine cells expressing helper functions for defective retrovirus production.

pUC-based plasmid vectors with RNA polymerase III promoter; Plasmids containing lentiviral helper proteins - see diagrams attached to risk assessment.

### Origin & function

The expression of inserts encoding siRNAs, consisting of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA, in human primary epidermal keratinocytes, mouse primary keratinocytes and mouse and human cell lines, including squamous carcinoma cells and telomerase immortalised keratinocytes. These cells will include those infected with lentiviruses or retroviruses engineered to include a LoxP sequence flanked cDNA sequence.

Also expression of non-oncogenic genes involved in these pathways.

Target genes are those of the pathways regulating epithelial stem cell fate, including Notch receptors, suppressor or hairless homologues, mastermind homologues, and the hairy/enhancer of split family of transcription factors. In addition components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins such as p21 Cip1 and Geminin will also be targeted.

Control siRNAs directed against enhanced green fluorescent protein and luciferase will be required for some experiments.

### Evaluation of foreseeable effects

The inserts encode either non-oncogenic proteins or short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes.

In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

The expression of the Cre recombinase will recombine the LoxP sites. Among other resulting deletions will be the gene for Cre itself.

Anon-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10 in which the potential hazard is specifically considered.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before eithe subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

02/03/2022
This work involves the cloning and expression of non-oncogenic proteins involved in pathways controlling epithelial cell fate. It also involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNAs. These genes targeted in this work are those for pathways controlling epithelial stem cell fate, components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled lentiviral or retroviral vectors, which require a helper t.c. line (or helper plasmids in a t.c. cell line) to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse cell lines, together with plasmids supplying helper functions, which give either ecotropic or amphotropic envelopes, to produce the disabled lentivirus with either type of envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras. 21-30, it was agreed that Class 1 is appropriate with the ecotropic envelope and Class 2 with the amphotropic.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

Cancer cells exhibit abnormalities in cell cycle progression, chromosome structure and segregation and in the capacity to repair DNA damage that are central to transformation. These abnormalities are often the result of mutations in tumour suppressor genes, such as the breast cancer gene BRCA2. The overall goal of our studies is to ascertain the molecular basis for the abnormal division of cancer cells, and their increased genetic instability.

Recipient or parental organism

Murine-embryo-fibroblasts and HeLa and other cancer cell lines.

Host/vector system

E.coli laboratory K12 derivatives/pUC based vectors; Vertebrate tissue culture cells including 293T cells, murine-embryo-fibroblasts and HeLa and other cancer cell lines/Lentiviral vectors, with polytropism through viral pseudo-typing using VSV-G protein.

Lentiviral system: The viral system to be used employs a well-characterised lentiviral vector and packaging cell lines(Refs below). A number of safety features are incorporated to eliminate or very greatly reduce the possibility of generating productive recombinants. The vector lacks gag, pol, env, tat, rev, vpr, vpu, vif and nef functions. A chimeric LTR offsets the requirement for Tat in expressing genes transcribed from the LTR. The Rev function is provided in trans from a separate plasmid in the packaging cells, as are the Gag/Pol functions. The viral vectors are self-inactivating due to deletions in both the LTRs, and thus incapable of replication after one round of infection of target cells. The packaging cell lines are effectively helper-free, since the rev, gag/pol and env (in this case, pseudo-typed with VSV-G protein) genes are expressed from separate plasmids. Rubinson et al Nat Genetics 34:231 (2003); Dull et al., J Virol 72:8463 (1998); Myoshi et al J. Virol 72:8150 (1998).

Origin & function

Specific aims with details of the categories of inserts to be used are as follows:

A) BRCA2-deficient cells exhibit defects in DNA repair (1). The defect is likely related to the inability of mutants BRCA2 to form functional complexes with RecA homologs in the Rad51 family (eg Rad51, xrc2 & 3, Rad51B-D). The molecular basis for this phenotype will be studied by functional and biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

B) Abnormalities of chromosome structure and number are abundant in BRCA2-deficient cells (2-4). To investigate the molecular basis for these phenotypes, the function of tenes controlling chromatin structure (eg histones, histone-modifying-enzymes, HP1), the cell cycle (eg cylins A, B, D, E; cdk1, 2 & 4, polo-like kinases), chromosome number and structure (eg SMCs1 & 3, scc1, Ecol), cytokinesis (eg chromokinesins, INCENP, Surviving) and the centrosome cycle (eg nek1, nap, g-tubulin, aurora kinases)
will be investigated by functional & biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied. C) We have shown that mutations inactivating mitotic checkpoint genes including Bub1 or Mad3L (BubR1), are necessary for the neoplastic transformation of cells lacking the BRCA2 tumour suppressor (5). Besides these, we will test the possibility that genes (eg chk1/chk2, cdc14A/cdc14B, PP1delta, cdc25C, m TERT or h TERT, ranGAP & cdh1) whose normal function is to regulate cell cycle progression and chromosome stability, particularly during the S phase and in mitosis, will be targets for inactivation by secondary genetic changes during tumour evolution in cells that lack genes such as BRCA2, using studies of transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

D) To identify novel genes that regulate these processes, cells will need to be transfected with pools (libraries) of vertebrate cDNAs or short-hairpin RNA molecules that interfer with the expression of vertebrate genes, for phenotypic screens. Here, the precise nature of the insert cannot be specified in advance.

In A-C above, fusions of wild-type & mutant genes to GFP or other fluorescent tags will be used to determine intracellular localisation.

**Project Containment**
The aim of this study is to identify genetic dependencies in metastatic cancer cells by utilizing retro and lentiviral vectors. Murine and human cells (packaging cells, primary cells, cancer cell lines and immortalized cell lines) are used as recipients. K12-derived E.coli strains (e.g., DH5alpha) are used for plasmid transformations and amplifications.
Stable gene transduction will be achieved by Moloney murine leukemia virus (MMLV) or Murine stem cell virus (MSCV) - derived retroviral (e.g. pBabe, pRetroX) or HIV1-derived lentiviral vectors (e.g. pGIPZ, pTRIPZ, pLVX). 293T human embryonic kidney cells and derivatives will be used as packaging/producer cells.

We will use commercially available retroviral and lentiviral packaging systems of the utilize split genes to provide viral packaging elements on individual plasmids that physically separate the viral envelope, env (VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating replication-competent lentivirus (RCL) because multiple recombination events are necessary to create a virus that harbors the sequences required for independent replication. Also, these systems contain a large deletion in the 3’ LTR making packaging cells will be used. Retroviruses can only infect both dividing and non-dividing cells and no stable packaging cells will be used. Retroviruses can only infect dividing cells and are therefore less hazardous. They will be produced using packaging cells that stably express the packaging constructs. In both cases, the packaged viruses are not able to replicate independently.

The 2nd generation lentiviral vetors contain several safety mechanisms:

- Reduced number of genes from HIV-1 (i.e. gag, pol, tat and rev).
- Separation of genes encoding the structural and other components required for packaging the virus to substantially reduce the risk of undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., J Virology 72 8463-8471 1998).
- None of the HIV-1 structural genes are present in the packaged viral genome and are therefore never expressed in the transduced targe cell.
- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral particles are produced.
- In some cases expression of the gene of insert of interest will be dependent on a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

These vectors contain the WPRE (Woodchuck hepatitis B virus post-transcriptional regulatory element). This element is used to increase lentiviral vector titre and gene expression. It includes the promoter for the X-protein and the part to the coding sequence for such protein, which may have oncogenic properties.

The viral vectors will not increase the pathogenicity of the host cells. The main hazard arises directly from the recombinant retroviruses produced from the packaging cells. These yield both ecotropic and amphotropic lentivirions and ecotropic and amphotropic retrovirions, depending upon the envelope proteins supplied by the cell.

Target cells:
Tumour cell lines, both established and those derived from patient samples. After infection is complete, cells wil be propagated as cell lines. Target cells include human and mouse cancer cells. Inserts include transcription factors, epigenetic regulators, metabolic enzymes, RNAi-constructs, the Cas9 nuclease, and guide RNA constructs. Some of them may be expected to confer some growth advantage on the recipient cells. In some instances we wil be transducing cells with known or putative oncogenes or constructs that target known or putative tumour suppressor genes.

Infected cells
After infection and selection, the manipulated cells will no longer be harbouring propagating virus, so they will no longer represent an infection hazard.

Origin & function
Genes and mutant derivatives thereof, usually of human or mouse origin, encoding transcription factors, metabolic regulators, epigenetic regulators and other cancer-related gene products identified through bioinformatic analysis, also potential or known oncogenes or tumour suppressor genes. Marker genes (GFP, luciferase etc.), CRE recombinase, RNAi constructs and genetic tags (HA, FLAG), antibiotic resistance genes, targeted nucleases (e.g. Cas9 and derivatives), nuclease guide RNAs. Some of the virus vectors may lead to growth arrest of mammalian cells, while others may promote cell proliferation. Because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Class II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these

This is typical lentivirus project, designed to introduce genes into mouse and human cells in vitro. It does not raise any unusual issues.
### Purposes of the contained use

The object of this study is to modulate the expression levels of Ras proteins in a number of well-established human and normal and cancerous cell lines, in order to investigate whether different levels of expression of mutant Ras proteins result in differing outcomes for the cell.

### Recipient or parental organism

Human cells (packaging cella, cancer cell lines and immortalized cell lines).

### Host/vector system

**Plasmid production:**
K12-derived E.coli strains (e.g. DH5alpha) of bacteria are used for transformations and amplification of plasmids.

**Retro/lentiviral production:**
Stable gene transduction will be achieved by Moloney murine leukemia virus (MMLV)-derived retroviral vectors (e.g. pBabe, pLPCX) or HIV1-derived lentiviral vectors (e.g. pLKO.1). 293T human embryonic kidney cells and derivatives will be used as packaging/producer cells.

We will use commercially available retroviral and lentiviral packaging systems that use split genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope sequence, env (VSV-G), from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating
replication-competent lentivirus because multiple recombination events are necessary to create a virus that harbors the sequences required for independent replication. Also, these systems contain a large deletion in the 3’ LTR marking these viruses replication-incompetent. Lentiviruses can infect both dividing and non-dividing cells and no stable packaging cells will be used. Retroviruses can only infect both dividing and non-dividing cells and no stable packaging cells will be used. Retroviruses can only infect dividing cells and therefore less hazardous. They will be produced using packaging cells that stably express the packaging constructs. In both cases, the packaged viruses are not able to replicate independently.

The 2nd generation lentiviral vectors contain several safety mechanisms:

. Reduced number of genes from HIV-1 (i.e. gag, pol, tat and rev).

. Separation of genes encoding the structural and other components required for packaging the virus to substantially reduce the risk of undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., J Virology 72 8463-8471 1998).

. None of the HIV-1 structural genes are present in the packaged viral genome and are therefore never expressed in the transduced target cell.

. The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

The viral vectors will not increase pathogenicity of the host cells. The main hazard arose directly from the recombinant retroviruses produced from the packaging cells, which yield amphotropic lentivirons and retrovirions.

Target cells:
Established tumour cell lines. After infection is complete, cells will be propagated as cell lines. Inserts include known oncogenes or constructs that target known oncogens.

Infected cells:
After infection and selection, the manipulated cells will no longer be harbouring propagating virus, so they will no longer represent an infection hazard.

Origin & function

Known oncogenes of human origin and silencing constructs (shRNA) targeting the same oncogenes, as well as marker genes (GFP) and antibiotic resistance genes (puromycin).

Evaluation of foreseeable effects

The main hazard is potential infection of persons working in the lab by the GM virus, for which a Class II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms and tissue culture cells are involved

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All class II waste will be treated as per Hutchison/MRC Research Centre guidelines. Currently, liquid waste will be treated with an equal volume of 10% Virkon solution, with a contact time of 30 minutes before disposal. This will be flushed down the sink with copious amounts of water.
Plastic waste, tissues, gloves etc. will be placed in biohazard. All class II waste will be autoclaved before leaving the building for incineration.

Class I waste will be disposed according to Hutchison/MRC Research Centre practice, currently: liquid waste will be inactivated with Virkon; bacterial plates will be autoclaved on site; remaining waste will be incinerated off site.

It is expected that this will give effectively 100% killing.

This is similar to many Ras for using mon-replicating lentivirus and retrovirus vectors to express genes and shRNAs in human cell lines in vitro, with Class II for production of, and infection by human host-range virus vectors. It raises no particular issues.

This is similar to many Ras for using mon-replicating lentivirus and retrovirus vectors to express genes and shRNAs in human cell lines in vitro, with Class II for production of, and infection by human host-range virus vectors. It raises no particular issues.
The aim of this study is to identify genes involved in regulating lung tumour development and progression.

Murine and human cells (packaging cells, primary cells, cancer cell lines and immortalised cell lines).

Laboratory K12 or B derived E. coli strains will be used for transformation, selection and amplification of plasmid DNA.

Lentiviral production:
Stable gene transduction will be achieved HIV1-derived lentiviral vectors (eg. pLKO.1, pBOBI, pGIPZ, pRRL etc). 293T Human embryonic kidney cells will be used as packaging/producer cells.

We will use commercially available lentiviral packaging systems that utilize split genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating replication competent lentivirus (RCL) because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Also, these systems contain a large deletion in the 3′ LTR making these viruses replication incompetent. Lentiviruses can infect both dividing and non dividing cells and no stable packaging cells will be used. The packaged virus will not be able to replicate independently.

The generation of lentivirus has been significantly modified for biosafety:
- The viral genes (env,tat, rev, vpr, vpu, vif and nef) have been deleted from the vector, so that it expresses no viral gene products.
- The vector has a self-inactivating LTR TATA box deletion) and
- Genes encoding the structural and other components required for packaging the vector, and the envelope glycoprotein, are provided on two or three separate plasmids.
All plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al, 1998)
  - No single plasmid contains all the genes necessary to produce packaged lentivirus. None of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell so no new replication-competent virus can be produced.
  - The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
  - In some cases expression of the gene insert of interest will be dependent on a tet-responsive promoter, and regulated by a co-transduced lentivirus doxycycline-responsive Tet regulator, giving an added level of safety for insert expression.

These vectors contain the WPRE (Woodchuck hepatitits B virus post-transcriptional regulatory element) as a means to increase virus titre and gene expression. As it included the promoter and partial coding sequence for the X-protein, it may have oncogenic properties.
**Target cells:**
Tumour cell lines, both human and murine will be used. After infection is complete, cells will be propagated as cell lines. Inserts include transcription factors, oncogenes, tumour suppressors, metabolic enzymes, and RNAi constructs. Some of them may be expected to confer some growth advantage on the recipient cells.

**Infected cells:**
After infection and selection, the manipulated cells will no longer be harbouring propagating virus, so they will no longer represent an infection hazard.

**Origin & function**
Genes and mutant derivatives thereof, usually of mouse or human origin, encoding putative oncogenes or tumour suppressor, transcription factors, metabolic enzymes. Marker genes (GFP, RFP etc), RNAi constructs and genetic tags (HA, FLAG) and antibiotic resistance genes.

**Evaluation of foreseeable effects**
Some of the virus vectors may lead to proliferation or alternatively growth arrest of mammalian cells. Because of the presence of the WPRE element in the vectors, the lentivirus constructs might transform infected mammalian cells.

The main hazard is potential infection of persons working in the lab by the GM virus, for which a Class 2 containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer be an infection hazard. Work with these genetically modified cells can be undertaken at Class 1.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Only micro-organisms and tissue culture cells are involved

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Full containment at level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at class 1.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Containment level 2 waste will be disposed of according to Hutchison-MRC SOPs. Currently solid waste is autoclaved (136°C for 10 min), before disposal offsite by specialist contractors; the waste is then rotoclaved. Liquid waste may be mixed with Virkon to a final concentration of 5% and stood for 30 minutes minimum before drain disposal. It is expected that his will give 100% killing.

**Project Ref** 3201/16.1

- **Date Ackn'd**: 12/05/2016
- **CU2 Project Title**: Functional analysis of oesophageal adenocarcinoma genomic variants
- **Class**: Class 2
- **Culture Volume Class 2**: ≤ 1 Litre
- **Non-GMM Consent Granted**: Consent Granted
- **Project notified under transitional arrangements**: N

**Project Additional Information**

**Purposes of the contained use**

This project aims to better understand the functional effects of genomic aberrations in oesophageal adenocarcinoma by permanently or transiently altering the genomic and transcriptomic state of in vitro models including oesophageal cell lines and organoids derived from primary tumour tissue. This requires the use of lentiviral RNAi and cDNA over-expression vectors as well as expression of targeted nucleases that will permanently alter cancer cell genomes.

**Recipient or parental organism**
1. Established human tumour cell lines and 2. Oesophageal organoid cultures derived directly from patient samples. These Organoids can be passaged >30 times in many cases, without transformation. The patient samples are not in general screened for blood-borne viruses, and we are not permitted to screen them, for ethical/consent reasons. There is a separate risk assessment for these cultures.

**Host/vector system**

K12-derived E. coli strains (e.g. DH5alpha) of bacteria are used for transformations and amplification of plasmids.

Stable gene transduction into human cells will be achieved using HIV1-derived 2nd generation lentiviral vectors such as pCW57.1 and pLX304. For CRISPR experiments, vectors such as pCW57.1, containing dox inducible Cas9, and pKLV-U6gRNA-EF-pGKpuro2ABFP, encoding guide RNAs, will be used. 293T human embryonic kidney cells and derivatives will be used as packaging/producer cells, using packaging plasmids such as psPAX2 and psMD2.G. Later generation systems with further safety mechanisms and higher efficacy may be adopted as they become established.

**Origin & function**

Inserts will encode reporters (e.g. EGFP, DsRed, luciferase); transcriptional regulators (e.g. Tet-On); normal and modified transcription factors or epigenetic regulators and other cancer-associated transcripts, including known oncogenes; shRNAi constructs, or targeted nucleases and their associated RNA molecules (CRISPR/Cas9), including constructs that functionally ablate known tumour suppressor genes or activate known oncogenes. Many of these Constructs are intended to oncogenically transform human cells. Genes will be expressed under the control of viral and mammalian promoters, both constitutive (e.g. CMV or E2F) and/or inducible (e.g. regulated by Tet-On trans-activator protein).

**Evaluation of foreseeable effects**

DNA grown up from clones should also be handled with care as it is potentially oncogenic because of the WRPE element and oncogenic inserts; i.e. gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

K12-derived E. coli strains (e.g. DH5alpha) of bacteria (containment level 1) are used for transformations and amplification of plasmids. No constructs will contain mammalian extra-cellular protein encoding genes driven by bacterial promoters as these could potentially enhance E.coli pathogenicity.

Viral particles will be filtered to remove any possible contamination by 293T cells, which could allow continued viral production. We will use 2nd generation lentiviral vectors containing several safety mechanisms:

- Reduced number of genes from HIV-1 in lentiviral construct (i.e. gag, pol, tat and rev are absent).
- Separation of genes encoding the structural and other components required for packaging the virus to substantially reduce the risk of undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., J Virology 72 8463-8471 1998).
- None of the HIV-1 structural genes are present in the packaged viral genome and are therefore never expressed in the transduced target cell.
- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- In some cases expression of the gene insert of interest will be dependent on a tet-responsive promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

Given the non-negligible hazards associated with the use of replication incompetent lentivirus in this case, particular attention will be paid to staff awareness when working with genes with a potential growth-promoting function (virus production, labelling, storage). No sharps will be used when working with lentiviruses. Also, appropriate personal protective equipment will be used (gloves, lab coats).

For some experiments, virus will be stored outside the Class 2 lab. For this, it will be in a designated section of a clearly designated freezer, in double containers, according to the Hutchison-MRC Research Centre Class 2 Code of Practice.

Lentiviral vectors contain the WPRE (Woodchuck hepatitis B virus post-transcriptional regulatory element), which may have oncogenic properties, so, whether or not the
inserts are oncogenic. All these lentiviruses are potentially oncogenic. The risk of Lentiviral infection of a worker during the packaging/infection step is small, but still not negligible. As the vector contains the complete WPRE element as well as tumorigenic inserts this part of the work is Class 2. However any theoretical hazard is only during initial contact since such viruses could not propagate. The prokaryotic cells are highly disabled and the plasmid vectors are non-mobilisable, therefore neither has any possibility of further spread.

In principle, there is a small risk that organoid cultures might carry HIV, which, by acting as a helper virus, would make the lentivirus inserts replication-competent. However, to our knowledge HIV does not replicate in cells such as oesophageal epithelium, so, provided the organoids have been passaged by disaggregation so that they do not also carry macrophages or lymphocytes, the risk of HIV is low. After infected organoids have been passaged further, the risk of active virus will be very low.

To cryopreserve cells in CL2, storage will be at -80 outside the CL2 lab as specified above for virus storage. When it is really necessary for long-term preservation to store cells in a vapour phase liquid nitrogen refrigerator this will be in a clearly designated location, in a double container, according to an agreed Hutchison-MRC Research Centre Class 2 Code of Practice and with explicit permission from the Hutchison Lab Manager responsible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

After infection, selection and passaging at least once, for cell line cultures only, NOT organoids, cells that are virus negative may be transferred to CL1. To show that cells are negative for replicating lentivirus, we will use well characterised methods such as the Molecular Probes’ EnzChek® Reverse Transcriptase Assay.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be disposed of according to Hutchison-MRC SOPs.

Containment level 2: Solid waste e.g. plastic waste, tissues, gloves etc. will be placed in clear biohazard autoclave bags provided. When full, bags will be sealed with tape and placed in the appropriate biohazard bin, it is then autoclaved (136°C for 10min). Final disposal is offsite by specialist contractors; the waste is then rotoclaved.

Liquid waste should be mixed with Virkon to a final concentration of 5% and stood for 30 minutes minimum before drain disposal. It is expected that this will give 100% killing.

Containment Level I: Solid waste, e.g. plastic waste, tissues, gloves etc. will be placed in yellow bags. When full, bags will be sealed with tape and placed in the appropriate biohazard bin. Bacterial plates are collected in clear biohazard autoclave bags and are autoclaved (136°C for 10min). Final disposal of all CL1 solid waste is offsite, by specialist contractors; the waste is then rotoclaved.

Liquid waste should be mixed with Virkon to a final concentration of 1% and stood for 30 minutes minimum before drain disposal. It is expected that this will give 100% killing.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This is principally a project to use lentivirus to manipulate cancer-relevant genes in human cells. The non-standard element of the proposal is that organoid cultures of human epithelium from unscreened patients are among the target cells to be used. Screening is not permissible for ethical reasons. Since such cultures might rarely be contaminated with HIV, the general principle that modern lentivirus constructs cannot propagate could break down, because the HIV could package the lentivirus vector, in effect creating a defective virus-helper virus system. However, the HIV itself is at least as great an ‘in principle’ risk, which we accept. Self-inactivating constructs would be preferable in this case, since they are less likely to transcribe packageable RNAs. An SOP for cryopreserving CL2 cells needs to be developed. The CRISPR work does not raise ‘gene drive’ issues and so, according to current views, raises no additional concerns.

Project Ref 3201/16.2

Date Ackn’d: 25/05/2016

CU2 Project Title: Lentiviral particles containing human open-reading frame (hORF) cDNA libraries to find novel druggable targets in human reporter cell lines

Class: 2

Culture Vol: < 1 Litre

Project notified under transitional arrangements N

Consent Granted

Date Projects Ceased

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

02/03/2022
The main purpose of the work is to create reporter cell lines in which human open-reading frame (hORF) eDNA libraries are expressed. Our starting material will consist of short coding sequences of human eDNA, encompassing much of the human transcriptome, encoding short peptides which may (or may not) represent in-frame, ordered human peptide sequences, but will not usually code for complete, functional human proteins. The above library will be subcloned, along with a selection marker into the pl VX-TetOne (Clontech), or similar vector and subsequently viral particles will be synthesised and titrated by Vectalys ltd, a contract research organisation (CRO). This virus will be used to infect human reporter cell lines in order to generate recombinant cell lines. In these cell lines, the hORF libraries will be randomly inserted into the host genome. Following selection, should tetracycline dependant vectors be used, these cell lines will be activated by Doxycycline treatment prior to assessment for reporter activity.

- Due to source material of cDNA hORF library, in-frame peptides cannot be guaranteed, therefore 66% of the library will consist of peptides coded by out-of-frame cDNA; 33% will consist of human ORF peptides.

Human cell lines including but not limited to: U20S, HCT1 16, D1 D-1, SW48, Panc-1, Hel a.

Laboratory strains of E.coli K12, pl VX-TetOne (Clontech ltd.) vectors and 3rd generation, self-inactivating lentiviral particles containing pl VX-TetOne with human open reading frame libraries. In E.coli and in tissue culture cells, the host cells are disabled and hazard group 1. Further to this, no expression of human protein should occur in bacterial cells, therefore no increase in pathogenicity of the bacteria should occur following transformation. The vectors are non-mobilisable; 3rd generation self-inactivating vectors exhibit negligible risk of replication-competent virus production. The transgenes have a limited potential to disrupt endogenous genes either by coding sequence insertion-mediated silencing, by promoter insertion-mediated dysregulation or by aberrant production of all or part of a hORF. The disruptive potential is limited by the autosomal nature of the genome together with the random nature of lentiviral insertion and secondly, in some cases by the inducible, chemically-dependant nature of the transgenes. The risk to environment is limited by the self-inactivating nature of the lentiviral particles and low probability of creating replication-competent lentivirus A small risk to user however remains, the provisional classification is therefore Class 2.

Our starting material will consist of short coding sequences of human eDNA, encompassing much of the human transcriptome, encoding short peptides which may (or may not) represent in-frame, ordered human peptide sequences, but will not usually code for complete, functional human proteins. These open-reading frames will be permanently inserted into the genomes of the target cell populations and will subsequently express protein fragments in either a constitutive or chemically regulated manner. In the case of pLVX-TetOne, the genetic material inserted between the viral L TRs will include both fragments of and intact wild-type human open-reading frame sequences (hORFs) from throughout the human transcriptome; sequences encoding a transactivation gene (TetOn3G); a tetracycline-responsive promoter (TRE3G) and a selection cassette to identify gene targeted clones.

The worst case scenario is that accidental infection of a user with lentivirus results in genetic modification of his/her cells and/or production of replication-competent lentiviral particles. However, there are multiple strong reasons why
such an event is unlikely to be hazardous in respect of human health or environmental safety. Firstly, deregulation of tumour suppressor genes by coding sequence insertion is unlikely, as the genes in question are largely encoded on autosomes, the lentiviral vectors do not encode regions of homology for specific insertion loci, and so the rate of random insertion into a specific and detrimental loci using lentiviral vectors makes it extremely unlikely that both somatic copies will be altered in a single cell. Secondly, in the case of an inducible system, the presence of an activating compound, doxycycline is required for effective transcription of the inserted transgene. As cells other than experimental cell lines are unlikely to have doxycycline at effective concentrations, accidental infection of a user is very unlikely to result in gain-of-function conditions by hORF insertion as the hORF should not be transcribed. Thirdly, when using lentiviral particles produced by 3rd generation packaging systems that utilise splitgenes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication (see diagram, p7). There is no evidence that when the inserted genetic material recombines with the host cells genomic DNA that any rep/cap sequences of the lentiviral genome are incorporated. In the recombinant lentiviral particles, lentiviral genomic sequences present are: WPRE, RRE, cPPT/CTS and*, (see p.5-6). Also, the Long Terminal Repeats (LTRs) are included, of which the U3 region of the 3'LTR is deleted, allowing genomic integration in host cells, but preventing subsequent first strand synthesis of viral RNA and therefore replication of integrated viral DNA. Finally (as detailed below), the vector/host systems are non-mobilisable and disabled, and the lentiviral particles are replication-deficient, rendering the potential to affect environmental safety very minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Project Additional Information**

**Purposes of the contained use**

To study the impact selected cancer driver genes have on the normal cellular functioning, clonal fate and proliferative dynamics in vitro using conditional expression of selected mutated genes in normal human breast cells. Some of the most commonly mutated genes in breast cancer include p53, PIK3CA, CCND1, PTEN, ERBB2, GATA3, and BRCA1/2.
genes (The Cancer Genome Atlas Network et al. Nature 2012). Cancer driver genes often contain mutations (such as frame shift, missense or truncation mutations) that lead to aberrant expression and activation of downstream growth factor Signalling cascades and activate proliferative pathways as shown in mouse transgenic models and breast cancer cell lines. It is not known how the mutations confer selection advantage in normal breast cells or whether there is cooperation between mutated and normal cells to drive tumorigenesis. The objective of this study is to induce expression of these mutations by cDNA expression of 3D organoid structures in selected mammary epithelial cells. Inserts will incluclude WT and mutated versions of the above genes of interest. Further, inserts will encode an inducible system (such as Tet-On/Off or Cre-ERT2) to induce expression at specific times and inserts will be fused to reporters such as GFP to determine cellular localisation. This work will involve difficult-to-transfect human breast cells, requiring the use of lentiviral systems for effective gene transfer. This assessment refers to work that will be carried out in vitro.

**Recipient or parental organism**

Infection of human breast cells (both primary and early passage cells) with packaged viral constructs. After infection, the cells will be cultured in media containing puromycin to select for transformants. The infected cells will then be cultured in 3D organoid systems and expression of mutations induced after 3D spheroid formation. These organoids will then be used for microscopy analysis and cells recovered for protein/gene expression analyses.

**Host/vector system**

*HOST:* Lentivirus will be packaged by co-transfection of lentiviral transfer plasmid, packaging plasmids and envelope plasmid into HEK293T cells.

*VECTOR:* Lentiviruses are produced using a second-generation packaging system. Three plasmids will be used to generate viral particles: (i) cDNA-containing vector (such as pLV), (ii) packaging plasmid (i.e. psPAX2) and (iii) envelope plasmid (e.g. pMD2.G or pCMV-VSVG). The lentiviral transfer plasmid, packaging plasmid and envelope plasmid are transfected into 293T packaging cells. Genes for replication and structural proteins are absent in the packaged viral genome since these genes are supplied by other plasmids in the packaging cells. The lentiviral vector contains a self-inactivating 3' lTR that renders it unable to produce infectious virus once it integrates into the host genome. Thus, the viral particles that form are self-inactivating and replication incompetent.

**Origin & function**

Inducible expression lentiviral vectors (such as Tet- or Cre-ERT2 systems) used for cDNA-mediated expression of genes of interest (WT and mutated versions) and commercially available via Addgene.

**Evaluation of foreseeable effects**

The prokaryotic and eukaryotic cells and cell lines, even if the latter are transformed with an oncogene, are highly disabled and the possibility of competent virus being generated is negligible. Therefore, they should be unable to propagate in the environment. The plasmid vectors are non-mobilisable, so neither has any possibility of further spread. The viruses are replication-incompetent and no live virus should reach the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All class 2 waste will be treated as per HutchisonMRC Research Centre guidelines. Currently, liquid waste will be treated with an equal volume of 10% Virkon solution, with a contact time of 30 minutes before disposal. This will achieve 100% kill. This will be flushed down the sink with copious amounts of water. Plastic waste, tissues, gloves etc. will be placed in biohazard bins provided. Double bags will be used. When full, bags will be sealed with tape and placed in the appropriate biohazard. All Class 2 waste will be autoclaved before leaving the building for incineration.

Please enter comments on the GM safety committee on the risk assessment

A standard CL2 lentivirus project, but the cells to be infected are going to be primary human breast epithelial cells. The most significant risk related to these cells is that they come straight from patients and hence they possibly contain also blood-derived cells. As per the associated risk assessment on human-derived cells, the primary human cell cultures will be kept in CL2 facilities until they have been confirmed to be negative for blood cells, after this they can be used also in CL1 facilities.

Project Ref  3201/18.2

Date Ackn’d  20/04/2018

CU2 Project Title  Transfection and infection of mammalian cell lines or cancer cell lines

Class  Class 2
CultureVolClass2  < 1 Litre
CultureVolumeClass3-4

Non-GMM  Consent Granted

Date Project  02/03/2022
The overall aim of the project is to gain insight into the mechanisms and processes that promote cancer initiation and progression. More specifically we seek to study the interplay between cellular plasticity, stemness, senescence and tumorigenesis during lung cancer initiation and progression as well as the autocrine and paracrine roles of cellular senescence.

Human/murine primary cells (primarily with a lung origin, but not excluding other organ/tissues) and commercially available human cell lines, human tumor cell lines, mouse cell lines and mouse cancer cell lines shall be used.

Retrovirus
Retroviral plasmids will be transfected into an ecotropic packaging cell line, Phoenix-eco or amphotropic/VSV-G pseudotyped recombinant retrovirus. The ecotropic env gene produces particles that only infect rodent cells. The amphotropic env gene allows infection of both murine and non murine cells.

Lentivirus
We shall be using second third and subsequent generation lentivirus such as FUW-M2rtTA, pLKO, pWPI, and others. Both the viral vector and recombinant virus have a broad host range when pseudotyped. 293T cell line shall be used to produce lentiviral particles.

On occasion adenoiviral (Ad) vectors shall be used. These include type 5 infection-ready, replication incompetent adenovirus expressing Cre recombinase (AdCMV-Cre), FLP recombinase (AdCMV-Flp) or fluorescent marker proteins and appropriate adenoviral controls. Commerially available Adeno associated virus (AAV) shall be used on occasions. AAV vectors consist of recombinant transgene sequences flanked by AAV inverted terminal repeats (ITR) and produced by triple transfection system: the ITR-containing plasmid, the plasmid encoding AAV the capsid (VP1, VP2 and VP3 proteins) and replicate genes and the adenoviral helper plasmid.

The classes of genes to be manipulated are genes involved in the oncogenic or tumor suppression activity, inflammation, pluripotency, development and differentiation, cellular signalling, cellular senescence, transcription and chromatin regulation, cell adhesion and polarity.

Human or mouse genes to be used:
1. Genes with cell autonomous effect including wild type and mutant forms of Ras (such as K-RasG12D or K-RasG12V), Raf, Mek, Erk, Beta catenin, Tcf/Lef, Rac, Rho,

02/03/2022
cdc42, TNF alpha, PI3K, Kif4, Oct4, Sox2, Myc or histone methyltransferases.

2. Genes with autocrine and paracrine effects. These include wild type and mutant constructs of alpha and beta integrin subunits, Ephrins and E-cadherin, components of the Stat3 family, nuclear factor Kb, signalling partway, Hedgehog signalling pathway, PI3K signalling pathway, Wnt signalling pathway, Notch signalling pathway, TGF-Beta signalling pathway and EGF signalling pathways.

3. Reporter genes with no growth-promoting capacity, such as GFP, luciferase, H2B-EGFP.

4. Other poorly characterised genes

### Evaluation of foreseeable effects

**Retrovirus**

The helper-free retroviral producer cell line Phoenix-eco, express gag-pol and envelope genes using different non-Moloney promoters to minimize both recombination and inter-typic recombination potential. The mouse cell line GP+envAm12 packaging line showed no evidence for a generation of wild type virus and both systems have a history of safe usage.

**Lentivirus**

Deletion of vpr, vpu, vif and nef accessory genes renders the lentiviral vectors used unable to replicate once they have transduced target cells. The third generation lentivirus production system are deleted for the tat gene and carry a SIN deletion. This results in selfinactivation of the lentivirus following the transduction of the target cells. Amphotropic retroviruses and the lentiviruses used (VSV-G-pseudotyped) are able to infect cells from a broad host range, including humans, but cannot replicate unless they recombine with endogenous virus.

**Adenovirus**

The commercially available viral particles will be replication incompetent due to deletion of E1 and E3 regions. The viruses received are prescreened to ensure replication deficiency.

**Adenoasssociated virus (AAV)**

These viruses are infectious to humans but they are not known to cause human disease. AAV vector genomes remain primarily episomal in target cells and have a low (if any) frequency of integration in target cells.

Although the viral vectors listed above will be able to infect human cells, they will not replicate unless recombined with an endogenous virus. In this event, it is unlikely that expression of a single oncogene or inactivation of a tumor supressor would cause tumors, as multiple genetic alterations (4-6) are required for tumor induction. Safeguard mechanisms exist impeding the accumulation of these alterations in the organisms. Single events such as ras or myc expression instead of leading to unrestrained proliferation, induce growth arrest and apoptosis (Hanahan and Weinberg, 2000).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All containment level 2 waste will be treated as per Hutchison/MRC Research Centre guidelines. All liquid waste will be inactivated by treatment with 3% Virkon for at least 30 minutes (overnight for large cultures) before disposal via the drains with copious amounts of water. This will achieve 100% kill. Any spillages will be treated with Distel or Chemgene at a final concentration of 5%. Plastic waste shall be soaked in Virkon solution overnight before disposal in the appropriate bins provided. Tissue and gloves used shall be disposed in the appropriate biohazard labeled bins. All solid waste shall be doublebagged. Bags shall be sealed with tape and placed in the biohazard containers. All solid waste shall be autoclaved before leaving the building for incineration.
To determine the viral titre of cells, well characterized methods that involves measuring reverse transcriptase activity shall be used. This is a direct readout of the presence of viral particles.

Routine disinfection of surfaces shall be achieved with 1% Distel or Chemgene solution. MSC are routinely fumigated and filters replaced, servicing every 6 months as per Hutchison/MRC Research Centre guidelines.

### Project Additional Information

**Purposes of the contained use**

We aim to identify genes that could play a significant role in the transformation of human oesophageal epithelium towards cancer via the development of Barrett's oesophagus and the acquisition of a malignant phenotype. Several candidate genes have been identified in literature as potential regulators for this switch in phenotype. Most of them are transcription factors, they include HoxGenes (identified in a current project in the lab), NHF4a, p63, CDX2 and C/EBP and they are potential oncogenes.

#### Recipient or parental organism

Packaging cells HEKs93  
Oesophageal cells:  
1. Primary cells will be isolated from human squamous oesophageal resection specimens and processed to obtain single cell suspension (separate Risk Assessment RCF 041 for human tissue). For this purpose freshly isolated, cultured cells will be used.  
2. Other established human oesophageal cell lines (normal and from cancer).

#### Host/vector system

**HEK293** (human embryonic kidney) cells, that, by producing the adenovirus E1 gene in trans, allow the production of infectious virus particles when cells are transfected with E1- deleted adenovirus vectors such as the pAdEasy-1.  
**Vector:**  
Purified recombinant Ad plasmid DNA is digested with the restriction enzyme Pac I to expose its inverted terminal repeats (ITR), and then used to transfect AD-293 (or HEK293) cells which have complemented in vivo viral assembly genes are:  
**Oesophageal cells/Adenoviral particles**  
**Hosts:**  
1. Primary cells will be isolated from human squamous oesophageal resection specimens and processed to obtain single cell suspension (Risk Assessment RCF 041). For this purpose freshly isolated, cultured cells will be used.  
2. Other established human oesophageal cell lines (normal and from cancer) might be used.  
**Vector:**  
The adenoviral particles generated as above. The regions E1 and E3 of the viral genome have been deleted. E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cell); the E3 region encodes proteins involved in evading host immunity. Therefore the host cells which do not have the E1 region cannot replicate the virus or integrate it into the genome.
Inserts will be from Human genomic DNA and cDNA sequences cloned in bacteria. These inserts will be genes thought to be relevant to the transformation of human oesophageal epithelium.

**Evaluation of foreseeable effects**

The bacterial construction system cannot generate hazardous particles from the cloned inserts and for this reason a Cat I containment level would be adequate and this part of the work is not described here.

The target cells (human oesophageal cannot replicate the virus or integrate its DNA in the genome. However, it is possible that the pathogenicity of the host cells would be enhanced by the inserts. In addition, the nature of the host cells (untested human primary cells) requires a containment level (Cat II) adequate to this risk. Furthermore, the regions E1 and E3 of the viral genome have been deleted. E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cell); the E3 region encodes proteins involved in evading host immunity. 

HEK293 contain the E1 gene that allows gene replication and therefore also the "amplification" of the viral stock solution requires an adequate (Cat II) containment level.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Cat II containment level is adequate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Only micro-organisms and tissue culture cells are involved
- For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
  - Full containment level 2 will be applied
- Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
  - Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% kill

- Is an emergency plan required according to regulation 20? N
- If yes, tick to confirm that it is attached to this form N
- Tick to confirm that you have attached a risk assessment to this form Y
- Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Please enter comments on the GM safety committee on the risk assessment**

This is a relatively typical case of adenovirus vector transduction of human cells in culture, and should be Class 2. The lab concerned already is familiar with Class 2 working, as the target cells are human primary material. The application specifically acknowledges the need to take care when storing adenovirus stocks outside the Class 2 lab, as discussed by the Hutchison-MRC safety committee.

Project notified under transitional arrangements N

Withdrawn N

Historical Significant Changes Project transferred from GM921 on 03/09/2013, project transferred to 3071

Project Additional Information

Purposes of the contained use

The project aims to investigate strategies to modulate the differentiation of human and mouse embryonic stem cells, differentiated cells and tumour cells by introduction of genes including transcription factors and cell cycle regulators using lentiviral vectors.

Recipient or parental organism

Murine and human cells (packaging cells, primary cells, cancer cell lines and immortalized cell lines).

Host/vector system

1) E.coli, laboratory K12 derivatives/pUC based vectors;
2) Vertebrate tissue culture cells including 293 T cells, embryonic stem cells, human cancer cell lines, and cells including fibroblasts and neuroblastoma and glioblastoma cell lines derived from patient samples.
3) Lentiviral vectors

3.2) Lentiviral systems: the two types of viral system to be used employs two well characterised lentiviral vector and packaging cell lines.

3.2.1) Type A (eg. pFUV and tet-ON derivatives thereof), 3rd generation:
. The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
. Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural and other components required for packaging the viral genome are separated onto four plasmids.
. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
. The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
. In some cases expression of our gene insert of interest will be drive expression off a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

3.2.2) Type B (eg. LentiX0HTX from Clonetech), 4th generation
The lentiviral packaging systems mentioned above are 3rd generation versions that utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Type B (Clontech’s Lenti-X HT) Packaging System also uses a split gene packaging strategy, but adds another level of safety by further uncoupling pol (RT and IN) from gag-pro. The result is that gag, pol and env reside on three physically distinct entities, rather than the standard two. This approach further reduces the possibility of creating RCL to a level below that of standard 3rd generation packaging systems, because extra recombination events are required to create such viruses. In fact, the emergence of RCL is undetectable from systems using this approach (Wu, X, et al. 2000) Mol. Ther. 2(1):47-55.) These improvements significantly increase the safety profile of our Lenti-X HTX Packaging System.

Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix (described above).

In brief, the number of genes from HIV-1 that are used in type B system has been reduced to four (i.e. gag, vpr-pol, rev and tat).
. Although the four packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293 T derived producer cell lines, none of them contain HIV-1 LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
. The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
. In this system, expression of tat is required in the packaging cell line, because the lentivirus vector contains an intact HIV-1 5LTR, which allows very high titers in viral preparations.
In some cases expression of our insert gene of insert of interest will be driven expression off a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard.

Origin & function

Genes and mutant derivatives thereof, usually of human, mouse or Xenopus frog origin, encoding both growth control proteins and transcription factors, along with marker genes such as GFP and antibiotic resistance genes.

Evaluation of foreseeable effects

Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Cat II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms and tissue culture cells are involved.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Historical Significant Changes

Project transferred from GM921 on 03/09/2013

Project Additional Information

Purposes of the contained use

The project aims to determine how candidate genes may function in tumour progression or stromal cell function (e.g. gp38). We will study their phenotypic and functional changes following modification: e.g. a) in cancer cells: the acquisition of malignant features such as increased motility and invasive capacity, b) in stromal cells: changes to junctional properties and interaction with infiltrating immune cells.

Recipient or parental organism

a) Murine cells (for example, isolated tumour and stromal cells and commercially available, immortalized well-established cell lines).

b) Human cells (including packaging cells e.g. HEK293, established well-characterised cancer and stromal cell lines).

Host/vector system

02/03/2022
1) E. coli, laboratory K12 derivatives/pUC based vectors;
2) Mammalian tissue culture cells including human cancer and mouse cell lines. Human hosts include for example, HEK293T packaging cells, well-established human cancer and stromal cell lines. Examples of mouse hosts include stromal cells such as fibroblasts (normal dermal, lymph node stromal and tumour-associated) and tumour cells either isolated or purchased as commercially available cell lines.

3) Viral vectors: The viral systems to be used employ well characterized vector systems packaging line
3.1) Lentiviral systems:
3.1.1) Commercially available, verified transduction ready viral transduction particles e.g. MISSION sequence verified shRNA lentiviral transduction particles (pLKO.1-puro).
3.1.2) Third generation lentiviral particle generation using the 3-plasmid method
   ● The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
   ● Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
   ● Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
   ● The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Virally transduced cells will not leave Class II containment until negative results are obtained from HIV-1 p24 ELISAS. This measures viral titres and ensures no residual viral proteins are present in the supernatant of transduced cells.

3.2) Adenoviral systems expressing Cre recombinase (AdCMV-Cre) or fluorescent marker proteins
3.2.1) Commercially sourced, pre-titred replication deficient virus constructs
   ● The adenoviral particles purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.

3.2.2) Assembly of virus using the AdEasy system (or similar)
   ● Cre recombinase is a Type I topoisomerase from P1 bacteriophage that catalyzes site-specific recombination of DNA between loxP sites. P1 sequences are not found in the human genome, therefore cre-recombinase expression would be expected to have no impact on the cell
   ● Recombinant adenoviruses exhibit a wide tissue tropism and could potentially infect a range of mammalian cells, however, the particles being used are replication deficient due to elimination of E1 and E3 genes.
   ● The vectors do not integrate into the genome.

Origin & function
Gene constructs and mutant derivatives thereof, usually of human or mouse origin, a) encoding candidates genes deemed important in tumour progression and stroma function e.g. gp38, b) cre recombinases to mediate specific recombination events, along with marker genes such as GFP and antibiotic resistance genes.

Evaluation of foreseeable effects
Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

The main hazard is potential of persons working in the lab by the GM virus, for which a Class II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Once negative viral titres have been measured, work with these genetically modified cells can be undertaken at a Class I level of classification.
Micro-organisms and tissue culture cells are involved

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class 1 level of classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

As per Hutchinson/MRC research Centre standard practice guidelines (unless the risk assessment demands more stringent measures)

CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus)

Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.

Bacterial Plates are autoclaved in the building.

Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contractor (Novus).

It is expected that these measures will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

This is a fairly standard proposal to use lentivirus (for various genes) and adenovirus (for cre) to genetically manipulate murine and human cells. The inserts proposed do not seem particularly hazardous.

Project Additional Information

Purposes of the contained use

We plan to use viral vectors to insert or delete candidates identified by transcriptomics or metabolomics analyses as being important in cell metabolism of both epithelia and stromal cell during tumorigenesis. We will study their phenotypic and biochemical changes following modification: e.g. a) in cancer cells: the changes of their malignant features such as increased motility and invasive capacity and changes in core metabolic pathways, b) in stromal cells: changes of core metabolic pathways and transdifferentiation into cancer associated stromal cells.

Recipient or parental organism

Murine fibroblasts and murine kidney epithelial cells obtained from Fumarate Hydratase deficient mice, primary and immortalised cell lines and tissues from other genetically engineered mice and well characterised human normal and cancer cell lines (including HEK293T that will be used as packaging cells for virus production).

Host/vector system

1) E. coli, laboratory K12 derivatives/pUC based vectors;

2) Mammalian tissue culture cells including human and mouse cell lines. Human hosts include for example, HEK 293T packaging cells, well-established human cancer and stromal cell lines. Examples of mouse hosts include epithelial cells, stromal cells such as fibroblasts and tumour cells either isolated or purchased as commercially available cell lines.

3) viral vectors including retrovirus, lentivirus and adenovirus as follows:
RETROVIRUS: Modified cell lines will be created by the transduction with retroviral particles generated from appropriate packaging cell lines (see below) after their transduction with retroviral plasmids and will be based mostly on the following backbones:
1. The pBABE vector is derived from the Moloney murine leukemia virus (MMLV).
2. The pRETROSUPER vector is derived from the Murine Embryonic Stem Cell virus (MSCV).

LENTIVIRUS: Modified cell lines will be created by the transduction with lentiviral particles generated from appropriate packaging cell lines (see below) after their transfection with lentiviral plasmids and will be based mostly on the following backbones:
2. TRC1 and TRC2 pLKO.1-puro
3. pGIPz
4. pTripz
5. Transduction ready particles generated from the above and purchase directly from the suppliers

ADENOVIRUS: modified cells will be obtained by direct infection with commercially available adenoviral particles of adenoviral particles generated as follows.

1) Commercially sourced, pre-titred replication deficient virus constructs
   • The Adenoviral particle purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.
2) Assembly of virus using the AdEasy system (or similar)

Origin & function
Gene constructs and mutant derivatives thereof, usually of human or mouse origin, a) encoding candidates genes deemed important in cell metabolism, b) cre recombinases to mediate specific recombination events, along with marker genes such as GFP and antibiotic resistance genes. c) fluorescent markers targeted to different subcellular compartments.

Evaluation of foreseeable effects
ADENOVIRUS
The adenoviral particles purchased will be replication incompetent due to deletions in the E1 and E3 regions. The virus arrives pre-screened to ensure replication deficiency.
Cre recombinase is a Type 1 topoisomerase from P1 bacteriophage that catalyzes site-specific recombination of DNA between loxP sites. P1 sequences are not found in the human genome, therefore cre-recombinase expression would be expected to have no impact on the cell.

Cells isolated from murine tissues with loxP sites will be from normal or tumour-associated tissues and are expected to be similar in nature to established fibroblast cell lines. Therefore, these calls are not anticipated to pose a hazard to human health.

Recombinant adenoviruses exhibit a wide tissue tropism and could potentially infect a range of mammalian cells, however the particles being used are replication deficient to elimination of E1 and E3 genes.
These Vectors do not integrate into the genome.

RETROVIRUS AND LENTIVIRUS

The main hazard arises directly from the recombinant viruses produced from the packaging cells. These yield both ecotropic and amphotropic lentivirions and ecotropic and
amphotropic retrovirions, depending upon the envelope proteins supplied by the cell. Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Retroviruses and lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. To further reduce the risks of virus utilization, we will

1. Use retroviral infections targeted to murine cell or human cells designed to express ecotropic receptors

2. Use third generation lentiviral expression vectors, where genes encoding the structural and other component required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

Some of the indicated vector might contain the WPRE (Woodchuck hepatitisB virus post transcriptional regulatory element). This element is used to increase lentiviral vector titre and gene expression. It includes the promoter for the X-protein and the part to the coding sequence for such protein, which may have oncogenic properties. Whenever possible we aim to use WPRE-less vectors such as the TRC-1-pLKO.1, thus limiting the oncogenic potential of the viral particles.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Micro-organisms and tissue culture cells are involved**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Containment level 2 will be applied only in specific circumstances such as:**

1. The use of lentivirus containing the WPRE elements
2. The modulation of the expression of known or suspected oncogenes or tumour suppressors.
3. The expression of toxic or inflammatory (e.g. cytokines) genes

Other infection and virus production work will be carried out in class I.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class 1 level of classification.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

As per Hutchinson/MRC Research Centre standard practise guidance (unless the risk assessment demands more stringent measures).

CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus).

Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.

Bacterial Plates are autoclaved in the building.

Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contractor (Novus).

It is expected that these measures will give effectively 100% killing.
This is a fairly standard proposal to use lentivirus (for various genes) and adenovirus (for cre) to genetically manipulate murine and human cells, but the human host range virus work falls on the borderline between class I and class II: innocuous inserts may be transduced in class I, but toxic, pathogenic or oncogenic inserts or vector components require class II.

Since we discourage use of Class II where it is not necessary - to minimize the number of people exposed to more hazardous material particularly clinical material - we consider that it is helpful to identify much of this work as acceptable in class I.

Most of the inserts are not overly hazardous, being marker genes or genes involved in metabolism, so in these cases use of lentivirus that lacks the WPRE element in class I seems acceptable. However, class II is required for experiments involving vectors with the WPRE element, or with inserts that might be oncogenic (including knockdown constructs for a tumour suppressor gene) or toxic or inflammatory (such as cytokines, peptide hormones).

Project Additional Information

Purposes of the contained use

The overall aim of the lab is to study genes that are altered by structural rearrangement of the cancer genome: these can be inactivated tumour suppressor genes or fusion genes analogous to those traditionally associated with leukaemias.

This project is to investigate the functions of these candidate genes by manipulating their expression using siRNA or expression of cDNAs in cultured cells. We plan to use a number of human cancer and normal cell lines, principally breast and ovarian, that can be particularly difficult to transfect by standard methods. We therefore plan to use viral vectors. The work will be carried out in vitro.

Description of procedure: cDNAs or shRNAs that target the gene of interest will be cloned into retroviral and lentiviral vectors. Recombinant retro/lentiviral vectors carrying the gene or shRNA of interest will be packaged in virus packaging cells. The viruses harvested will be used to infect human or mouse cell lines. The transformed cell line will be used in vitro for functional assays such as cell cycle, apoptosis and cell-mobility assays.

Recipient or parental organism

E. coli and established human and mouse cell lines in vitro. We may also use human cell lines engineered to express the ecotropic receptor (but such lines will not be constructed under the risk assessment).

Host/vector system

The host/vector systems are (i) plasmids in E. coli for construction steps; (ii) transfection of retrovirus or lentivirus vector into packaging cell line systems to generate virus; and (iii) infection, with the packaged retroviral or lentiviral constructs, of human or mouse cell lines. Retrovirus/lentivirus and the packaging lines will be chosen to match the target cells and to repeat published experiments. Broadly, lentivirus will be used on less vigorous human cancer cell lines.

i) Generation of the construct to express the genes of interest.

INSERT: the insert is chosen to modulate the expression levels of genes of interest by overexpression or downregulation. We will begin for example with NRG1, which has been proposed as both a tumour suppressor gene and an oncogene. However, we will apply this technology to other known and candidate cancer genes. We will include knockdown of the known tumour suppressor gene, p53, and overexpression of the known oncogene, Ras, as controls.

a) Constructs for overexpression: these constructs are engineered using cDNAs that will encode for candidate cancer genes and rearranged forms of these genes, such as fusions of these genes, internal partially duplicated mutants and deletion mutants. These inserts will be either purchased or designed ad hoc and inserted into lentiviral or retroviral vectors.

b) Constructs for downregulation of gene expression: these constructs are shRNAs that will downregulate the expression of chosen target genes. These constructs will be purchased or designed ad hoc and inserted into lentiviral or retroviral vectors.

For custom design of shRNAs, to be cloned into the MSCV-miR30 vector, we will use the Hannon lab shRNA retriever (http://katahdin.cshl.org/siRNA/RNAi.cgi?type=shRNA)

We will also use microRNA-adapted shRNAs constructs already cloned into appropriate plasmids (see below) mostly, but not exclusively from Open Biosystems (thermoscientific)
VECTOR: the vectors described here will be used to express the insert in proliferating and non-proliferating mammalian cells by means of viral transduction and could be either retrovirus- or lentivirus-based.

RETROVIRAL
The retrovirus vectors to be used are derived from Moloney murine leukaemia virus (MMLV) and its relative Murine Embryonic Stem Cell virus (pMSCV). Currently, these are pBABE, MSCV-miR30, pRETROSUPER and LPC. For all the vectors, the env genes, provided by the packaging plasmid, determines host range.

Vectors mainly for cDNAs.
1. pBABE (Morgenstern & Land) is derived from Moloney murine leukaemia virus (MMLV). The vector provides the viral package signal, transcription and processing elements, and a target gene. Transfection into a package cell line, such as Phoenix, produces high titre replication-incompetent viruses.
2. LPC system. The LPC vector was constructed at CSHL by S L (Cold Spring Harbor Lab) for efficient expression of cDNAs.

Vectors Specifically designed for shRNA inserts:
3. The MSCV-miR30 vector (also developed by S L's lab) is derived from the Murine Embryonic Stem Cell virus (pMSCV), closely related to MMLV. The vector contains the mir 30-styled shRNA expression cassette expressed from the U6 promoter. The vector has a specifically designed 3'LTR that has a deletion in the LTR promoter elements. This deletion results in inactivation of the LTR mediated transcription upon retroviral integration. The phosphoglycerate kinase (PGK) promoter drives the expression of the puromycin resistance gene for selection in eukaryotic cells. The MSCV-miR30 plasmid can be propagated in E. coli under ampicillin (AMP) selection.
4. pRETROSUPER vector is also derived from the Murine Embryonic Stem Cell virus (pMSCV) and is commercially available.

Either cDNA or shRNA:
5. pOZ-FH-C is a retrovirus vector that has been used to coexpress an insert of interest with IL-2, so that infected cells can be affinity purified by IL-2 antibody (Nakatani and Ogryzko, 2003).
6. pWZL, a commercially available retroviral vector available with various selection markers, made by J M, the maker of pBABE.
7. Related established retroviral vectors to achieve coexpression with marker genes.

LENTIVIRAL
For cell lines where proliferation is limited we may need to use lentiviral vectors. We will use metabolisation-defective lentivirus (third-generation lentiviral vectors). One packaging plasmid lacks both LTRs, viral packaging signal (y) and viral genes (env, tat, rev, vpr, vpu, vif and nef). Rev is supplied in-trans on a second plasmid. Envelope is expressed on a third plasmid. The vector to be packaged has a self-inactivating LTR and expresses no viral gene products.

Lentiviral vectors used include:
1. PLKO vector is widely used and commercially available - see below.
2. Lenti-miR30 is a vector adapted by CSHL to express shRNAs as part of simulated microRNAs. Other lentiviral vectors in current use by our colleagues may also be used. They include:
1. pRSI-U6-(sh)-UbiC-RFP-2A-Puro: HIV-based lentiviral shRNA cloning vectors with H1, U6, or H1 tet-regulated promoters for expression of shRNA and a choice of a single or dual selection marker (GFP, RFP, Pyr, BleoR, NeoR, Hygro-HK, etc.) expressed from a single CMV EF1α, PGK, UbiC, or other promoters. It contains 18-nt bar code compatible with the Illumina HT Sequencing platform.
2. pLKO1-puro: The viruses generated using these plasmids were used to generate the TRC1 and TRC2 collection of commercially available shRNAs. This construct contains a 3' self-inactivating long terminal repeat. pLKO-puro is available in two forms. The TRC1-pLKO vector does not contain WPRE (Woodchuck hepatitis B viruspost-transcriptional regulatory element), while the TRC2-pLKO vector does not contain it.
3. pGIPz: this vector contains a TurboGFP expressed by an IRES in tandem with the shRNA. These constructs contain a WPRE.
4. pTripz-inducible shRNAs plasmids with TurboRFP that marks inducible shRNAmir expression
5. Transduction ready particles generated from the above and purchased directly from the suppliers.
Generation and expansion of plasmids carrying construct/gene of interest

cDNAs and shRNA plasmid constructs will be generated by subcloning cDNAs and shRNAs of interest into the empty backbones indicated above.

VECTOR: Recombinant lentiviral and retroviral plasmids will be transformed and amplified in laboratory strains of E. coli after selection with the appropriate antibiotics. Lentiviral and retroviral plasmid DNA will be purified by maxi prep.

HOST: E. coli: laboratory TOP10 chemically competent E. coli will be used for selection and amplification of plasmid DNA.

(ii) Transfection of retrovirus or lentivirus vector into packaging cell line systems to generate virus.

RETOVIRUS

Cell lines such as Phoenix cells (http://www.stanford.edu/group/nolan/retroviral_systems/phx.html) will be used as packaging cell lines. Phoenix, based on the 293T cell line, is a second-generation retrovirus producer line for the generation of helper free ecotropic and amphotropic retroviruses and has stably integrated three plasmids that provide the retrovirus proteins in trans. In order to infect human cell lines we will use the packaging cells Phoenix Ampho. Also, well characterised and commercially available PT67 cells with appropriate tropism would be used if the Phoenix system proves inadequate.

Virus will be packaged by transient transfection.

LENTIVIRUS

Lentivirus will be packaged by co-transfection of lentivirus vector and packaging plasmids into 293T cells.

(iii) Infection, with the packaged retroviral or lentiviral constructs, of human or mouse cell lines.

VECTOR: Replication deficient lentiviral or retroviral transduction particles harbouring construct/gene of interest and appropriate resistance gene or fluorescent marker. These particles can be obtained as indicated above or purchased as 'Ready-to-use lentiviral particles' from certified sources.

HOST: Well characterised human normal and cancer cell lines, mouse cell lines, or human cell lines engineered to express the ecotropic receptor. Successfully transduced cells will be selected with appropriate antibiotics and in the case of inducible of an inducible system activated by doxycycline.

Determination of viral titre in packaging cells and GM-cells supernatant

Generally, we will determine the viral titre of transducing particles suspension only if a specific MOI is required for the infection. We will determine the viral titre in the supernatant of the genetically-modified cells to assess the suitability to transfer infected cells from CL2 to CL1, when CL2 tissue culture has been used for the infection. To determine the viral titre of cell supernatant we will use well characterised methods such as the Molecular Probes' EnzChek® Reverse Transcriptase Assay, a convenient, efficient and inexpensive assay for measuring reverse transcriptase activity, a direct readout of the presence of viral particles.

Genes will be genes that are mutated or rearranged in cancers, from human or mouse, and may be in normal form or mutant/rearranged variants of the genes, such as fusion genes. cDNAs-either cloned or synthesised- or shRNAs that target the gene of interest will be cloned into retroviral and lentiviral vectors.

Evaluation of foreseeable effects

HAZARD IDENTIFICATION: Host

MODIFIED BACTERIA TO AMPLIFY THE CONSTRUCTS

Laboratory strains of modified E. coli K12 such as TOP10 are recognised as non-colonising and may be considered to be ACDP hazard group 1.

CELL LINES

02/03/2022 Page 13395 of 15326
Phoenix cells are widely used and they have a history of safe usage. The gag-pol and env genes are expressed from non-moloney promoters to minimise recombination potential. Different promoters for gag-pol and envelope were used to minimise their inter-recombination potential. Amphotropic Phoenix cell lines have been extensively tested for helper virus production and established as being helper-virus free. The 293T cell line, in addition to other well characterised human normal and cancer cell lines, has a history of safe usage and is not expected to represent a hazard to human health.

HAZARD IDENTIFICATION: Vector
RECOMBINANT RETRO/LENTIVIRAL VECTORS
Retroviruses and lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission.

1. The retroviral vectors used are replication defective. To produce a replication-competent retroviral genome three recombination events are required between the vector of interest, the gag-pol regions of the packaging cell line and introduction of the split genome packaging cell lines.

2. We will use third generation lentiviral expression vectors, which contain multiple safety features, as follows;

   • The majority of lentiviral genes have been eliminated (Δ vpr, vif, vpu and nef). The number of genes from HIV-1 that are used in this system has therefore been reduced to three (i.e. gag, pol, and rev).
   • Genes encoding the structural and other components required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al J Virology 72 8463-8471 1998).
   • Although the packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gag, pol, rev, env) in the 293T derived producer cell lines, none of them contain 3’ LTRs. This results in elimination of the promoter-enhancer region, which avoids promoter interference issues and further negates the possibility of viral replication.
   • No single plasmid contains all the genes necessary to produce packaged lentivirus. None of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
   • The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Some of the indicated vector might contain the WPRE (Woodchuck hepatitis B virus post-transcriptional regulatory element). This element is used to increase lentiviral vector titre and gene expression. It includes the promoter for the X-protein and the part to the coding sequence for such protein, which may have oncogenic properties.

The main hazard arises directly from the recombinant retroviruses and lentiviruses produced from the packaging cells. These yield amphotropic lentivirions and retrovirions.

HAZARD IDENTIFICATION: Insert
Our genetic experiments will include knockdown of known (p53) and potential tumour suppressor genes (e.g. NRG1) and overexpression of known (Ras) and potential oncogenes (e.g. NRG1 again). However, at least 4 different genes should be expressed for tumorigenesis in human tissues (W.C. Hahn et al., Nature 400, 464) and we expect that a contamination of more than 4 virus supernatants would be extremely unlikely.

None of the cell lines used is capable of colonising a healthy individual and we do not expect any of our proposed manipulations to change this. The amphotropic retrovirus and lentivirus would be able to infect human but could not replicate unless the improbable event occurs that it recombines with endogenous retroviruses. Even then, it is unlikely that expression of a single oncogene or suppression of a tumour suppressor could cause tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and safeguard mechanisms exist impeding the accumulation of these alterations in the organisms.

HAZARD IDENTIFICATION: Lab Personnel
The principal hazard is gene transfer to human cells when using the human host-range packaged viruses. Attention should be paid to staff awareness of this and to storage and labelling of any stocks. Virus will be removed from the lab Catll rooms only for storage and kept in designated -80°C freezers according to the agreed guidelines and
SOPs in the Hutchinson/MRC Research Centre. Work will therefore be done in:
Class II: production and infection work with lentivirus and amphotropic retrovirus.
Cell lines produced by infection that are virus-free after infection using the methods indicated above will be transferred to Class I for work with plasmids in E. coli.

HAZARD IDENTIFICATION ENVIRONMENT
The prokaryotic and eukaryotic cells and cell lines are highly disabled and the possibility of competent virus being generated is negligible. Therefore they should be unable to propagate in the environment. The plasmid vectors are non mobilisable, therefore neither has any possibility of further spread.
The viruses are replication-incompetent and no live virus should reach the environment.
The risk to the environment is therefore effectively zero

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Containment level 2 will be applied to work packaging and infecting with the human host-range viruses.
Infection and virus production of ecotropic retrovirus will be carried out in class 1.
After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will be transferred to class 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
CL2: all solid waste is autoclaved in the building and then incinerated off site by a contractor (Novus).
Liquid waste is disinfected with Virkon to final concentration of 5%; contact time of 30 minutes minimum before disposal to drain.
CL1: Liquid waste is disinfected with Virkon to final concentration of 1%; contact time of 30 minutes minimum before disposal to drain.
Bacterial Plates are autoclaved in the building.
Solid waste (including for example culture flasks, plastic pipettes) is bagged, and incinerated off site by a contactor (Novus).
It is expected that these measures will give effectively 100% killing

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
This is similar to many Ras for using non-replicating lentivirus and retrovirus vectors to express genes and shRNAs in human cell lines in vitro, with Class II for production and infection by human host-range virus vectors. It is quite broadly based as a variety of genes and host cells may be used, but raises no particular issues.

Since the applicant group leader is the BSO (competent person) note that the committee that has considered this risk assessment includes two others with long experience of GM risk assessment. Dr P B, formerly of MRC-LMB, and Dr P J, the previous BSO for this building.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Contaminated waste will be placed into sealed containers which will then be removed from the site by an independent contractor. The contractor will be a specialist waste management company who will dispose of the waste in accordance with all relevant legislation and guidelines applicable to clinical waste. The contractor will be required to provide documentation confirming that the method of disposal complies with the relevant legislation.

Y

Give brief details of the genetic modification safety committee

The Biological Safety Committee (BSC) is comprised of five members. The members have been chosen from senior management, bioscience and biochemical engineering functions. All members have PhD. Degrees in their respective fields, i.e. biochemistry, molecular genetics and chemical engineering. GMM risk assessments are reviewed and approved via e-mail as per procedure S01E01P01 - Genetically Modified Microorganism Risk Assessment Procedure for Laboratory Scale Activities. Briefly, the Principal Investigator submits the completed GMM risk assessment form to the Biological Safety Officer (BSO), who forwards the form for review and comment by the BSC. Once any review comments have been addressed satisfactorily, the BSO approves the GMM risk assessment on behalf of the BSC. The BSC meets once per month in person to discuss the maintenance of standards and continuous improvement with regard to contained use of GMMs.

02/03/2022
Depending upon chemical composition, aqueous biological waste shall be classified as either conventional or special waste. All aqueous biological waste shall be sterilised using a validated autoclave cycle prior to disposal. The temperature profile for the autoclave cycle is logged by the autoclave and the trend archived. In addition to specialist quarterly and annual servicing, the waste autoclave cycle shall be revalidated once per annum using e.g. Attest indicators. Autoclaved conventional waste shall be disposed of via laboratory drains and autoclaved special waste shall be collected for disposal by authorised waste disposal specialists.

All solid waste shall be double bagged in biohazard bags ensuring steam access to the solid waste and autoclaved using autoclave tape as an indicator of sterility. Depending upon chemical composition, the solid waste shall be classified as either conventional or special waste.

Spills shall be contained using absorbant materials and spill kits (as appropriate) and disposed of with solid waste. Affected areas (e.g. bench-top) shall be sanitised with e.g. isopropanol or similar biocide (Virkon), contacting the areas with liquid disinfectant for a minimum of 15 [min]. Gass laboratory fermenters shall be bunded as appropriate.

Glass ware and other re-usable equipment contacting GMMs shall be either autoclaved prior to washing or sprayed with e.g. isopropanol or similar suitable biocide (Virkon), contacting the affected surfaces with liquid disinfectant for a minimum of 15 [min] prior to washing.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The below revisions to the original GMM risk assessment were added to the assessment as per advice from the Biological Safety Committee members:

"This is a proprietary strain to be provided by Life Technologies, Grand Island, New York, and is designed specifically as a laboratory strain to host genetically modified plasmids. The strain will be used in accordance with the manufacturer's instructions."

"A DNA sequence will be generated from this amino acid sequence that is optimised for E. coli expression and this will be synthesised by a commercial company."

"This vector is a proprietary expression vector to be supplied by Life Technologies, Grand Island, New York, and is designed specifically as a laboratory expression vector. This will not be modified beyond insertion of the synthesised gene sequence in accordance with the manufacturer's instructions."

"The expression vector is designed to over produces the enzyme of interest; in this case we would expect the quantity of MDD to be in excess of 100 fold its normal cellular concentration. However, there is no evidence to suggest this will increase to potential for hazard or increase the survivability of the modified organism."

"Clear up will involve disinfecting the area using the proprietary anti viral and anti bacterial agent Virkon."

"Loss of selective pressure is likely to result in loss of the ampicillin resistance plasmid as replication of the plasmid represents an energetic disadvantage."

**Purposes of the contained use**

To enable the generation and use of recombinant self-inactivating third generation lentiviral particles (by commercial research organisations or in house using commercially available 3rd generation lentivirus systems) encoding:

1. Open Reading Frames (ORFs), cDNAs, peptides
2. Specific gene sequences
3. Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro)

**Recipient or parental organism**

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues.

The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which plasmids containing lentiviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

**Host/vector system**

The lentiviral vectors which will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent. However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences.

For example, second and third generation Lentiviral Expression Systems include the following key safety features:

- In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and nef) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.
- In addition to this in the third generation lentiviral vectors:
  - The Lentiv expression vectors contain a deletion in the 3’ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
  - The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
  - Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
  - Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types.

This means that the viruses produced for this experiment could potentially infect a number of species, including man.

**Origin & function**

Selectable markers – examples (but not restricted to);

- Ampicillin resistance: E. coli derived
Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to);
- Fluorescent proteins as reporters:
  - GFP derived from the jellyfish Aequorea victoria and variants of this
  - Luciferase – class of oxidative enzymes used in bioluminescence
  - Renilla luciferase derived from the Sea pansy (Renilla reniformis)
  - Firefly luciferase derived from the firefly Photinus pyralis.

Open reading frames, cDNAs and gene sequences encoding GFP or Luciferase proteins and/or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding GFP or Luciferase proteins).

Evaluation of foreseeable effects

The lentiviruses are, at worst, amphotropic or pseudo typed with VSV G protein, either of which confers a broad host tropism including human cells. However, the retrovirus is self inactivating and there if thus no possibility of it multiplying further.

Since some of the inserted DNA could code for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.18-20).

Even for the non oncogenic inserted DNA, there is a slight but non negligible risk due to the presence in the lentiviral vector of the Woodchuck Post-transcriptional Regulatory Element. The WPRE containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.13)).

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:
- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

Second or third generation retrovirus vectors will be used in all experiments

Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. our 2nd or 3rd generation lentivirus vector systems), gloves should be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits invasion of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.
Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Eurobin container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

<td>L3 L3 L3 L3 L4</td>
</tr>
</tbody>
</table>
The aim of this project is to use retroviral delivery systems to introduce various mammalian DNA sequences into mammalian cells in culture. These sequences direct expression of either (i) RNA species (siRNAs or antisense RNAs) that interfere with the expression of various mammalian proteins or (ii) the corresponding mammalian proteins themselves; for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of generating stable cell lines expression fluorescent proteins, potential drug targets or therapeutic proteins, etc.

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues. The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which plasmids containing retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

Host/vector system

The retroviral vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse
Mammary Tumour Virus (MMTV) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents.

- On the other hand, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types.
- This means that the viruses produced for this experiment could potentially infect a number of species, including man.

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.
- Second, third generation or Self INactivating vectors retrovirus vectors will be used in all experiments (see SACGM compendium of guidance part2, section 2.11 (Retroviruses) pp117

Selectable markers – examples (but not restricted to);
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene

Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to);
- Fluorescent proteins as reporters;
- GFP derived from the jellyfish Aequorea victoria and variants of this
- Luciferase – class of oxidative enzymes used in bioluminescence
  - renilla luciferase derived from the Sea pansy (Renilla reniformris)
  - firefly luciferase derived from the firefly Photinus pyralis.

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and / or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) – all human derived.

This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation.

Evaluation of foreseeable effects

Although these retroviruses are categorized at ACDP 1, a number of factors could increase the containment that will be required to work with them. We therefore need to consider worst case scenarios:

The virus is packaged using an amphoteric system to allow transfection of human cells and this may have knock on effects when considering

i) Biological properties of the gene product

ii) The expression characteristics and

iii) Provirus insertion (see below)

i) In the case of the introduction of retroviruses carrying DNA sequences encoding either antisense or RNA species into cells it is possible to envisage a scenario in which the knockdown of the mRNA targeted by the siRNA or antisense RNA, and hence the reduction in level of the encoded protein will have an effect on cell metabolism.
Perhaps the most extreme example of this would be the reduction in the levels of a protein that normally facilitates cell apoptosis i.e. a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of a serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of "knockdown" achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost. More caution is required with respect to retroviruses encoding mammalian proteins. The worst case scenario is likely to be expression of a potential oncoprotein. Clearly this could result in transformation of infected cells.

However, over-expression of proto-oncogenes in primary mammalian cells tends to result not in transformation; instead the result is either the induction of cellular senescence or the activation of apoptotic pathways resulting in cell death.

ii) The promoter could be highly active in a wide range of cell types (e.g. the CMV promoter).

iii) (From the SACGM compendium of guidance part 2, page 121) 'The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression. Therefore, retrovirus infection might induce permanent changes in a cell, resulting in tumourigenesis. It is recognized that, in humans, this appears so far only to have occurred in the context of deliberate transduction of large numbers of stem cells with a retrovirus vector. Furthermore, the transferred gene enabled the cells to proliferate in response to cytokines, and the many ensuing cycles of cell replication may have allowed additional, co-operating events to occur. High-titre inoculations are required to establish a clinically significant level of infection or gene transfer, and accidental infections of this magnitude are unlikely during standard laboratory-based manipulations of retroviruses. Nevertheless, retrovirus vectors have been shown to have transforming properties in vivo and a cautious approach to handling them is advised.'

Whilst it is possible that production of individual siRNAs or antisense RNAs could disrupt normal function in a single infected cell, it is unlikely that this effect will propagate further. The worse case scenario might be the reduction in the levels of a protein that normally facilitates cell apoptosis i.e. a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of a serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of "knockdown" achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost.

More caution is required with respect to the retroviral vectors directing expression of mammalian proteins. The worst case scenario is likely to be expression of a potential oncoprotein. Clearly this could result in transformation of infected cells.

The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the retroviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM is visualized.

Give brief details of the genetic modification safety committee

We intend to begin work in our laboratory in November 2013. Work will be confined to culturing CHO DG44 cells expressing human proteins in disposable systems supplied by GE Healthcare. The Company is at present small and the Biological Safety Committee will comprise the CSO (with 35 years experience in the field) and three other senior members of staff with GM and protein purification experience. These staff begin work on 4th November. We also propose Prof J M of the University of Surrey as an Independent Chair. J is founder of the company but has no responsibility in its day to day running. He has been chair of other ACGM committees for many years.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Laboratories:
Solid biological waste that is not contaminated by any hazardous chemicals which would be released into the atmosphere, or by sharps (including plastic pipette tips etc) which would puncture the bags is placed in appropriate plastic bags within disposable plastic containers and collected regularly.

(i) Sharps (including plastic pipette tips) contaminated with biological waste must be thoroughly decontaminated in bleach in an appropriate container before disposal with the other sharps.

(ii) Liquid biological waste in plastic containers and glassware (flasks bottles etc) would be decontaminated with bleach and then autoclaved.

(iii) Glassware (flasks, bottles etc) contaminated with biological waste should have their caps removed and placed in the blue plastic boxes for autoclaving.

(iv) Any spills should be clean with either bleach or an appropriate disinfectant (i.e. Bioguard).

(v) Labcoats used when culturing any class 1 microorganisms are placed in an appropriate plastic bag, autoclaved and washed weekly.

(vi) Autoclaves are routinely serviced and regular checks to ensure autoclave are reaching the required temperatures using thermo logs

Non-GMM  Consent Granted
Methicillin-resistant Staphylococcus aureus (MRSA) is any strain of Staphylococcus aureus that has developed through the process of natural selection, resistance to beta-lactam antibiotics. The evolution of such resistance does not cause the organism to be more intrinsically virulent than strains of S. aureus that have no antibiotic resistance, but resistance does make MRSA infection more difficult to treat with standard types of antibiotics and thus more dangerous. People are very commonly colonized with Community associated -MRSA and are completely asymptomatic.

Pseudomonas infection is caused by strains of bacteria found widely in the environment; the most common type causing infections in humans is called Pseudomonas aeruginosa. Pseudomonas infections usually occur in people in the hospital and/or with weakened immune systems and are a common cause of ear infections and rash. In both cases, careful attention to routine infection control practices, especially hand hygiene and environmental cleaning, can substantially lower the risk of infection.

None of the organisms above mentioned neither are nor will be genetically modified in these premises.

Parental organisms: Mycobacterium smegmatis, Pseudomonas aeruginosa and methycilin resistant Staphylococcus aureus.

Non-pathogenic E. coli strains (DH5 alpha, BL21, Rosetta)

The only GMM used for the experiments will be three common E. coli strains (DH5 alpha, BL21 and Rosetta). In this instance the modifications will be mutations that will overexpress the corresponding non-toxic recombinant protein.

E. coli DH5 alpha strain and other related strains (BL21 and Rosetta) used in our premises are not known as hazards to human health and nor is there any reason to suppose that it could be unless specifically modified to express toxic proteins or proteins that produce toxic products. There is no reason known to us why these E. coli strains should be a human health hazard under the conditions used in our experimentation. These modified bacteria will be equally non-pathogenic and, therefore, will not pose an environmental hazard.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratories:
Solid biological waste that is not contaminated by any hazardous chemicals which would be released into the atmosphere, or by sharps (including plastic pipette tips etc) which would puncture the bags is placed in disposable plastic containers and collected daily.

(i) Sharps (including plastic pipette tips) contaminated with biological waste must be thoroughly decontaminated in bleach in an appropriate container before disposal with the other sharps.

(ii) Liquid biological waste in plastic containers and glassware (flasks, bottles etc) should be decontaminated with bleach and then autoclaved.

(iii) Glassware (flasks, bottles etc.) contaminated with biological waste should have their caps removed and placed in the blue plastic boxes for autoclaving

(iv) Any spills should be clean with either bleach or an appropriate disinfectant (i.e. Bioguard)

(v) Labcoats used when culturing any class 2 microorganisms are placed in an appropriate plastic bag, autoclaved and washed.

(vi) Autoclaves are routinely serviced and regular checks to ensure autoclave are reaching the required temperatures using thermo logs

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This document has been read and approved by all the members of the safety committee and there are no comments at this time but to confirm that the Class 2 organisms described above neither are nor will be genetically modified in these premises.

Yes

Give brief details of the genetic modification safety committee

The Royal Institution has established a GMSC for the demonstration of genetically modified organisms for teaching purposes. These demonstrations will always be a class 1 activity. The GMSC of the Royal Institution has been made in conjunction with Oxford University. If in the future a GMO is to be shown as part of a lecture from another University, then that University's GMSC will be consulted by the Royal Institution GMSC in the same way.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Oxford GMSC and the Royal Institution GMSC consider these activities as class 1 and are satisfied that appropriate containment measures are in place. Their comments are as follows:

"The use of gfp- or rfp-tagged nematodes on culture plates and microscopic slides for teaching purposes represents no hazard to either human health or the environment. The transgenic worms will be completely contained within their culturing plates and cannot escape nor would they survive should they escape. All genetically modified material will be destroyed by chemical disinfection and/or autoclaving off-site. Assignment of the activity to non-notifiable transgenic work at Containment level 1 is appropriate."

The GMO will be handled by trained personnel only, and will not be handled by the public at any time. The disposal of GMOs will be made in conjunction with the GM-regulated areas at University College London. A risk assessment for the demonstration has been made and is kept at the Royal Institution to be referred to by the Royal Institution GMSC.

Give brief details of the genetic modification safety committee:

The Genetic Modification Safety Committee comprises:
- Chair (currently Research Manager, Microbiology)
- Secretary (appointed by Committee)
- Members: Site Safety and Health Executive (SHE) representative
  - Laboratory Safety Representative
  - 3 research scientists with expertise in Microbiology and Use of GMO's

The committee currently meets as required but will move to regular meetings once HSE approval is received to work with GMO's. The GMSC oversees experimental work involving GMO's, including facility and procedures, considering potential impact on human health and environment. The GMSC operates under the aegis of the group SHE and in accordance with Croda corporate social responsibility (CSR) goals and policies.

**Other(s)**

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

All waste potentially containing viable GM material is deactivated by autoclaving (using regularly maintained and calibrated autoclaves) before disposal to drain (for liquid waste) or incineration (solid waste). The laboratory drains discharge through a dedicated effluent treatment plant, operated under EA permit. Regular monitoring of the water treatment plant will be supplemented with specific tests for any GM material used onsite. Spills of material containing GM components are deactivated by treatment with suitable disinfectant (e.g., Vircon) which is validated against each GMO used in the facility. Samples derived from manipulation of GMO's are sterile filtered and routinely monitored for content of GM material by validated PCR test before further processing in other laboratories.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid wastes (e.g. culture medium): 1% Virkon according to manufacturer's guidelines.
Plasticware: autoclaving (126°C, 11 min). Plastics are soaked in 1% Virkon and then double-bagged before being taken in a large plastic box with lid to autoclave room, the performance of which are inspected every 6 months.
Autoclaved wastes are stored in orange bags in designated plastic boxes which are kept in a metal cage outside the laboratory building. These orange bags are collected by the NHS waste disposal services regularly.
Sharps: We anticipate that the level of sharp waste generated will be zero, and any contaminated broken glass will be soaked in 1% Virkon, placed in Cin Bins, bagged and incinerated.
Laboratory benches are wiped down daily with 1% Virkon.

Autoclaved waste from the autoclaves is regularly monitored (6 monthly checks) to verify the effectiveness of the inactivation procedure. The procedures are expected to kill as close to 100% of bacteria and bacteriophage as can be expected, although an absolute guarantee of 100% kill is not possible. According to its manufacturers (Antec) Virkon is effective against gram negative bacteria such as E. coli, and bacteriophage such as M13K07.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Section 7: Confirmation is required that all of those researchers named will have a supervisory role - only these people need to be listed at this point.
Section 8: Rather than summing the experience with GM of all the supervisors give the individual experience of key persons.
General: Where possible define abbreviations to ensure the clarity of the text and ease of understanding for the non-specialist
Additional information section: Question 7 - There are two chemical kill methods where possible we normally recommend avoiding multiple chemical disinfectants unless there are good reasons. The concentration of the Presept should be stated.

N C sent the following comments
Section 2: the applications should be from the person who is an employee or officer of Scotia Biologics and who is leading on the work. The forms then need to be signed by the same person.
Section 3: it would be better if section 3 said just "Scotia Biologics Ltd"

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC) in the company comprises of four people from different roles within the company including workers and management (expertise in many areas including microbiology and working with GMM). Any work involving GMM will be reviewed and approved by the GMSC. Before any new work is to be carried out a risk assessment will be submitted to the GMSC who will review the risk assessment and discuss the work and assessment in a meeting with all committee members present (any discussions are documented by meeting minutes and actions circulated after the meeting). The committee will then ask for further information if needed by submitting individual, approve or reject the risk assessment. If any work is required or deemed as level 2 GMM then the HSE will be notified.

### Laboratory

- Level 1 (GMMs): Yes
- Level 2 (GMMs)
- Level 3 (GMMs)
- Level 4 (GMMs)
- Non-microbial

### Animal Unit

- Other (please specify) Tick if confidential
**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Disinfection and autoclaving will be carried out where required. All waste materials will be disposed of into autoclave bags, yellow clinical waste bags/bins or sharps bins as required. All contaminated solid waste (agar plates, disposable plasticware etc) will be placed in autoclave bags and will be autoclaved and disposed of via designated route. Liquid cultures will be chemically-inactivated (Virkon 1% or PeraSafe 0.16% for 30 mins) or autoclaved prior to disposal. All contaminated glassware and reusable plasticware will be decontaminated as above.

- **a) Disinfection.**
  1% Virkon will be used for disinfection. The surfaces of the microbiological safety cabinet will be disinfected with 1% Virkon after use. Laboratory benches will be swabbed with 1% Virkon after any activity.

- **b) Autoclaving.**
  Autoclaves are not present in the laboratory for waste treatment. However, a large central autoclave facility is located on site at Alderley Park (please see next section for the further details of the Waste management process and derogation request)
  The autoclave is subject to twice yearly servicing and annual validation using a 12-point thermocouple procedure which includes a probe placed in a representative load.

---

**Please enter comments of the GM safety committee on the risk assessment**

The GMSC held a meeting on 24th February to discuss the Risk assessment for Class 1 activities reference number 13AB004. The committee went through each section of the risk assessment and discussed each section in turn.

Where unclear the text from the original document was clarified e.g. the use of sharps was asked to be removed from the risk assessment as no activities would be conducted with these organisms with the use of any sharps. It was agreed by all parties of the committee that the risk assessment was fit for purpose and that the activities outlined by the risk assessment were deemed satisfactory with no significant risk to human health or the environment. In particular the expression of the proteins/genes of interest do not give the host organism any increase in selective advantage or virulence. The organisms themselves cannot, even with these genetic modifications survive outside the confines of a laboratory environment.

Y

Give brief details of the genetic modification safety committee

The Departmental Genetic Modification Safety Committee is incorporated into the Departmental Biological Safety Committee (DBSC). The DBSC includes management representatives, e.g. the Head and Administrator of the Department, the Departmental Biological Safety Officer, the Departmental Safety Officer, two Principal Investigators belonging to the Department, one representative of the general staff who have access to the genetic modification facilities, as well as the Safety Officer for the School of Clinical Medicine.

The members of the DBSC meet formally face to face on a termly basis. The agenda is sent prior to the DBSC meeting, the points are raised/ discussed/ actions to be taken agreed during the meeting and the minutes are sent back to each member by email.

**Project Additional Information**

**Purposes of the contained use**

This project aims to functionally investigate the mechanisms of tumourigenesis in renal cell carcinoma, phaeochromocytoma and paraganglioma, as there are currently no curative therapies and better treatments are urgently required. We believe that the identification of the genetic basis of the inherited forms of those diseases will highlight those genes and pathways that are critical for tumourigenesis and will provide insights into the pathogenesis of sporadic diseases.

The objectives are therefore to generate and characterise human cell line models for renal cell carcinoma, phaeochromocytoma and paraganglioma. We will compare paired isogenic cell lines transiently or stably transfected with wild-type/mutated/knocked down versions of established genes involved in those kinds of tumours and we will particularly monitor the effects on cell viability, proliferation, apoptosis and cell metabolism. We will also study in the same way newly identified genes. In addition, gene editing (specific gene knockout with complete loss of function) will be engineered using the RNA-guided CRISPR (clustered regularly interspaced short palindromic repeats) – associated nuclease Caspase 9 technology. In parallel, we will test therapeutic agents that selectively target cells deficient in those genes, hoping that these new drug screening studies will enable advances in the treatment of those diseases.

**Recipient or parental organism**

We will use disabled or especially disabled E. coli bacterial strains, non-pathogenic to humans such as DH5α. They are unable to survive or propagate outside of laboratory culture.

We will use a panel of human cell lines from kidney origin (derived from normal or cancerous tissues), commercially available, well characterised and considered ACDP Hazard Group (HG) 1 (such as HK2, UOK262, SKRC39, KTCK26, 786-0 cells). All of these hosts have a safe history of use and can be classified as especially disabled or non-colonising as defined in ACGM Compendium of Guidance. We may use in the future primary human cells and finite lines which, while of similar low risk to established cell lines themselves, are not fully characterised and authenticated; they may contain adventitious infectious agents, therefore we will handle these at CL2.

The packaging cells (Phoenix) will be of second-generation, amphotropic, based on the human embryonic kidney cell line 29.

**Host/vector system**

For bacteria: commercially available cloning (e.g. pBluescript) vectors and mammalian expression vectors (see below).

For mammalian cell lines: commercially available cloning and expression vectors (e.g. pcDNA3.1, pIRESneo, pEGFP-V-RS shRNA and derivatives).

For viruses: replication defective retroviruses based on the Murine Moloney Leukemia Virus (such as pBabe) will be used to infect cell lines, as well as replication incompetent versions of lentiviruses based on the human immunodeficiency virus HIV1 backbone. For gene editing, we will use the plentiCRISPR plasmid, which is based on the lentiviral backbone; it expresses the human codon-optimized Cas9 protein and puromycin resistance from EFS promoter and CRISPR chimeric RNA element with customizable single guided RNA (sgRNA) from the U6 promoter. Packaging vectors have been modified to make development of pathogenic recombination-competent virus extremely unlikely. All plasmid vectors used are non mobilisable and free from harmful sequences, except the plentiCRISPR plasmid which contains the WPRE motif (that may contribute to oncogenic potential of the viral vector) and will not survive when removed from tissue culture conditions.

**Origin & function**

In most cases the inserted genetic material will be cDNAs encoding recognised wild-type tumour suppressor genes of human origin (e.g. von Hippel-Lindau (VHL), Fumarate Hydratase (FH), Folliculin (FLCN), succinate dehydrogenase subunit B (SDHB)), as well as the corresponding mutated variants. These genes will also be knocked down via shRNA, siRNA and CRISPR-Cas9 technology. The same approach will be used to transfect cell lines with newly identified genes involved in hereditary RCC, phaeochromocytoma and paraganglioma diseases. In parallel, we will selectively target cells deficient in all those inherited gene functions by screening phosphatase and kinase siRNA libraries and comparing the effects with their wild-type counterparts. Apart from their role in causing RCC, phaeochromocytoma and paraganglioma, none of the proteins that we are dealing with has any known toxicity (e.g. production of toxins, cytokines, allergens, hormones) or oncogenicity, is of no selective advantage to other organisms and none of the inserts will be secreted proteins. It is anticipated however that the products of the mutated versions, as well as the knock-downs will
cause reduction/ loss of tumour suppressor ability and have some effects on cellular processes, such as growth, differentiation, apoptosis and metabolism, coupled with the resulting effects on downstream genes and pathways.

The following is a summary of what is known of the function of the main proteins we are studying:

VHL tumour suppressor gene product has multiple functions, the best characterised function is the ability to regulate the HIF-1 and HIF-2 transcription factors (as part of an E3-ligase complex that targets HIF-alpha subunits for proteasomal degradation in normoxic conditions). Inactivation of VHL protein with consequent stabilisation of HIF-1/HIF-2 causes activation of an extensive repertoire of downstream target genes such as VEGF, PDGF, TGFα and CCND1. Recent work from a number of groups has indicated that HIF2 is the major driver of renal oncogenesis while HIF-1 may be anti-oncogenic.

In contrast to VHL, most other inherited RCC genes have not been reported to be frequently mutated in sporadic forms of RCC. Nevertheless, though the function of these genes is less well characterised than that of the VHL gene product, the pathways linked to inherited RCC genes have been implicated in the pathogenesis of sporadic RCC. Thus inactivation of SDHB and FH is associated both in vivo and in vitro with activation of HIF-1/HIF-2 related pathways (mimicking that observed in VHL deficient cells).

The FLCN gene product has been linked to regulation of the AMPK/mTOR pathways though more recent studies have suggested that the effects of folliculin on mTOR signalling are complex and context dependent. In unpublished studies we have identified novel folliculin interacting proteins that link folliculin function to Wnt, cadherin and Rho signalling pathways. A recent report has identified deregulation of the KEAP/NRF2 pathway in FH-associated and sporadic Type 2 papillary cancer.

Evaluation of foreseeable effects

The genetic modifications are not expected to overcome disablement of the host cells, nor affect host specificity, tissue tropism or susceptibility to host defence mechanisms. The organisms will remain enfeebled and unable to infect or cause pathology in wider animal or human populations. The environmental fitness of the modified hosts will remain severely limited and the modified organisms will be unable to survive.

The retroviral vector system used is based on the Murine Moloney Leukemia Virus. Replication defective retroviruses will be made by transient transfection of retroviral transfer plasmids (such as pBMN, pLXIN and pQXCI series) into packaging cells lines such as Phoenix. These viral vectors could deliver oncogenic genes or down-regulate tumour suppressor functions. The vectors can integrate into the host cell DNA so transgene expression is long term possibly leading to an oncogenic phenotype. However, the risk of human infection using the above viral system is extremely low as the virus can only infect via direct inoculation. Thus, if no sharps are used in combination with good laboratory practice the risk of infection is extremely low. In addition, these vectors only infect dividing cells.

The lentiviral vectors we will use are based on the HIV backbone. Although this is a HG 3 pathogen, vectors are all third generation replication defective and considered class 1; virus replicative, packaging and envelope functions and the transgene vector are split over four or more plasmids, requiring multiple recombination events to generate replication competent retrovirus (RCR). Any RCR generated would lose the transgene during recombination events. Many accessory functions/pathogenicity determinants have been deleted and the vectors used will be self-inactivating (SIN). A deletion inactivates transcription from the proviral LTR so reducing the potential for transcriptional activation of cellular genes and also prevents mobilization of any RCR. However these vectors can infect non-dividing cells and can integrate into the cell genome so could deliver oncogene or depress suppressors on a long term basis leading possibly to an oncogenic phenotype.

The resultant GM cell lines will not be viable outside the provided growth conditions, therefore pose little or no risk to human health and environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing GMMs will be inactivated via chemical disinfection with 1% Virkon (final concentration) for 16 hours, then disposed to drains. Expected degree of kill – 100%. All solid, disposable culture/lab ware will be directly incinerated on site at Addenbrooke’s Hospital. Recyclable lab-ware will be soaked in a 1% Virkon solution (stocks replaced every 3 days) for 16 hours. Bench/cabinet surfaces will be wiped down with 70% ethanol. Any spills of media/cell lines will be covered by Virkon powder for 3 minutes, mopped up, rinsed with 1% Virkon and wipes incinerated. Validation of GMM inactivation methods will be performed and recorded termly: aliquots of GMMs will undergo the same treatment as GMM waste and will be plated back in normal growth media for 24 hours before being tested for viability. Access to an autoclave is also granted in case of emergencies on level 4 of the Addenbrooke’s Treatment Centre/ Institute of Metabolic Science building.
Following review of the enclosed risk assessment, all GMSC members were satisfied that the genetic modifications involved will not overcome disablement of the recipient cells, nor affect host specificity, tissue tropism or susceptibility to host defence mechanisms. Therefore, the panel agreed that the resulting genetically modified micro-organisms will pose little risk to human health and no risk to the environment and confirmed that the safety control measures put in place will be adequate and sufficient to fully protect the workers and the environment of any harm.

Historical Significant Changes

Historical Date of Additional Info
Mutational processes leave characteristic imprints in the genome, which we term mutational signatures. To date, work from our group has identified six rearrangement signatures from studying 560 breast cancer genomes. Out of the six rearrangement signatures (RS), three are associated with defective homologous recombination (HR) DNA repair: RS-3 with defective BRCA1 function, RS-5 with defective BRCA1 or BRCA2 function, and the mechanism of RS-1 is currently unknown.

To identify the mechanistic underpinnings of these signatures, we attempt to generate genome-wide targeted double strand breaks (OSBs) in human cells using (a) a well-characterized restriction enzyme system (AsiSI-ER); and (b) an engineered multiplex CRISPR-Cas9 system. The inducible nature of both of these systems will allow us to modulate and control the DSB induction inside host cells. Following induction, we intend to map the induced DSBs using a targeted DSB sequencing technique and to study their repair profiles and rearrangement patterns using whole-genome sequencing (WGS), generating mutational signatures as readouts. By contrasting the DSB damage maps and rearrangement signatures in repair-deficient cells against their repair-proficient wild type counterparts, we aim at systematically determine the qualitative and quantitative features of how cells accrue different somatic rearrangements, and how the rearrangement patterns change given the annulment of critical components of compensatory DNA repair pathways.

AIM 1
First, to derive direct causative evidence for the mutagenic effect of BRCA 1/2 loss-of-function mutations, we plan to knock out BRCA1 and BRCA2 in a near-haploid cell line, HAP-1 as well as some other human cell lines (such as MCF10A, MDA-MB-231 and H1 299) using CRISPR-Cas9 either in the form of (a) ribonucleoprotein complex (RNP) nucleofaction or (b) plasmid based transfection with lipid-based transfection reagents. In cases where knock-out of a gene induces cell lar toxicity (i.e. essential genes), we would use inducible shRNA’s (e.g. Tet-pLKO, SMARTvector inducible lentiviral shRNA) for conditional knock-down. In addition to normal cell culture condition, we also plan to induce genome-wide targeted breaks in these BReA1 or BRCA2 deficient cell lines using a well-characterised restriction enzyme system, AsiSI-ER. In this system, restriction enzyme AsiSI is fused to an oestrogen receptor binding domain and is only actively translocated into the nucleus to cut the DNA in the presence of 4-hydroxytamoxifen (4-OHT). Under this stress condition, we expect to see an increased mutation accumulation rate and more rearrangements. Retroviral plasmids pBABE-AsiSI-ER and pAID-AsiSI-ER will be used for this purpose. For pAID-AsiSI-ER, the engineered AsiSI-ER is further fused to an auxin-induced degron (AID) such that the enzyme would be depleted upon auxin addition.

AIM 2
To allow for a more flexible and refined system where we could control both the numbers and the sites of damage (in this case DSBs) in cells, we plan to engineer an all-in-one multiplex CRISPR-Cas9 system. In th is system, individual single guide RNAs (sgRNAs) are flanked by tRNA sequences such that one could clone in multiple sgRNAs for targeting breaks to different parts of the genome. A Tet-On inducible promoter drives the expression of a fusion Cas9 protein (DD-Cas9) in which Cas9 is fused to a destabilizing domain (~O) such that it is only stabilized and active in the presence of the ligand Shield-1. With this system, we envision that Cas9 expression would be tightly controlled with doxycycline; and Cas9 protein activity could be induced and tuned with Shield-1 post-translationally. The vector will be constructed in a PiggyBac vector backbone because of its large cargo size limit for lentivirus particle packaging.
and used in conjunction with a transposase plasmid (HyPbase) for establishing stable cell lines capable of being induced for DNA breaks. Note that should the final transfer plasmid size be small enough to be packaged into lentivirus particles, we may use the lenti CRISPRv2 plasmid backbone (Addgene 52961), and pTRE3G vectors from Takara (Clontech) to establish these stable cell lines.

AIM 3 & OVERARCHING GOALS

Health and Safety

Executive

To systematically investigate how cells with different DNA repair defects modulate their repair outcomes post damage induction, we plan to use the genome-wide OSB induction system developed in AIM2 across a panel of CRISPRCas9-edited DNA repair mutant cells (RNP or plasmid-based gene editing, non-virus method). Here, we aim to primarily target key components of the DNA repair pathways, including but not restricted to common tumour suppressor genes such as BRCA1, BRCA2, TP53, etc. For a more comprehensive list of examples of the genes we plan to study in the project, please refer to supplementary Table S1 attached at the end of this form. The data generated from this study could potentially offer mechanistic insights into how certain rearrangement patterns arise in human cancers and provide an avenue for leveraging them for therapeutic purposes.

Recipient or parental organism

Molecular cloning and transformation will be done in common competent E.coli cells for cloning such as NEB Stable, DH5a, NEB10 beta and their derivatives. All are commercially available from NEB. XL 10-Gold ultra-competent cells are available from Agilent. E. coli IOG SUPREME electro competent cells from Cambridge Bioscience.

For lentivirus or retrovirus work, packaging of viral particles will be achieved in eukaryotic helper packaging cell lines, such as the well characterised and commercially available HEK-293T, Plat-A (Cell Biolabs), Phoenix-AMPHO (ATCC).

Most of the CRISPR editing work will be done in HAP-lor eHAP cell lines (Horizon Discovery). To validate or reproduce some of the findings in other human cell lines, we might use a panel of lines from multiple tissue lineages (can be normal and cancerous) such as MCF10A, MDA-MB-231, MDA-MB-436, EUFA423F, hTERT-HME1, HCC1937, DLD-1, etc. All cell lines are publicly or commercially available.

All bacterial cells and mammalian cell lines are considered to be disabled and pose no risk to human health.

Host/vector system

All of the plasmid constructs will be made through Gibson assembly-based methods. Molecular cloning and transformation will be done in common competent E.coli cells for cloning such as NEB Stable, DH5a, NEB10 beta and their derivatives (all are commercially available from NEB). XL 10-Gold ultra-competent cells are available from Agilent. E. coli IOG SUPREME electro competent cells from Cambridge Bioscience.

For lentivirus or retrovirus work, packaging of viral particles will be achieved in eukaryotic helper packaging cell lines, such as the well characterised and commercially available HEK-293T, Plat-A (Cell Biolabs), Phoenix-AMPHO (ATCC).

Most of the CRISPR editing work will be done in HAP-lor eHAP cell lines (Horizon Discovery). To validate or reproduce some of the findings in other human cell lines, we might use a panel of lines from multiple tissue lineages (can be normal and cancerous) such as MCF10A, MDA-MB-231, MDA-MB-436, EUFA423F, hTERT-HME1, HCC1937, DLD-1, etc. All cell lines are publicly or commercially available.

For CRISPR-Cas9 knockout of DNA repair genes

CRISPR-Cas9 cloning backbones for sgRNA such as pX458 (#48138), pX459 (#62988), pX330 (#98750), lentiCas9-Blast (#52962), lentiGuide-puro (#52963), pCFD5/6 (#73914. 73915) - all vectors are available from Addgene.
Alternatively, RNP nucleofaction with synthetic guide RNAs and Gas9 protein will be used. Non-virus based.

For knockdown of essential genes (i.e. BRGA1/BRGA2)
Inducible shRNA vector Tet-pLKO-puro (Addgene #21915) for inducible expression of shRNA or SMARTvector
Inducible lentiviral shRNA (Dharmacon). Both vectors differ in the selection markers in host cells. Lentiviral-based.
Lentiviral Gasg vectors for targeted DSBs
Lentiviral vectors are HIV1/2 based 3rd generation virus, e.g. DO-Cas9 with filler sequence and Venus (#90085),
inducible pTRE3G vectors, pGMV-Tet3G and pEFa-Tet3G regulator plasmids with pTRE3G, pTRE3G-mCherry,
pTRE3G-Bi-mCherry, pTRE3G-Bi-ZsGreen1 response plasmids - all from Takara (Clontech ). These vectors are all based on Tet-inducible promoters in combination with different fluorescence markers.

Retroviral vectors for targeted DSBs (restriction enzyme)

Health and Safety

Executive

Retrovectors based on MMLV, MSCV, (e.g. pBABE-puro plasmid from Addgene, pRetroQ and pRetroX from Takara Clontech). AsiSI restriction enzyme plasmids were modified from pBASE backbone, in which the enzyme is fused to an oestrogen receptor binding domain as detailed in AIM1 (EMBO J. 2010 Apr 21 ; 29(8): 1446-1457). AsiSI-ER restriction enzyme was cloned into pAID1.1-N vector (BioROIS) to produce pAIO-AsiSI-ER in which the enzyme can be depleted with the addition of auxin. Retroviral-based.

For stable integration if plasmid cargo size> 10.5 kb
PiggyBac plasmids pCAG/pCMV-hyPBase (Yusa et al., 2011) were obtained through Sanger Institute clone requests service (https://www.sanger.ac.uk/form/-CXJaC-oRKGLQziN7jxNw).

All viral vectors to be used in the study are either the originals or in some instances, modified from the above without changing its tropism or its inability to replicate. E.g. to change the reporter from an antibiotic resistance gene to a fluorescence protein without altering the backbone sequences. Note that though all of our lentil retrovirus associated work will be amphotropic in nature, we are ONLY working with human cell lines.

Origin & function

Lentiviruses based on Human Immunodeficiency Virus type 1 and 2 (HIV-1/-2) however vectors to be used will be disabled 3rd generation and so risk level is reduced.
Retroviruses: used in vector systems are murine in origin but are amphotropic targeting only dividing cells. Mammalian cell lines from a mix of cancerous and normal human derived - will be transfected with plasmids encoding bacterial-derived Cas9 endonuclease together with single guide RNAs (sgRNAs) for generating stable cell lines with the desired targeted gene edits or with the ability to generate genome wide targeted double strand break (DSB). In addition to Cas9, we will also use restriction enzyme AsiSI-ER (EMBO J. 2010 Apr 21 ; 29(8): 1446-1457) to generate DSBs in these cells as a means to induce DNA damage.
Wherever possible we will use a similar Cas9 targeted system which can be tightly controlled and induced with the addition of Doxycycline (Tet-On 3G vectors from Takara Clontech) in cell culture media (e.g. Tetracycline inducible promoter, and DD-Cas9). Such a system would allow the transcript expression under Tet-promoter to be mediated by controlling the presence and/or concentration of doxycycline. The Tet-On system used in the studies will only be activated in the presence of Dox. With OD-Cas9 system (Addgene Plasmid# 90085), Cas9 will only be active in the presence of the ligand Shield-1. In Tet-pLKO-puro system, shRNA will only be expressed in the presence of Oox.

Evaluation of foreseeable effects

The genetic modifications are not expected to overcome disablement of the host cells or susceptibility to host defence mechanisms. The organisms will remain enfeebled; the environmental fitness of the modified hosts will remain severely limited and the modified organisms will be unable to survive.
The consequence of inducing or stabilising Cas9 expression, and hence DSBs would result in activation of DNA repair pathways to mediate the damage and initiate repair predominantly through cellular pathways: non-homologous end joining (NHEJ), homologous recombination (HR) or alternative NHEJ (alt NHEJ)). Mutations (e.g. indels, frameshift mutations, premature stop codons) at the DSB sites may also potentially result in target genes being knocked out as a result of misrepair. In the instance of Tet-plKO-puro/SMARTvector for shRNA, targeted transcripts will be knocked down.

The viral vectors we use could potentially down-regulate tumour suppressor functions. The vectors can integrate into the host cell DNA so transgene expression is long term possibly leading to an oncogenic phenotype. The resultant GM cell lines will not be viable outside the provided growth conditions, therefore pose little or no risk to human health.

Lentiviral vectors are generated with an amphotropic envelope (VSV-G) which may broaden the tropism of the vectors, rendering them capable of infecting human cells of many tissue types. Lentiviral vectors are also capable of transducing non-dividing cells. As a result they may pose a potential increased risk of infectivity to humans.

This connected programme of work will change the expression of a variety of genes which may be hazardous. It should be noted that a transduction event (even by a viral vector that is replication-defective) will result in integration of the gene edit into the genome of the host cell. If the expression of the gene is driven by a constitutive promoter, that expression will be permanent. While the vector itself will not proliferate, cell division may result in a population of cells expressing the transgene.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing GMMs will be inactivated via chemical disinfection with 1 % Virkon (final concentration) overnight (expected degree of kill 100%): or autoclave inactivated prior to disposal to drains (expected kill 100%). All disposable culture/lab ware will be chemically or autoclave inactivated prior to incineration on site at Addenbrooks Hospital.

Bench cabinet surfaces will be wiped down with disinfectant solution followed by 70% ethanol. Any spills of media/cell lines will be treated with 1% Virkon solution or covered by Virkon powder for 5 minutes and mopped up; rinsed with 1% Virkon followed with 70% Ethanol.

All general laboratory waste will be incinerated on site.

An autoclave is based in the laboratory where work is performed. Access is also granted in case of emergencies on level 4 of the Addenbrooke's Treatment Centre Institute of Metabolic Science building.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

Following initial review of the enclosed risk assessment and given the genome-wide scope of the project, the GMSC members requested to clarify the vectors used by detailing and grouping the plasmids, retroviral vectors and lentiviral vectors separately, as well as depending on the aim of the study. In order to be more specific, the GMSC also demanded to insert a table (in appendix) listing the main DNA damage response genes targeted by the CRISP-Cas9 system. Finally, the GMSC noted that the viral particles of VSV G pseudotype may have the potential to alter the mode of transmission and tropism, however the members were satisfied that the genetic modifications involved will not overcome disablement of the recipient cells, nor should decrease the susceptibility to host defence mechanisms. Therefore, the panel agreed that the resulting genetically modified micro-organisms will pose little risk to human health and no risk to the environment and confirmed that the safety control measures put in place will be adequate and sufficient to fully protect the workers and the environment of any harm.

### Project Additional Information

#### Purposes of the contained use

The study objectives are to:
- Characterise the surface expression of markers on cell lines including P2X7 -transfected hosts
- To assess the biology of P2X7 ion channels on transfected cells
- To utilise a variety of in vitro assays including FACS, ELISA, Western blot, cell imaging, cell death, antibody binding, gene expression on cells transfected HEK293 cells
- Analyse in vitro cell killing by antibody-dependent cell-mediated cytotoxicity using the stably transfected Jurkat cells.

#### Recipient or parental organism

**Cell Lines**

Commonly used tissue culture human cell lines characterised as Biohazard Group 1 and 2: Examples include
- HEK293 cells (Cl2), K562 (Cl1), Molt4 (Cl1), KG-1a (Cl1), THP-1 (Cl1), KG-1 (Cl1), Hel (el1), Ramos (Cl1), Rec-1 (el1), MV4-11 (el1), U266B1 (Cl1), RPMI8226 (el1), SP2I0 (CL1), SK-A-NS, Kelly (CL1), Colo205 (Cl1).
- HCT -116 (C1), HT -29-(C1), MiaPaCa2 (el1), PC3 (elL 1), DU145 (el1), InCap (C1), LU2 (C1), NCI-H460 (CL 1), MCF-10a (Cl1), NC’-H520 (C1), MCF-7 (Cl1), A375 (CL 1), HT-1080 (Cl1), SCC-9 (C1), SK-MEL-5 (Cl1), SK-MEL-28 (Cl1) and Jurkat cells stably expressing the FcyRllla (As part of ADCC Reporter Bioassay (Promega).

#### Host/vector system

Mammalian cells will be transfected with non-viral expression vector using commercially available pcDNA3.1 plasmid as previously described in Adinolfi et al 2005. pCMV6-AN-mRFP and pEZ-M02 p/asmids will be used as well. Where necessary plasmids will be propagated using commercially available Escherichia coli k-12 derivatives (TOP 10 series and DH5-alpha, genotype F- mcrA A(mrr-hsdRMS-mcrBC) lp801ac.ltl.M1511.JacX74 nupG recA1 araD139 A(araleu) 7697 galE15 9alK16 rpsl(StrR) endA 1, - ) as hosts. TOP10 and DH5-alpha bacteria have been reported to be auxotrophic for various essential amino acids.

The source of these vectors will be Prof. Francesco di Virgillio. University of Ferrara and/or D C, Biosceptre International Ud, Sydney.

#### Origin & function

**Insert ONAs**

**Health and Safety**

**Executive**

- Forms of the P2X7 gene, including full length, splice variants, and SNPs, from various mammalian species including but not limited to humans, sheep, mouse, rat, rabbit and dog.
- Fluorescent proteins i.e. GFP and RFP to monitor transgene transfection and expression.
- One commercially available cell line is transfected with human FcgRllla. This cell line is composed of Jurkat cells transfected as part of the ADCC Reporter Bioassay Kit sold by Promega.
We intend to transfect various cell lines with siRNA targeting P2X7 mRNA. Using this we can elucidate the biology of the P2X7 gene and identify the target of our therapeutic.

**Evaluation of foreseeable effects**

**BACTERIAL SPECIES:**
The hazardous potential of the GMMs created is considered no greater than that of the parental line. The E. coli strains used are K-12 derivatives and these have been recognised as non-colonising and disabled. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and are auxotrophic for various essential amino acids that are unlikely to be satisfied outside the laboratory environment. It is unlikely that the expression of human P2X7 gene will have an effect on the pathogenicity of bacterial species, furthermore the bacteria are auxotrophic for essential amino acids and this will impair their accidental release into the environment.

**siRNA OF MAMMALIAN CELLS:**
Introduction of siRNA constructs is designed to remove intracellular mRNA for the target genes. The predicted effect is the down regulation of the corresponding protein expression from the target cells. This treatment is expected to have little impact on the nature of the target cell.

**TRANSFECTION OF MAMMALIAN CELLS WITH P2X7:**
The major risk with the transfection of mammalian cell lines is the introduction of viral promotores, i.e. CMV. Waste management measures to avoid accidental exposure and release of potentially hazardous material is described in section 12. Furthermore, overexpression of the P2X7 gene in human cell lines, HEK293 cells, has been shown to increase replication in vitro and in vivo (Adinolfi et al.2012). Therefore, great care will be taken to prevent exposure of the operator to the bacterial vector containing human P2X7 or the transfected GM cell lines.

Introduction of constructs expressing siRNA or fluorescent proteins is expected to have little impact on the nature of the target cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable, only microorganisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
All waste disposed of according to the Babraham Research Campus -Hazard Group 2 Waste disposal S.O.P (waste sealed in 30L Euro bins and sent offsite for incineration by Velspeed (GM authorisation GM898, notification GM105/14.1).

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Tissue culture waste will be treated with 1% Virkon for a minimum of 12 hours before disposal down sinks or in yellow biological safety bins. Any contamination of work surfaces will be wiped with a 1% Virkon solution. Periodically we will assess the degree of killing by trypan blue counts or fluorescent viability dyes. The primary risk is the generation of viral particles and the Virkon S by Du Pont records 99.9999% killing of 58 viral, 31 bacterial and 6 fungal species. All other solid waste (e.g. gloves, plastic ware, cell pellets) will be rendered inactive by autoclaving at 121c for 15 minutes.

Glass ware will be treated with 1% Virkon for a minimum of 1 hour before cleaning.
The primary contact and person involved in the GM safety committee will be a Senior Research Scientist and Biological Safety Officer, previously trained to PhD level in biology. The bso has attended an IOSH accredited Biological Safety course by One Nucleus entitled Biological Safety: Management and Practise. Supporting members of the committee will include the Chief Scientific Officer, a research scientist and a member from the Babraham Research Institute Health and Safety Team including BBT H&S Officer. A supporting role will be played by a contracted external Health and Safety Advisor.

Comments from GMO Safety Committee:
- Change group leader name and number of research staff (as mentioned in section 1.2.7) to accommodate the restructuring of the company.
- Remove 'Examples of from 'Examples of cell lines being used in the lab include: HEK293 Cells' from section 1.2.6.
- Add two additional plasmid vectors and their details to section 2.3.1. These include pCMV-AN-mRFP and Pezm02

Non-GMM Consent Granted
The study objectives are to:
- Modify expression of P2X receptors by cancer and 1*100 cancer cell lines to gain insights into its role in cancer biology.
- Create cell lines stably knocked down for P2X.
- Create cell lines for overexpressing variants of P2X.

Recipient or parental organism

Human derived cells such as Neonatal Fibroblasts (C12), Adult Fibroblasts (C11), Keratinocytes (C11) purchased from ATCC.

Host/vector system

Cells will be transduced with commercial available viral shRNA vectors such as PIK01 (sigma) or pLVX-shRNA2 vector (Clontech) containing shRNA targeted to P2X receptors or scrambled controls and a selection marker such as antibiotic resistance (Puromycin, Blasticidin or G418) or Fluorescent protein expression (RFP or GFP).

Mammalian cells will be transduced with viral expression vectors such as lenti X expression system (Clontech) containing P2X receptor expression constructs and a selection marker such as antibiotic resistance (Puromycin, Blasticidin or G418) or fluorescent protein expression (RFP or GFP).

Lentiviral particles for transduction will be made in HEK293T packaging cells with 3rt1 generation packaging systems. lentiviral partides may also be bought ready made from Sigma (Mission shRNA lentiviral particles) or Santa Cruz (sc-42S75-Vor sc:108080).

All lentiviral transduction systems used will involve replication incompetent lentivirus, made with at least 3 separate
vectors, which do not contain the necessary 'liral elements for viral replication. Where necessary plasmids will be propagated using commercially available Escherichia coli K-12 derivatives (TOP 10 series and DH5-alpha, genotype F- mcrA (mrr-hsdRMS-mcrBC) <p80lacZIil.M1 5 il.IacX74 nupG recAI araD139 6(ara- leu)7697 galE15 galK16 rpsL(StrR) endA 1 ) as hosts.

**Evaluation of foreseeable effects**

**BACTERIAL SPECIES:**
The hazardous potential of the GMMs created is considered no greater than that of the parental line. The E. coli strains used are K-12 derivatives and these have been recognised as non-colonising and disabled. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and are auxotrophic for various essential amino acids that are unlikely to be satisfied outside the laboratory environment. It is unlikely that the expression of human P2X7 gene will have an effect on the pathogenicity of bacterial species, furthermore the bacteria are auxotrophic for essential amino acids which will impair their accidental release into the environment.

**shRNA OF MAMMALIAN CELLS:**
Introduction of shRNA constructs is designed to remove intracellular mRNA for the target genes. The predicted effect is the down regulation of the corresponding protein expression from the target cells. This treatment is expected to have little impact on the nature of the target cell.

**TRANSDUCTION OF MAMMALIAN CELLS WITH vectors expressing P2X receptors:**
The major risk with the transfection of mammalian cell lines is the introduction of viral promoters, i.e. CMV. Waste management measures to avoid accidental exposure and release of potentially hazardous material is described in section 12. Furthermore, over expression of the P2X7 gene in human cell lines, HEK293 cells, has been shown to increase replication in vitro and in vivo (Adinolfi et al 2012). Therefore, great care will be taken to prevent exposure of the operator to the vector containing human P2X7 or the GM cell lines.

**TRANSDUCTION OF CELLS WITH LENTIVIRAL CONSTRUCTS**
Lentiviral transduction system are capable of infecting human cells and must be handled with care. However, all lentiviral transduction systems used will involve replication incompetent lentivirus, made with at least 3 separate vectors, which do not contain the necessary viral elements for viral replication. This makes production of whole replicating virus essentially impossible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable, only microorganisms (including tissue culture cells) are involved in this work.
All waste disposed of according to the Babraham Research Campus -Hazard Group 2 Waste disposal S.O.P (waste sealed in 30L or 60L Euro bins and sent offsite for incineration by Vetspeed (GM authorisation GM898, notification GM105/4.1 ).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture waste will be treated with 1% Virkon for a minimum of 12 hours before disposal down sinks or in yellow biological safely bins. Any contamination of work surfaces will be wiped with a 1% Virkon solution. Periodically we will assess the degree of killing by Irypan blue counts or fluorescent viabiliy dyes. The primary risk is the generation of viral particles and the Virkon S by Du Pont records 99.999910 killing of 58 viral, 31 bacterial and 6 fungal species.

Disposable waste material will be placed in sealed 30 or 601 eurobins and sent offsite for incineration by Vetspeed (GM authorization ref. GM898) according to Babraham Institute disposal notification GM1054.1. Prior to disposal clip a RED LID onto the eurobin and ensure it is firmly attached. Then close the lid and push down firmly around the edges of the bin to seal. Place a category 2 sticker, which contains the UN 3373 diamond sign, onto the eurobin. Spray the bin all over with 2% Trigene.

Glass ware will be treated with 1% Virkon for a minimum of 1 hour before cleaning.

Liquid waste from lenti viral work will be collected and solidified with absorbeZe powder in plastic containers which will be disposed as solid waste in sealed 30l or 60l Euro bins and sent offsite for incineration by Vetspeed (GM authorisation GM898, notification GM105/4.1).

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Y

**Give brief details of the genetic modification safety committee**

Composition: Geomicrobiology Laboratory Manager, Health & Safety Officer, 2 x Union reps. Centre for Ecology and Hydrology (CEH) Health and Safety Officer will be occasional member of the committee in an advisory capacity

Frequency of meeting: Annually, or when new activities are proposed.

Operation procedures: Agenda distributed in advance, meetings minuted and the minutes made freely available to all staff to consider issues of safety around the GM work.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Y

02/03/2022
Role of the Genetic Modification Safety Committee

- To advise on risk assessment
- To monitor and review GM activities carried out within the Department
- To develop Local Rules for work involving genetic modification
- To consider accidents or incidents involving genetic modification
- To consider the findings from safety inspections where these relate to activities involving genetic modification.

Constitution of the Committee

The Committee should be composed of:

- Chairperson (elected by the Committee)
- Secretary
- Head of Department or representative (may be Chair of Committee).
- Biological Safety Officer
- Departmental Health and Safety Officer
- Technical Staff representative
- Representatives from University Safety Office.

The BSO should no be the chair of the Committee.

There should be a mechanism for consulting and informing organisations affected by the GM activities conducted within the department (e.g. cleaning and maintenance etc.).

The occupational helath representative should be invited to attend in connection with issues relating to the management of health risks.

The committee should report to the Health and Safety Group.

Role of the GM Chair

The GM Chairperson should be an academic member of Canterbury Christ Church University staff. They must be nominated by the GMSC and formally appointed by the Head of Dean of Faculty.

The GM Chair must:

- Ensure that local rules are drawn up and followed for the safety of all.
- Advise on the training of personnel in appropriate microbiological practice.
- Investigate accidents or spillage etc in the laboratories and taking any action they consider necessary.
- Appropriate records and reports should be made.
- Ensure that accurate records are kept.
• Ensure that appropriate disinfection procedures for the laboratories are in place and are followed.
• Participate in locally organised inspections.
• Ensure that control measures and equipment are tested and appropriately maintained.
• Ensure appropriate waste disposal procedures are used and records kept.
• Provide technical support to the GMMSC on risk assessment and classification.
• Ensure all statutory notifications are made to the HSE with copies to University's RPG.
• Ensure the adequacy of arrangements for the physical security of the laboratories.

Duty/Role of GMSC Members

The GMSC members must be familiar with the following:

• GMO (Contained Use) Regulations.
• ACGM Compendium of Guidance.
• Advisory Committee on Dangerous Pathogens (ACDP) "The management, design and operation of microbiological containment laboratories" ISBN 0 71762034 4.
• Control of Substances Hazardous to Health (COSHH).
• All other relevant publications.

Awareness of these documents will be raised to the committee members by the BSO in the first instances and any other persons who may receive relevant documentation.

The Chair and members should:

• Seek advice from the BSO, when necessary. The BSO will seek confidential technical advice from sources outside the committee as and when appropriate.
• Have an understanding of the risks to both human and animal health, and to the environment that may arise from any proposed GM activity.
• Check the accuracy of the risk assessment presented to the committee.
• Review in detail GM risk assessments presented to the committee.
• Review in detail GM risk assessments presented to the Committee and advise accordingly. Ensure the risk assessment has been completed in accordance with the GMO (Contained Use) regulations and other relevant ACGM guidance.
• Advise on the genetic modification safety training requirements needed to carry out the work.
• Consider whether the appropriate containment facilities, as indicated by the risk assessment, are suitable and by what means such work may otherwise be carried out.
• Keep projects discussed within the Committee confidential.

Meetings of the Genetic Modification Safety Committee (GMSC)

The Committee should meet regularly, at least termly. Dates of the meetings should be fixed in advance. Notice of the meetings should be circulated one week in advance and accompanied by an agenda, minutes of the last meeting and papers for discussion. The Minutes of the Committees should be reported to the University RPG.

An accurate record of the meeting must be kept of:
- Date of meeting.
- Attendees.
- Apologies/absences.
- Title of projects submitted to the Committee, principal investigator, department, division and location of work to be carried out in.
- Risk assessment and other forms submitted for the Committee’s consideration.
- Agreed classification of projects and whether notification to the HSE is required.
- Containment level required.
- Any further control measures to be taken by the personnel involved with the project.
- Amendments to be made to the risk assessment form.
- Comments and concerns raised by the GMSC members regarding the project.
- Dissenting opinion and agreed outcome.
- Actions to be taken and the named responsible person.

Minutes must be distributed to Head of Department and to the University Safety Manager.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

<table>
<thead>
<tr>
<th>Prior to final discharge/disposal of waste from contained use activities, any risks to humans and the environment associated with any GMO must be removed by use of validated inactivation methods. Inactivation refers to the complete or partial destruction of GMMs so as to ensure that any contact between the GM plant material and humans or the environment is limited to provide a high level of protection to both humans and the environment.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Experimental materials, including soil, should be clearly marked and be treated by a validated means before disposal to kill any residual organisms, such as seeds, tubers etc.</td>
</tr>
<tr>
<td>Plastic consumables should be made safe by autoclaving (126-132°C for 15 mins) and solids disposed of via the industrial waste stream for landfill or incineration. Liquids (eg samples, culture supernatants, tissue culture media) should be made safe by autoclaving (126-132°C for 15 mins) and discharged to drains. Agar plates - should be autoclaved (126-132°C for 15 mins) and disposed of via the industrial waste stream for landfill or incineration. 1% (w/v) Virkon disinfectant solution should be used to decontaminate surfaces (10 min) contact time). Large spills will be treated with Virkon powder and mopped up with paper towel. This will be autoclaved as for solid waste.</td>
</tr>
<tr>
<td>Autoclaving, effectively 100% kill (annual validation)</td>
</tr>
<tr>
<td>Chemical disinfection with Virkon, used according to manufacturers instructions under standard conditions, manufacturers validation (e.g. 99.998% kill)</td>
</tr>
</tbody>
</table>

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

| GMSC members reviewed the proposed risk assessment and deemed the questions asked would thoroughly and comprehensively cover any potential GM activities proposed to be undertaken within the department.  
It was noted that no GM activities of a class 2 nature or above would be carried out in the department within the foreseeable future |

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

02/03/2022

Page 13481 of 15326
Genetic Modification Safety Committee

a) Terms of Reference
1. To receive and review in detail and in a systematic manner every proposal for genetic modification work and to judge the adequacy of the risk assessment and the identification of appropriate containment and other risk control measures.
2. To periodically review risk assessments.
3. To advise on the preparation and review of local rules to cover work involving genetic modification.
4. To advise on the needs for training, equipment and resources for genetic modification work.
5. To consider any accidents or incidents relevant to genetic modification work.
6. To consider and recommend arrangements for health monitoring or surveillance where appropriate.
7. To disseminate legislation and approved guidance relevant to work with genetic modification.
8. To promote a knowledge and understanding of genetic modification within the University.
9. To assist and advise the Authorised Person to discharge the responsibilities for statutory notifications and record keeping.
10. To annually report on its activities to the Health and Safety Manager

b) Frequency
The Committee will meet 6 monthly, or more frequently should the need arise.

c) Constitution
There are no hard-and-fast rules governing the make-up of a GMSC. Ideally it should have balanced representation of both management and employees with its members also being representative of all persons having access to the genetic modification facilities or who might otherwise be exposed to such work.

It should have enough members, with sufficient depth and range of knowledge and experience to:-
• Understand the risks to both human health and the environment arising from the normal range of activities undertaken, and the extent to which risks are uncertain.
• Judge the adequacy of the risk assessment.
• Test its emerging conclusions by discussion so that the advice given is genuinely that of a committee and not an individual.

d) Composition
• A Chairperson.
• Representatives of management with responsibility for GM work.
• Representatives of those leading work with GM.
• Representatives of Technical Staff supporting work with GM.
• Representatives of persons having access to the GM facilities or who might otherwise be exposed to GM work, e.g. ancillary staff, administrative support staff, contractors.
• The Biological Safety Officer (the person appointed to comply with the legally required notifications and record keeping).
• Co-opted persons to supplement expertise where necessary.
• Note: Medical surveillance is not a specific requirement and a supervisory medical officer is not required to be appointed.

The composition (but not names) of the GMSC must be notified to the HSE as part of notification of first use of premises for GM activities. Any changes to the composition should also be notified.

Other(s) Mammalian cell lines derived from human, mouse or any other group depending on the project requirements

For activities involving GMMs, describe the waste management measures which will apply to the activity

- **Solids** (e.g. plastic-ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

- **Liquids** (e.g. samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

- **Sharps** (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All Risk Assessment were approved with no further action required.

The committee agreed classification of the projects/products and that the HSE should be notified that Synpromics Ltd is ready to commence work.

**Project Additional Information**

**Purposes of the contained use**

Mammalian cell line cultures derived from human, mouse or any other origin depending on the project requirements.

Primary cell cultures of animal and human origin.

Transient and stable transfection of promoter activity reporter vectors.

Screening of promoter libraries using the following recombinant viral vectors: AAV (adeno-associated virus), adenoviral, baculoviral, retroviral and lentiviral vectors.

**Recipient or parental organism**

Human, mouse, rat or any other mammalian organism depending on the needs of each project.

**Host/vector system**

**Host**

Mammalian cell line cultures derived from human, mouse or any other origin depending on the project requirements.

Primary cell cultures of animal and human origin.

**Vector system:**

Commericially available recombinant viral vectors including: AAV (adeno-associated virus), adenoviral, baculoviral, retroviral and lentiviral vectors.

Libraries of promoter elements/parts will be cloned in recombinant viral vectors. GFP, Luc or any other reporter gene will be used to detect transcriptional activity depending on the particular needs of each project.

**Origin & function**
The intended use of the GMOs is to screen libraries of premoter elements/parts cloned upstream of a reporter gene (GFP, Luc or any other gene of interest depending on the detection method used for the screen) in mammalian cells to identify premoter elements/parts active in the cells and/or conditions of interest depending on each individual project.

For biosafety reasons, the viral genes for packaging in the recombinant viral vectors have been split in different plasmids and these plasmids do not share any sequence homology between them and the lentiviral screening vector. This strategy prevents the generation of replication-competent virus and the resultant viral particles cannot replicate autonomously in target cells.

Give brief details of the genetic modification safety committee

There are three members of the genetic modification committee and they also hold positions in the health and safety committee; the head of both committees is the CEO of the company. The Biological Safety Officer sits on both committees and the third member comes from the scientific staff and has experience of working with GMOs. The committee meets every three months and any issues that require discussion are communicated beforehand. The status of any impending actions is followed up at meetings.

All waste will be autoclaved at 134°C for 20mins to ensure sterilisation. The sterile waste will then be disposed of as clinical waste for incineration. In addition to using autoclave tape, the autoclave prints out the conditions achieved each run and indicates if the program passed or failed and this information is logged and stored. The autoclave is serviced 6 monthly and calibrated annually.

DNA diagnostics; bacteria are to be transformed with truncated target genes

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

The work is of low risk as the bacterium is derived from a non-pathogenic strain and none of the genetic material to be transformed into the bacteria are functioning genes. Nonetheless, the work will be carried out under containment level two conditions to further minimise risk.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee
Promexus Ltd is a fully owned subsidiary of the Avacta Group plc (Unit 706, Thorp Arch Estate, Wetherby, LS23 7FZ).
The Avacta Group consists of the following companies which are all located on the Thorp Arch Estate, Avacta Life Sciences, Avacta Animal Health and Avacta Analytical

As both Promexus and Avacta Life Sciences use the same core protein technology platform, we plan to use the Genetic Modification Safety Committee (GMSC) that has already been established at Avacta Life Sciences to review all risk assessments relating to the creation, use and disposal of genetically modified organisms.

Given the scope of operations within the Avacta Group, they have extended the role of the Genetic Modification Safety Committee (GMSC) to take account of general biological, chemical and physical safety. As a consequence of the widened role, the GMSC has been renamed the Laboratory Safety Committee (LSC).

The membership of the Committee is as follows:

Chair:
PhD (University of Nottingham) – Received training in molecular biology techniques at Queen’s Medical Centre, Nottingham and transferred systems to research lab. Gained extensive molecular biology experience including cloning, PCR, DNA purification and mutational analysis. Optimised protein expression in E. coli and devised protein purification protocols.

2003-2010 PDRA (University of Leeds) – Used standard molecular biology methods regularly and frequently cultured E. coli in various media.
2010-2012 Application Scientist (Farfield Group, Manchester) – Responsibilities included oversight of lab health and safety.
2012-present Applications Scientist (Avacta Analytical, Wetherby) – Member of lab and biological health and safety committee.

Biological Safety Officer (at Avacta Life Sciences):
University of Sheffield (2000-04), PhD: Cat 2 work with Bacillus cereus.
Abcam (2005-2013): Leaving Position - Head of R&D. Corporate BSO, management of Cat 2 work and Class 1 GMO work.
Avacta Life Sciences (2013-present), Head of R&D.

Other committee members: Lab based staff and management representatives from Avacta Life Sciences, Avacta Animal Health, Avacta Analytical and Promexus Ltd.
The combined laboratory experience of this committee exceeds 50 person years in both academic and commercial setting

Other (please specify) Tick if confidential
E. coli K12 strains (and their associated DNA plasmids) will be used to manipulate the gene for the creation of engineered protein variants of human Stefin A. The engineered proteins will be expressed and purified from a range of hosts to produce enough material for pre-clinical animal studies and stability testing (100's mgs). The expression hosts will include E. coli, mammalian cells e.g. CHO cells (a well established hamster cell line that cannot survive outside the lab environment) and yeast (pichia pastoris). There will also be a need to occasionally express proteins of human or animal origin to support pre-clinical research. Again these will be expressed either using E. coli, CHO or yeast.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Waste potentially contaminated with Cat I GMM, such as pipette tips and other disposable plastics; solid microbiological growth media and liquid waste such as biological growth media and waste water from the cleaning of glassware.

Liquid waste will be inactivated by incubation and cleansing with a proprietary cleaner such as Virkon, and disposed of via the drain.

Solid waste, including microbiological growth media, cell pellets and plastics, will be inactivated by autoclaving onsite before disposal via incineration by an approved contractor.
**Project Additional Information**

**Purposes of the contained use**

Phage display selection, production of proteins using mammalian cell line for transient or stable expression and use of transient cell lines to assess the potency effect of the selected proteins.

**Recipient or parental organism**

E.coli, HEK293 (Human embryonic Kidney cells) for transient expression, CHO (Chinese Hamster Ovarian) cell line for stable expression. Fully characterised cell lines, including but not limited to, Jurkat and RAW cell lines or transient cell lines commercially available. Those can be used to assess potency.

**Host/vector system**

Mammalian expression vector

**Origin & function**

1-For example HEK 293 is a virally transformed, stable well established human epithelial kidney cell line that is routinely used in expressing plasmid derived proteins. This cell line has been established for laboratory use only and would not survive long without specific culturing conditions. The HEK293 cells contain DNA from Adenovirus 5. The cell line will be cultured for production of therapeutic proteins.

Regarding other expression cell line as CHO, it is established that 2-In order to assess the potency of the therapeutic proteins reporter genes such as GFP, RFP and luciferase have been used in various transgenic animal systems and have been shown to have no harmful effects on the organisms.
HEK293, CHO or the other cell lines are unable to survive outside their laboratory environments and require cell maintenance therefore they are unlikely to cause any harm to other organisms. Also, the work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents and will be non-self cell lines that will not be able to colonise those involved with the work. Indirect hazards to human health associated with possible adventitious agents have been considered separately in a general Risk Assessment relating to work with human derived materials. All human derived samples are treated as though capable of causing disease.

**Evaluation of foreseeable effects**

HEK293, CHO or the other cell lines are unable to survive outside their laboratory environments and require cell maintenance therefore they are unlikely to cause any harm to other organisms. Also, the work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents and will be non-self cell lines that will not be able to colonise those involved with the work. Indirect hazards to human health associated with possible adventitious agents have been considered separately in a general Risk Assessment relating to work with human derived materials. All human derived samples are treated as though capable of causing disease.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A - full containment of the live cells will be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GMM liquid waste will be disposed off into appropriate disinfectant (2% sodium hypochlorite, 1 % Virkon or a 1:10 dilution of Distel or Chemgene) within a Class II Microbiological Safety Cabinet (MSC) where all work using these organisms will be carried out. After 24 hours, this waste will be discarded into the drains. Bacterial culture plates will be sealed, double-bagged inside the cabinet before being autoclaved on site (see attached Risk Assessment for details of cycles). Contaminated tips will be soaked in appropriate disinfectant (see above) and disposed of in a sharps container. Any contaminated glassware (kept to minimum) will be soaked in appropriate disinfectant for 24 hours, then rinsed prior to normal cleaning. Other solid waste (plasticware) will be autoclaved on site prior to disposal via the clinical waste route. Autoclave logs will be monitored and waste will only be disposed of if the run is successful. Fresh dilutions of each disinfectant will be made weekly. Virkon is a bactericidal agent, which is used at a concentration of 1 %. It has been shown to cause a 5-log reduction in bacterial counts (Hernandez, A. 2000. Journal of Hospital Infection. 46: 203-209). Low concentrations of sodium hypochlorite (bleach) have a biocidal effect on mycoplasma and vegetative bacteria.
in seconds in the absence of high amounts of organic material (Dychdala GR Disinfection, sterilization, and preservation. 2001 :135-157). S. aureus, Salmonella choleraesuis, and P. aeruginosa have been shown to be inactivated in <10 minutes by sodium hypochlorite (Rutala WA et al. Infect Control Hosp. Epidemiol. 1998;19:323-7). Distel I Chemgene are bactericidal and effective in destroying type strain cultures of P. aeruginosa, S.aureus, MRSA and VRE with contact time of 1-5 minutes. Solid waste are incinerated by a laboratory waste management company.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment will be reviewed as the company is moving in a new site.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A - full containment of the live cells will be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The disinfectants and concentrations (unless otherwise stated) we use are: Virkon (at a final concentration of 1 % [w/v]; hereafter referred to as “Virkon”), 1 % (v/v) Distel and 70 % (v/v) ethanol. Virkon is a high-level laboratory disinfectant that is used as a bactericidal, fungicidal, and virucidal agent. It is effective in the presence of blood-borne diseases (HIV/Hepatitis B).

Cleaning and recycling of reusable laboratory equipment, such as glassware, that has been in contact with biological agents of HG 2 will require a minimal 10-30 minute incubation with Virkon (as per SOP ALS-WE000002) prior to dishwashing (as per SOP ALS-WE000144; wash at 80 °C, drying at maximum temperature), or manual dishwashing (as per SOP ALS-WE000114) and autoclaving (as per SOP ALS-WE000006) at 121°C for 15 minutes. Autoclaves will be validated by twice yearly servicing and autoclave tape with each run.

Liquid waste will be inactivated by an incubation of minimum 30 minutes to overnight with Virkon prior to disposal via the sink.

Aspirators are used whenever possible when liquid is being removed from flasks, bottles, reservoirs etc. to waste. Aspirators provide a closed system whereby aerosol production is kept to an absolute minimum. Aspirators must always be used with the correct filter, cleaned with Virkon and water after each use the waste is disinfected with Virkon as per SOP ALS-WE000115. Where possible the contents of the reservoir should be left overnight to ensure decontamination before discarding to waste down the sink. Minimum contact time is 30 minutes.

Surfaces are to be cleaned with 1 % Distel followed by 70% ethanol.

All disposable plasticware that has been in contact with cells of HG 2 (including pipette tips, stripettes, plates, falcon tubes, reservoirs and flasks) must, after removal of liquid waste, be placed into a fully-sealable clinical waste burn-bin, UN3291 labelled, and stored in a secure bin shed on site. Bins must be sealed before leaving the laboratory to prevent risk of release into the environment during transport. All solid biological wastes are incinerated off-site by waste management company LabWaste, permit no. EPR/SP3895VG, Waste Carriers License: CBDU66492.
The risk assessment will be reviewed frequently during H&S meetings.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 3228/19.1

Date Ackn'd 08/02/2019

CU2 Project Title

This is a connected Programme of work: Class 2 activities involving the use of lentiviral and retroviral vectors to overexpress proteins and affimers intracellularly or on the surface of mammalian cells (primary cells and cell lines).

Date Project Ceased

Class 2

< 1 Litre

Non-GMM Consent Granted

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
**Project Additional Information**

### Purposes of the contained use

Overexpression of human, primate and rodent genes in various cells and cell lines using lentiviral/retroviral vectors in order to assess the activity/potency of Affimer therapeutic in immuno-oncology in vitro.

### Recipient or parental organism

- Primary Cells (human T cell)
- Primary cells (Mouse T cell)
- LK35.2 (mouse hybridoma B cell line)
- DO1110 (mouse hybridoma T cell line)
- HEK293 (Human Embryonic Kidney cell line)

### Host/vector system

**Lentivirus:**

The major risks to be considered for work with HIV-1 based lentivirus vectors are the potential for generation of replication-competent lentivirus (RCL), and the potential for oncogenesis via random chromosomal integration. The viral regulatory genes gag, pol, and rev are encoded in a separate plasmid and the gene of interest is encoded by the transfer vector which lacks any transacting structural genes. These constructs have been altered to contain non-overlapping sequences, hence minimizing the possibility of recombination. In addition non-essential genes have been eliminated from the virus, thus any replication-competent virus generated would lack essential factors for replication and virulence in vivo. Thus, even though the virus particles could infect human cells at the virus packaging stage, the virus is replication deficient.

The nature of the transgene must also be considered in assessing risk. These risks can be mitigated by the nature of the vector system (and its safety features) or exacerbated by the nature of the transgene insert encoded by the vector (e.g., expression of a known oncogene with a constitutive strong promoter may require heightened safety precautions). The genes used in this work are not oncogenes with constitutive promoters, thus the risk is minimal.

**Evaluation of foreseeable effects.**

The potential for generation of RCL from HIV-1 based lentivirus vectors depends upon several parameters, the most important of which are the number of recombination events necessary to reassemble a replication competent virus genome and the number of essential genes that have been deleted from the vector/packaging system. On this basis, later generation lentivirus vector systems (3rd and 4th generation) that are used in this project are likely to provide a greater margin of personal and public safety than earlier vectors, because they use a heterologous coat protein (e.g., VSV-G) in place of the native HIV-1 envelope protein, thus reducing the risk of RCL generation. Later generation vector systems also separate vector and packaging functions onto three or four plasmids and they include additional safety features such as the deletion of Tat, which is essential for replication of wild-type HIV-1, and altered 3' LTR that renders the vector “self-inactivating” (SIN).

### Origin & function

The genes of interest that are transferred to host cells using the lentiviral vector system are genes of human, rodent or primate origin and normally involved the regulation the immune system during inflammatory activation and/or in immuno-oncology. The intended use of these genes is exploiting their natural function to evaluate the anti-tumor potency of affimer therapeutics in vitro. The genes will be expressed on host cells and their role in immune
Evaluation of foreseeable effects

There are three different GMO's being produced during this process:

1) Bacteria with the individual components: Bacteria will not contain more than one viral component and therefore are unable to produce viral particles. Bacterial strain used is standard K-12 derivative DH5α E.coli, which is the most popular and widely available laboratory strain, and the presence of the vectors is not expected to alter pathogenicity of the bacteria, nor alter their survivability in the environment.

2) Lentivirus/retrovirus: Individual components for the virus are transfected into HEK293 cells where they are packaged and released. The lentivirus particles obtained from the packaging cells is infectious and will be handeled accordingly. As lenti viral particles are capable of infecting non-dividing cells, the most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on skin, or mucous membrane exposure of the eyes, nose, and mouth. Another route would be inhalation via aerosols depending on the use of equipment such as centrifuges or vortex mixers. Care will be taken when pipeting in order to avoid splashing or generation of aerosols. Immunocompromised individuals will not work with lentivirus. Work involving the virus particles will be in a microbiological safety cabinet level 2. Gloves and laboratory coats and other PPE will be worn and no sharps will be used. Furthermore, it should be borne in mind that the viral particles produced are non-replicative and self inactivating. The presence of the inserts (gene of interest) will not alter this and therefore unlikely to alter survivability in the environment.

3) Infected mammalian cell lines: As the viral particles are non-replicative and self inactivating, once the target cells are infected, the virus will integrate and express the desired proteins, but will not cause any further viral production. Thus, after about 5 days of transduction, the infected mammalian cells will be free of infective viruses and safe to handle. In the mean time during the 5 days transduction period the cells will be considered infective and handeled accordingly. As the genes used to generate the GMOs are normally found in mammalian cells, the trasduced cell lines are not expected to have altered survivability and impact on the envionment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No large GMO are involved as this is an in vitro work using cultured cells.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: All solid materials that come in contact with virus-containing solutions or vessels will be decontaminated by spraying with 1% sodium hypochlorite (10% bleach) or 1% Virkon and exposed for 20-30 min, contained before exiting the biosafety cabinet. Solid waste will be collected in a double layer biohazard bag inside the Biosafety Cabinet. Pipet tips are considered to be sharps and will be collected in a disposable plastic box (such as an empty P-1000 box), and the box closed and deposited into the biohazard bag (in the Biosafety Cabinet) at the end of the work session. At the end of the work session, the biohazard bag will be closed, sprayed with 70% EtOH, and deposited into a biohazardous waste container for incineration. The biohazard waste container will be closed all the time.

Liquid Waste: Liquid waste including media and solutions will be pipetted into a 500 ml bottle containing bleach with 1% final concentration of sodium hypochlorite or 1% Virkon. For example, 50 ml of bleach that contains 10% sodium hypochlorite will be added to the 500 ml bottle before starting the lentivirus work and placed in the BSC.
After finishing work with the lentivirus, the liquid waste will be left in the bleach for 20-30 minutes for effective
decontamination. The decontaminated liquid waste will then be poured down the sink and cold water will be run for
minimum 5 minutes to flush the corrosive disinfectant from the sink. The bottle can be rinsed and reused. Liquids
disinfected with bleach will not be autoclaved to minimize generation of chlorinie gas.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

The overall risk is low as all the organisms to be used are classified at hazard group 2 and the activity is classified

CU2 Project Title  Raising Affimers Against Adenovirus 5

Class  Class 2  
CultureVolClass2  Not Applicable  
CultureVolumeClass3-4  
Non-GMM  Consent Granted  

Project notified under transitional arrangements  

Project Additional Information

Purposes of the contained use

The project is to raise Affimers against attenuated Adenovirus 5. This Risk Assessment specifically covers the work involving attenuated Adenovirus 5. Risk Assessments for the screening and growing of Affimers are covered elsewhere.

Recipient or parental organism

The wild type Adenovirus serotype 5 causes sub-clinical infections and is categorised by the ACDP as Hazard Group 2.

Host/vector system

Attenuated Adenoviral Vector System

The adenoviral vectors to be used are attenuated through deletion of the E1 region of the genome (containing E1A and E1B) and through insertions and deletions within the E3 gene that inactivate it. This has several effects on the virus. Firstly, deletion of the E1A gene eliminates the potential for viral transformation of cells, since the E1A gene product is absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operates with E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication. The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatibility complex MHC polypeptides in the endoplasmic reticulum. However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune surveillance. The E4 gene product is required for formation of an active complex between the E1B gene product and the E4 gene product.

The attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Beck T. C et al Methods Cell. Biol. (1994) 43, 161-89). Recombination with a wild-type virus would, by the nature of the
recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

**Origin & function**

The adenoviral vectors to be used are attenuated through deletion of the E1 region of the genome (containing E1A and E1B) and through insertions and deletions within the E3 gene that inactivate it. This has several effects on the virus. Firstly, deletion of the E1A gene eliminates the potential for viral transformation of cells, since the E1A gene product is absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operates with E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication. The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatibility complex MHC polypeptides in the endoplasmic reticulum. However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune surveillance. The E4 gene product is required for formation of an active complex between the E1B gene product and the E4 gene product. The attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Beck T, C et al Methods Cell Biol. (1994) 43, 161-89). Recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

**Evaluation of foreseeable effects**

Under conditions where an organism (human or non-human mammalian) already was suffering from an adenoviral infection, it is possible that the recombinant virus could be replicated and packaged. Since this is likely to be a relatively rare event, and not one that could sustain a population of recombinant virus, the risks are extremely low. Additionally, any wild-type virus would be at a significant growth advantage with respect to the recombinant virus (for the reasons mentioned above concerning attenuation of the virus), meaning that the wild-type virus would outgrow the recombinant one very quickly.

There will a GFP gene inserted in the adenovirus. The GFP gene product is non-hazardous and non-oncogenic. There are no additional hazards of the GFP sequence being transferred to related Adenovirus. The adenovirus is attenuated by deletion of the E1 region of the genome and unable to propagate in the environment. They are replication incompetent, so do not have any possibility of further spread. They will be easily outcompeted.
by any wild-type Adenovirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Laboratories where GMM will be used have chemically impervious flooring (linoleum) that is easy to clean. Laboratory benches and sinks are made of impervious materials (Trespa or steel) that are easy to clean. Any vessels containing GMMs that are being shaken or centrifuged must be closed. Aerosol formation must be avoided.

Pipettes must be cleaned after they have been used with adenovirus with 1% (v/v) Distel solution followed by 70% (v/v) ethanol.

GMMs are stored in safe areas as (incubators, fridges or freezers) within the laboratories. Entry into the building is via key fob only. The building and all internal doors are locked overnight, and the building is protected by a security system.

All work involving open virus shall be undertaken in a Class 2 BioSafety Cabinet, or if not practical in a fume cabinet. This includes phage selection up to the stage the bacteriophages are eluted; as the phages are eluted in 0.2M Glycine, pH2.2, this will permanently inactivate the adenovirus. As an extra precaution, the eluted phage will be heated at 60°C for 15 minutes to ensure complete inactivation of any residual adenovirus. Care will be taken with the eluted bacteriophage, but amplification of phage will take place on the bench in the R&D laboratory. Any ELISA involving viable adenovirus will be carried out wholly in the Class 2 BioSafety Cabinet, until reading the ELISA plate on the plate reader, where the plate will be sealed with an adhesive plate seal and read on the plate reader in the main lab.

**Personal Protection**

Staff and visitors are required to wear a lab coat and protective eyewear when in the lab, whether at the bench or not, and to wash hands in a dedicated sink when leaving the lab. Gloves are provided and are recommended when working with GMMs.

Mouth pipetting is explicitly forbidden, as is eating or drinking or the application of cosmetics in the lab.

**Waste and Spills**

All waste potentially contaminated with GMM is to be treated as detailed in section 4.3 prior to disposal.

Spill kits are available under the sink in both labs. Liquid spills may be treated with powdered Virkon, and mopped up from outside the spill. All solid waste resulting from cleaning the spill should be autoclaved prior to disposal.

All solid contaminated materials, including waste destined for incineration, will be placed into a yellow clinical waste bin. These bins will be collected by a specialist lab waste disposal company (LabWaste Ltd., Hinckley, UK or an equivalent waste contractor). Cleaning and recycling of reusable laboratory equipment, such as glassware, will require a minimal 30 minutes incubation with 1% Virkon (or an equivalent bactericidal detergent) (10 min for metal items due to corrosive nature of Virkon) prior to dishwashing (wash at 80°C, drying 65°C) and autoclaving. Glassware that has been contacted with bacteriophage will be treated with 2% Virkon.

Liquid waste will be inactivated for at least 30 min or overnight with 2% Virkon prior to disposal via the sink.
Surfaces are cleaned with 1% Virkon or 70% ethanol (if no open flame is present). Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

For activities involving GMMs, describe the waste management measures which will apply to the activity

All solid waste (e.g. plasticware) will be discarded in designated GMM waste bins containing Biohazard marked waste bags. This waste will be collected and removed for incineration at Discovery Park by Park Serve, a contractor that specialises in the handling and disposal of hazardous biological waste. All liquid waste will be inactivated by adding to Virkon to make a 1% Virkon solution and incubated for >15 minutes, likewise pipettes and glassware will be soaked in 1% Virkon solution and incubated for >15 minutes before disposal down a sink. Areas where GMM work has taken place will be disinfected with a 1% Virkon solution once completed.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Genetic Safety Committee deems that the use of cell lines with biosafety level 1 can be used in the laboratory under containment level 1 conditions with the correct waste management and handling as laid out in the risk assessment.
## Project Additional Information

**Purposes of the contained use**

| Use of biosafety level 2 designated mammalian cell lines and primary human cells in experiments to determine the efficacy and mode of action of novel therapeutics |

**Recipient or parental organism**

| Not applicable |

**Host/vector system**

| Mammalian cell lines and primary human cells |

**Origin & function**

The origins of the biosafety level 2 designated cell lines are mammalian and are all available from commercial sources such as Public Health England. In most cases these cells have been transformed with a viral vector to immortalise them or they may have been demonstrated to be infected with a pathogen. This requires them to be handled and disposed of under containment level 2 conditions. Human primary cells such as peripheral blood mononuclear and natural killer cells will be obtained from commercial sources where they have been tested for the presence of pathogens. However, the cells still need to be treated as potentially infectious and will therefore also be handled under containment level 2 conditions. The cell lines may be transiently or stably transfected with human proteins using non-viral methods in order to express that protein on the cell surface for functional studies. These proteins will be non-infectious.

**Evaluation of foreseeable effects**

The cell lines are potentially infectious, although with organisms that do not cause serious human disease and have been designated BSL-2 by ATCC and ECACC. The pathogens and their risks are well documented and all cell lines will be purchased from commerical sources. The risks to human and environmental health are thus low. The primary human cells to be purchased from commercial sources are potentially infectious, although they will have been screened for the serious human pathogens HIV, Hep B & Hep C. The risk to human and environmental health is therefore moderate, but warrants use under containment level 2 conditions. The proteins that may be transfected to the cell lines will be naturally occurring human wild-type or mutant variants of human proteins and are not infectious.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| Not applicable |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| All solid genetically modified waste (e.g. plasticware) will be removed by contractors (Park Serve) and incinerated on site according to validated methods |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| All solid waste (e.g. plasticware) will be discarded in designated GMM waste bins containing Biohazard marked waste bags. This waste will be collected and removed for incineration at Discovery Park by Park Serve, a contractor that specialises in the handling and disposal of hazardous biological waste. Areas where GMM work has taken place will be disinfected with a 1% Virkon solution once completed. Staff will receive full training on the handling and disposal of GMM waste |
The committee deems that containment level 2 conditions will be suitable for the use of both BSL-2 designated cell lines and potentially infectious human cells, provided that they are procured from a source that has prescreened the primary cells for the presence of HIV, HCV and HBV. Staff must be fully trained in the requirements for working under containment level 2 conditions as laid out in the risk assessment and local and HSE guidelines. Written records of this training must be kept on record.

Project Ref 3230/16.1

Assessment of infectivity and recombinant gene expression by conditionally replication competent adenoviruses encoding non-pathogenic animal proteins

1-50 Litres

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
### Purposes of the contained use
To determine the ability of tumour specific adenoviruses to infect and lyse human cancer cell lines and to express reporter proteins or other non-pathogenic animal proteins encoded by the engineered virus.

### Recipient or parental organism
Human cancer cell lines e.g. A549

### Host/vector system
Adenovirus, e.g. type 5 background

### Origin & function
Genetic manipulation of the starting adenovirus background will be performed by an external contractor, who will then produce and supply purified virus particles for use in in vitro assays. Genetic manipulations will be performed in shuttle vectors before the full length viral plasmid is created. Manipulations will involve 1) deletion/disruption of one or more viral genes to confer conditional replicative ability of the virus in human cancer cells and 2) insertion of non-pathogenic animal proteins including common reporter proteins such as green fluorescent proteins.

### Evaluation of foreseeable effects
Naturally occurring adenovirus is a hazard group 2 human pathogen. Adenovirus infection is often asymptomatic. Symptomatic infection is most commonly associated with mild respiratory illness but can also cause, particularly in children or immune-compromised individuals, gastroenteritis, cystitis, conjunctivitis, bronchitis or pneumonia. Most infections are mild and require no therapy. Where required, symptomatic therapy is provided. The engineered viruses to be used carry mutation(s) to reduce replication in normal human cells whilst maintaining replicative ability in human cancer cell lines. However, it is likely that the strains will still be able to replicate to a degree in normal human cells. Inserted genes encoding non-pathogenic animal proteins will not alter the infectivity or pathogenesis of the virus. The animal proteins encoded by the virus are not endogenous human proteins but the risk to human health from expression in an individual through accidental exposure is low. Human adenovirus may be poorly replicative/infectious in certain mammalian species. The animal proteins encoded by the virus are either endogenous to all mammalian species (except humans and Old World Monkeys) or are completely harmless reporter proteins that do not affect cellular processes.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

An autoclave is not available in the laboratory or building for heat-inactivation of solid waste contaminated with GMMs, therefore the following arrangements for disposal of GMM solid waste have been made. All solid genetically modified waste (e.g. plasticware) will be removed from the laboratory in sealed bags by contractors (ParkServe) and autoclaved then incinerated at an on site waste disposal facility run by a specialist hazardous waste management contractor (Augean).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid genetically modified waste (e.g. plasticware) will be removed from the laboratory in sealed bags by contractors (ParkServe) and autoclaved then incinerated at an on site waste disposal facility run by a specialist hazardous waste management contractor (Augean). All liquid waste will be inactivated in a minimum 1% Virkon solution for at least 30 minutes before disposal via the drains. Laboratory areas where GMM work has taken place, i.e. class II microbiological safety cabinets, will be disinfected with a 1% Virkon solution at the end of each working sessions. Staff will receive full training on the handling and disposal of GMM waste.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities Y

Give brief details of the genetic modification safety committee

The Duties of the Genetic Modification Safety Committee are fulfilled by the XCellR8 Health and Safety (H&S) Committee. There is no provision within XCellR8 for a separate Genetic Modification Safety Committee at this time, due to the small size of the organisation.

The H&S Committee is comprised from members of staff from different tiers of the organisation:

- H&S Co-ordinator & Chair
- Scientific or other Director
- Laboratory Manager
- Member of the Technical Staff
- Researcher / Student (by invitation)

Operating Procedures & frequency of meetings

1. Chair invites members to a quarterly meeting to discuss H&S matters and to review either new, or current, risk assessments.
2. During the meeting the relevant risk assessments will be discussed and any amendments required will be made with the consensus of the committee, after liaison with the staff involved in drafting the original risk assessment.
3. The amended risk assessment will then be approved by the committee and circulated to all staff.

</tr>
</tbody>
</table>
The GMMs proposed for use in this study are as follows: (Also see accompanying Working Practices document).

• Disabled strains of mammalian cell lines, principally human lymphoblastoid line (TK6) and human keratinocyte cell line (KeratinoSens), ACDP Classification - Class 1

Standardised Working Procedures will be adopted when handling Class 1 GMMs, consistent with, and often exceeding, those required for Class 1 containment.

Inactivation and disposal of items contaminated with Class 1 GMMs

• All re-usable items contaminated with Class 1 GMMs, such as laboratory glassware and small pipetting troughs, will be disinfected by total immersion in freshly prepared 1% (w/v) Virkon solution (Antec International) for 24 hours (see note 1). Items will then be washed and autoclaved following standard laboratory procedures, prior to re-use (See note 2).

• All disposable items contaminated with Class 1 GMMs, such as polypropylene pipette tips, sample vials, microplates and gloves, will be sealed in small bags containing absorbent material, labelled as
'biohazard', and either inactivated via autoclave before appropriate disposal by conventional routes (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender’s contact details.

- Stock cultures of Class 1 GMMs, when no longer needed, will be sealed in small bags containing absorbent material, labelled as 'biohazard', and either inactivated via autoclave before appropriate disposal (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender’s contact details. Alternatively, larger volumes of culture can be inactivated by autoclave whilst contained within culture flasks, before appropriate disposal by conventional routes (see note 2).

Work areas will be disinfected after use using 70% ethanol / water solution (see note 3).

Spillage Containment

- Liquid spills of Class 1 GMMs on the bench or floor will be contained with absorbent paper tissue, or Virkon powder. Absorbent paper and powdered Virkon waste will be sealed in small bags containing absorbent material, labelled as 'biohazard', and either inactivated via autoclave before appropriate disposal by conventional routes (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender’s contact details. The affected floor/bench area will be disinfected with 70% ethanol/water solution (see note 3).

- Contaminated broken glass will be inactivated by total immersion in freshly prepared 1% Virkon solution for 24 hours before appropriate disposal by conventional routes (See note 1). The affected bench/floor area will be disinfected with 70% ethanol/water solution (see note 3).

Note 1: Virkon is a peroxygen compound that was found to be effective against strains of Saccharomyces cerevisiae, bacteria and viruses after 5 minutes contact time at 1% (see www.antecint.co.uk and references therein). It has minimum environmental impact and a red colour in solution indicating its activity. 99.999% degree of kill is assumed after 24 hours contact with 1% Virkon solution.

Note 2: Items sterilised, and GM cells inactivated, by autoclave are subject to a temperature of 121°C for a duration of 20 minutes. 100% degree of kill would be achieved.

Note 3: Alcohols give a very rapid kill of micro-organisms, but do not provide sustained microbial action. 99.999% kill would be achieved.

Tick to confirm that you are attaching a summary of the risk assessment [Y]  
Tick if you are claiming exemption from disclosure for sections of the risk assessment [ ]

Please enter comments of the GM safety committee on the risk assessment

All members of the current XCellR8 Health and Safety Committee were involved in the drafting of risk assessments for this work. The Committee has subsequently approved the final risk assessment as an accurate account of the risks inherent to the work and a correct description of the protocols, sufficient for safe containment and use of GMMs in these projects, within the XCellR8 laboratory. The risk assessments will be reviewed annually and as any significant variations in protocols arise.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee (GMSC) is a subcommittee of the main Biological Safety Committee (BSC). It consists of the Biological Safety Officer (BSO) and three subject matter experts. Their remit is to review the relevant risk assessments pertaining to GMMs and recommend appropriate action.

<table>
<thead>

Any liquid solutions in contact with GMMs will be hard piped from laboratories or production suites to hold tanks and subjected to sterilization by heat treatment prior to discharge. The effectiveness of the procedure will be fully validated and tested periodically. Plate counts will be used to monitor the presence of GMM in the waste. There will also be the option to remove waste by tanker should the heat treatment be incapacitated.

Disinfection will also be employed when necessary.

Any plasticware, laboratory consumables and personal protective equipment (PPE) in contact with GMMs will be autoclaved prior to disposal. Where this is not possible, they will be discarded in biohazard waste containers for incineration.

The development of bioprocesses, up to 200L in scale, using cultured mammalian cells

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The attached risk assessment was circulated to the BSO and GMSC. There were no further comments as the proposed work is not disimilar to that being undertaken at the existing CPI facility at Wilton. Safeguards and risk assessments already in place at the Wilto facility will be employed at the NBMC.
Adeno-associated viral vector (AAV) mediated therapy has some potentially interesting applications in clinical research. As the wild type virus is not associated with any diseases in humans or any other organism, its use as a vehicle to deliver functional genes into cells is very compelling. For its potential to be realised we need to develop robust and scaleable manufacturing process for the production of AAV. To do this, we need to develop analytical techniques to measure and quantify the AAV. We need to develop ways of producing the viral vector in host cells and methods of purifying the viral vector.

The work undertaken at CPI will allow these promising therapies to be further realised.

**Recipient or parental organism**

Parental organism is adeno associated virus (AAV). Parental organism will be used to infect HEK293 cells (the recipient)

**Host/vector system**

HEK293 host cells.

**Origin & function**

The genetic material of the viral vector is derived from adeno associated virus genome (145 nucleotides from the virus termini). The function is to allow the transfer of genes into host cells for therapeutic purposes. Other external genetic elements (adeno associated virus genes Rep and Cap and adenoviral genes E1, E2, E4 and Va) will allow the replication of the vector in the host cells. These genes will not be present in the replication deficient, non-pathogenic viral vector generated.

**Evaluation of foreseeable effects**

AAV is not known to cause any disease in humans. Research carried out by using wild type AAV and AAV derived vectors (rAAV) has been designated
as BSL1 by the NIH [http://osp.od.nih.gov/sites/default/files/NIH_Guidelines.html, Appendix B-I. Risk Group 1 (RG1) Agents]. The viral vector genome is significantly deleted and will be replication deficient outside specific controlled systems. Once used to transduce a cell, it is highly improbable for these viral vectors to form more transducing particles since we are using replication-deficient vectors which lack the essential gene products (supplied by plasmids/producer cells during the initial production of the particle) required to produce a novel viral vector particle. Since the viral vector plasmid shares no DNA sequence homology with the helper plasmids or the genome in the producer cells, therefore there is no likelihood of homologous recombination events resulting in reconstitution of a replication competent virus. The proposed host cell line HEK-293 is of human origin, however it is widely used in the field since 1973 without any incidents. Since the integrated DNA in the cells is of adenoviral (and not adeno associated viral) origin, any GMM resulting from this work would not contain the AAV viral elements making it more pathogenic than the wild type. All waste produced will be bagged and autoclaved prior to disposal. All viral vector and viral particles in the liquid waste will be destroyed by the addition of virkon to a final concentration of 1%. Waste will be transported in sealed and bunded containers from the lab. All research carried out will be documented. In addition, the generation of any GMOs (new viral vectors, transduced cells, etc), their storage and their destruction, will be documented.

The only likely methods of these replication deficient, non-pathogenic, viral vectors ever escaping containment are through the escape of treated animals, untreated waste or through a needle stick injury or aerosol inhalation by the laboratory workers. The laboratory personnel would be trained in the correct treatment of the waste and in the use of the viral vectors, to prevent any contamination to them. Animal models are not used at CPI. Since there is a very small likelihood that the viral vectors might, potentially, transduce laboratory workers through needle stick injuries or open wounds or as aerosols, we will limit the use to needles to procedures where they are absolutely essential [with safeguards such as double gloving and proper training], prohibit any personnel with open wounds and scratches from working with them and ensure that the personnel use masks when the vectors are taken outside the microbiology safety cabinets. We will also carry out routine analysis for the detection of potential AAV contamination of any escape routes (doors, shoes, wash basins, switches, equipment, etc) using qPCR for the viral termini.

Thus, all measures have been taken to train the personnel in the correct use of these non-pathogenic viral vectors and in their destruction. However, since they require two additional adeno-associated virus genes along with four adenovirus genes, should these replication-deficient, non-pathogenic viral vectors ever escape the laboratory, it is impossible for them to form a self-sustaining population. Even in the highly unlikely event of a needle stick injury, these vectors would be cleared by the host immune system.
## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| n/a |

## For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| n/a |

## Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| All the details about the generation, storage and/or destruction of GMOs generated in the facility will be recorded and will be available to internal and external auditors. Following the use of GMOs in a safety cabinet, clean the surface of the cabinet with 1% Chemgene, and switch on the UV (wherever available) for a minimum of an hour. Disinfection: Decontaminate work areas with 1% Virkon (for non-metallic surfaces) or 1% Chemgene (Trigene) solutions for 30 minutes. Follow with water to rinse of residue. Spill and Accident Procedures. Evacuate area, remove contaminated PPE and allow agents to settle for a minimum of 30 minutes. Initiate spill response procedure. Cover the spill with absorbent material. Starting at the edges and work towards the centre. Carefully pour disinfectant over the absorbed spill, again starting at the edges. Saturate the area with disinfectant. Allow sufficient contact period to inactivate the material in the spill. Non-viscous spills require 15-20 minutes: viscous spills require 30 minutes. Use paper towels to wipe up the spill, working from the edge to centre. Use tongs or forceps to pick up broken plastics, glass or other sharps that could puncture gloves. Discard absorbent material in Chemical waste bags. Clean the spill area with fresh paper towels soaked in disinfectant. Thoroughly wet the spill area, allow to disinfect for 15-20 minutes longer, and wipe with towels. Discard all cleanup materials (soaked with disinfectant) in Chemical bag, and any contaminated PPE in a biohazard bag. Close and secure the bags. Place bag in a second biohazard bag, secure and remove for incineration. Destruction of GMOs: Cells transduced with GMOs will be exposed to 1% Virkon for an hour (alternatively, the flasks/dishes can be bagged and autoclaved) before disposed. Fluids/containers in contact with GMOs (cell culture medium, PBS, etc) will be made up to 1% Virkon and left for an hour prior to disposal. Gloves that come in contact with GMOs will be sprayed with 1% Chemgene and binned. Sealed samples of GMOs (vials) will be sterilised by autoclaving. Bacteria and flasks (used for transformation of GMO plasmids) would be destroyed either by the process (plasmid preparation) or with a final concentration of 1% Virkon. The facility is provided the capability for Vaporised Hydrogen Peroxide decontamination of the room. |

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste will be disposed of via the Babraham waste disposal derogation GM1 05/04.1 which states that "Liquid Waste is inactivated by the addition of "Virkon" according to the manufacturer's instructions prior to disposal to the drainage system. Waste from laboratories carrying out GM work at Class 1 and Class 2 will be placed into suitably labelled hermetically sealable bins. The bins are 60 litre UN approved to Class 3 Type 3H21Y30/S/2003. They will be sealed by the producer of the waste and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections by the local registered clinical /GM waste incinerator contractor (VetSpeed) will be made three times a week to prevent a build-up. The site has 24/7 security.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

- [Y]

Give brief details of the genetic modification safety committee

GMSC includes the Facilities and EHS Manager, Biological Safety Officer and Microbiological and Molecular Biologists and Cell Culture Scientists, all with experience of working at activity class 1 and 2. Collectively many decades worth of experience in similar organisations undertaking preclinical research and development. Where additional support is required the staff needed will be added/adapted to allow for the most relevant expertise and input. External advice from H&S Consultant/Biosafety Practitioner will be contracted on an ad hoc basis where necessary to supplement internal expertise if required.

The committee will meet every 4 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the initial risk assessments.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Briefly, Liquid waste will be disinfected using a minimum of 1% Virkon or other suitable alternative for the specified contact time, or by autoclaving (with/without prior chemical inactivation). Solid waste contaminated with GMMs will be autoclaved on site, prior to uplift for secondary inactivation (incineration). Surfaces potentially in contact with GMMs will be cleaned routinely using 1% virkon, 70% Ethanol or other commercial disinfectant. SOPs govern all working practices and emergency procedures. All equipment is maintained and checked / validated at regular intervals, including autoclaves. SOPs govern all working practices, and all equipment is maintained and checked / validated at regular intervals, including autoclaves.

**Tick to confirm that you are attaching a summary of the risk assessment**

 Tick if you are claiming exemption from disclosure for sections of the risk assessment  

**Please enter comments of the GM safety committee on the risk assessment**

The GMSC has reviewed all of the Health & Safety Implications of the proposed work. We have not identified any risks that are greater than working with non-GM versions of the species.
Each cell line will be risk assessed prior to acceptance on site.
We unanimously believe that the research should be classified as Containment Level 1.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
**Purposes of the contained use**

Evaluation of the safety and efficacy of a recombinant HVT vaccine in broiler chickens under semi-commercial conditions required as part of the registration package.

**Recipient or parental organism**

The HVT parent strain is FC-126

**Host/vector system**

None

**Origin & function**

Herpesvirus of turkeys (HVT) expressing the following genes:
1. The F gene of Newcastle disease virus and
2. The VP2 gene of infectious bursal disease virus (IBVO)

These genes have the following functions within the native viral particle:

- **NOV F** protein is an envelope glycoprotein required for virus cell fusion and is important for vaccine induced immunity.
- **VP2** protein is a major structural protein and the host protective immunogen of IBOV.

The expression of these gene products from the recombinant HVT will serve as vaccines that should induce protective immunity in vaccinated poultry against the original virus whose gene is expressed.

**Evaluation of foreseeable effects**

<table>
<thead>
<tr>
<th>Hazards to human health:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i) Hazards associated with the recipient microorganisms (e.g. bacterial host or viral vector)</td>
</tr>
</tbody>
</table>

HVT is currently classified in the subfamily of alphaherpesvirinae, and is also known as MeJeagrid herpesvirus 1, turkey herpesvirus, or Marek's disease virus serotype 3. The virus was first described around 1970 as a herpesvirus infecting turkeys and sharing antigenic features in common with Marek's disease virus (MDV). Whilst MDV is highly pathogenic for chickens, HVT is non-pathogenic and could therefore be used for effective vaccination against infection and disease caused by MDV (Okazaki et al., 1970, Avian Diseases, vol. 14, p. 413-429). Since then, vaccination of chickens against MDV by using HVT has become part of the standard vaccination program of billions of chickens produced worldwide every year.

The HVT virion has all the features of a typical herpesvirus, and is about 160nm in size in its enveloped form. It possesses a large genome (approximately 159 kb) comprising linear double stranded DNA. The HVT genome has a long history of manipulation; in particular its non-pathogenic properties have led to research into the use of HVT as a viral vector for expression and delivery of various proteins to the chicken. Examples are the expression of genes coding not only for antigens from other poultry pathogens such as: infectious bursal disease virus (IBDV) (Darteil et al., 1995, Virolology, vol 21, p. 481-490), Newcastle disease virus (NOV) (Sondermeijer et al., 1993, Vaccine, vol. 11, p. 349-358) and avian influenza (U et al., 2001, Vaccine, vol. 29, p. 8257-8266). But also the expression has been described of a parasite antigen (Cronenberg et al., 1999, Acta Virol., vol. 43, p. 192-197), or of a cytokine, to manipulate the chicken's immune response (NO 2009/156, 367; Tarpey et al., 2007, Vaccine, vol. 25, p. 8529-8535).

Such work has led to the development of commercial vaccines using such technology, including the Vaxxitech product range (Meria), the Vectormune HVT product range (Ceva) and the Innovax product range (Merck Animal Health), thus providing convincing data in a large number of birds of the safety of HVT vectored IBO and ND vaccines. Therefore there are no perceived hazards associated with the recipient microorganism.

(ii) Hazards arising directly from the inserted gene product (e.g. cloning of a toxin or oncogene)
The fusion (F) protein in NOV is involved in attachment and entry into host cells and is the major antigen responsible for immunity against NOV infection. It is also a determinant for virulence based on the presence of a basic Cleavage site which is typically present in high virulence field strains such as Herts 33/56. The gene encoding the fusion protein of NOV was however originally cloned from a lentogenic NOV vaccine strain (Clone 30) which does not contain this basic cleavage signal.

VP2 protein is a major structural protein and the host protective immunogen of IBDV. The VP2 gene is derived from a virulent classic type of IBOV field strain. Overall the risk of hazards arising directly from the inserted gene products is considered low.

(iii) Hazards arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response)

HVT is a non-pathogenic alpha herpesvirus with a host range restricted to chickens and turkeys. The F protein of NOV is a typical membrane anchored glycoprotein containing a secretion signal, it is likely to be expressed only partially at the surface of HVT/F infected cells. NOV has been associated with mild conjunctivitis and influenza-like symptoms in man and it is therefore possible that the presence of the F protein in the virus envelope could result in transmission to man. HVT however is typically cell associated and does not generate enveloped viral particles in the supernatant of infected cultures such as is seen with most other herpesviruses, although infectious cell-free virus has been detected in the feather dust of chickens vaccinated with HVT. The VP2 protein of IBDV does not have features like a signal sequence or transmembrane anchor region as is found with the F protein from NOV or most of the glycoproteins from herpesviruses and is therefore not expected to be exposed on the cell surface.

Therefore overall the risk of hazards arising from alteration of the existing traits of the HVT vector is considered low.

(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms

The HVT backbone of the HVT-ND-IBD construct has been modified by the insertion of fragments containing the NOV F and IBDV VP2 genes and their associated promoter sequences. There have been no gene deletions. The phenotype of the recombinant strain is therefore the same as that of the HVT backbone. If the inserted fragments were to be lost, this would result in the wild type HVT, which is also avirulent. There have never been reports of the recombination of HVT with other related herpesviruses of poultry, e.g. virulent (serotype 1) MDV or serotype 2, and the possibility of recombination with a virus capable of infecting humans is therefore considered extremely small. Genetic transfer to other organisms in the environment has never been described for herpesviruses, and is therefore considered to be unlikely.

Hazards to the environment:

(i) Hazards associated with the recipient microorganisms (e.g. bacterial host or viral vector)

The host range for HVT is limited to avian species and replication does not occur in mammals. Furthermore HVT is non-pathogenic in all avian species tested and in consequence would be classified as ACDP hazard group 1. In laboratory studies the parent HVT strain has been shown to replicate in chickens and turkeys but not in ducks or pigeons after direct inoculation. The natural route of infection is via inhalation of feather follicle dust. The shed and spread capability of the HVT ND-IBD construct is expected to be similar to its parent HVT. Shedding of HVT from inoculated chickens is of low level and sporadic in nature (Zygraich and Huygelen 1972, Avian Diseases, 16: 793-798; Cho, 197 1, Poultry Science, 50: 881-887; Cho, 1974, Avian Diseases, 19: 136-141; Cho, 1976, Poultry Science, 55, 1830-1833). Further, the inserted genes provide no competitive advantage for the GMO and it is anticipated, based on similar constructs, that replication efficiency will be reduced, with no significant spread observed between chickens. HVT is endemic and ubiquitous in domestic turkeys so the likelihood of spread in turkeys is also potentially constrained by prior immunity. There are therefore no perceived environmental hazards arising from recipient organism.
(ii) Hazards arising directly from the inserted gene product (e.g. cloning of a toxin or oncogene)
The fusion (F) protein in NOV is involved in attachment and entry into host cells and is a major determinant for
virulence based on the presence of a basic cleavage site which is typically present in high virulence field strains such as
Herts 33/56. It is also the major antigen responsible for immunity against NOV infection. The gene encoding the
fusion protein was however originally cloned from a lentogenic NOV vaccine strain (Clone 30) which does not contain
this basic cleavage signal.
VP2 protein is a major structural protein and the host protective immunogen of IBDV. The VP2 gene is derived from a
virulent classic type of IBDV field strain. Overall the risk of environmental hazards arising directly from the inserted
gene products is considered low.
(iii) Hazards arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism)
HVT is a non-pathogenic alpha herpesvirus with a host range restricted to chickens and turkeys. The HVT virion has
all the features of a typical herpesvirus, it is about 160 nm in size in its enveloped form and possesses a large
genome (approximately 159 kb) comprising linear double stranded DNA. Key proteins for interaction with host cells
are glycoproteins inserted in the viral envelope. In cell culture HVT does not produce enveloped viral particles
however infectious cell-free virus has been detected in the feather dust of chickens vaccinated with HVT. The gene
encoding the fusion protein was originally cloned from a lentogenic NOV vaccine strain (Clone 30) which does not
contain the basic cleavage signal. Since F is a typical membrane anchored glycoprotein containing a secretion signal,
it is likely to be expressed at least partially at the surface of HVT/F infected cells although this has not been confirmed
by immunofluorescence staining using F-specific antibodies. Any effect on virulence of an HVT recombinant is very
unlikely since the vector is proven to be non-pathogenic and the inserted F gene originates from a non-virulent NOV
strain. This conclusion has meanwhile been confirmed in many laboratory studies as well as years of experience with
the commercial product Innovax-NO that contains the HVT/F vector strain. The VP2 protein does not have features
like a signal sequence or transmembrane anchor region such as F from NOV or most of the glycoproteins from
herpesvirus and is therefore not expected to be exposed on the cell surface. Commercial vaccines using recombinant
HVT technology, including the Vaxxitech product range (Merial), the Vectormune HVT product range (Ceva) and the
Innovax product range (Merck Animal Health), have been available for many years with no adverse effects reported,
thus providing convincing data in a large number of birds of the safety of HVT vectored IBO and NO vaccines. Overall
the risk of environmental hazards arising directly from the alteration of existing traits is considered low.
(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms
The HVT backbone of the HVT-NO-IBD construct has been modified by the insertion of fragments containing the NDVF
and IBDV VP2 genes and their associated promoter sequences. There have been no gene deletions. The
phenotype of the recombinant strains is therefore the same as that of the HVT backbone. If the inserted fragments
would be lost, this would result in the wild type HVT, which is also avirulent.
The potential for recombination of the HVT recombinants with virulent Marek's Disease virus would be no greater than
can occur with current vaccines containing HVT. HVT is commonly present in vaccinated chickens that become
"superinfected" with virulent MDV. Furthermore, serotype 3 (HVT) is often given with serotype 2 and/or serotype 1
strains as a polyvalent vaccine. As there have never been reports on the recombination of HVT with either the
virulent (serotype 1) MDV or serotype 2, this possiblity can be considered extremely small. Genetic transfer to other
organisms in the environment has never been described for herpes viruses, and is therefore considered to be unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(i) Animal carcasses, bedding and waste from animal accommodation will be bagged and sealed. The surface of these bags will then be disinfected with Virkon S as per manufacturers instructions for Mareks disease (1:200) before bags are stored in a sealed clinical waste skip and/or burn bins, prior to being sent off site for incineration by a licensed contractor.
(ii) The room and all equipment will be sprayed with Virkon S as per manufacturers instructions for Mareks disease. Following the appropriate contact lime, equipment will be cleaned, allowed to dry and placed in storage. The room will be steam cleaned, disinfected again and left to dry as per the local SOP for biosecurity.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

This study and its associated risk assessments have been reviewed by the GMSC and has been categorised as class 2.

Project Ref 3240/16.1

Date Ackn’d 28/04/2016  
CU2 Project Title To evaluate the efficacy and safety of a live Salmonella vaccine for use in chickens to aid in preventing infection and colonisation by Salmonella enterica  
Date Project Ceased  
Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Liter
Non-GMM Consent Granted
### Project Additional Information

#### Purposes of the contained use

To generate data suitable for use in licensing a live Salmonella vaccine for use in chickens.

#### Recipient or parental organism

- Salmonella enterica of serogroups B, C, 0 and E typically
- S. Enteritidis
- S. Typhimurium
- S. Anatum
- S. Hadar
- Other serogroup representative serovars may be used.

#### Host/vector system

None

#### Origin & function

- Salmonella enterica of serogroups B, C, 0 and E typically
- S. Enteritidis
- S. Typhimurium
- S. Anatum
- S. Hadar
- Other serogroup representative serovars may be used.

#### Evaluation of foreseeable effects

Hazards to human health:

1. Hazards associated with the recipient microorganisms (e.g. bacterial host or viral vector)
   - Salmonella infection may cause acute gastroenteritis with sudden onset of abdominal pain, diarrhoea, nausea and vomiting.
   - The routes of infection may be ingestion or parenteral inoculation; the importance of aerosol exposure is not known.
   - The infectious dose varies with the susceptibility of the host, the strain of the organism and the form of ingestion. The infectious dose was thought to be > 10^5 in healthy individuals, but outbreaks caused by chocolate and egg borne organisms suggests that the dose may be as low as 1 - 100 organisms.
Salmonella infections usually resolve in 5-7 days and often do not require treatment unless the patient becomes severely dehydrated or the infection spreads from the intestines.

(ii) Hazards arising directly from the inserted gene product (e.g. cloning of a toxin or oncogene)

Not applicable

(iii) Hazards arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response)

None foreseeable.

None foreseeable.

(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms

The genes are only mobilisable by transducing phage or recombination. In the unlikely event of this happening the receiving strain would lose its ability to produce flagellin and or survive in vivo. This would not be considered as having the potential to increase its virulence.

Hazards to the environment:

(i) Hazards associated with the recipient microorganisms (e.g. bacterial host or viral vector)

The recipient organisms were originally isolated from poultry although Salmonella enterica strains of these serovars are not normally a pathogen for poultry. However, they may be capable of infecting other, more susceptible species and must be considered as being still capable of surviving in the environment.

(ii) Hazards arising directly from the inserted gene product (e.g. cloning of a toxin or oncogene)

Not applicable.

(iii) Hazards arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism)

None foreseeable.

(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms

The genes are only mobilisable by transducing phage or recombination. In the unlikely event of this happening the receiving strain would lose its ability to produce flagellin and or survive in vivo. This would not be considered as having the potential to increase its virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

In a facility where class 2 work is undertaken it is a legal requirement to have an autoclave in the building. There is an autoclave on site in the laboratory, however there is not an autoclave in each specific animal accommodation building. For this project no requirement for an autoclave in the animal accommodation is forseen and we therefore request a derogation from this requirement.

Waste on this project from the animal accommodation will be managed as follows:

There will be dedicated PPE (gloves, overalls, hairnets, wellies) in rooms containing vaccinated birds, when not being used these will be kept in lockers with in those rooms to prevent contamination with dust. PPE except wellies will be disposable. Wellies will be washed and disinfected with Virkon S 1 % prior to being removed from the room. Waste will only leave the room(s) in sealed, disinfected bags (with Virkon S) or sharps boxes and be placed in burn bins.

Animals will be euthanased with in the rooms and carcasses double bagged, bags will then be disinfected and removed from the rooms and placed in burn bins.

At study end, waste material will be double bagged, bags will then be disinfected and removed from the rooms.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(i) Solid and liquid waste including animal carcasses, bedding and laboratory waste will be placed in suitable containers as applicable and then bagged in clinical waste bags. The surface of these bags will then be disinfected with a Virkon S at 1% before bags are stored in a sealed clinical waste skip and/or burn bins, prior to being sent off site for incineration by a licensed contractor.

(ii) The room and all equipment will be sprayed with Virkon S at 1% which will be allowed contact time of at least 12 hours. Following the appropriate contact time, equipment will be cleaned, allowed to dry and placed in storage. The room will be steam cleaned, disinfected again and left to dry as per the local SOP for biosecurity.

(iii) Re-usable glassware will be decontaminated by autoclaving using a validated cycle before cleaning.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

This study and its associated risk assessments have been reviewed by the GMSC and it has been categorised as Class 2.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste that is potentially contaminated with the GMOs will be de-contaminated over night in disteland disposed of as clinical waste by SRCL for incineration. This procedure is well established at XenoGesis for non-GMO clinical waste. Due to the fragile nature of animal cells outside the body and outside controlled environment (37C, humidified atmosphere, in specific culture media etc) and because distel and its predecessor, Trigene are well established for this purpose, assessment of the disinfection efficiency is considered unnecessary.

The person suggested the following:

- Treatment of GMO waste with Distel which was the approved procedure in previous employment.
- Use of a biological safety class II cabinet for all cell culture manipulations.
- It was discussed that the planned work using cell lines commercially available from reputable sources is class 1
- Waste from the lab should be removed frequently.
- It was discussed that the negative air pressure in premises used for GMO's class 1 is not necessary.

## Premises Conditions

**Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities**

Y

**Give brief details of the genetic modification safety committee**

Originally registered jointly with Immunocore Ltd as GM centre no. 742, Adapimmune Ltd established its own independent Biological and Genetic Modification Safety Committee (GM centre no. 3242) in 2014 when both companies separated. The Committee conducts its business both electronically and in regular and ad hoc meetings. The Committee's main remit is to provide guidance on safe and compliant working practices with biological materials proposed within the company and to review and approve biological and genetic modification risk assessments.

The Committee currently consists of 7 Adapimmune Ltd members:

Chairman of the Committee (Head of Platform Research Group)
Biological Safety Officer
Health and Safety Officer
Four additional representatives from a selection of main laboratory groups
First activity will be class II, therefore see activity notification form CU2

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

n/a
The primary aim of this work is to generate T cells expressing wildtype or engineered T cell receptors with specificities to the following cell types:

a) Cells expressing cancer antigens, including but limited to, NY-ESO, gp100 and MAGE A3.
b) Cells expressing viral epitopes from viruses, including but not limited to, human immunodeficiency virus (HIV), cytomegalovirus (CMV), Epstein Barr Virus (EMV) & human papilloma virus (HPV).
c) Cells expressing putative-immune disease antigens or in graft rejection antigens. The auto-immune diseases to be studied include but are not limited to diabetes mellitus type 1, rheumatoid arthritis, autoimmune hepatitis, & multiple sclerosis.

The T cells will also express reporter genes that allow for the selection of transformants and subsequent detection in immunological assays. These include but are not limited to: Green Fluorescent Protein (GFP), Red Fluorescent Protein (RFP), dsRED and/or luciferase genes.

The secondary aim of this work is to generate antigen presenting cells (APCs) carrying the relevant HLA to allow specific antigen presentation for testing the potency and safety of the T cells engineered to express the TCRs above.

The lentivirus system would allow us to derive T cell clones stably expressing the TCR of interest, or T cells transiently expressing these genes. T cell clones expressing ectopic TCR would be used in cellular assays to test antigen specific response, including using the APCs produced above.

Recipient or parental organism

The recipient cells will be:

a) Human T cells not derived from the blood of the user.
b) Fully characterised cell lines, including but not limited to HEK293T, Jurkat and SupT1 cell lines.

The work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents and will be non-self cell lines that will not be able to colonise those involved with the work. Indirect hazards to human health associated with possible adventitious agents have been considered separately in a general Risk Assessment relating to work with human derived materials. All human derived samples are treated as though capable of causing disease.

Host/vector system

Two types of vectors will be used:

Type A:
Commercially acquired vectors, typically third (or sometimes fourth) generation Lentiviral expression systems including but not limited to:
ViraPower lentiviral Expression systems sold by Invitrogen Ltd. The vectors are: pLenti6iVs-Directional TOPO, pLenti6.2-GW/EniGFP, pLP1, pLP", and pLP/VSVG plasmids.
Lenti-X lentiviral Expression systems sold by Clontech Laboratories, Inc. The vectors include: pLVX-Puro, pLVXDsRed-Monomer-CI, Lenti-X FIT packaging system.

Type B
Vectors constructed by our academic collaborators e.g. University of Pennsylvania (Upenn).
These will typically be third generation type systems including but not limited to:
Vectors obtained from 'University of Pennsylvania; Upenn': Lentiviral vector derived from the 'Dull' vector (Dull et al. J Viral 1998), and 3 packaging plasmids (gag/pal, rev, VSVG envelope) similar to that used by Zufferey (Zufferey et al, Nat Biotech 1997)

These Lentiviral Expression Systems are third or fourth generation lentivirus systems. The lentivirus can infect mammalian cells but cannot replicate in these cells. These systems include some or all of the following safety features:
1. Expression vectors containing a deletion of the 3' LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell, Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a viral particle.
2. The number of HIV-1 genes that are used in the system has been reduced to three or four only: gag, pol, tat and sometimes rev.
3. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope gene (env)
4. Genes encoding the structural and other components required for packaging the viral genome are separated onto multiple plasmids. These plasmids have been engineered not to contain any homology regions to prevent recombination events.
5. Although the plasmids allow expression in trans of proteins to produce lentivirus progeny in producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are present in the packaged viral genome and are thus never transduced in the target cell. No new replication-competent virus can be produced.
6. The lentiviral particles produced in these systems are replication-incompetent and only carry the genes of interest.
7. Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript.

Any T cells transduced using these vectors would only present a potential hazard to the original T cell donor. Transduced T cells and derived T cell clones will not be derived from the blood of any personnel working in Adaptimmune's Cell Biology laboratories thus removing this potential hazard.

Origin & function

Reporter genes such as GFP, RFP and luciferase have been used in various transgenic animal systems and have been shown to have no harmful effects on the organisms.
The TCR gene inserts encode for proteins known to be functionally expressed by T cells only, as they require the presence of cellular CD3 proteins only found in T cells. Expression of TCRs by cells other than T cells renders the TCR non-functional. In the case of cancer and viral epitope-specific TCR genes, their expression in T cells
should only induce a response to cells expressing tumour antigens or viral antigens (including virally infected cells).

TCR genes specific for putative auto-antigens or self antigens do present a hazard to the worker performing the work but only if the worker's own T cells were transfected to express the genes. This could result in T cells that would target normal tissue and would not be recognised by the workers immune system as non-self. For this reason, the use of self cells is strictly prohibited.

HLA is expressed by the majority of human cells and confers no harmful properties.

**Evaluation of foreseeable effects**

The hazards to workers and the environment posed by the vector with insert are considered negligible due to the containment level II measures employed. All work will be carried out in purpose-built, access-controlled laboratories. Skin contact with the organisms or the transfected cells will be avoided by minimising aerosols (by working in a Class II biosafety cabinet), and by use of gloves and safety glasses. If a worker does accidentally infect themselves with the virus, in all likelihood it will be rapidly destroyed by the workers' immune system. The routine procedures employed (e.g., autoclaving or chemical inactivation of all cellular material prior to disposal) will ensure an adequate level of safety.

In the extremely unlikely event of transfected T cell clones gaining entry to the worker, the cells in all likelihood would be rapidly destroyed by the workers' own immune system by virtue of being "non-self" HLA mis-matched cells (i.e. similar to the immune rejection of non-matched transplant tissue).

Transfected mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, temperature, and nutrient conditions.

Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein-buffered media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus cannot replicate and so the consequences of escape are considered negligible, therefore risk is effectively zero. Infected mammalian cells are not able to establish themselves and spread in nature and the vectors selected are either disabled or attenuated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This solid waste and the majority of the liquid waste generated during this procedure will be collected in specialised containers and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Registration Number; NAAo5o. The autoclaved solid waste will be disposed of via incineration through an appointed specialist waste management company; Grundon Waste Management Limited. Autoclaved liquid waste will be disposed of through a sink to public sewer. Any remaining liquid waste will be treated with an over-kill concentration Virkon (2% final wt/vol) or 10% ChemGene according to the manufacturers instructions (DuPont/MediMark Scientific for which independent validated efficacy against retrovirus exists.

**Is an emergency plan required according to regulation 20?**

### Project Ref 3242/16.1

- **Date Ackn’d:** 21/04/2016
- **CU2 Project Title:** Expression of TCRs and reporter genes in pluripotent human Embryonic Stem (ES) cells and in ES-derived differentiated T cells
- **Class:** Class 2
- **CultureVol:** 1-50 Litres

### Project Additional Information

**Purposes of the contained use**

The primary aim of this work is to generate human T cells derived from ES cells that express native or engineered T cell receptors with recognition specificities to the following cell types:

1. Cells expressing cancer antigens, including but not limited to, NY-ESO and other cancer antigens expressed in cancer cells.
b) Cells expressing viral epitopes from viruses, including but not limited to, human immunodeficiency virus (HIV),
cytomegalovirus (CMV), Epstein Barr Virus (EMV) & human papilloma virus (HPV).
c) Cells expressing putative-immune disease antigens or in graft rejection antigens. The auto-immune diseases to be
studied include but are not limited to diabetes mellitus type 1, rheumatoid arthritis, autoimmune hepatitis, & multiple
sclerosis.
(Similar work with non-ES cells has previously been submitted and approved under reference: GM3242/14.1 entitled
“Lentivirus carrying genes encoding for T Cell Receptors, HLA and marker molecules”).
The modified ES cells will also express non-pathogenic genes that allow for the detection and/or selection of
transformants and/or subsequent analysis in immunological assays. These include but are not limited to: Green
Fluorescent Protein (GFP), Red Fluorescent Protein (RFP), tdTomato Red and/or luciferase and/or puromycin
resistance genes.

Recipient or parental organism

The recipient cells will be:
Human ES cells and several derived cell lineages resulting from biological treatment regimes designed to differentiate
these ES cells into what are ultimately stable T cells.
The ES progenitor cells will have been genetically-modified prior to receipt and use by Adaptimmune (details of these
modifications are included in Section 17). These stable genetic modifications are designed to reduce allogeneic
rejection by the host immune system. Where appropriate, these GM ES cells will have also been gene modified prior
to Adaptimmune's use by the inclusion of cell fate "suicide genes" which provides an additional measure of safety
against immune tolerance in vivo. These genetically-modified ES cells do not produce any viruses (GM or otherwise).
The work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of
our knowledge, free of adventitious agents.

Host/vector system

Two types of lentivectors will be used to transduce the previously-modified ES cells at Adaptimmune (as previously
described in GM3242/14.1):

Type A:
Commercially acquired third (and fourth) generation lentiviral systems including but not limited to:
ViraPower Lentiviral Expression systems sold by Invitrogen Ltd. The vectors are: pLenti6N5-Directional TOPO,
pLenti6.2-GW/EmGFP, pLP1, pLP2, and pLPNSVG plasmids. Lenti-X Lentiviral Expression systems sold by Clontech
Laboratories, Inc. The vectors include: pLVX-Puro, pLVX-DsRed-Monomer-C1 , Lenti-X HT packaging system.

Type B.
These are third generation type systems, including but not limited to: lentiviral vectors derived from the 'Dull' lentiviral
vector transgene plasmid (Dull et al. J Viral 1998), and its three packaging plasmids, e.g. pMDLgpRRE (gag/pol),
 pRSV-rev (rev) and pMDG.1 (VSVG envelope) or Adaptimmune pCI-VSVG (VSVG envelope), and other systems
similar to that used by Zufferey et al., (Zufferey et al, Nat Biotech 1997).
The WPRE region (which contains the potentially oncogenicX-protein gene sequence) of the recombinant lentiviral
vector genome has been removed.
The above Lentiviral Expression Systems are third or fourth generation replication-defective lentiviral vector systems.
The lentiviral vector particles can infect mammalian cells but cannot replicate in these cells. These systems include
the following safety features:
1. The number of HIV-1 genes that are used in the system has been reduced to three or four only: gag, pol and rev
with or without tat.
2. The VSV-G envelope gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein (env) thus
reducing the chance of creating an HIV-1 virus.
3. Genes encoding the structural and enzymes required for packaging the viral genome are separated into multiple plasmids and does not contain L TR or packaging signal sequences. All three/four plasmids have been engineered to contain minimal homology regions. This reduces the chance for homologous recombination events to occur which may lead to the formation of an HIV-1 virus.
4. The lentiviral particles produced in these systems are replication-incompetent and only express the transgene. The integrated lentiviral genome is no longer capable of producing a viral particle simply because it only contains a small portion of the HIV gag structural gene and the transgene. It requires the presence of at least the whole HIV gag-pol polygene and the HIV env gene within the two L TRs in order to produce a viral particle.
5. The transgene cassette contains a deletion of the 3' L TR (U3) to remove the promoter/enhancer element that does not affect generation of the viral genome in the producer host cell line, but results in a "self-inactivation" of the lentiviral vector after transduction of the target cell. Once integrated into the transduced target cell, there is no promoter/enhancer element present in both L TRs to transcribe any gene downstream.

Origin & function

The pre-modified ES cells will contain several knockout mutations and the ectopic expression of non-classical HLA genes that separately and together will cause a stepwise increased reduction in the potential for recognition and rejection by the immune system. ES cells will also be modified to include selection genes (e.g. puromycin selection) All genes expressed are synthetic genes codon-optimised for expression in mammalian cells. Where relevant, the risks to the workers associated with these host immunity reduction modifications will be removed by the prior inclusion of cell fate "suicide" genes so that these cells can be selectively killed by the administration of approved small molecule drugs that selectively activate intracellular death pathways. The TCR genes to be used encode for proteins known to be functionally expressed by T cells only, as they require the presence of cellular CD3 proteins which are only found in T cells. Expression of TCRs by cells other than T cells renders the TCR non-functional. In the case of cancer and viral epitope-specific TCR genes, their expression in T cells should only induce a response to cells expressing tumour antigens or viral antigens (including virally-infected cells).

Reporter genes such as GFP, RFP and luciferase have been used in various cellular and transgenic animal systems and have been shown to have no harmful effects on the organisms.

Evaluation of foreseeable effects

The hazards to workers and the environment posed by the vector with insert are considered negligible due to the containment level II measures employed. All work will be carried out in purpose-built, access-controlled laboratories. Skin contact with the organisms or the transfected cells will be avoided by minimizing aerosols (by working in a Class II biosafety cabinet), and by the use of gloves and safety glasses. The use of sharps during procedures is prohibited. The routine procedures employed (e.g., autoclaving or chemical inactivation of all cellular material prior to disposal) will ensure an adequate level of safety. Transfected mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, temperature, and nutrient conditions. Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein-buffered media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus cannot replicate and so the consequences of escape are considered negligible, therefore risk is effectively zero. Infected mammalian cells are not able to establish themselves and spread in nature and the vectors selected are either disabled or attenuated.

Although the aims of the project are to confer immunological avoidance properties to the ES cells, modifications will
be added in a logical step-wise manner, with the addition of safety systems such as suicide genes prior to the knockout of molecules that would normally allow the hosts immune system to recognise and destroy the ES cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
The primary aim of this work is to generate human T cells derived from iPS cells that express native or engineered T cell receptors with recognition specificities to the following cell types:

a) Cells expressing cancer antigens, including but not limited to, NY-ESO, gp100 and MAGE A3.
b) Cells expressing viral epitopes from viruses, including but not limited to, human immunodeficiency virus (HIV), cytomegalovirus (CMV), Epstein Barr Virus (EMV) & human papilloma virus (HPV).
c) Cells expressing putative-immune disease antigens or in graft rejection antigens. The auto-immune diseases to be studied include but are not limited to diabetes mellitus type 1, rheumatoid arthritis, autoimmune hepatitis, & multiple sclerosis.

The modified iPS cells will also express non-pathogenic reporter genes that allow for the selection of transformants and subsequent detection in immunological assays. These include but are not limited to: Green Fluorescent Protein (GFP), Red Fluorescent Protein (RFP), dsRED and/or luciferase genes.

(This work expands on embryonic stem cell work previously submitted and approved under reference GM3242/ entitled "The use and genetic modification of human embryonic stem cells")

The recipient cells will be:
Human iPS cells and several derived cell lineages resulting from biological treatment regimes designed to differentiate these iPS cells into what are ultimately stable T cells.

The iPS progenitor cells will be generated by an external company using somatic cells derived from healthy donor tissue (e.g. peripheral blood/cord blood). Somatic cells will be reprogrammed using a combination of transcription factors (e.g. OCT3/4, SOX2, c-MYC, KLF4, NANOG and LIN28). Gene delivery systems to induce reprogramming of somatic cells could include: Adenovirus mediated transduction, sendai virus mediated transduction, mRNA transfection or episomal transfection. Vectors used in the reprogramming phase should not persist beyond a few cell passages. For added safety, vector clearance will be demonstrated and confirmed prior to release of iPS cells to Adaptimmune or external collaborators.

Genetic modification of iPS cell lines will be conducted by our collaborator Universal Cells prior to use by Adaptimmune. A recombinant adeno-associated virus delivery system will be used to knock-out (RFXANK, RAG and beta-2 microglobulin) and knock-in (HLA-E and TCR) genes. These stable genetic modifications are designed to reduce allogeneic rejection by the host immune system. Where appropriate, these GM iPS cells will have also been gene modified prior to Adaptimmune's use by the inclusion of a cell fate "suicide gene" which provides an additional measure of safety against immune tolerance in vivo. These genetically-modified iPS cells do not produce any viruses (GM or otherwise).

The work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents.

### Host/vector system

Two types of lentivectors will be used to transduce the modified iPS cells:

**Type A:**
- Commercially acquired vectors, typically third (or sometimes fourth) generation Lentiviral expression systems including but not limited to:
  - ViraPower Lentiviral Expression systems sold by Invitrogen Ltd. The vectors are: pLenti6/Vs-Direction TOPO, pLenti6.2-GW/EnIgFP, pLP1, pLP2, and pLP/VSVG plasmids.
  - Lenti-X Lentiviral Expression systems sold by Clontech Laboratories, Inc. The vectors include: pLVX-Puro, pLVXDsRed-Monomer-Cl, Lenti-X FIT packaging system.

**Type B:**
- Vectors constructed by our academic collaborators e.g. University of Pennsylvania (UPenn).
  - These will typically be third generation type systems including but not limited to:
    - Vectors obtained from 'University of Pennsylvania; UPenn': Lentiviral vector derived from the ‘Dull’ vector (Dull et al. J Viral 1998), and 3 packaging plasmids (gag/pal, rev, VSVG envelope) similar to that used by Zufferey (Zufferey et al, Nat Biotech 1997)

These Lentiviral Expression Systems are third or fourth generation lentivirus systems. The lentiviruses can infect mammalian cells but cannot replicate in these cells. These systems include some or all of the following safety features:

1. Expression vectors containing a deletion of the 3’ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a viral particle.
2. The number of HIV-I genes that are used in the system has been reduced to three or four only: gag, pol, tat and sometimes rev.
3. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-I envelope gene (env).
4. Genes encoding the structural and other components required for packaging the viral genome are separated onto multiple plasmids. These plasmids have been engineered not to contain any homology regions to prevent recombination events.
5. Although the plasmids allow expression in trans of proteins required to produce lentivirus progeny in producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-I structural genes are present in the packaged viral genome and are thus never transduced in the target cell. No new replication-competent virus can be produced.
6. The lentiviral particles produced in these systems are replication-incompetent and only carry the genes of interest.
7. Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-I RRE in the gag/pol mRNA transcript.
### Origin & function

The pre-modified IPS cells will contain several knockout mutations and the ectopic expression of non-classical HLA genes that separately and together will lead to a stepwise reduction in the potential for recognition and rejection by the immune system. IPS cells will also be modified to include selection genes (e.g., puromycin selection). All genes expressed are synthetic genes codon-optimised for expression in mammalian cells.

Where relevant, the risks to the workers associated with these host immunity reduction modifications will be removed by the prior inclusion of cell fate "suicide" genes so that these cells can be selectively killed by the administration of small molecules that selectively activate intracellular death pathways.

The TCR gene to be used encode for proteins known to be functionally expressed by T cells only, as they require the presence of cellular CD3 proteins which are only found in T cells. Expression of TCRs by cells other than T cells renders the TCR non-functional. In the case of cancer and viral epitope-specific TCR genes, their expression in T cells should only induce a response to cells expressing tumour antigens or viral antigens (including virally-infected cells).

Reporter genes such as GFP, RFP, and luciferase have been used in various cellular and transgenic animal systems and have been shown to have no harmful effects on the organisms.

### Evaluation of foreseeable effects

The hazards to workers and the environment posed by the vector with insert are considered negligible due to the containment level II measures employed. All work will be carried out in purpose-built, access-controlled laboratories. Skin contact with the organisms or the transfected cells will be avoided by minimizing aerosols (by working in a Class II biosafety cabinet), and by the use of gloves and safety glasses. The routine procedures employed (e.g., autoclaving or chemical inactivation of all cellular material prior to disposal) will ensure an adequate level of safety.

Transfected mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, temperature, and nutrient conditions. Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein-buffered media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus cannot replicate and so the consequences of escape are considered negligible, therefore risk is effectively zero. Infected mammalian cells are not able to establish themselves and spread in nature and the vectors selected are either disabled or attenuated.

Adaptimmune genetically modifies human T cell receptors (TCRs) and then uses lentiviral vectors to transduce these TCRs into human T cells so that these transduced T cells are better able to recognise and kill cancer cells or cells infected with viruses. The transduction of T cells with modified TCRs can also be adapted to create regulatory T cells that can potentially block the natural T cells that cause autoimmune disease.

The primary aim of this connected programme of work is to transduce human T-cells with a range of non-replicating self-inactivating transgene-integrating lentiviral vectors. Each vector encodes a disease-associated α/β heterodimeric TCR together with one of several additional genes designed to enhance the effectiveness of T cells in specific situations.

The gene combinations assessed here comprise α/β TCR genes alongside either genes with co-stimulatory properties; genes with anti-inhibitor properties; genes to enhance T cell killing, “Suicide” genes (and their activating pro-drugs) and genes that help create antigen-dependent immunosuppression. These properties may affect not only the recipient T cells but may also act on other immune and non-immune cell types as bystanders to potentiate the anti-disease immune response.

The resulting genetically-modified human primary T cells and T cell lines will be used for in vitro cell-based assays of T cell function. Additional assays will assess if the T cells still retain their target antigen-specific functionality.

### Recipient or parental organism

**Recipients:**
- Human HEK293T cell line and its derivatives - Lentiviral vector packaging cell line
- Human primary T cell lymphocytes
- Human T cell lines - not virally infected (e.g. SupT1, Jurkat and T cell hybridomas e.g., 58α- β-) - Blood-derived CD4+ and CD8+ T cells.

### Host/vector system

Replication-defective, self-inactivating lentiviral particles of one or more alternative types of 3rd and 4th generation lentiviral vector systems (commercially-acquired or made in-house):

All lentiviral systems are based on lentiviral transgene plasmids that carry a “self-inactivation (SIN)” mutation that inactivates the promoter and enhancer functions in both of the LTR sequences that flank the integrated transgene region Zufferey et al., (J.Virol 72, 9873-9880 1998).

Characteristics of the vectors:
- The number of HIV-1 open reading frame genes that are used in the system has been reduced to a minimum of gag, pol and rev.
- Genes encoding the above structural proteins and enzymes which required for packaging the viral genome are separated onto multiple plasmids and do not contain LTR or packaging signal sequences. All plasmids have been engineered to contain minimal homology regions. This reduces the chance for homologous recombination events to occur which may lead to the formation of a viable retrovirus.
- The VSVg envelope gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein (gp160 env) gene thus further reducing the chance of creating a viable retrovirus by homologous recombination events. NB the host range of the VSVg is very broad allowing the lentiviral particles to potentially transduce any dividing mammalian cell type.
- The lentiviral particles produced in these systems are replication-incompetent and only express the transgene in the transduced cells. The integrated lentiviral genome is no longer capable of producing a viral particle
- The transgene vector plasmid contains a deletion in the 3’ LTR (U3) to remove the promoter and enhancer elements. This does not affect the generation and packaging of the viral RNA genome in the lentiviral transgene particle producer host cell line, but results in “self-inactivation (SIN)” of the lentiviral transgene vector after its reverse transcription in the target cell. Prior to integration into the DNA of the transduced target cell, the 3’ SIN LTR is copied and in the process replaces the wt 5’ LTR.
• None of our lentiviral transgene constructs contains a WPRE sequence (and hence none contain the open reading frame for the potentially-oncogenic Protein X that this sequence encodes).

Replication-defective lentiviral particles will be produced by co-transfection of human HEK293T cells with both a lentiviral TCR-based transgene vector plasmid together with a complimentary set of lentiviral packaging plasmids (All of these recombinant DNA transfection plasmids had previously been generated in E.coli).

The resulting lentiviral vector particles will be used to transduce human T cells and T cell lines. The transduced T cells are designed to express both the affinity-enhanced TCR and a companion gene that enhances the functionality of subsequent T cell immunotherapy. Functionality will be assessed first in vitro using culture human cells that naturally or ectopically express and display cognate or non-cognate TCR peptide/MHC antigens.

Origin & function

Parental organism of inserts:
Human cDNA genes or synthetic equivalents of these genes without introns and based on the amino acid sequences of WT/GM human proteins - Full length, truncated and/or mutated forms of human genes. Genes not associated with oncogenicity, viral virulence or any pathogenicity.

WT or mutant alpha / beta TCR chain pairs (These TCR chains are sequence-modified to enhance specific binding to peptide/HLA antigens relevant to cancer). The transduced T cells are designed to express both the affinity-enhanced TCR and a companion gene that enhances the functionality of subsequent T cell immunotherapy. Functionality enhancement will be achieved by one or more of the following:
Gene(s) with co-stimulatory functions including various genes enhancing / complimenting antigen-dependent TCR signalling in T cells;
Gene(s) to block inhibitory signals including various genes enhancing the activity of T-cells by blocking anti-T-cell inhibitory signals;
Stimulatory cytokines / cytokine receptor gene(s) includes various cytokine and/or cytokine receptor genes that stimulate T cells and/or act on surrounding cells types to enhance immunotherapy;
Genes to modify T cell metabolism includes various genes enhancing the metabolism of T cells especially in the tumour microenvironment;
Gene(s) to enhance T cell killing includes various genes that potentiate antigen-specific target cell killing;
Genes (and their activating pro-drugs) confer conditional cell fate "suicide" mechanisms;
Gene(s) to enable an immunosuppressive environment by helping to create antigen-dependent immunosuppression.

Refer to Box 17 for confidential details of inserts.

Evaluation of foreseeable effects

The most hazardous GM vector/insert combinations in this assessment are the packaged lentiviral TCR transgene vector particles. These particles are pseudo-typed with the VSV-G envelope protein which allows them to transduce virtually any mammalian cell line. These particles are not in themselves viable viruses, they cannot replicate in their transduced host cells. They can however functionally express the genes they carry in other cells in the body they transduce.

The lentiviral transgene vectors express TCR genes plus accessory genes designed to further enhance T cell function. The TCR alpha and beta chains that are expressed can only function in T cells as they require the presence of CD3 signalling proteins which are themselves only found in T cell lineages (except for TCR-CD3z fusion proteins). Should the TCR molecules find themselves in a permissive cell type they are unlikely to cause harm as the TCR will only signal in response to cognate peptide/HLA antigens.

The conceivably most hazardous GM lentiviral vectors would be:
1. Those with inserts that, when expressed by any cell transduced by the lentiviral vector, produce:
   a. a transient local inflammatory response (transduced body cells are not immortal). This response can however be managed by generalised immunosuppressive drugs.
   b. a transient local bystander cell death response. This may be additionally limited by self-triggering of the death response in the insert-expressing cells themselves;
   c. a transient local immunosuppressive environment, temporarily potentiating an existing infectious or other chronic or acute disease that is normally controlled by
immune surveillance and/or temporarily inhibiting "non-self" protection. Some such inserts may act as growth factors for established tumours and as a factor that assists the differentiation of immunosuppressive Treg T cells. However, as above, these effects would only be local and limited.

Most Hazardous GMMs:
HEK293T cells packaging lentiviral TCR transgene vector particles present no more risk than the particles themselves. This cell-based vector packaging system is only able to produce vector particles under in vitro tissue culture conditions. Production of particles in these cells is transient (maximum ~72 hours). Packaging requires a genomic vector RNA transcript and a set of packaging proteins; both are transiently expressed from non-integrated non-replicating plasmids transiently introduced into the HEK293T packaging host cell line by transfection with these DNA plasmids. Primary T cells and T cell lines transduced by these lentiviral particles present negligible risk to the laboratory worker as they cannot produce functional virus. Transactivation of host genes by inserted LTR-flanked TCR transgene cassettes is blocked because each LTR carries a large deletion that inactivates both the promoter and enhancer activities of the LTRs. To avoid the issue of transduced T cell tolerance the use of self T cells by laboratory workers is expressly forbidden. This self T cell barrier is effectively managed by written protocols and training.

Packaged lentiviral particles can infect human primary cells of multiple lineages. The genes co-expressed with the TCR genes might suppress bystander cell proliferation but this will be self-limiting. All transgene-expressed genes other than very short animal picornavirus 2A skipping sequences all genes are of non-oncogenic human amino-acid sequence origin and are unlikely to elicit any deleterious immunological or allergic responses even if the individual had previously received an anti-human picornaviral virus vaccination.

The research concerned combines enhanced affinity TCRs which have not previously been tested for safety in a clinical setting with additional genes enhancing T cell function. If lentiviral particles containing both were to be inadvertently injected into the bloodstream of the scientist and enter their own T cells, and subsequently these T cells were to encounter cognate antigen to switch them on (which is unlikely), there would be a potential risk of an adverse immune reaction in the worker. For this reason the use of needles and sharps and working with "self" T cells is strictly prohibited during lentivirus work.

Inadvertently injected transduced/transfected GMO T-cells may attack normal tissue but these T-cells are normally recognised by the individual’s immune system as non-self and are efficiently eliminated by the host-immune system. Theoretically however an allergenic reaction and/or an allergic response could be generated that might ultimately prove fatal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no disease vectors which could disseminate GM human T-cells.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most liquid waste is inactivated in freshly prepared 1% Virkon (final concentration) for at least one hour contact time before being poured down the foul drain. Non-human tissue solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste under Adaptimmune Limited’s Environment Agency Waste Registration Number; OLT130. The autoclaved solid waste will be disposed of via incineration through an appointed specialist waste management company; Grundon Waste Management Limited. Autoclaved liquid waste will be disposed of through a sink to public sewer.

HTA-defined human tissue solid and contained liquid waste is disposed of directly (without prior disinfection) into dedicated bins which are wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incineration through Grundon Waste Management Limited as above.
Any remaining liquid waste will be treated with Virkon (1% final wt/vol) or 10% ChemGene according to the manufacturers instructions (DuPont/MediMark Scientific) for which independent validated efficacy against retrovirus exists.

# Project Additional Information

## Purposes of the contained use

The primary aim of this project is to overexpress notch receptor 1 in a mammalian cell line. This genetically modified cell line will then be used as a tool to select ("pan") from Antibody Phage Displayed Libraries for agonistic antibodies against notch receptor 1. The GM cells may also be used as part of a signalling reporter system aimed at assessing the agonistic properties of notch specific antibodies in in vitro assays.

## Recipient or parental organism

The recipient cells will be human (HG2) and mouse (HG1) cell lines. For further confidential details of recipients please refer to Section 17.

## Host/vector system

Two types of lentivectors could be used to transduce the mammalian cell lines:

**Type A:**
Commercially acquired vectors, typically third (or sometimes fourth) generation Lentiviral expression systems including but not limited to:

- ViraPower Lentiviral Expression systems sold by Invitrogen Ltd. The vectors are: pLenti6iVs-Dfrecional TOPO, pLenti6.2-GW/EniGFP, pLP1, pLP2, and pLPNSVG plasm ids.
- Lenti-X Lentiviral Expression systems sold by Clontech Laboratories, Inc. The vectors include: pLVX-Puro, pLVXDsRed-Monomer-CI, Lenti-X FIT packaging system

**Type B:**
Vectors constructed by our academic collaborators e.g. University of Pennsylvania (UPenn). These will typically be third generation type systems including but not limited to:

- Vectors obtained from 'University of Pennsylvania; UPenn): Lentiviral vector derived from the 'Dull' vector (Dull et al. J Viral 1998), and 3 packaging plasm ids (gag/pal, rev, VSVG envelope) similar to that used by Zufferey (Zufferey et al, Nat Biotech 1997)

These Lentiviral Expression Systems are third or fourth generation lentivirus systems. The lentiviruses can infect mammalian cells but cannot replicate in these cells. These systems include some or all of the following safety features:

1. Expression vectors containing a deletion of the 3’ L TR (L1U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a viral particle.
2. The number of HIV-I genes that are used in the system has been reduced to three or four only: gag, pol, tat and sometimes rev.
3. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-I envelope gene (env).
4. Genes encoding the structural and other components required for packaging the viral genome are separated onto multiple plasmids. These plasm ids have been engineered not to contain any homology regions to prevent...
**Origin & function**

Human cDNA genes or synthetic equivalents of these genes without introns and based on the amino acid sequences of WT/GM human proteins: Full length synthetic forms of human genes codon-optimised for expression in human and mouse cells, e.g. Notch Receptor 1 (a potential oncogene); constitutive promoters; selection genes (e.g., puromycin resistance) and reporter genes (such as GFP, RFP and luciferase).

Notch receptor 1 over-expression will be used to select agonistic antibodies against Notch1 for further study. For further confidential details of inserts please refer to Section 17.

**Evaluation of foreseeable effects**

The most hazardous GM vector/insert combinations in this assessment are the packaged lentiviral transgene vector particles. These particles are pseudo-typed with the VSV-G envelope protein which allows them to transduce virtually any mammalian cell line. These particles are not in themselves viable viruses, they cannot replicate in their transduced host cells. They can however functionally express the genes they carry in other cells in the body they transduce.

The lentiviral transgene vectors express the Notch 1 gene plus an accessory constitutive promoter gene designed to induce overexpression of notch receptor 1 on the surface of human or mouse cell lines. Inhibition of Notch1 has been shown to have an anti-proliferative effect in certain cancers. Notch1 is therefore considered to be a potential oncogene and co-expression of Notch1 stimulatory genes is likely to enhance this effect. If the lentiviral vector inadvertently enters the body, it is able to transduce any body cell due to the broad host range of the VSV-G enveloping gene and such cells may then induce malignant tumours or cancer in the recipient.

Packaging cell lines transduced with above vectors present no more risk than the particles themselves and are only able to transiently produce vector particles under in vitro tissue culture conditions. Human primary cells in general are considered as especially disabled hosts, provided they are unable to colonise the worker (i.e. non-self), and to the best of our knowledge they contain no adventitious agents which are potentially harmful. Should infected cells gain entry to the worker, the cells would in all likelihood be rapidly destroyed by the workers' immune system by virtue of being antigenically "non-self".

Packaged lentiviral particles can infect human primary cells of multiple lineages. There is therefore a risk of transducing your own cells if the lentivirus should enter your body. Although mutations that constitutively activate Notch 1 have been associated with a number of leukemias (e.g., T-All and Cll) there is no direct evidence that NOTCH1 directly induces cellular transformation in mature mammalian cells. In such cases it is an additional driving force but not the initial cause of the cancer.

Inadvertently injected transduced/transfected GMO cells will be picked up by the individual's immune system as nonself and should be efficiently eliminated by the host-immune system. Severely immunocompromised individuals may be at risk as they may have issues detecting and clearing genetic modified cells should they enter the body. However, such severely immunocompromised people would be ill and would not have access to the lab.

**Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)**

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no disease vectors which could disseminate GM human T-cells.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is inactivated in freshly prepared 1% Virkon (final concentration) or 10% ChemGene for at least one hour contact time before being poured down the foul drain.

All CL2 waste is autoclaved before disposal (121°C for 25 minutes for 100% kill) - the autoclave is efficacy-tested using Thermalog strips every 3 months and a complete validation programme is performed annually during maintenance.

Upon autoclaving, solid waste is disposed of as 'hazardous waste' for off-site incineration by an approved and licenced hazardous waste contractor.

Human Tissue waste is disposed of directly (without prior disinfection) into dedicated bins and collected by an approved and licenced hazardous waste contractor for specialist off-site incineration.

Project Ref 3242/17.4

Date Ackn'd 03/05/2017  
CU2 Project Title Expression of the parent proteins for peptide MHC/HLA antigens  
Class 2  
CultureVolClass2 1-50 Litres  
CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

This document relates to studies aimed at producing human cell lines expressing the genes for the parent proteins of T cell antigens. These proteins are processed into peptides that are presented by MHC/HLA molecules. These peptide-MHC antigens are then recognised by antigen-specific T cell receptors (TCRs). We wish to study the peptide/MHC binding properties of engineered TCRs so that we can evaluate their suitability as components to be used in T cell-mediated adoptive cell therapy.

**Recipient or parental organism**

Recipients:
- Human primary cells and established cell lines (HG2 - potential but not confirmed pathogen presence) to be transduced with lentiviral antigen-presenting cells
- Human HEK293T cell line and its derivatives (for lentiviral vector packaging)

**Host/vector system**

Replication-defective, self-inactivating lentiviral particles. One or more alternative types of 3rd and 4th generation lentiviral vector systems.

**Type A:**
Commercially-acquired
Third and fourth generation lentiviral vector packaging systems including but not limited to:
- "ViraPower" Lentiviral vector expression systems (Invitrogen Ltd). The plasmids include pLenti6N5-Directional TOPO, pLenti6.2-GW/EmGFP, pLP1, pLP2, and pLPNSVG plasmids.
- "Lenti-X" Lentiviral expression systems (Clontech Laboratories, Inc). The vectors include: pLVX-Puro, pLVXDsRed-Monomer-C1, Lenti-X HT packaging system.

**Type B:**
Made in-house:
These are third generation type systems, including but not limited to:
Lentiviral vectors derived from the ‘Dull’ lentiviral vector transgene plasmid (Dull et al, J Virol 72, 8463-8471 1998),
and its three packaging plasmids i.e., pMDLgpRRE (Gag/Pol), pRSV-rev (Rev) and pMDG.1 (VSVg envelope) or an alternative Adaptimmune pCI-VSVG (VSVg envelope) plasmid. Allentiviral systems are based on lentiviral transgene plasmids that carry a "self-inactivation (SIN)" mutation that inactivates the promoter and enhancer functions in both of the LTR sequences that flank the integrated transgene region Zufferey et al. (J. virol. 72, 9873-9880, 1998)).

Characteristics:

- The number of HIV-1 open reading frame genes that are used in the system has been reduced to a minimum of gag, pol and rev.
- Genes encoding the above structural proteins and enzymes which required for packaging the viral genome are separated onto multiple plasmids and do not contain LTR or packaging signal sequences. All plasmids have been engineered to contain minimal homology regions. This reduces the chance for homologous recombination events to occur which may lead to the formation of a viable retrovirus.

• The VSVg envelope gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein (gp160 env) gene thus further reducing the chance of creating a viable retrovirus by homologous recombination events. NB the host range of the VSVg is very broad allowing the lentiviral particles to potentially transduce any dividing mammalian cell type.

• The lentiviral particles produced in these systems are replication-incompetent and only express the transgene in the transduced cells. The integrated lentiviral genome is no longer capable of producing a viral particle.

• The transgene vector plasmid contains a deletion in the 3' LTR (U3) to remove the promoter and enhancer elements. This does not affect the generation and packaging of the viral RNA genome in the lentiviral transgene particle producer host cell line, but results in "self-inactivation (SIN)" of the lentiviral transgene vector after its reverse transcription in the target cell. Prior to integration into the DNA of the transduced target cell, the 3' SIN LTR is copied and in the process replaces the wt 5' LTR.

• None of our in-house lentiviral transgene constructs contains a WPRE sequence (and hence none contain the open reading frame for the potentially-oncogenic Protein X that this sequence encodes).

Origin & function

Origins: Human (synthetic or semi-synthetic functional and non-functional gene sequences, some of which are associated with oncogenicity or tumourigenesis); Jellyfish (reporter genes) and Bacterial HG1 (drug resistance genes)

All inserts will consist of wholly or partially synthetic human genes based on the amino acid sequences of wildtype or modified human proteins. Sometimes they will be co-expressed with reporter genes (e.g., eGFP) and/or drug selection genes (e.g., Puromycin resistance). In other circumstances the parent gene will be co-expressed with a Class I or Class II MHC/HLA antigen-presenting gene (this can be with or without the additional expression of a beta 2m gene). On occasion the presentation of the peptide antigen will be assisted by genetic fusion of the gene to a ubiquitination signal or by genetic fusion to ubiquitin itself to promote efficient peptide antigen processing.

The parent protein can be a cancer-specific protein e.g., from a mutated K-ras gene. Alternatively, the gene product can be a Cancer-Testes antigen (e.g., from a MAGE family or NY-ESO gene). If the parent protein gene is a known or potential oncogene (e.g., K-ras) it will only be expressed in a non-functional form e.g., as a truncated gene fragment. These genes for TCR antigen presentation are not restricted to cancer. We also wish to express and study other antigenic human proteins as targets for TCR-based autoimmune disease therapy.

In addition to these intended TCR target antigen genes we wish to express control parent antigen genes. These can be non-mutated wild-type versions of the antigen genes. Alternatively, the control genes can be other human genes that are potentially recognised by a TCR but not associated with tumourigenesis or autoimmunity.
The most hazardous GM vector/insert combinations in this assessment are the packaged lentiviral transgene vector particles. These particles are pseudo-typed with the VSVg envelope protein which allows them to transduce virtually any mammalian cell line. These particles are not in themselves viable viruses, they cannot replicate in their transduced host cells. They can however functionally express the genes they carry in other cells in the body they transduce.

The lentiviral transgene vectors express proteins associated with cancer or autoimmunity. However, the cloning and expression of functional known or putative oncogene proteins is not permitted.

Mammalian cells (including the HEK293T lentiviral vector packaging cells) that are transduced with antigen parent protein gene lentiviral transgene vector particles should present no more risk than the particles themselves. Furthermore, the transduced human cells produced will have a HLA tissue type different from the laboratory staff and hence will be detected and efficiently eliminated by the immune systems of any inadvertently contaminated worker. Working with 'self' materials is strictly prohibited.

Severely immunocompromised people, who conceivably would be most at risk, do not have access to the lab.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no disease vectors which could disseminate GM human T-cells.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most liquid waste is inactivated in freshly prepared 1% Virkon (final concentration) for at least one hour contact time before being poured down the foul drain.

#### Project Ref 3242/17.5

- **Date Ackn'd**: 04/05/2017
- **CU2 Project Title**: Disruption of genes in human primary stem cells and cell lines
- **Class**: Class 2
- **Culture Vol Class**: 1-50 Litres
- **Consent Granted**: Non-GMM

#### Project Additional Information

- **Project notified under transitional arrangements**: N
- **Tick if notifying a connected programme of work**: N
### Purposes of the contained use

The primary aim of this project is to disrupt and thereby inactivate genes in human cells. The gene disruptions(s) are designed to stably change the genotype and phenotype of the cells. Cells with disrupted genes will be used for various purposes such as:

1. Evaluating if a host cell protein or an MHC-presented peptide derived from this protein is immunogenic. e.g. to attempt to confirm if the peptide/antigen target for a T cell receptor (TCR) is derived from the product of a known host gene.
2. Determining if gene disruption(s) will alter the pathways of differentiation of a stem cell line
3. Determining if disruption of a host gene(s) can boost the viral vector packaging capability of a cell line.

### Recipient or parental organism

**Recipients:**
- Human primary cells, established cell-lines and stem cells (HG2 - potential but not confirmed pathogen presence):
  - Human primary cells
  - Established human cell lines
  - Human Haematopoietic Stem Cells (Adult bone marrow-derived Haematopoietic Stem Cells)
  - Human Embryonic Stem (ES) Cells (Embryo-derived Stem Cells)
  - Human Induced Pluripotent Stem Cells (Stem cells induced by Yamanaka factors)
  - Human HEK293T cell line and its derivatives (Lentiviral vector packaging cell line (human neuro-adrenallineage))

Refer to Box 17 for confidential details of recipients.

### Host/vector system

Gene editing technology (Plasmid for expression of the functional components needed for CRISPR/Cas9 genome editing in mammalian cells with an additional orange fluorescent protein (OFP) transfection reporter gene (OFP not knocked in))

All-in-one lenti-Cas9 (System Biosciences) (3rd generation lentiviral vector packaging system:

- Lentiviral vector transgene plasmid to be packaged into VSVg pseudotyped replication incompetent lentivirus.
- Contains 5’LTR, 3’SIN LTR, RRE and WPRE sequences and expresses Cas9 and CRISPR gRNA sequence in the target cell.

All plasmids non-mobilisable assembled and propagated in E.coli laboratory strains.
- The VSVg envelope gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein (gp160 env) gene thus further reducing the chance of creating a viable retrovirus by homologous recombination events. NB the host range of the VSVg is very broad allowing the lentiviral particles to potentially transduce any dividing mammalian cell type.
- The lentiviral particles produced in these systems are replication-incompetent and only express the transgene in the transduced cells. The integrated lentiviral genome is no longer capable of producing a viral particle.

### Origin & function

Synthetic gene disruption sequences with partial homology to the gene targeted for disruption are chemically synthesised DNA insert genes assembled by standard Molecular Biology techniques. They function as transcribed guide RNAs to direct Cas9 to cleave DNA at specific sequences within human genes.

Knock in gene sequences are synthetic or semi-synthetic DNA sequences bearing partial homology to the gene targeted for disruption. They also contain either additional synthetic gene sequences that allow for genotypic screening or semi-synthetic sequences that additionally allow for the expression of either reporter genes (e.g. GFP)
for the phenotypic screening of gene disruption or drug resistance genes (e.g. puromycin resistance) that are expressed to provide a mechanism for selecting cells carrying disrupted genes.

NB All gene knock-in sequences are designed for gene disruption screening or selection. The knocking-in of any other type of functional gene will require specific risk assessment.

The genes to be disrupted are:-
1. Genes in human tissue culture cell lines that are associated with the adaptive immuno-surveillance of cancer or autoimmunity.
2. Genes in human stem cells (Haematopoietic Stem Cells, Embryonic Stem Cells, Induced Pluripotent Stem Cells) especially those that are associated with cell lineage differentiation.
3. Genes in human cell lines whose disruption may boost the production of packaged lentiviral vector particles.

It must be stressed that the inserts in the vectors that are used for gene knock-in contain only non-functional truncated versions of parts of the targeted gene. Furthermore, no known tumour suppressor genes will be disrupted.

Refer to Box 17 for confidential details of inserts.

### Evaluation of foreseeable effects

The most hazardous GM vector/insert combinations in this assessment are the packaged lentiviral vector particles. These particles are pseudo-typed with the VSVg envelope protein which allows them to transduce virtually any human cell type. These particles are not in themselves viable viruses, they cannot replicate in their transduced host cells. They can in theory unintentionally express the targeted CRISPR/Cas9 genes they carry in other cells transduced with these lentiviral vectors.

CRISPR/Cas9 constructs disrupting anti-apoptotic genes could, if inadvertently entered into the body, cause local cell death. To minimise the likelihood of this occurring such constructs will not be used in any lentiviral vectors. Instead these gene disruptions will be limited to non-viral vectors that require additional cell transfection reagents and protocols.

The human pluripotent stem cells are potentially tumorigenic. However, stem cells modified to be able to evade the immune system will not be used in this project and would quickly be destroyed by a person's own immune system. Cells transduced with non-viral or lentiviral CRISPR/Cas9 gene disruption constructs should be no more hazardous than the equivalent non-transduced cells.

Other potentially hazardous GM lentiviral vectors would be those with expressable inserts that, when expressed by any cell transduced by the lentiviral vector, produce a potentially antigenic Cas9, screening and/or drug selection protein resulting in a transient local inflammatory response (transduced body cells are not immortal). This response can however be managed by generalised immunosuppressive drugs.

Packaged lentiviral particles can infect human primary cells of multiple lineages. Introducing potentially antigenic inserts into the body may result in a transient local inflammatory response. CRISPR/Cas9 constructs disrupting anti-apoptotic genes could, if inadvertently entered into the body, cause local cell death. Severely immunocompromised people, who conceivably would be most at risk, do not have access to the lab.

Refer to Box 17 for confidential details of vectors.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure “Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs” as there are no disease vectors which could disseminate GM human T-cells.
Most liquid waste is inactivated in freshly prepared 1% Virkon (final concentration) for at least one hour contact time before being poured down the foul drain. Non-human tissue solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste under Adaptimmune Limited’s Environment Agency Waste Registration Number; OL T130. The autoclaved solid waste will be disposed of via incineration through an appointed specialist waste management company. Autoclaved liquid waste will be disposed of through a sink to public sewer. HTA-defined human tissue solid and contained liquid waste is disposed of directly (without prior disinfection) into dedicated bins which are wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incineration through Grundon Waste Management Limited as above. Any remaining liquid waste will be treated with Virkon (1% final w/v) or 10% ChemGene according to the manufacturers instructions (DuPont/MediMark Scientific) for which independent validated efficacy against retrovirus exists.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Genetic Modification Committee discussed the proposed work, and after consultation with the Scientists that will be undertaking the laboratory work, the project was approved and the Biological Safety Officer was actioned to complete the HSE Notification for a subsequent class 2 activity.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 3242/17.6
The primary aim of this project is to produce HEK293T cell lines with increased capability to produce packaged lentiviral particles. This will be achieved by transducing and/or transfecting them with vectors carrying genes that change the packaging cell's phenotype to enable it to produce higher amounts of packaged lentiviral vectors for longer. GMO RA 248 describes the work of packaging lentiviral vectors into HEK293T cells. These packaged lentiviral vectors are subsequently transduced back into HEK293T cells, where this time they integrate into the genome and coexpress the inserts of interest together with the reporter or selection gene.

Recipient or parental organism

Recipients:
- Human HEK293T cell line and its derivatives - Lentiviral vector packaging cell line

Host/vector system

Recipients:
- Human HEK293T cell line and its derivatives - Lentiviral vector packaging cell line
  - None of our lentiviral transgene constructs contains a WPRE sequence (and hence none contain the open reading frame for the potentially-oncogenic Protein X that this sequence encodes).

As alternative to inserting genes into lentiviral vectors to integrate them stably into the packaging cell genome, some inserts will be cloned into non-viral plasmid vectors or EBV-origin based plasmid vectors. These are subsequently transfected into HEK293T cells. The EBV-origin plasmid vectors will remain in the cytoplasm of the HEK293T cells and will enhance the production of packaged particles without integrating into the genome of these cells. In the absence of continued drug selection these plasmid vectors will then gradually be lost as the cells divide. Plasmid vectors include pCI, pClneo,
pPur plasm ids; pREP4, pCEP4 plasmids (All non-viral and EBV virus oriP origin/EBNA-1 recombinant DNA mammalian gene expression plasmids that co-express a detection/selection gene. Non-mobilisable).

**Origin & function**

**Parental organism of inserts:**
Human cDNA genes or synthetic codon-optimised equivalents of these genes based on the amino acid sequences of these proteins - Full length, truncated and/or mutated forms of human genes. Genes not associated with oncogenicity, viral virulence or any pathogenicity.

Synthetic sequence-modified genes derived from the sequences of mammalian viral genes; Synthetic gene constructs that express shRNA molecules for the specific knockdown of host cell mRNAs (Gene based on viral sequence are substantially altered to prevent hypothetical homologous recombination).

**Overview of Inserts:**
1. Genes expressing human proteins to enhance lentiviral vector production
2. Synthetic genes expressing viral protein sequences (but not homologous to viral gene sequences) to enhance lentiviral vector production
3. Synthetic genes to express shRNA sequences that target host mRNA molecules to reduce expression of host genes that impede lentiviral vector production
4. Reporter genes to detect transfected/transduced mammalian cells
5. Drug resistance genes to allow selection of transfected/transduced mammalian cells
6. tRNA genes

Refer to Box 17 for confidential details of inserts.

**Evaluation of foreseeable effects**

The most hazardous GM vector/insert combinations in this assessment are the packaged lentiviral transgene vector particles. These particles are pseudo-typed with the VSVg envelope protein which allows them to transduce virtually any mammalian cell line. These particles are not in themselves viable viruses, they cannot replicate in their transduced host cells. They can however functionally express the genes they carry in other cells in the body they transduce.

The lentiviral transgene vectors express pro-viral genes or genes that antagonise anti-viral genes. These genes are not expected to cause significant changes to any host cells that are transduced.

HEK293T cells transduced with pro-viral lentiviral transgene vector particles present no more risk than the particles themselves. Furthermore, these novel cell-based vector packaging system are only able to produce vector particles under in vitro tissue culture conditions.

Packaged lentiviral particles can infect human primary cells of multiple lineages.

The conceivably most hazardous GM lentiviral vectors would be those with inserts that, when expressed by any cell transduced by the lentiviral vector, produce an antigenic protein resulting in a transient local inflammatory response (transduced body cells are not immortal). This response can however be managed by generalised immunosuppressive drugs. Severely immunocompromised people, who might conceivably be most at risk, do not have access to the lab.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
The primary aim of this project is express human or viral proteins in human cells that are known to be or are suspected to be oncogenic. The purpose of this work is to produce positive control cell lines to be used when analysing the levels of mRNA for oncogenes/potential oncogenes that are found in human tumour samples and in human cell lines.

A second use of these cell lines is to study the production of antigenic peptides that are derived from oncogenic proteins which are then presented on the surface of cells by human leukocyte antigen proteins (HLAs). Peptide-HLA antigens (pHLAs) are recognised by T Cell Receptors (TCRs) on T cells. We will use these oncogene-derived pHLA antigen cell lines as targets for human T cell clones and for human primary T cell lines stably transduced with lentiviral vectors that express recombinant TCR genes.

Recipient or parental organism
Recipient cells: Human primary cells and human cell lines.

Host/vector system
Bacterial non-mobilisable mammalian expression shuttle plasmids that do not contain a viral origin of replication (e.g., pCl, pClneo and pPur plasm ids). These plasm ids cannot be used to produce packaged virus-like transduction particles

Origin & function
Parental organisms for inserts: Oncogenes or potential oncogenes in the form of human and viral cDNA or fully synthetic DNA.
Full length, truncated and/or mutated forms of human or viral genes whose proteins have oncogenic or potentially oncogenic properties:
Human cDNA genes encoding proteins or synthetic codon-optimised equivalents of these genes based on their amino acid sequences.
cDNA or synthetic sequence-modified oncogenes derived from the sequences of mammalian viral genes.
NB: No actual virus will be handled at any stage, only DNA based on viral DNA sequences.
Further detail is provided in Section 17

**Evaluation of foreseeable effects**

The most hazardous GM vector/insert combinations in this assessment are bacterial plasmids that express known oncogenic proteins.
Plasmids carrying oncogenes do not present a hazard in themselves as they lack the mechanism to enter cells without special techniques.
The most hazardous GMOs in this assessment are human primary cells that have been immortalised by the expression of oncogenic proteins.
Oncogenes on plasmids will only very infrequently be integrated into the DNA of the transfected cells. Cells transformed with plasmids carrying an oncogene could in principle cause cancer:
If the oncogenes are integrated into DNA of primary cells such cells could potentially cause cancer on accidental introduction into the bloodstream if not recognised by a worker's own immune system (e.g. own cells; defective immune system; cells manipulated to evade the immune system)
As long as workers only work with non-self cells, these transformed cell lines will be efficiently recognised and destroyed by the worker's immune system if their immune system is healthy. It is for this reason that no one is allowed to transfet their own cells or to use cells that are engineered to evade immune surveillance / destruction.
If plasmids carrying oncogenes are integrated into the DNA of established cell lines they would not present more risk than the immortalised cell line in itself for workers with a healthy immune system.
It is recognised that workers with a (temporarily) ineffective immune system will be at increased risk of developing cancer if the cell lines carrying them were inadvertently introduced into their bloodstream.
Such people include but are not limited to HIV carriers; diabetics; those on steroids; those with latent other infections etc.
Since it is impossible to know at any moment whether a worker's immune system is functioning adequately, we will ensure we build in the controls of strict prohibition of handling sharps when working with these oncogenic GMs / GMOs and any skin abrasions are adequately covered.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no disease vectors which could disseminate these GMOs.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Non-human tissue solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of...
chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. Autoclaved liquid waste will be disposed of through a sink to public sewer.

HTA-defined human tissue solid and contained liquid waste is disposed of directly (without prior disinfection) into dedicated bins which are sealed once full and wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incineration through an appropriately licenced waste company as above. Any remaining liquid waste will be treated with 1% Virkon (final wt/vol) or 5% ChemGene (final wt/vol) for both of which independent validated efficacy against human tissue exists. The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months.

The Genetic Modification Committee discussed and commented on the proposed work, and after consultation with the Scientists that will be undertaking the labortory work, the project was approved on 7 September 2017 and the Biological Safety Officer was actioned to complete the HSE Notification for a subsequent Class 2 activity.
### Project Additional Information

#### Purposes of the contained use

Commercially available KILR retroviral vector particles (DiscoverX) expressing a beta-galactosidase/human "housekeeping" gene reporter fusion protein will be transduced into human primary cells and human cancer cell lines so that these cells can be used as targets in improved T cell cytotoxicity assays.

#### Recipient or parental organism

- Human primary cell lines - ACDP Hazard Group 2
- Human immortalised cell lines - ACDP Hazard Groups 1-2

#### Host/vector system

- Moloney Murine leukemia virus (MoMLV) - with wildtype L TRs (not Self Inactivating SIN L TRs)
- pMoMLV backbone with wildtype 5' and 3' L TRs, G418 antibiotic resistance (expression driven by 5' retroviral L TR promoter), KILR reporter gene insert expression driven by CMV promoter.

#### Origin & function

- Non-pathogenic laboratory E.coli strain (beta galactosidase gene) - Non-hazardous
- Normal human amino acid sequence for a "housekeeping" gene - Non-hazardous

(NB: two returns were entered in the website link to fit it onto the page).
Evaluation of foreseeable effects

The most hazardous GM constructs are the retroviral vector particles. Although replication-defective these expression vectors stably integrate into the DNA of human cells in a near-random fashion and hence this might possibly cause oncogenic insertional transformation of primary cells.

A more serious concern is that these retroviral particles contain wildtype 5' and 3' LTR as direct repeat sequences which function both as promoters and as enhancers (indeed the vector G418 drug resistance selection gene is expressed from the functional 5' LTR). These promoters/enhancers could increase the expression of host genes that are adjacent to the sites of random insertion of the vector; again with potential oncogenic effect.

The retroviral vector particles are pseudo-typed with the VSV-G envelope protein significantly broadening the host range of cell lines that can be transduced to include any human cell or cell lines. However, once inside the cell these particles cannot replicate or generate progeny that can further transduce cells.

The most hazardous vector/insert/host combinations are cell lines transduced with KILR-retroviral vector particles but these present significantly less risk than the viral vector particles themselves. These cells are not able to produce more vector particles.

Effects on human health:

The 'gene expressed in human cells is a non-hazardous beta-galactosidase/ host protein fusion gene reporter, which is unlikely to elicit any deleterious immunological or allergic responses.

Since the LTRs are not attenuated or disabled they may act as a promoter and/or enhancers to express genes adjacent to the insertion, which may cause cell immortalisation. Therefore, using these KILR retroviral vector particles carries a slightly higher risk of initiating tumours than corresponding LTR self-inactivating (SIN) viral vector particles if they were to be accidentally introduced into a worker. This increased risk is mitigated with enhanced controls.

If transduced "self" cells were inadvertently reintroduced into the worker, the immune system would be unable to recognise and eliminate the cells. However, the recipient cell lines are always from another individual or are commercially available cancer cell lines both of which will present non-self HLA allotypes.

These non-self transduced GM cells, if accidentally injected into the worker, would at most cause a temporary and limited local immune reaction in those with a healthy immune system.

Neither the expressed reporter gene nor the cancer cells themselves are expected to adversely affect human health. However, in the unlikely event that insertional mutagenesis or insertion adjacent to an oncogene upregulated by the retroviral LTRs creates a tumour cell, those whose immune response is less acute (e.g. those with latent infections, diabetics, people on steroid medication or pregnant-breastfeeding women) which does not recognise non-self cells sufficiently, could potentially contract cancer in a worst-case scenario.

Since we cannot effectively exclude such people from coming in contact with the GMOs we are putting robust controls in place to minimise the likelihood of this happening.

8.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no disease vectors which could disseminate these GMOs.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Non-human tissue solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months.

Autoclaved solid waste will be treated as Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. HTA-defined human tissue solid and contained liquid waste is disposed of directly (without prior disinfection) into dedicated bins which are sealed once full and wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incineration through an appropriately licenced waste company as above.

Any remaining liquid waste will be treated for a minimum contact time of 1 hour (preferably overnight) with 1% Virkon (final wt/vol) or 5% ChemGene (final wt/vol). For both chemicals proven independent validated efficacy exists against human tissue.

Autoclaved or chemically treated liquid waste will be disposed of through a sink to public sewer.

Project Ref 3242/17.9
GMO RA 256 Gene disruption in human cells using packaged Adeno-Associated Viral (AAV) vectors

Date Project Ceased: 14/12/2017

Consent Granted: Non-GMM

Class 2: < 1 Litre

Project notified under transitional arrangements: N

Historical Significant Changes:

Historical Date of Additional Info:

Withdrawn: N

Tick if notifying a connected programme of work: N

Project Additional Information

Purposes of the contained use:

Individual genes will be permanently disrupted by transducing human cells with packaged Adeno-Associated Viral (AAV) vectors. These single-stranded DNA vectors will be constructed as shuttle plasmids in E. coli then packaged as infectious particles in modified HEK293 cells. The resultant non-replicating and integration-deficient viral vector particles will then be used to transduce human cell lines and stem cells to cause gene disruption. The gene-disruption AAV vectors covered by this GMO RA differ from the wildtype AAV virus and some MV-derived gene expression vectors as they do not use the AAV-encoded viral integration pathway. Instead these MV-derived vectors carry regions of DNA that are homologous to the gene chosen for disruption. They also contain a promoter and drug selection gene combination that is inserted between the two regions of DNA homology. Drug selection can then be used on vector-transduced cells to select for rare DNA copying events where the AAV vector DNA replaces the matching host DNA. Disabling modifications in the vector DNA homology regions can be used to permanently disrupt the target host gene. If required, the promoter/drug selection gene that is used can be precisely removed at a later date. The removal of the drug selection combination is achieved by the transient introduction of a Cre recombinase gene expression plasmid. Expressed Cre recombinase protein precisely deletes the promoter/section DNA by catalysing an exact homologous recombination event between two sequence-defined short tandem DNA repeat LoxP motifs that are included in the design of the AAV gene disruption vector.

Recipient or parental organism:

Escherichia coli - Disabled laboratory K12 strains of E. coli for standard gene cloning and shuttle plasmid vector preparation. ACGM Class 1.

AAV-293 cells - Human HEK293-derived cell line that stably expresses the Adenoviral E1 gene. ACGM Class 2. This will be used to package AAV vectors.

AAV-HT1080 cells - Human cell line which stably expresses the Adenoviral E1 gene. ACGM Class 2. This will be used for titration of AAV vectors.
Our gene editing vectors are based on the Agilent AAV Helper-Free System which eliminates the requirement for viral co-infection during both the AAV vector production and AAV stock titration steps, thereby making the system safer. Nevertheless, the Agilent System still requires co-transfection of the vector plasmid with a helper plasmid that expresses a limited number of the viral genes that are essential for viral vector packaging. The AAV Helper-Free System (Agilent Technologies, https://www.genomics.agilent.com/enNiral-MediatedDelivery/AAV-Helper-Free-System?cid=AG-PT-183&tabid=AG-PR-1006) will be adapted for use in our studies. It allows the production of packaged infectious recombinant human Adeno-associated virus-2 (AAV-2) vector virions without the use of a helper virus.

The AAV Helper-Free System takes advantage of the known Adenovirus gene products that mediate the replication and assembly of the AAV virus and the demonstration that these gene products can be introduced into the host packaging cell line by a combination of the stable transfection of the packaging cell line and co-transfection with a helper plasmid. In the AAV Helper-Free System, most of the Adenovirus gene products required for the packaging of infective (but non-replicating) AA V vector particles are supplied on the plasmid pH-helper (which expresses the Adenoviral E2A and E4 proteins, and the Adenoviral VA RNA gene). This is co-transfected into cells alongside the plasmid DNA that encodes the human AAV-2 based viral vector. The remaining essential Adenoviral gene product is supplied by the AAV-293 host cells, a modified HEK293 human cell line that stably expresses the Adenoviral E1 gene.

The wild-type AAV-2 viral genome contains just two coding sequences rep and cap (encoding the replication and capsid genes, respectively). These are flanked by inverted terminal repeats (ITRs) that contain all the cis-acting elements necessary for viral replication, packaging and chromosomal integration. In the Agilent AAV Helper-Free System, the rep and cap genes have been removed from the viral vector and are supplied in trans on the plasmid pAAV-RC. The removal of the AAV rep and cap genes allows for insertion of up to 4.5Kb of DNA between the ITR sequences.

In our gene disruption protocols (see Khan et al., Nature Protocols 16, 482-501 2011) we will use 2 DNA regions of ~1.5Kb which are homologous to one or two exons of the gene targeted for disruption. These homology regions are separated by a promoter-drug selection gene together with a termination/polyadenylation Signal sequence. After drug selection for the relatively rare stable disruption of the target gene the drug selection moiety can be removed by the transient delivery of Cre recombinase (via plasmid-mediated transient transfection). Cre causes site-specific recombination between the LoxP sequences that flank the selection moiety. Recombination leaves just the disrupted target gene behind containing just a single copy of the LoxP sequence. In traditional viral delivery systems, regeneration of wild-type virus by recombination is a major concern. In our system, as with the parental Agilent AAV Helper-Free system, the AAV-2 ITR-containing gene disruption plasmids do not share any regions of homology with the rep and cap-gene expression plasmid (pAAV-RC), thereby preventing the production during packaging of viable AAV virus through homologous recombination.

Conventional AA V vector titration methods involve co-infection by wild-type Adenovirus and the AA V vector stock. The Agilent AAV Helper-Free system uses a virus-free AAV vector titration method, which removes the requirement for Adenoviral co-infection.

AAV-2-derived vectors have proven to be especially valuable for gene-editing due to the high vector titre achievable (enabling a very high multiplicity of infection for efficient gene disruption). The gene-disruption AAV vectors covered by this GMO RA differ from the wildtype AAV virus and some MV-derived gene expression vectors as they do not use the AAV-encoded viral integration pathway. Instead these MV-derived vectors carry regions of DNA that are homologous to the gene chosen for disruption. They also contain a promoter and drug selection gene combination that is inserted between the two regions of DNA homology. Drug selection can then be used on vector-transduced cells to select for rare DNA copying events where the AAV vector DNA replaces
the matching host DNA. Disabling modifications in the vector DNA homology regions can be used to permanently disrupt the target host gene.

Vectors used:
1. Modified pAAV-MCS plasmids (based on the pAAV-MCS plasmid supplied by Agilent); 2. pCMV-MCS plasmid (containing the same expression cassette as pAAV-MCS but without ITRs); 3. pAAV-LacZ plasmid (contains the AAV backbone -including ITRs but excluding rep and cap- with a gene expression cassette for lacZ); 4. pAAV-hrGFP plasmid (as 3 but with cassette for hrGFP); 5. pAAV-RC plasmid (encoding AAV genes rep and cap); 6. pH helper plasmid (containing the Adenoviral helper genes E2A, E4 and VA); 7. pCMV-Cre (System BioSciences).

Plasmids 5 and 6 will be co-transfected into AAV-293 cells with the engineered AAV vector gene homology plasmid (modified Plasmid 1) or with Plasmid 3 or 4 for the production of AAV homology vectors alongside their respective LacZ and/or hrGFP AAV vector controls.

All AAV vector, helper plasmid, vector control and the Cre recombinase plasmid are shuttle plasmids that are nonmobilisable in E.coli (all derived from pUC plasmids).

These plasmids all carry a bacterially-expressed beta-lactamase penicillin-resistance genes (as is standard in many laboratory E.coli plasmids).

Gene inserts are promoter/drug resistance gene combinations flanked by LoxP recombination sites and then flanked on either side by approximately 1.5kb of human genomic DNA. Each -1 .5kb sequence is matched with an exon (or two exons) of the human gene that is targeted for disruption.

For safety reasons tumour suppressor genes will not be targeted for disruption using this technology.

Origin & function

GM constructs:
The most hazardous GM constructs are the packaged AAV viral vector particles. This is because they could potentially infect both non-dividing and proliferating human cells including those of laboratory workers (e.g., through needlestick injury).

However, these AAV vector constructs are not replicating viruses. They do not express viral proteins and cannot easily integrate into host data via their ITR sequences. Recombination by homology-driven targeting of human genes is very inefficient. Non-homologous targeting is even less efficient. Hence, although the transient extrachromosomal expression of the AAV vector and its drug resistance gene is likely, stable exogenous gene expression is unlikely. The packaged AAV virion envelope proteins are encoded by the packaging system and not by the AAV vector so cannot be expressed and, in any case, they are poorly immunogenic in man (this is supported by the safe use of AAV gene expression vectors in human gene-modified cell therapy).

There are three types of GMOs created:
*1. E. coli containing the AAV transgene plasmid - these GMOs are not more hazardous than the disabled E. coli itself.
*2. HEK293T containing AAV transgene and packaging plasmids. This cell creates packaged viral vector (see above). The hazard of these GMOs is equal to that of the packaged virions they produce.
03. Human cell lines / stem cells / lab worker's own cells containing packaged AAV viral vector.

If tumour suppressor genes would be knocked out in lab workers' own cells this could theoretically result in cancer. For this reason we will strictly prohibit the use of AAV virions to knock out tumour suppressor genes. Otherwise, the cells will not gain additional hazards to either humans or the environment from being transduced with these virions.

It is theoretically possible to generate a fully immuno-privileged cell line by a combination of several gene
disruptions and Class1 b MHC gene expression. The generation of an immuno-privileged cell line is therefore prohibited unless the cell line already contains a functional and validated cell fate "suicide" gene. The AAV virus does not cause disease or a significant immune response in humans. The AAV-based gene disruption vectors used in this study are expected to be further disabled. We will not disrupt any tumour suppressor genes. No categories of human individuals are thought to be at increased risk. This is also true of humans latently infected with either Adenovirus or Herpes virus. This is because our AAV-based vectors do not carry the rep and cap genes that required for both AAV viral replication and viral packaging and for ITR-driven chromosomal insertion. None of the drug resistance genes used provide resistance to antibiotics that are currently clinically-relevant and none of the proteins expressed from these drug resistance genes are known to be especially toxic or abnormally allergenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

1) Containment Level 2 is not required for the GM Class 1 work producing non-expression shuttle plasmids in E. coli.
2) We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as there are no such disease vectors which could disseminate these GMOs.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Non-human tissue solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Chemical Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. Autoclaved liquid waste will be disposed of through a sink to public sewer.

HTA-defined human tissue solid and contained liquid waste is disposed of directly (without prior disinfection) into dedicated bins which are sealed once full and wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incideration through an appropriately licenced waste company as above. Any remaining liquid waste will be treated with 1 % Virkon (final w/w) or 5% ChemGene (final w/w) for both of which independent validated efficacy against human tissue exists.

The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y
The Genetic Modification Committee discussed and commented on the proposed work, and after consultation with the Scientists who will be undertaking the laboratory work, the project was approved on 29 November 2017 and the Biological Safety Officer was actioned to complete the HSE Notification for a subsequent Class 2 activity.

### Project Additional Information

**Purposes of the contained use**

- The objective of these projects is to use gene editing techniques to edit the host cell genome.

- The genome editing can be used to correct or introduce specific mutations in target genes or the targeted “knock-in” of desired transgene sequences and associated
regulatory elements. In addition, this approach can also be adopted to knock out specific gene expression by the introduction of stop codons into the reading frame of the target gene and the expression of the transgene from the endogenous promoter.

Furthermore, the approach can be used to completely knock out the function of a target gene by the incorporation of a selectable marker into the reading frame of the targeted sequence.

Cells which undergo the genome editing will be used for various purposes such as:
1. The incorporation of fluorescent proteins into the coding sequence of host cell genes that are only expressed in certain cell lineages. This will allow the real-time imaging and monitoring of cell differentiation from pluripotent stem cells.
2. The expression of a single exogenous human T cell receptor (TCR) α and/or β-chain sequence from a specific locus.
3. The knock-in of specific genes e.g. HLA alleles or genes encoding host proteins that we wish to confirm are immunogenic in cells that normally lack the expression of these proteins.
4. The addition of epitope tags to the coding sequence of host cell proteins e.g., to enable antibody-mediated purification or detection by FACS.
5. The mutation of host cell proteins in order to modify function e.g., mutation of an amino acid that is post translationally modified.

**Recipient or parental organism**

Recipient organisms:
- Escherichia coli - Disabled laboratory K12 strains of E.coli for standard gene cloning and shuttle plasmid vector preparation. ACDP Hazard Group 1
- AAV-293 cells - Human HEK293-derived cell line that stably expresses the Adenoviral E1 gene. ACGM Class 2. This will be used to package AAV vector
- AAV-HT1080 cells - Human cell line which stably expresses the Adenoviral E1 gene. ACGM Class 2. This will be used for titration of AAV vectors
- Human primary cells ((ACDP HG2 - potential but not confirmed pathogen presence); established human cell lines; human HEK293T cell line and its derivatives - Human HEK293-derived cell line that stably expresses the Adenoviral E1 gene. ACGM Class 2. This will be used to package AAV vector.

**Host/vector system**

Adeno-associated viruses (AAVs) are naturally replication-deficient small ssDNA genome human parvoviruses (aka Dependoparvoviruses, ACDP HG2). AAV viruses infect the cells of humans and some other primate species. Natural AAV replication requires co-infection with a helper Adenovirus or Herpes virus. AAV by itself does not cause any disease in humans and only elicits a very mild immune response. Recombinant AAV vectors can infect both dividing and quiescent cells and persist for many cell divisions in an extrachromosomal state without integrating into the genome of the host cell. The native virus and some AAV-derived viral vectors can undergo ITR-dependent integration into a single genetic on the long arm of chromosome 19 (19q13-qter), termed the AAVS. The AAV vectors that we will use are unable to perform ITR-dependent integration and are further disabled by the removal of both the replication (rep) and structural capsid (cap).

Our AAV genome editing vectors are designed to contain regions of DNA that are homologous to the sequence of the target locus to be edited with the transgene insertion. During cell division and DNA replication this homology permits the site-specific incorporation of extrachromosomal recombinant AAV vector ssDNA at a low frequency. These relatively rare homology-driven gene editing events require drug selection for the identification and isolation of resultant gene disrupted cell lines. If required, the drug selection gene can be removed afterwards using a plasmid that expresses a site-specific recombinase such as Cre or FLP.

Our gene editing vectors are based on the AAV Helper-Free System which eliminates the requirement for viral co-infection during both the AAV vector production and AAV stock titration steps, thereby making the system safer. The AAV Helper-Free System requires co-transfection of the vector plasmid with a helper plasmid that expresses a limited number of the viral genes that are essential for viral vector packaging.

rAAV vectors for transgene expression incorporating the AAV Internal Tandem Repeat sequences (ITRs) at the extreme 5’ and 3’ ends.
The packaging plasmids encode REP CAP proteins and adenoviral accessory proteins. These plasmids may incorporate:

- fluorescent proteins and reporter genes;
- T-cell receptor proteins;
- HLA proteins;
- Suicide genes;
- Adenoviral accessory proteins;
- REP CAP proteins

### Origin & function

**Originating organisms of inserts:**

- **Human** - (Synthetic codon-optimised sequences from gDNA and mRNA) - ACDP HG1
- Various non-pathogenic species (e.g. jellyfish Aequorea Victoria, tomato, plum, Discosoma sp.) - Reporter sequences - ACDP HG1
- Picornavirus-derived sequences – e.g. Poliovirus; Rhinovirus; Encephalomyocarditis virus (IRES), e.g. Foot and Mouth virus, Porcine Teschovirus; Equine Rhinitis A virus; Thosea asigna virus (2A-like skip sequence peptides). - ACDP HG3 / SAPO Group 3-4 (but all sequences used are non-pathogenic synthetic sequences)
- Simian virus 40; Cytomegalovirus (gene expression promoter for drug resistance; polyA sequences) - ACDP HG2 (synthetic non-pathogenic sequences)
- Streptomyces alboniger; Escherichia coli; Aspergillus terreus); Streptocolloteichus hindustanus; Klebsiella pneumoniae (synthetic antibiotic resistance genes) - ACDP HG1-2 (synthetic non-pathogenic sequences)
- Herpes simplex virus Type 1– (synthetic thymidine kinase) - ACDP HG2 (synthetic non-pathogenic sequences)
- Cow, rabbit – (synthetic polyA sequences) - ACDP HG1 (synthetic non-pathogenic sequences)
- E. coli bacteriophage P – (synthetic Cre recombinase gene) - ACDP HG1 (synthetic non-pathogenic sequences)
- Saccharomyces cerevisiae – (synthetic FLP recombinase) - ACDP HG1 (synthetic non-pathogenic sequences)

The AAV vectors will target transgene expression to a defined loci. The AAV vector will contain the AAV ITR sequence, homology arms transgene and selectable marker. Several loci may be targeted for transgene expression. For example:

1. Loci that express genes with high constitutive expression e.g genes with house-keeping function
2. Knock in of the transgene with exogenous promoters into genomic safe harbour sites e.g AAVS1
3. Insertion of transgenes into loci associated with a defined cell lineage so that lineage differentiation from stem cells can be followed
4. Insertion of transgene sequences into human cell lines which may be used for the production and packaging of lentiviral vector particles.
5. Knock in of a specific HLA allele or another gene encoding a human protein/variant

Intentional insertion of oncogenes or targeting of known tumour-suppressors will not be permitted.
The most hazardous GM constructs are the packaged AAV viral vector particles. This is because they could potentially infect both non-dividing and proliferating human cells including those of laboratory workers (e.g., through needle stick injury).

However, these AAV vectors are not replicating viruses. They do not express viral proteins and cannot easily integrate into host data via their ITR sequences. Recombination by homology-driven targeting of human genes is very inefficient. Non-homologous targeting is even less efficient. Hence, although the transient extrachromosomal expression of the AAV vector and its drug resistance gene is likely, stable exogenous gene expression is unlikely. The packaged AAV virion envelope proteins are encoded by the packaging system and not by the AAV vector so cannot be expressed and, in any case, they are poorly immunogenic in man (this is supported by the safe use of AAV gene expression vectors in human gene-modified cell therapy).

Other gene constructs disrupting anti-apoptotic genes could, if inadvertently entered into the body, cause local cell death. To minimise the likelihood of this occurring such constructs will not be used in any AAV vectors. Instead these gene disruptions will be limited to non-viral vectors that require additional cell transfection reagents and protocols e.g. electroporation of ribonucleoprotein complexes.

There are four types of GMOs created:

- E. coli containing the AAV transgene plasmids or lentiviral vector expressing sequence specific nuclease – these GMOs are not more hazardous than the disabled E. coli itself.
- HEK293T containing AAV transgene and packaging plasmids. This cell creates packaged viral vector (see above). The hazard of these GMOs is equal to that of the packaged virions they produce.
- HEK293T containing the lentiviral vector and associated packaging plasmids. This cell creates packaged viral vector (see above). The hazard of these GMOs is equal to that of the packaged virions they produce.
- Human cell lines / stem cells / lab worker’s own cells containing packaged AAV viral vector.

- If tumour suppressor genes would be knocked out in lab workers’ own cells this could theoretically result in cancer. For this reason we will strictly prohibit the use of AAV virions to promote the integration of the transgene at loci with known tumour suppressor function, nor will we permit the expression of functional known human oncogenes (e.g. KrasV12) from the transgene. Otherwise, the cells will not gain additional hazards to either humans or the environment from being transduced with these virions. In addition, we strictly prohibit the use of this technology to promote the expression of pathogenic proteins (e.g. bacterial toxins) that may be harmful to human health.
- It is theoretically possible to generate a fully immuno-privileged cell line by a combination of several gene disruptions and lack of Class1b MHC gene expression. The generation of an immuno-privileged cell line is therefore prohibited unless the cell line already contains a functional and validated cell fate “suicide” gene.
- Cells whose genome has been edited should be no more hazardous than the equivalent non-transduced cells.

The AAV virus does not cause disease or a significant immune response in humans. The AAV-based gene disruption vectors used in this study are expected to be further disabled. We will not target any tumour suppressor genes for transgene insertion nor will we express oncogenic proteins in the transgene. In addition, we strictly prohibit the use of this technology to promote the expression of pathogenic proteins (e.g. bacterial toxins) that may be harmful to human health.

Constructs disrupting anti-apoptotic genes could, if inadvertently entered into the body, cause local cell death. Given the nature of the project the risk of any disruption is very low. In addition suicide systems will be incorporated.

No categories of human individuals are thought to be at increased risk. This is also true of humans latently infected with either Adenovirus or Herpes virus. This is because our AAV-based vectors do not carry the rep and cap genes that required for both AAV viral replication and viral packaging and for ITR-driven chromosomal insertion. None of the drug resistance genes used provide resistance to antibiotics that are currently clinically-relevant and none of the proteins expressed from these drug resistance genes are known to be especially toxic or abnormally allergenic.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

1) Containment Level 2 is not required for the GM Class 1 work producing non-expression shuttle plasmids in E. coli.

2) We do not require the measure “Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs” as there are no disease vectors which could disseminate these GMOs.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most liquid waste is inactivated in freshly prepared 1% Virkon or 5% Chemgene (both final concentration wt/vol) for at least one hour contact time before being poured down the foul drain.

At CL1, solid waste is disinfected where practicable and disposed of as hazardous waste for off-site incineration.

At CL2, non-human tissue solid waste will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. The autoclaved solid waste will be disposed of as Hazardous Waste via incineration through an appointed specialist waste management company.

HTA-defined human tissue solid and contained liquid waste is disposed of directly (with or without prior disinfection) into dedicated bins which are wiped on the outside with 70% ethanol before disposal as Human Tissue Waste for special incineration through an appointed specialist waste management company.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The Genetic Modification Committee discussed the proposed work, and after consultation with the Scientists that will be undertaking the laboratory work, the project was approved and the Biological Safety Officer was actioned to complete the HSE Notification for a subsequent class 2 activity.

Human Clinical Applications
# Project Additional Information

## Purposes of the contained use

The purpose of this project is to produce virus-based gene expression vectors that will be used for transducing primary human cells or cell lines of immune effector cell types such as lymphocytes, macrophages, dendritic cells or natural killer cells for research and development purposes. The vectors will encode Immuno-modulatory proteins/complex or pools/libraries of Immuno-modulatory proteins/complexes. Immuno-modulatory proteins/complexes are members of the immunoglobulin superfamily (IgSF) which control innate and adaptive immunity, and are possible candidates for use in cell-based treatment of malignancies, autoimmune diseases and infectious diseases.

## Recipient or parental organism

- **Bacteria, ACDP Hazard Group 1:** Laboratory strains of diasabled Escherichia coli K12. For shuttle plasmid preparation, not for gene expression.
- **Human cell lines, ACDP Hazard Group 2, ACGM Class 2:** e.g., HEK293T host cell line for viral vector packaging, Jurkat cell line as vector target cells to evaluate Immuno-modulatory proteins/complexes.
- **Viral vector, ACGM Class 2:** Packaged viral vector particles.
- **Human primary cells, ACDP Hazard Group 2:** Immune effector cell types as vector target cells to evaluate Immunomodulatory proteins/complexes.
Packaged replication-defective, self-inactivating lentiviral vector particles:
Third Generation lentiviral vector packaging systems (without the HIV-1 Tat gene) made in-house or commercially acquired: Consisting of 3 or more shuttle plasmids that express viral packaging proteins plus a transgene vector expression plasmid. The transgene vector is transcribed into RNA in the packaging host cell line. Packaged vector RNA is converted to DNA in the transduced target cell, then integrated into the target cell genome to permit stable transgene expression.

Origin & function

Origins:
Human immuno-modulatory genes (cDNA and synthetic)
Human primary T cell lymphocytes and cell lines (ACDP HG2)
Human primary Natural Killer cells and cell lines (ACDP HG2)
Human primary Macrophages and cell lines (ACDP HG2)
Human primary Dendritic Cells and cell lines (ACDP HG2)
Human HEK293 and HEK293T cell lines and their derivatives (ACDP HG2)
Lentiviral vector host cell lines, containing adenoviral E1 genes. HEK293T cell line also contains the SV40 Large T-antigen.

Intended functions:
The above cell lines will be transduced with lentiviral vectors so that they then stably express immuno-modulatory proteins as possible candidates for use in cell-based treatment of malignancies, autoimmune diseases and infectious diseases.
The GMM produced (vectors and cells) will be used for in vitro studies performed in Containment level 2 laboratories and as such have been assessed as ACGM Class 2

Evaluation of foreseeable effects

The most hazardous foreseeable effect is transduction of the laboratory workers own "self" cells with lentiviral vector particles.
The consequences of this are potentially significant but are limited to the cells transduced as the vector is not capable of producing viable progeny vector.
The cell-based consequences of the transduction of self cells are limited to the lifespan of the primary cells transduced. None of the immuno-modulatory genes are associated with onogenic transformation. In addition, the immunomodulatory genes to be studied are only functional in a limited number of cell types.
In respect of both primary cells and cell lines there are a number of immune compatibility barriers such as MHC. For this reason workers are not allowed to use self cells.
Furthermore the use of sharps and needles is prohibited.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

1. Containment Level 2 is not required for the E.coli GM Class 1 work where shuttle plasmids are produced which cannot express the immuno-modulatory genes being studied in human cells.
2. We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as no disease vectors capable of dissemination will be in use.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. Autoclaved liquid waste will be disposed of through a sink to public sewer.

The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months

Any remaining liquid waste will be treated with 1% Virkon (final w/vol) or 5% ChemGene (final w/vol) for both of which independent validated efficacy against human tissue exists.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The Genetic Modification Committee discussed and commented on the proposed work, and after consultation with the Scientists that will be undertaking the laboratory work, the risk assessment was approved by the Committee on 7 September 2017

Project Ref 3242/19.2

Date Ackn’d 02/03/2022  CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4
The purpose of this project is to produce or purchase non-viral gene expression vectors that will be used for transfecting either primary or immortalised mammalian cell lines with oncogenic, potentially-oncogenic and/or mitogenic mammalian and viral genes. In some circumstances gene expression will be controlled not by the direct expression of ORF sequences but by other means including siRNA. Potentially-oncogenic and/or mitogenic proteins and the inhibition of the function of tumour suppressor genes will be restricted to non-viral vector systems that, for safety reasons, rely on nucleic acid-based mammalian cell transfection. These cells / cell lines will be used, amongst other purposes, as systems to elicit and/or measure responses from immunologically-active cells (e.g., T cell responses to target cell-produced cancer antigens).

Recipient or parental organism

Bacteria, ACDP Hazard Group 1: Laboratory strains of disabled Escherichia coli K12. For shuttle plasmid preparation, not for bacterial gene expression.

Mammalian cell lines, ACDP Hazard Group 2, ACGM Class 2 (e.g., human lines including HEK293T, Jurkat, A375, SupT1, HT1080 and animal cell lines such as COS-7, CHO-K1 and BHK21 and their derivatives).

Transfected mammalian primary cells, ACDP Hazard Group 2, ACGM Class 2 (e.g., Human primary T cells, NK cells, NKT cells, follicular dendritic cells, macrophages, hepatocytes, cardiac myocytes).

Host/vector system

All gene expression plasmids will be non-viral, non-mobilising and non-mobilisable in E.coli. The only exception being mobilisable plasmids based on the pBR322 origin of replication which will be restricted to E.coli strains that lack the mobilising function of F factor (as either free or integrated F plasmid).

Gene expression shuttle plasmids requiring transfection include transient and/or stable gene expression plasmid vectors based on the SV40 virus T antigen coupled with the SV40 origin or, alternatively, vectors based on the EBV viral EBNA-1 gene coupled with the EBV OriP origin of replication.
The non-viral vector transfection of mammalian cells with potential oncogenes can be transient or stable. Stable transfection can be via random integration or by specific gene targeting. Targeting can be assisted by co-transfection of a gene editing gene knock-in system. The knock-in template oncogene must not be supplied via a viral vector. Transposon-based gene expression systems.

**Origin & function**

**Origins:**
- Health and Safety
- Executive

**Potentially-oncogenic and/or mitogenic genes including known or suspected mammalian or viral oncogenes and natural or synthetic genes that decrease or inactivate tumour suppressor genes or proteins (cDNA or synthetic origin). These genes can be expressed as proteins with antigenic epitope and/or purification tags (e.g., Biotin, His-tag, HA-tag, Myc-tag, FLAG, GST, MAP, CAT, V5) or co-expressed with reporter genes (e.g., GFP and other fluorescent protein genes from marine invertebrates, luciferase from insect species and beta-galactosidase genes from bacteria), gene expression control protein genes (e.g., Tet-On or Tet-Off repressor proteins from bacteria), RNA-silencing suppressor genes (plant virus and mammalian viral origin) and/or antibiotic resistance genes (e.g., G418/Kanamycin, Puromycin, Zeocin, Blasticidin and other antibiotic resistance genes of bacterial origin).

**Replication-defective, self-inactivating retroviral vectors derived from murine retroviruses (ACDP HG2)**

**Plasmid vectors based on the SV40 T antigen with the SV40 origin (ACDP HG2) or alternatively vectors based on the EBV viral EBNA-1 gene with the EBV OriP origin of replication (ACDP HG2).**

**Transposon-based gene expression systems adapted from eukaryotic cell transposons (ACDP HG2).**

**Mammalian primary cells and cell lines (ACDP HG2)**

**Intended functions:**

The above cells and cell lines will be transfected with non-viral vectors so that they then express potentially oncogenic/mitogenic proteins. These cells / cell lines will be used, amongst other purposes, as systems to elicit and/or measure responses from immunologically-active cells (e.g., T cell responses to target cell-produced cancer antigens). The GMM produced (plasmids, packaged viral vectors, transposon systems and mammalian cells) will be created using shuttle plasmids assembled and prepared in E.coli (ACGM Class 1). Plasmid DNA and transposon expression vector transfections of mammalian cells (ACGM Class 2) will performed in Containment level 2 laboratories as will all experiments using the resulting transfected mammalian cells.

**Evaluation of foreseeable effects**

The most hazardous foreseeable effect is the inadvertent (albeit extremely unlikely) transfection of the laboratory workers own primary "self" cells which might then result in their oncogenic transformation. It is for this reason that viral vectors are expressly disallowed.

The likelihood of serious consequences of such a transfection of "self" cells is limited as there are a number of immune compatibility "non-self" barriers to cell growth including MHC alloreactivity. To retain these barriers workers are not allowed to deliberately transfected their own "self" cells. Furthermore, the use of sharps and needles is prohibited.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

1. Containment Level 2 is not required for the E.coli GM Class 1 work on the assembly and production of DNA shuttle
plasmids as the transgenes are not expressed in bacteria.

2. We do not require the measure "Efficient control of disease vectors (e.g., for rodents and insects) which could disseminate GMMs" as no such disease vectors capable of dissemination will be in use.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. Autoclaved liquid waste will be disposed of through a sink to public sewer.

The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months.

Any remaining liquid waste will be treated with 1 % Virkon (final w/vol) or 5% ChemGene (final w/vol) for both of which independent validated relevant decontamination efficacy exists.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The Biological Genetic Modification Safety Committee discussed and commented on the proposed work, and after consultation with the scientists that will be undertaking the laboratory work, the attached representative risk assessment GMO RA 270: Expressing surface target antigens (oncogenes and potential oncogenes) was approved by the Committee on 20th March 2019.

Project Ref 3242/19.3
The purpose of this project is to produce or purchase both non-viral and virus-based gene expression vectors that will be used for transfecting or transducing either primary or immortalised mammalian cell lines with various mammalian and viral genes. In some circumstances gene expression will be controlled not by the direct expression of ORF sequences but by other means including siRNA. Most importantly, the expression of potentially-oncogenic and/or mitogenic proteins and the inhibition of the function of tumour suppressor genes will be avoided.

Recipient or parental organism

Bacteria, ACDP Hazard Group 1: Laboratory strains of disabled Escherichia coli K12. For shuttle plasmid preparation, not for bacterial gene expression.

Mammalian cell lines, ACDP Hazard Group 2, ACGM Class 2: i.e., Host cell lines for viral vector packaging (e.g. human HEK293T) as well as vector-transfected/transduced recipient cell lines (e.g., human lines including HEK293T, Jurkat, A375, SupT1, HT1080 and animal cell lines such as COS-7, CHO-K1 and BHK21 and their derivatives)

Packaged viral vector particles ACDP Hazard Group 2, ACGM Class 2 (e.g., packaged AAV or lentiviralretroviral vectors)

Vector transfected/transduced mammalian primary cells, ACDP Hazard Group 2, ACGM Class 2 (e.g., Human primary T cells, NK cells, NKT cells, follicular dendritic cells, macrophages, hepatocytes, cardiac myocytes).

Host/vector system

All virus-based and non-viral gene expression plasmids will be non-mobilising and non-mobilisable in E.coli. The only exception being non-mobilisable plasmids based on the pBR332 origin of replication which will be restricted to E.coli strains that lack the mobilising function of F factor (as either free or integrated F plasmid).

Packaged replication-defective, self-inactivating retroviral and lentiviral transduction vector particles:
Murine retroviral and third generation lentiviral vector packaging systems (without the HIV-1 Tat gene, without WPRE sequences) made in-house or commercially acquired: Packaging of retroviral and lentiviral vectors with or without shuttle plasmids that express viral packaging proteins (including various alternative viral pseudotyping proteins) plus a transgene vector expression plasmid. The transgene vector is transcribed into genomic RNA in the packaging host cell line. Packaged vector gRNA is converted to DNA in the transduced target cell, then usually integrated (some vectors will be intentionally integration-deficient) into the target host cell genome to permit stable transgene expression. These virus-based vectors are incapable of self-replication, unable to produce infectious progeny and will use LTR insertion sequences that contain "self-inactivating" deletions that disable their LTR promoters. None of these vectors will use potentially-oncogenic WPRE sequences to boost gene expression.

Non self-replicating AAV gene expression transduction vectors (both episomal and stably-integrated).

Transfection of mammalian cells with non-oncogenic genes can also be transient or stable. Stable transfection can be via random integration or by specific gene targeting. Targeting can be assisted by co-transfection of a gene editing gene knock-in system. The non-oncogenic gene to be knocked in could be supplied on a viral (e.g., AAV) or non-viral (e.g., plasmid or transposon) template.

Non-packaged expression shuttle plasmids requiring transfection including vectors based on the SV40 virus T antigen with the SV40 origin or, alternatively, vectors based on the EBV viral EBNA-1 gene with the EBV OriP origin of replication.

Transposon-based gene expression systems.

**Origin & Function**

**Origins:**
- Non-oncogenic, non-mitogenic genes (cDNA and synthetic) including mammalian HLA-MHC class I (with or without beta 2m), HLA-MHC class II, reporter genes (e.g. GFP and other fluorescent protein genes from marine invertebrates, luciferase from insect species and beta-galactosidase genes from bacteria), gene expression control protein genes (e.g., Tet-On or Tet-Off repressor proteins from bacteria), RNA-silencing suppressor genes (plant virus and mammalian viral origin), antibiotic resistance genes (e.g., G418/Kanamycin, Puromycin, Zeocin, Blasticidin and other antibiotic resistance genes of bacterial origin), genes for the parent proteins of immunological epitopes, viral protein genes used for viral vector packaging (lentiviral vector packaging plasmids: Gag-Pol and Rev from HIV-1 plus pseudotyping envelope protein genes from VSV and other viruses. AAV vectors: Adenoviral and AAV genes) (ACDP HG1 and HG2).
- Expressed ORFs to optionally include antigenic epitope and/or purification tags (e.g., Biotin, His-tag, HA-tag, Myc-tag, FLAG, GST, MAP, CAT, V5).
- Plasmid vectors based on the SV40 T antigen with the SV40 origin (ACDP HG2) or alternatively vectors based on the EBV viral EBNA-1 gene with the EBV OriP origin of replication (ACDP HG2).
- Transposon-based gene expression systems adapted from eukaryotic cell transposons (ACDP HG2).
- Replication-defective, self-inactivating retroviral vectors derived from murine retroviruses (ACDP HG2).
- Replication-defective Adeno-associated viral (AAV) expression vectors (ACDP HG2).
- Mammalian primary cells and cell lines (ACDP HG2).
- Human HEK293 and HEK293T lentiviral and AAV viral vector packaging cell lines and their derivatives containing integrated adenoviral E1 genes. The HEK293T cell line also contains the SV40 Large T-antigen (ACDP HG2).

**Intended functions:**
- The above cells and cell lines will be transfected with non-viral vectors or transduced with viral vectors so that they then stably express non-oncogenic non-mitogenic proteins or so they express genes that suppress host genes not including host tumour suppressor genes.
The GMM produced (plasmids, packaged viral vectors, transposon systems and mammalian cells) will be created using shuttle plasmids assembled and prepared in E.coli (ACGM Class 1). Plasmid DNA and transposon expression vector transfections and the viral vector transduction of mammalian cells (ACGM Class 2) will performed in Containment level 2 laboratories as well all experiments using the resulting transfected/transduced mammalian cells.

**Evaluation of foreseeable effects**

The most hazardous foreseeable effect is the inadvertent transduction of the laboratory workers own primary "self" cells with viral vector particles that have broad cellular tropisms. The consequences are limited to the properties of and host reaction to these transduced "self" cells. GM viral vectors used are not capable of producing viable infectious self-replicating progeny and are designed not to recombine with endogenous viral sequence to produce viable progeny. Furthermore the consequences of the transduction of "self" cells are limited to the lifespan of the primary cells transduced as no oncogenic or mitogenic transformation will occur. Lastly, for both primary cells and cell lines there are a number of immune compatibility "non-self" barriers to cell growth including MHC alloreactivity. To retain these barriers workers are not allowed to transfet or transduce their own "self" cells. Furthermore, the use of sharps and needles is prohibited.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

1. Containment Level 2 is not required for the E.coli GM Class 1 work on the assembly and production of DNA shuttle plasmids as the transgenes are not expressed in bacteria.
2. We do not require the measure "Efficient control of disease vectors (e.g. for rodents and insects) which could disseminate GMMs" as no such disease vectors capable of dissemination will be in use.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste and some liquid waste generated during this procedure will be collected and sterilised by autoclaving at 121°C for 25 minutes for 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste. The autoclaved solid waste will be disposed of via incineration through an appropriately licenced hazardous waste company. Autoclaved liquid waste will be disposed of through a sink to public sewer. The waste cycle on the autoclave is fully validated and temperature-tested every 12 months and the efficacy of steam penetration is tested using Thermalog strips every 3 months. Any remaining liquid waste will be treated with 1% Virkon (final wt/vol) or 5% ChemGene (final wt/vol) for both of which independent validated relevant decontamination efficacy exists.

All liquid waste containing Class I GMMs will be chemically inactivated using 1% Virkon for at least 30 minutes and washed down designated laboratory sinks with copious amounts of cold water. Virkon kills 99.9995% of GMMs in 10 minutes. This will be routinely tested using agar plate colony assays.

All solid waste containing Class I GMMs will be chemically treated as above (if it contains any liquids) and after liquid disposal, the solid material will be autoclaved (124°C for 15 minutes). This effectively kills 100% of the GMMs and will be tested annually as above. The autoclaved material will then be disposed of as laboratory waste by Grundon contractors.

For activities involving GMMs, describe the waste management measures which will apply to the activity

This risk assessment was reviewed by the committee and after minor modifications and suggestions, it was approved. This risk assessment was also approved by Imperial College when the project was carried out there, prior to being spun out into a commercial enterprise.

Give brief details of the genetic modification safety committee

The Symbiosis GM safety committee has been established and has met.

The committee comprises of experienced Technical staff from core staff representatives, project management, Quality, manufacturing and Engineering. Further expert specialist technical advice will be available as required from external sources or the QP.

The GM safety committee meet to review each new potential GM project. Routine process's will be monitored and feedback collated via the routine 'SAFE' meetings with the minutes circulated to all of the GM safety committee.

The Symbiosis process utilises single use disposable items for all product contact materials throughout the MHRA licensed formulation and vial filling process. Further to this, Symbiosis utilise a specialist licensed contract waste management company with a pathway for clinical waste incineration. It is intended that all waste materials used in the manufacturing of the vector will be decontaminated with an appropriate agent and contained post treatment for disposal by incineration.

Agents for Decontamination:
A technical evaluation of disinfectant antiviral activity for the proposed project has been completed. Based on this study, it is proposed to utilise a suitable concentration of NaOH. After sodium hydroxide treatment items are placed in sealable containers in preparation for collection by a licensed contractor for incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GM safety committee noted, that the product has been previously assessed and approved by the client at the primary/upstream manufacturing facility as requiring containment level 1. It was further noted that the purified viral vector is not considered as 'live' at the formulation and filling stages to be completed at Symbiosis. The project involves the use of a minimal HIV-1 vector, in that most of the viral genes have been removed from the vector genome. Furthermore, these vectors are unable to replicate and are self-inactivating and would not survive beyond the facility to cause infection.

It was noted that modifications to the waste stream are required to incorporate exposure to NaOH. It is also proposed to install a Cat II Microbiological safety cabinet for the bulk pooling step which currently presents the greatest risk of operator exposure to the largest volume of product.

Give brief details of the genetic modification safety committee

The IONTAS Ltd genetic modification committee will consist of:

1. The biosafety officer who has extensive experience of genetic modification issues, being currently in charge of biosafety for a large research institute. The biosafety officer will chair all genetic modification committee meetings.
2. The Chief Executive Officer has 26 years experience of genetic modification and previously ran research groups both in industry and academia. His function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.
3. Group Leader who has 25 years experience of genetic modification in E. coli and mammalian cells. He will provide advice and ensure the actions arising from the committee meetings are implemented.
4. Research Scientist who is a specialist in mammalian cell culture has 8 years experience. She will provide advice and write the minutes of the meetings.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.

Level 1 (GMMs)

Yes

Level 2 (GMMs)

Level 3 (GMMs)

Level 4 (GMMs)
We intend to adopt the waste disposal procedure currently used by the Babraham Institute (GM105) and other companies on the Babraham Research Campus (BRC) under derogation (GM105/04.1): Waste from laboratories carrying out GM work at Class1 will be placed into suitably labelled hermetically sealable bins. The bins are 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003. They will be sealed by the producer of the waste and removed to a central collection point where they will be placed into 210 litre yellow labelled “Eurobins”. Collections by the local registered clinical/GM waste incinerator contractor (Vetspeed – GM 898) will be made three times a week to prevent a build-up. The BRC has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be maintained on site, as required by the Regulations, in case of loss of the contractor's facilities.

Liquid waste is inactivated by the addition of "Virkon" according to the manufacturer's instructions prior to disposal. Validation experiments will be carried out in-house using microbiological testing. (Smaller volumes (i.e. <10ml) will then be disposed of in sealed tubes with the solid waste. Larger volumes will be disposed of via the drainage system. This is then processed through our own sewage treatment plant which is closely monitored. This results in approximately 5 litres of diluted inactivated waste from each

Tick to confirm that you are attaching a summary of the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

Prior to handling of GMM on site a verified liquid decontamination method is to be transferred in from the manufacturer of the GMM drug substance. For decontamination of waste from GMP manufacture if waste is present from operations within an isolator a clear bag is to be used and sealed with a cable tie prior to removal from the isolator as captured under “safe bag” procedure and placed within a UN3291 yellow biohazard waste bin. If waste is generated in GMP manufacture outside of an isolator then waste is to be added into a yellow UN3291 biohazard waste bag and prior to placing in a yellow biohazard waste bin sealed with a cable tie. All surfaces of the yellow biohazard waste bin are decontaminated with 1% Virkon and given a 20 minute contact time prior to removal from the GMP suite. Subsequently the yellow biohazard waste bins are removed from the GMP suite and stored in the dedicated biohazard storage area ready for collection by the licenced waste collection service for incineration.

Should GMMs be used for analytical development activities samples and consumables where feasible will be submerged in 1% Virkon with a minimum contact time of 30 minutes prior to disposal in a yellow biohazard waste bin. Where submerging of consumables is not feasible they are to be directly placed into a yellow biohazard waste bag within a yellow biohazard waste bin.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment Y

Please enter comments of the GM safety committee on the risk assessment

The laboratory and manufacturing facilities at Quay Pharmaceuticals are prepared for working with human hazard class 2 microorganisms and would leverage these biosafety controls for safe handling of class 1 GMMs. Due to the nature of Quay's operations in handling a diverse range of microorganisms effective cleaning and disinfection procedures are at the forefront of Quay’s practices and will continue to be applied for handling and manufacture with class 1 GMMs.
To assess the impact to viability when lyophilising or spray drying M. pneumoniae liquid cultures to establish a low moisture, stable drug substance material. Should success be seen then further development work would be performed to create a stable drug product formulation that could proceed to GMP manufacture and usage in a human clinical trial.
Client procedure and literature have been consulted to determine a suitable decontamination procedure and this has been verified using the wildtype strain.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A chemical disinfection procedure is to be performed to dispose of waste generated. Waste to be generated can include the liquid culture samples received from the client that are no longer required, liquid samples generated in analytical testing and dehydrated samples generated from freeze drying and spray drying studies not consumed in analytical testing.

Samples are to be submerged in 1% Virkon for 30 minutes and subsequently disposed in UN3291 yellow biohazard. The UN3291 yellow bins are stored in the dedicated biohazard storage area ready for collection by the licenced waste collection service for incineration.

The Virkon solution is to be made fresh on the day of usage and where a liquid dilution is taking place from the sample it will not exceed 5% of the 1% Virkon volume, if so a Virkon solution should be created to account for dilution factor to maintain a 1% concentration. Following the contact time in 1% Virkon the Virkon solution itself is to be held for a minimum of 24 hours before being disposed of.

Should the project being performed be successful and a GMP manufacture desired by the client a review of decontamination procedure will be performed to assess practices to be employed for waste management and decontamination of GMP facilities.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

Although gene mutations have been made to the microorganism to attenuate its virulence and gene inserts are not anticipated to influence virulence there is not sufficient evidence to assign its hazard group assessment lower than that of the wildtype strain.

Give brief details of the genetic modification safety committee

The Committee comprises the following members:

Five full-time University of Roehampton academic staff members (2 Lecturers, 2 Senior Lecturers, 1 Reader) with research experience in mammalian cell biology and microbiology (including the designated co-chairs below).

One full-time University of Roehampton technical laboratory manager with extensive H&S experience.

Two full-time staff members from the University's Health and Safety Office with extensive H&S regulatory experience;

One external consultant (staff at Medical Research Council Head Office) with H&S and GMO regulatory experience.

All academic staff members have PhDs in relevant disciplines and several years of expertise in CL1 and CL2 work and work with GMOs.

The Committee will meet quarterly to discuss shared issues (external consultant may participate by videoconference), and will be chaired by one of the co-chairs in rotation; the other will take minutes. Laboratory inspections will be performed at least twice a year to review compliance, in conjunction with these meetings. Risk assessments will be drafted by the staff member responsible for each project, reviewed internally by a member of staff with relevant expertise (mammalian cell biology or microbiology, as appropriate) and, in case of any doubt or unresolved issues, referred to the external consultant for input. The final risk assessments will be circulated to the Committee with a recommendation to approve/revise/reject, and generally approved by email.

### Microbiology

Bacterial cultures will be grown in liquid or on solid media in sealed containers/flasks in microbiological incubators. According to established laboratory procedures, solid waste will be autoclaved (121°C for 15 min), liquid waste will be de-activated using 10% bleach overnight. Small spillages will be treated with 70% ethanol, while large spillage will be trapped with congealing powder (which will then be autoclaved) and the area further deactivated with 70% ethanol. Bacterial isolates will be cryopreserved in glycerol stocks at -80°C. Work will take place in CL1 laboratory facilities. Laboratory workers will wear personal protective equipment at all times. All stored samples will be labelled in compliance with regulations.

### Mammalian cell culture

Live cell cultures will be handled in a Class II Biosafety cabinet, and cryopreserved in a liquid nitrogen Dewar container. All work will take place in a dedicated tissue facility suitable for CL1 work. All stored samples will be labelled in compliance with regulations.

Inactivation will proceed as follows. Liquid waste will be treated with 10% bleach overnight before sink disposal. Solid waste will be collected in double autoclave bags, and autoclaved on site.

Cell preparations for further analysis will be chemically fixed (2% paraformaldehyde or alcohols) or subjected to detergent extraction following frozen storage, and following use will be further inactivated as described above for liquid waste.

---

CU 1 2000 (rev 11/08) Page 4 of 9

The GM safety committee has approved the risk assessment.
This is a class 2 connected programme of multidisciplinary work with the broad aim of elucidating how genetic and environmental variables and cell interactions conspire to determine the outcomes of infectious, immune-mediated, neurological, and malignant diseases.

The microbiological arm of this project is based on the use of unbiased genome-wide screens for the identification of molecular factors involved in S. aureus and P. aeruginosa infection. The objective is to dissect the interaction of S. aureus with mammalian host cells during intracellular survival and proliferation, to gain biologically relevant insight into the host factors that are co-opted by this pathogen or used against it. For P. aeruginosa, the aim is to determine how genes control and affect virulence in this extracellular pathogen and how this is linked to the pathogen’s antibiotic resistance. This work has the potential to lead to the identification of novel chemotherapeutic targets and a better understanding of the determinants of susceptibility to S. aureus and of virulence and susceptibility in P. aeruginosa, respectively.

A complementary arm of this project involves the genetic manipulation of the mammalian host to study the role of host determinants of resistance or susceptibility to infection. One focus will be on antigen presentation to T cells as a critical step in activating an adaptive immune response. These studies will have broader implications, as well, for antigen presentation in transplantation, vaccine design, autoimmunity, and antitumour immunity. Related pathways contributing to inflammation and immunity (e.g., phagocytosis, activation of respiratory burst, autophagy, pathogen sensing) will also be investigated.
- Escherichia coli DH5 alpha and other K12-derived host strains commonly used in molecular biology
- Staphylococcus aureus NCTC13626
- Pseudomonas aeruginosa PA14

Eukaryotic
- Human immortalised (transformed or malignant) cell lines, such as HeLa, 293T, U937, THP-1, KG-1, and existing mutants and transfectants of these cell lines
- Murine immortalised cell lines, such as A2O-II, and existing mutants and transfectants of these cell lines
- Dedicated packaging cell lines for retro- and lentiviral transduction, such as Phoenix-A, derived from immortalised cell lines
- Human Epstein Barr virus (EBV)-transformed B-cell lines, and derived somatic cell mutants and transfectants
- Short-term cultures derived from human leukocytes, such as monocyte-derived dendritic cells or peripheral blood mononuclear cells.

**Host/vector system**

E. coli and S. aureus / pALC1743 and pIMAY
Pseudomonas aeruginosa PA14 / Mariner based MAR2xT7 transposon

Eukaryotic cells:
- These will be transformed with plasmid, retroviral, or lentiviral vectors, for example:
  - HeLa, U937, or KG-1 transduced with Mission LentIPlex Human Pooled shRNA Library based on pLKO.1-puro vector (Sigma-Aldrich Co.), or similar specific shRNA constructs
  - 293T cells transfected with P12-MMP, pMD-MLV-ogp, pMD2.G
  - EBV-transformed B cell lines transduced with retroviral particles produced in Phoenix-A cells transfected with pBMN-IRES-<marker> vectors, where <marker> refers to genes any screenable or selectable marker, such as GFP, LacZ, or resistance to antibiotics such as neo(R), hygro(R), puromycin(R).

**Origin & function**

Origins:
- The genetic material to be inserted will be obtained from commercial sources (e.g., Sigma-Aldrich), from collaborating academic or industry laboratories, or amplified from appropriate cells of origin (which include the cells identified above as recipient cells).

The intended functions of the genetic material include:
- Expression or repression of genes that mediate or regulate microbial antibiotic resistance or virulence
- Expression or repression of genes that mediate or regulate host cell responses to bacterial infection
- Expression or repression of genes that mediate or regulate antigen presentation to T cells of the immune system

**Evaluation of foreseeable effects**

a) Foreseeable effects on human health.
- from vectors carrying selectable markers

Selectable markers used commonly in plasmid vectors include genes that encode bacterial antibiotic resistance. The possibility exists of spreading antibiotic resistance to lab workers' commensal flora on accidental exposure. This risk is normally managed at CL1 unless other factors necessitate use of CL2.
- from viral vectors

This project will rely heavily on the use of lentiviral or retroviral particles. Lentiviral and retroviral vector constructs are highly efficient vehicles for in vivo gene delivery into mammalian cells. Use of lentiviral vector systems is particularly desirable because of their ability to integrate transgenes into dividing, as well as non-dividing cells.

However, there are risks associated with working with lentiviral or retroviral vectors, and these must be carefully controlled. The major hazards to exposed lab workers are the potential generation of replication competent virus, the potential of viral particles to trigger an antiviral immune response with possibility of immune pathology, and the potential for oncogenesis through insertional mutagenesis. These hazards necessitate the use of Containment Level (CL) 2 for all work with these vectors.

To minimise the risk of re-creating replication-competent virus, we will use vector systems and producer cell lines with inherent safety features, which greatly reduce this
possibility. This is accomplished by splitting the vector system into several plasmids, which produce different proteins required for viral assembly (at least two helper plasmids and one vector containing the vector genome plus transgene). Thus, a number of recombination events would be required to form a complete replication-competent virus increases, which is extremely unlikely.

In order to minimise the risk of insertional mutagenesis or virally-induced inflammation following accidental infection of lab workers with viral vectors, lentiviral/retroviral samples will be handled at CL-2 (Containment Level 2). The cell lines producing viral particles and the particles will be handled in a CL-2 microbiological safety cabinet; double gloves pulled over the cuffs of the laboratory coats will be used at all times. All work will be conducted in a lab with access restricted to authorised and trained personnel. Further, Pasteur pipettes will be substituted with plastic disposable tips. Contaminated labware and equipment will be treated with appropriate decontaminants, e.g., bleach, immediately after use.

-- from inserted genes of interest

Many of the inserts are expected to cause gene expression changes which, in themselves, carry minimal risk to human health (requiring no containment above CL1), but will be performed at CL2 if the host cell requires this level of containment (e.g., use of EBV-transformed B-cell lines as hosts).

The expression of potential oncogenes or the knocking down of tumour suppressor genes may lead to cellular tumorigenic transformation. The silencing of genes by using the RNAi technology will rarely generate a complete lack of gene expression. The heterogeneous expression of the targeted genes may alter the regulatory networks and the stoichiometry of different proteins involved in a variety of cellular processes. RNAi may also trigger a cellular antiviral response, leading to inflammation and the non-specific inhibition of protein synthesis.

-- from recipient cells

One of the sub-projects involves work with Methicillin-resistant Staphylococcus aureus strains. S. aureus is an important cause of skin and soft tissue infections, abscesses, pneumonia, endocarditis, osteomyelitis, foreign-body infections, toxic shock syndrome and sepsis. Because of this, S. aureus is classified as a class II human pathogen. Vancomycin and daptomycin are the first-line antibiotic choices for MRSA bacteremia. The genetic modification of S. aureus NCTC13626 will not involve the generation of either vancomycin nor daptomycin resistant strains. We will generate transiently S. aureus mutants resistant to chloramphenicol. Nevertheless, the deletion mutants will have no added antibiotic resistances.

In the agr deletion mutants, we will inactivate the master regulator of the virulence of this S. aureus. This could make an unpredicted increase of virulence and/or transmissibility in the strain. However, based on previous literature (Infect. Immun. May 2011 vol. 79 no. 5 1927-1935), agr affected mutants are fully-attenuated strains of MRSA. The deletion mutants will be made in-frame to avoid the polar effects on the expression of adjacent genes. The complementation of the deletion mutants will most likely not be fully achieved due to the cost of harboring extra-chromosomal material to the fitness of the mutant strains.

For work related to P. aeruginosa: All the bacteria are loss-of-function mutants, making it very unlikely that they will outcompete the wild-type. PA14NR mutants do carry a gentamicin-resistance cassette for selection purposes, rendering this antibiotic ineffective in treating hypothetical infections.

EBV-transformed B cells generally are latently infected with low levels of infectious virus, or none, being produced in culture. Moreover, adult lab workers will generally have been infected with EBV already and carry immunity to the virus. Nonetheless, there is the possibility of de novo EBV infection of previously unexposed lab workers, which might trigger infectious mononucleosis and increase the long-term risk of malignancy. All work with EBV-transformed B-cell lines will therefore be carried out at CL2, even if the genetic modification itself does not carry hazards to human health.

b) Foreseeable effects on the environment.

Work on host responses to S. aureus

The retroviral vectors will be pseudotyped with the surface glycoprotein of vesicular stomatitis virus (VSV-G), which will increase their range of host tropism becoming pan tropic. In addition, their resistance to dehydration and their ability to survive in the environment may be higher. However, we will generate replication-incompetent viral particles, thus diminishing their chances of spreading.

The pIMAY vector used for this work has an E. coli origin of transfer on its sequence, which could potentially make it a mobilizable plasmid. However, this vector has been adapted to produce deletion mutants on MRSA strains efficiently. Circumventing a strong restriction barrier, combined with an improved deletion and transformation protocol, has allowed the genetic manipulation of previously untransformable MRSA strains. In addition, the set of genes that code for the bacterial conjugation systems are species specific (Microbiol. Mol. Biol. Rev. June 2003 vol. 67 no. 2 277-301) and therefore the chances of transmission of this plasmid from the MRSA target strain to other bacteria are very low. To propagate the pIMAY vector and its derivatives, we will only use E. coli strains that lack the specific set of genes to allow the transfer of this vector via conjugation, minimizing the possibility of its spread.

S. aureus is not considered a specified animal pathogen by the DEFRA. In addition, MRSA strains have lower fitness in comparison with commensal staphylococci part of the natural flora of different animals. However, the transmission of MRSA strains to domestic animals has been increasingly reported by veterinarians (ILAR J.
2010;51(3):233-44).
P. aeruginosa
As all the bacteria are loss-of-function mutants of a lab adapted strain (PA14) and it is very unlikely that they will out-compete environmental wild-types. As it is the nature of the project to investigate determinants of virulence using a near-whole genome library, it is not impossible that some mutants will have altered and heightened patterns of virulence factor production, leading to potentially more severe disease phenotype in the bacterium’s plant, invertebrate or vertebrate hosts.
Eukaryotic host cells
These cells are not viable in the natural environment, so no risk to the environment (other than that to human health, see above) is expected to arise from accidental release.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>Waste Management Measures</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>E. coli will be grown in liquid or on solid media in sealed containers/flasks in microbiological incubators. According to established laboratory procedures, solid waste will be autoclaved (121°C for 15 min), liquid waste will be de-activated using 10% bleach overnight. Small spillages will be treated with 70% ethanol, while large spillage will be trapped with congealing powder (which will then be autoclaved) and the area further deactivated with 70% ethanol. Bacterial isolates will be cryopreserved in glycerol stocks at -80°C. Work will take place in CL1 laboratory facilities. Laboratory workers will wear personal protective equipment at all times. All stored samples will be labelled in compliance with regulations.</td>
<td></td>
</tr>
<tr>
<td>Work involving MRSA and P. aeruginosa will be carried out following the rules of class 2 containment level supplemented by the principles of good microbiological practice. Lab coat and gloves are used as a matter of routine in the lab. Class II Safety cabinets are inspected and validated annually. Bacterial cultures will be grown in liquid or on solid media in sealed containers/flasks in microbiological incubators. According to established laboratory procedures, solid waste will be autoclaved (121°C for 15 min), liquid waste will be de-activated using 10% bleach overnight. Small spillages will be treated with 70% ethanol, while large spillage will be trapped with congealing powder (which will then be autoclaved) and the area further deactivated with 70% ethanol. Bacterial isolates will be cryopreserved in glycerol stocks at -80°C. Work will take place in CL2 laboratory facilities with restricted access. Laboratory workers will wear personal protective equipment at all times. All stored samples will be labelled in compliance with regulations.</td>
<td></td>
</tr>
</tbody>
</table>

All students/staff receive general safety information. Students receive advice and guidance on safety procedures within the laboratory, including culture and disposal of pathogenic micro-organisms. Specialist guidance or training in handling of microorganisms can be provided by the laboratory technicians. Risks of infection are not large providing good microbial practice is maintenance. If skin is breached whereupon individuals should seek medical attention at the nearest available hospital. Such individuals should declare if the organism being handled carried any antibiotic resistance markers. Trained First Aiders would normally be contacted in the event of emergency and incidents would be recorded in the accident book.

Mammalian cell culture: Live cell cultures will be handled in a class 2 safety cabinet, and cryopreserved in a liquid nitrogen Dewar container. All work will take place in a dedicated tissue facility suitable for CL2 work. All stored samples will be labelled in compliance with regulations. Inactivation will proceed as follows. Liquid waste will be treated with 10% v/v household bleach overnight before sink disposal. Solid waste will be collected in double autoclave bags, and autoclaved on site. Cell preparations for further analysis will be chemically fixed (2% paraformaldehyde or alcohols) or subjected to detergent extraction following frozen storage, and following use will be further inactivated as described above for liquid waste.

For the work carried out with viral particles, the following measures will be applied:
- Good laboratory techniques will be strongly emphasised. Designated workers will be trained in good laboratory techniques before commencing work with potentially oncogenic DNA sequences. They will be made fully aware of the potential hazards of such work.
- Access to the laboratory will be limited to authorised personnel and designated workers.
- All experimental procedures will be performed so as to minimise aerosol production. Procedures which are likely to generate aerosols such as the use of sonicators, vigorous shaking and mixing etc. will be avoided, or where necessary, will be carried out in closed containers or a class II microbiological safety cabinet.
- Procedures using lentiviral particles, packaging cell lines and exposed cells will only be carried out in the tissue culture suite.
- Safety cabinets will be routinely disinfected prior to and following use.
- Double gloves pulled over the cuffs of the laboratory coats will be used at all times.
- Designated microbiological safety cabinets to be used.
- Only plastic pipettes will be used in the tissue culture facilities which will be treated with bleach immediately after use. Furthermore, all contaminated materials and media including waste destined for subsequent incineration will be autoclaved. The use of sharps will be prohibited and all precautions will be taken to identify procedures or devices that might be used in these projects which could cause an injury to the researchers.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. Appropriate disinfectants for inactivating lentiviral particles on surfaces include 70% ethanol and 1% Virkon solution. Liquid waste should be treated with 10% bleach overnight before sink disposal.

The Committee comprises the following members:

- Five full-time University of Roehampton academic staff members (2 Lecturers, 2 Senior Lecturers, 1 Reader) with research experience in mammalian cell biology and microbiology (including the designated co-chairs below).
- One full-time University of Roehampton technical laboratory manager with extensive H&S experience.
- Two full-time staff members from the University's Health and Safety Office with extensive H&S regulatory experience;
- One external consultant (staff at Medical Research Council Head Office) with H&S and GMO regulatory experience.

All academic staff members have PhDs in relevant disciplines and several years of expertise in CL1 and CL2 work and work with GMOs.

The Committee will meet quarterly to discuss shared issues (external consultant may participate by videoconference), and will be chaired by one of the co-chairs in rotation; the other will take minutes. Laboratory inspections will be performed at least twice a year to review compliance, in conjunction with these meetings. Risk assessments will be drafted by the staff member responsible for each project, reviewed internally by a member of staff with relevant expertise (mammalian cell biology or microbiology, as appropriate) and, in case of any doubt or unresolved issues, referred to the external consultant for input. The final risk assessments will be circulated to the Committee with a recommendation to approve/revise/reject, and generally approved by email.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The GM safety committee will comprise four individuals from within, and external, to the establishment and all familiar with the activity performed within the organisation. All four members have 10 or more years of experience of working with the same or similar GMOs at multiple research institutes and have experience of generating risk assessments for GMO activity. Members roles are: Director of Cell Therapy Research (Formerly Research Fellow, Cardiff Medical School), Director of Cell Production (Formerly Senior Research Scientist, University of Manchester), Professor of Immunology (University of Manchester) & Senior Research Fellow, Institute of Cancer Sciences, University Of Manchester who has also been a member on the GMO committee within the host academic institution for >5 years.

The committee will meet annually to discuss any necessary issues related to the work, but can also meet at intervening periods to discuss any pressing issues that may need to be addressed. New and amended applications will be circulated and reviewed by the committee members and where appropriate additional expertise will be sought on an ad hoc basis. Once there is a unanimous agreement between the committee members for a new project risk assessment which meets the contained use licence for the organisation the project will be approved to start.

Any incidents or changes to the use or risk of GMO activity will be reported to the committee for review to identify the best course of action if required.

Decontamination
Contaminated plasticware will be decontaminated using hyperchlorite solution, or where minimal residual GMM material remains will be disposed of in yellow container for incineration. Contaminated liquids will be decontaminated in hyperchlorite solution for >1 hour. Decontamination in hyperchlorite solution such as Actichlor provides 100% decontamination of all bacteria, fungi and viruses. The decontaminated liquid can then be disposed of down the sink with excess water.

Spillages
Any minor liquid spillages (<20ml) will be removed by soaking up with an absorbent wipe or for larger liquid spillages by the addition of absorbent matts and transfer into a yellow container prior to autoclave. The area will then be sprayed with an anti-microbial agent (with demonstrated virucidal activity i.e. Klercide A, S, or C (GMP use) or hyperchlorite solution (non-GMP use)). After inactivation, the area will be wiped and the wipe placed into a yellow container. The area will then be sprayed and wiped with 70% isopropyl alcohol and the wipe placed into the yellow container. The container will be sealed and sent for incineration as above.

Centrifuge spillage
If breakage occurs during a run, the centrifuge will be stopped, and left for 30 minutes to allow the aerosol to disperse. On opening all liquid will be absorbed using absorbent material and placed into a yellow box. The rotor and/or buckets will be removed and all surfaces sprayed and wiped with an anti-microbial agent (with demonstrated virucidal activity Klercide C (GMP use) or hyperchlorite solution (non-GMP use)). After inactivation, the area will be wiped and the wipe placed into a sharp proof container. The area will then be sprayed and wiped with 70% alcohol and the wipe placed into the sharp proof container. The container will be sealed and sent for incineration as above.

All clinical lab waste is sent for incineration and will leave the building within locked large yellow thick plastic transport containers.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Decontamination

All clinical lab waste is sent for incineration and will leave the building within locked large yellow thick plastic transport containers.
One member suggested changes which further highlight the safety of the GMO. The wording was altered slightly to clarify the safety of these class 1 modified GMO.

Three members had no comments to make and were happy with the risk assessment.

Purpose:

1. Generation of plasmids using Biosafety Class I disabled prokaryotic strains
2. Generation of retro/lentiviral vectors using packaging lines or Transient transfections using Biosafety Class I lines such as PG13 or 293T.
3. Genetic modification using plasmid or retro/lentiviral transfection of Biosafety Class I/II cell lines such as Jurkat, RAJI, K852, Daudi, HT-1080 as models and targets to assess and enhance T cell function in the anticancer cell.
therapy context.

[4] Pre-clinical and clinical trial development for Human cell therapies using Plasmid, Retro/Lentiviral transfection of primary human cells to produce anti-cancer specificities

Recipient or parental organism

[1] Preliminary plasmid vector creation will be performed using Biosafety Class I bacterial strains such as the disabled E.coli strains including Xl1 Blue, Xl-10 Gold or Top10

[2] Transfection of Biosafety Class III cell lines such as PG13, 293T, Jurkat, RAJI, K562, Daudi, or HT-1080 with TCR, CAR, cancer-antigens or stimulatory or co-stimulatory molecules using plasmids, retro- or lenti-viral vectors

[3] Transfection of Primary human cells such as peripheral blood mononuclear cell derived T-cells, Monocytes or NK cells, Tumour derived cells with TCR, CAR, cancer-antigens or stimulatory of co-stimulatory molecules using plasmids, retro- or lenti-viral vectors

Host/vector system

Non-viral systems
Plasmid vectors such as pcDNA3.1, pBluescript (Strategene) and TOPO (Invitrogen) based plasmid vectors.

Viral systems
Second, third or fourth generation lentiviral and retroviral vectors deleted of any viral expressed sequences and packaged using either: transient multi-plasmid transfection in cell lines such as 293T or pre-transfected stable packaging cell lines such as PG13.

Origin & function

The genetic material which will be transferred within the vector system will be derived from human cells and synthesised by an external company to generate genetic material which is codon optimised for mammalian expression. The material will then be transferred to mammalian cells in vitro to generate cells with enhanced antitumour activity, with the anti-tumour activity monitored by one or more standard immunological assays.

The genes will form several groups:

1) Cancer specific T-cell receptors (TeR): TeR specific for antigens, including but not limited to, NY-ESO, gp100, MAGE A3, WT1, p53 and surr ...

2) Virus specific TeR: T-cell receptors specific for viruses implicated in oncogenic transformation, including but not limited to, cytomegalovirus, Epstein-Barr virus and human papilloma virus

3) Chimeric antigen receptors (CAR): CARs specific for tumour associated antigens, including but not limited to, carcinoembryonic antigen (CEA), 5T4 and melanoma-associated chondroitin sulphate proteoglycan (MCSP).

4) Pro-survival genes: Genes which enhance the pro-survival potential of modified cells

5) Synthetic genes: Synthetic genes which can be used to modulate the growth or presence of gene-modified T-cells in vitro or in vivo. For example suicide gene which can be used to selectively deplete gene modified T-cells after infusion into patients.

Evaluation of foreseeable effects

Introduction of genetic material into cells in vitro will generate genetically modified cells with the capacity for enhanced anti-tumour activity; as models to assess function; and as replication disabled co-culture targets to enhance cell expansion. The genetically modified cells will be monitored in vitro using standard assays including basic microscopy, flow cytometry and ELISA.

Potential hazards to human health and control methods:

1) Contamination of user with retro/lentiviral supernatant: The risk to the user of the lentiviral supernatant is low, The
main risk to health would occur in an instance where long-lived dividing somatic cells come into contact with retro/lentiviral particles for a period long enough for infection to occur. This risk is reduced further by the operator using standard biosafety PPE (lab coat, nitrile gloves etc) and manipulating the contained use within a biosafety class 2 cabinet, Class IIIIE isolator or negative pressure cabinet.

2) Contamination of user/operator with GMO: The main risk to the operator would come with the unintentional administration of GMO to themselves. This only poses a risk when the GMO is derived from self tissue as there will be no immune rejection. To prevent this the operator will be strictly forbidden from performing manipulations or cell culture on cells derived from themselves.

3) The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (Details of the origins and deletions within the specific retro/lentiviral constructs are provided within the specific risk assessments).

4) The primary dangers in working practice are expected to be the formation of aerosols and use of sharps. We propose to carry out all manipulations in a Class II microbiological safety cabinet following GLP and any additional local safety guidelines appropriate to this work and minimise the use of sharps where possible and where sharps are necessary operators must work within the constraints of the sharps usage and safety policy.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

70% alcohol and the wipe placed into the sharp proof container. The container will be sealed and sent for incineration as above. All clinical lab waste is sent for incineration and will leave the building within locked large yellow thick plastic transport containers.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

One member suggested the risk assessment was modified to include extra vectors that may be used in production of medicinal products and/or research and development. One member suggested the policies regarding the use of sharps was modified. The use of sharps in the production of medicinal products cannot be avoided due to the nature of the containers that the virus is supplied in. This is indicated in the risk assessment. This policy does not cover the R&D lab and as such the use of sharps remains prohibited in this situation. One member had no comments and was happy with the risk assessment. One member raised some queries regarding viral stability. This was clarified by rewording the section to highlight differences in stability of viruses at 37°C and at room temperature. Queries were also raised over provision of vaccinations for staff and the wording of the risks associated with tumour targeting of GMOs. Reworking was again sufficient to clarify these points.

Yes

Give brief details of the genetic modification safety committee

Our GM committee comprises of the company's CEO, one of the senior scientist and an external consultant. The committee meets twice a year to discuss safety measures in place in the laboratory and approve Genetic Modification Risk Assessments. When scientist plan to use a new genetically modified organism, the consultant advises on safety procedures.

The CEO and senior scientist make sure the suggested safety measures are incorporated into SOPs and are being followed

Bacteriology Parasitology Transgenic Birds Microbiology Research

02/03/2022
Contaminated sharps are collected in closed sharp bins, tagged and are removed by clinical waste contractors for incineration.

Culture flasks, tubes and other lab consumables used in experiments are collected in a closed bin and once this is filled, are autoclaved at 134 deg C for 15 minutes for de-contamination. The it is disposed with clinical waste for incineration.

Liquid waste (culture media etc.) is disinfected and de-contaminated using 1% solution of Virkon following manufacturer's instructions. Then it is poured down the sink and flushed with copious amounts of water.

The autoclave used for de-contamination is serviced twice a year.

For activities involving GMMs, describe the waste management measures which will apply to the activity.

Please enter comments of the GM safety committee on the risk assessment:

Comments from the GM Committee meeting on 19 November 2014:

GM Committee consider the risk assessment and approved category 1 work involving GM organisms on Progenitor Labs premises.

Project Ref 3253/14.1

1. Knockdown with lentiviral particles discovered in our small molecule screening campaigns. 2. Generation of PAX7 (and other reporter cell lines via lentiviral transduction)

Class 2  Consent Granted

Non-GMM
Project Additional Information

Purposes of the contained use

1. We want to validate selected targets from our small molecule screening campaigns through shRNA delivery by lentiviral particles.
2. We want 10 generic reporter cell lines to screen small molecules activating the expression of a particular gene.

Recipient or parental organism

1. Recipient cells will be human embryonic stem cells or other types of stem cells and progenitor cells. After lentiviral transduction, the expression of one of their genes will be downregulated. Recipient cells will be characterised by qPCR and Western Blotting to assess the function of the lentiviral constructs. Cells transduced with lentiviral particles will be kept in a dedicated incubator. After processing the samples, waste will be conveniently inactivated and discarded.
2. Same as in 1. but upon differentiation of the stem cell, they will express GFP or another colour marker.

Host/vector system

1. Self-incactivating replication incompetent lentivirus based on pKO backbone and purchased from established vendors like Sigma-Aldrich. These vectors carry an shRNA used to knock-down the expression of a target gene.
2. Self-incactivating replication incompetent lentivirus purchased from Applied Biological Materials or other vendors.
Vector system are lentiviral vectors (PlK01 backbone)

Origin & function

Evaluation of foreseeable effects

1. The cell lines transduced with lentiviral particles will show downregulation of a specific gene.
2. The cell lines transduced with the reporter construct will not show any phenotype unless the target gene is stimulated, in that case they will express GFP or another colour marker. Cells lines will be characterised by qPCR and Western Blotting.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable material exposed to lentiviral particles will be inactivated with Virkon, disposed in appropriate plastic bags and autoclaved. All surfaces of the cell culture hood will be cleaned and sterilized with 70% ethanol.

Is an emergency plan required according to regulation 20? N

Y

Give brief details of the genetic modification safety committee

The committee is composed of four members including the biosafety officer, a research scientist (providing staff representation and an executive director of the company along with a University Academic, with extensive experience in human and environmental safety, acting as an expert advisor, The Safety Committee fulfills the responsibilities under GMO Contained Use Regulations to approve risk assessments and provides guidance and direction on good bio-safety practice at the laboratory. The Safety committee is representative of all people having access to the laboratory and will encourage discussion to ensure the views of all members are taken into account. Risk assessments will be circulated amongst the committee for scrutiny and commented on electronically & revisions will be made as necessary. The committee will meet at minimum twice a year with the ability to additionally meet promptly as and when needed.

Solid waste and liquid waste - chemical disinfection using disinfectants with literature precedent for the viruses in the study.
Excess virus stock - validated autoclave cycle.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
1. The material safety data sheets supplied identify Biosafety Level 2 practices and containment facilities as required for use of their vectors. You should make sure that you are satisfied that these are not required for the proposed work.

The SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms (other than those associated with plants) Page 13 states that:

‘Wild-type adenoviruses are ACDP hazard group 2 pathogens and should be handled at Containment Level 2. Many adenoviral vector strains have been constructed that are deleted for E1, encoding key genes required for viral growth. These strains are disabled and incapable of establishing a productive, transmissible infection in humans. These vector strains can be considered to be avirulent and may be handled safely at Containment Level 1.’

To ensure replication deficiency of the virus particles the vendors have deleted the E1 and E3 regions allowing the particles to safely be used as a gene delivery tool. In addition, the gene delivered by the viruses in this project encodes enhanced Green Fluorescent Protein (eGFP) that has no direct effect on cellular processes. For these reasons, although the viruses will be used under containment levels 2 conditions due to the use of primary human cells, the GMO activity is class I.

2. I note from SignaGen's website that some of their vectors include WPRE sequences. As described in the SACGM Compendium (Part 2 section 2.2 para 45, some versions of this element "are capable of expressing part of the X protein from WHV which may have oncogenic properties, and risk assessments should take into account the possible harmful effects of this sequence. Vectors containing these forms of WPRE should be assigned to class 2 or higher." If the vectors you are using do incorporate WPRE sequences you should check whether or not they include sequences encoding part or app of the X-protein and modify the assessment accordingly.

Communication with the vendors indicated the plasmids used to generate the viral particle to be sent do not contain WPRE and do not present oncogenic risk. The comprehensive risk assessment has been amended to reflect this confirmation.

3. Is there any potential for insertional activation (e.g. of potentially oncogenic genes) by the vectors?

Delivery of any nucleic acid could theoretically cause insertional mutagenesis if it integrates into the genome. There has been much debate around Viral gene delivery but studies suggest the risk is low. Integration is usually at the site of active genes.

References

4. Is there supporting data regarding the methods used for disinfection

AD-eGFP and AAV-eGFP vendor documentation (attached) states both viruses are susceptible to 1% sodium hypochlorite and recommends 30 minute contact times.
It is also reported that 0.9% virkon for more than 5 minutes is an effective disinfectant for adenoviruses reducing potency by greater than six logs upon a five minute exposure (McCormick L, Maheshwari G 2004, Sakudo A & Shintani H, 2011).

References
1) Mammalian Expression Plasmids (pcDNA3.1, pcDNA6, pCRII-TOPO) for transfection of HepG2 cells with HBV genome (either full or over length) or human sodium taurocholate co-transporting peptide (hNTCP), the entry receptor for HBV.

2) HepG2.2.15 and HepAD38 cell lines which are transfected HepG2 cells which stably express infectious HBV, in the case of HepAD38 under tetracycline control.

3) Cell culture derived virus from the above cell lines used to infect primary human hepatocytes.

Origin & function

The Hepatitis B genome used to stably transflect HepG2.2.15 and HepAD38 cells was isolated from patient serum of HBsAg sub type ayw. Full or overlength HBV genonomes used to transiently tranfect HepG2 cells will be chemically synthesised from publically available sequences for HBV of different genotypes. The function of the inserted HBV genetic material is to enable the cells to replicate HBV virus and produce infectious virions. The virus produced is itself a GMO and it will be used to infect cultures of primary human hepatocytes and optionally non-parenchymal cells, resulting in these cells exhibiting all steps of the viral life cycle and producing infectious virus.

The sequence for hNTCP will be chemically synthesised from publically available sequences. Transfection of hNTCP into HepG2 causes overexpression of NTCP which renders the cells susceptible to infection by HBV.

Evaluation of foreseeable effects

The purpose of the genetic modification is in all cases to cause cells to replicate HBV, except in the case of hNTCP overexpression where the result is a cell which is more susceptible to infection.

Hazard to human health

The transfected and infected cells will produce HBV at titres up to 10 billion IU/ml which has been shown to be infectious in in vitro cell cultures, humanised liver chimeric mice and chimpanzees. It is highly likely this virus would be infectious to humans.

Hazard to the environment

Minimal as the cell cultures are only viable in specialised cell culture conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMO will be used in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved at 121oC for 20 min before being disposed of by incineration as clinical waste. Prior to autoclaving the solid waste contaminated with GM material, e.g. flasks or plates containing GM cells, will be contacted with 2% Virkon disinfectant for at least 1 hour.

The cycles used on the autoclave for make safe of waste will be validated using 12 point thermocouple tests which will be repeated every 6 months. Only loads similar to those validated will be run. A thermal indicator will be included in each load and records for each load will be kept.

Liquid waste, to include cell culture media containing virus will be contacted with 2% Virkon for at least 1 hour before disposal to drain. Virkon contains an indicator to show it remains active, fresh Virkon to be made up at least every 7 days. Literature shows 1% Virkon for 10 minutes is sufficient to reduce HBsAg to undetectable levels.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
CN Bio Innovations competent person reviewed the risk assessments and found 2 areas to be addressed: i) The description of the mammalian expression plasmids to be used was too generic, ii) Risks posed by the presence of long tail repeats from Moloney murine leukemia virus (MoMLV) needed to be assessed. Following addition of descriptions of extra mammalian expression plasmids and a risk assessment of MoMLV the competent person considered the risk assessment satisfactory.

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC) consists of new people both of whom have more than 20 years experience handling GMMs. One is a member of the management who additionally has 4 years experience of being on the GMSC of a global pharmaceutical company which included reviewing over 50 GMM proposals every year. Any new pieces of work will be assessed by a written proposal which will then be reviewed.

Disinfection and autoclaving will be carried out where required. All waste materials will be disposed of into autoclave bags, yellow clinical waste bags/bins or sharps bins as required. All contaminated solid waste (agar plates, disposable plasticware etc) will be placed in autoclave bags and will be autoclaved and disposed of via designated route. Liquid cultures will be chemically-inactivated (Virkon 1% or PeraSafe 0.16% for 30 mins) or autoclaved prior to disposal. All contaminated glassware and reusable plasticware will be decontaminated as above.

a) Disinfection.
1% Virkon will be used for disinfection. The surfaces of the microbiological safety cabinet will be disinfected with 1% Virkon after use. Laboratory benches will be swabbed with 1% Virkon after any activity.

b) Autoclaving.
Autoclaves are not present in the laboratory for waste treatment. However, a large central autoclave facility is located on site at Alderley Park (please see next section for the further details of the Waste management process and derogation request).
The autoclave is subject to twice yearly servicing and annual validation using a 12-point thermocouple procedure which includes a probe placed in a representative load.

Please enter comments of the GM safety committee on the risk assessment

The GMSC met on 29th April 2015 to review Risk Assessment 004 which had been given a provisional class 1 risk assessment. It was agreed that this was appropriate as there was no significant risk to either the environment or operator.

Give brief details of the genetic modification safety committee

A risk assessment has been carried out by a competent person. This assessment is subject to the university's Sign-off and review procedures. The main findings of the risk assessment, along with the necessary control measures, will be brought to the attention of all the relevant staff and students and discussed as appropriate by the quartely school and University Health and Safety Committees. Where necessary, specific representation will be made at these Committees from Biologically qualified staff, with expertise in GM work, to supplement existing School/University Management and Occupational Health and Safety staff.

Gene Therapy

02/03/2022
The GMMs to be used will be class 1 and the risk assessment for the work does not identify risks to either human health or to the environment. It is, however, Quotient's policy to inactivate all biological waste and 100% kill is anticipated. All solid waste containing class 1 GMMs will be autoclaved in the laboratory. Autoclave cycles (121°C for 30 minutes) will be validated using biological indicator strips. The autoclave is subject to statutory test and examinations. All liquid waste will be incinerated or treated with 1% (final concentration) Virkon solution overnight prior to disposing to drain. Surfaces will be cleaned with azowipes (79% isopropanol aq.) or 70% ethanol aq.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The competent individual has reviewed the risk assessment for the proposed work and concluded that the activities to be performed are class 1: the modified progenitor bacteria are Hazard Group 1, as classified under Part I of Schedule 3 of the Control of Substances Hazardous to Health Regulations 2002 (as amended) and: the planned genetic modification will alter metabolic pathways and are considered very unlikely to alter pathogenicity traits or present a hazard to the environment.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The proposed work will involve culturing class 1 GMMs (e.g. actinomycetes)

Give brief details of the genetic modification safety committee

The Edge Hill University Genetically Modified Organisms Committee has been formed as a reporting sub-group to the Bioscience Building Health and Safety Committee. The first meeting of the group was held on the 8th May 2014, followed by a secondary meeting on the 3rd June 2014. During these meetings the remit and terms of reference for the committee was agreed. The group will be in charge of reviewing all risk assessments for new practical’s and research that involve genetic modification of organisms. Responsibility to ensure that facility containment is appropriate will also rest with this committee. The group is chaired by the Senior Technician in charge of research facilities and is attended by the Head of Department, Senior Research Academics, Chair of the Biosciences Health Safety Committee, with invitations to Student Union representatives from each academic year and PhD students with relevant experience. Any individual who has a working interest within the institution will also be allowed to attend.

Level 1 (GMMs)

Yes

Level 2 (GMMs)
Yes

Any material contaminated by GMO’s such as tips, petri dishes, syringes, swabs, and cleaning materials will be fully autoclaved to kill contaminants. Autoclaved waste will then be double bagged, or placed into specified sharps bins and will be destroyed via incineration. All surfaces will be sanitised using ethanol or Vercon based cleaning products.

**Tick to confirm that you are attaching a summary of the risk assessment**

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

**Please enter comments of the GM safety committee on the risk assessment**

The committee agreed with the suitability of the current risk assessment format. No future proposals were made for work that required containment levels above that of level 1. It also agreed that the facilities and disposal methods are appropriate for this level of containment and that it would meet and review this status on at least an annual basis or as new GMO related projects arise.
### Project Additional Information

#### Purposes of the contained use

The purpose of the contained use is to enable the development and/or use of viral and plasmid vectors to manipulate the expression of genes associated with development, disease pathogenesis and treatment. Gene expression changes, such as overexpression or knock down, are anticipated to result in changes to cellular structure, signalling, interactions, metabolism and ultimately function. These changes can lead to cellular death, cellular reprogramming and directed differentiation into specific cell types.

All vectors used are disabled either by being devoid of the genes required for replication and/or being split between separate plasmids which must be combined to produce a viral particle. In addition to this, packaging plasmids are required in order to aid entry into the cell. These vectors will have no impact on the environment as they will be created, used, contained and disposed of under strict class 2 laboratory conditions.

#### Recipient or parental organism

Recipient organisms include primary cell cultures obtained from human and mammalian tissue, induced pluripotent stem cells (iPSCs), embryonic stem cell (ESC) lines, adult stem cells, established mammalian and invertebrate cell lines and bacterial and fungal species.

Example tissues include placenta, lung, skin, liver, brain, spleen, heart, intestines, kidneys, foetal and embryonic material. Additional primary cell cultures include keratinocytes, fibroblasts, epithelial, CFBE cells.

IPSCs will be derived from human and mouse cell cultures.

Human and mouse ESCs and adult stem cells will be obtained commercially or from collaborators or repositories.

Established mammalian cell line examples include HeLa, HaCaT, KBM-7, HAT1, A549, ISHIKAWA, BeWo, HEK 293, 293T, H441, NHBE, CFBE, A549, KELLY, CHO, 1HAEO, A549, HBE, SK-N-BE(2).

Insect cell line examples include Sf21.

Example bacterial cells include Agrobacterium tumefaciens and LBA4404.
Plasmids for direct gene expression of foreign genetic material include pcDNA-DEST53, 47, 40
Plasmids for lentivirus production include pLenti6/UbC/V5-DEST, pLenti6.2/C-Lumio/V5-DEST, pBABE-puro, STEMCCA, MISSION® pLKO.1-puro
Plasmids for adenovirus production include pShuttle-Cre-HA
Binary Plasmids include Pgreeni
Helper plasmids and entry vectors include pENTR
Transcribed lentiviruses, adenoviruses
Nanovesicles

Cell hosts and viral packaging cells include HEK 293, AdenoX 293 and Agrobacterium tumefaciens cells.
Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) CAS9

The foreign genetic material inserted includes human and mammalian cDNAs that are involved in aspects of cellular transformation, self-renewal, proliferation, signalling, structure, metabolism, ion transport, differentiation and apoptosis. These genes would include, but are not limited to transcription factors, enzymes, growth factors, signalling molecules, ion channels and angiogenic factors and cytokines, some of which can be seen in the list below:

- **Transformation** - hTert, Bmi1, cMYC
- **Self renewal** - cMyc, Klf4, Oct4, Sox2
- **Proliferation** - NUDT2, TP53, MYCN
- **Signalling** - IGF
- **Structural** - JUP, NF1, DNAH5,
- **Metabolism** - ALOX12B, ALOXE3, PNPL2, ApoE, LCAT
- **Ion transport** - ENaC, CFTR,
- **Differentiation** - TGM1, CERS3, ABCA12, LIPN, NIPAL4, IL6, MRTF-B,
- **Apoptosis** - MRTF
- **Joint lubrication** - PRG4

Viral DNA to be inserted into insect cells - BaculoDirect™ C-term Linear DNA Gateway® Cassette contains the genetic information that enables cutting and ligation of insect DNA in one reaction.

In addition to the above, reporter genes would be expressed constitutively or conditionally as cellular markers. Reporter genes include fluorescent markers (GFP, YFP, CFP, mCherry, PicoGreen, DY677, Cy3), luminescent markers (firefly, gaussia and vargula luciferases) and biochemical markers (AFP, CAT).

The expression of genes, such as those above, would be manipulated by overexpressing genes (introduction of trangege, gene correction), causing exon skipping, or by expressing specific complementary nucleotide sequences in the form of siRNA, shRNA and GAPMERS to reduce or prevent gene expression. The CRISPR CAS9 system will also be used to produce mutations in target genes and reduce or prevent their expression.

### Evaluation of foreseeable effects

Primary human tissues and cells have the potential to carry pathogenic organisms such as viruses and bacteria. Established cell lines and embryonic and adult stem cells are often pre-screened for such pathogenic organisms. Under no circumstances will researchers be permitted to culture their own cells.
To reduce the risk of generating replication competent lentivirus (RCL), the parts of the genome critical for viral replication are deleted or severely modified enabling the transduction of target cells but preventing the production of new virions. After transduction and integration into the target cell's DNA, self-inactivating mutations prevent further transcription. Lentiviral genes necessary for packaging are carried in separate plasmids reducing the risk of generating RCL by increasing the number of recombination events required for their generation.

Adeno
Adenoviruses are DNA viruses capable of causing respiratory tract and intestinal infections and can be spread via mucous membrane contact including the inhalation of droplets. Shuttle and adenoviral genes are carried on separate plasmids. To minimise the potential for adenoviral vectors to replicate, portions of the Early Regions 1 (E1) and 3 (E3) of wild-type adenovirus have been deleted from the genome. The elimination of E1 elements means that it requires a cell line that expresses E1 genes for viral replication and transcription of the viral DNA. Exposure of somatic cells that do not express E1 genes leads to a transient non-cytopathic infection that is not replicated or actively transcribed. Packaging of this viral vector after the transfection of E1 gene containing cells, is capable of infecting human cells. Therefore, adenoviruses capable of expressing oncogenes will not be created so as to avoid any chance of these genes being expressed in vivo.

Adeno Associated Viruses (AAV)
AAVs are replication-limited and typically not known to cause disease in humans. AAVs have a small packaging capacity and can transduce both dividing and non-dividing cells with a low immune response and low toxicity.

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion and fate. Also, some have known or suspected oncogenic or tumour suppressor properties.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Shuttle and adenoviral genes are carried on separate plasmids. Viral vector expressing potential oncogenes are a potential environmental risk as host infection could elicit a transformation event. All work is carried out in a class II cabinet and all liquid waste inactivated by virkon treatment and solid waste autoclaved.

Primary cells infected with viral vector containing potential oncogene would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

The recombinant viral vectors are all highly disabled vectors, the design of which has greatly reduced the risks associated with them. In addition, to minimise contact with viral particles, all research involving viral vector production and use will take place under strict containment level 2 conditions in class II biological safety cabinets. This will minimise exposure to liquid aerosols. The use of sharps will be minimal and restricted to pipette tips. Single entry biohazard labelled sharps containers for tips will be present in the work space to prevent handling.

Bacterial and fungal species
Group 2 bacterial and fungal species have the potential to cause human disease via contact with mucous membranes including inhalation and sharps injuries. Agrobacterium tumefaciens causes crown gall disease of a wide range of plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All surfaces will be disinfected pre and post carrying out GMO work use using 70% ethanol, 1% virkon or an anti-viral disinfectant such as Bacillolcid. Spillages will be...
cleaned using 70% ethanol, 1% virkon or Baccilocid. Solid waste (mainly plastic ware such as flasks and tubes) will be collected in autoclave bags and autoclaved using a make safe cycle (121-125oC for a minimum of 15 minutes). Excess liquids will be discharged into drains and solids disposed of solids via clinical waste stream for incineration. Solid waste can also be collected in biohazard labelled clinical waste bags and taped up when 80% full, using biohazard tape. These bags will be transferred, by trained laboratory staff, to large, plastic clinical waste eco-lock bins that will be collected by a registered waste contractor for off site incineration. Sharps, including pipettes and tips, will be disposed of in plastic biohazard labelled sharps containers. Sharps boxes will be autoclaved at 134 oC for a minimum of 15 minutes and removed and incinerated by waste contractors. Liquids (eg samples, culture supernatants, tissue culture media) will be autoclaved using a make safe cycle (121-125oC for a minimum of 15 minutes) and discharged to drains. Agar plates will be autoclaved using a make safe cycle (121-125oC for a minimum of 15 minutes). Excess liquid will be discharged into drains and solid waste will be disposed of via the clinical waste stream for incineration.

Autoclaves used to inactivate waste must will be subject to regular validation, calibration and maintenance. Validation of inactivation of waste will take place using a biological indicator such as Geobacillus stearothermophilus. Autoclave tape will be used to ensure that sterilisation temperatures have been reached. Calibration of the autoclaves will be carried out annually or as required. An autoclave will be located in the same building as the GMO work is being carried out. Records of GMM inactivation will be kept by the University for a period of 12 months and available on request.

The Genetic Modification Health and Safety (GMOHS) Committee at Edge Hill University reviewed the CU2 application and risk assessment at a meeting on 26.01.18. Minor revisions were suggested and made including changes to inactivation and waste disposal procedures, the addition of validation measures for autoclave inactivation and it was decided that pregnant personnel would be advised against carrying out work with class II GMOs. The revised document was subsequently approved for submission by the committee.

Give brief details of the genetic modification safety committee

The Directors of London Biological Laboratories have appointed a Safety Committee (SC) which is responsible for reviewing and providing advice on contained use risk assessments to the management. The SC consists of the Biological Safety Officer (BSO), two directors of London Biological Laboratories, and any additionally appointed advisers with relevant expertise as necessary. Principal investigators are required to submit risk assessments to the SC, who will review and provide advice on adequacy of the risk assessment. The BSO will integrate this advice into the risk assessment and give final advice, with respect to approval for the contained use to take place, to the person responsible. The members of the SC represent a balance of experienced scientists, management, and lab users. The committee members include individuals with extensive postgraduate biological research experience. The BSO, particularly, has an extensive background working in class 2 contained use settings. Through partnerships with local universities and other scientific institutions, the SC has access to a wide range of experts from who are willing to provide advice on risk assessments for contained use.

All lab users receive an induction into the procedures for the handling and containment of GMO, and this includes a section on waste management and monitoring measures. These procedures are regularly reviewed and updated by our internal safety committee, and also by external review by competent assessors and are detailed in our Standard Operating Procedures documentation.

Ensuring that lab users follow the practices in compliance with the published procedures is enforced by the BSO with the full support of the management.

According to established practice all waste (solid and liquid) and equipment that have come into contact with GMO are autoclaved at 121°C at 15 psi for at least 15 minutes. This is reported to reduce the number of viable organisms by six logs (99.9999% degree of kill) and therefore this is our preferred method for GMO inactivation.

Autoclaving is done on site in the biolab, and all users are trained to operate the autoclave and to run a daily test. Monitoring of the level of inactivation is performed monthly by the use of a plate growth assay.

For activities involving GMMs, describe the waste management measures which will apply to the activity
The autoclave is tested to ensure that it is functioning to the manufacturer’s specification, and this is done in two ways, firstly using a programmed pressure/vacuum test is run and secondly autoclave test strips are used to ensure that the necessary temperature has been obtained. The results of these tests are recorded in a log book.

These requirements are codified in our SOPs and all lab users are required to follow them strictly. Further, to ensure surfaces are free of contamination, worktops are cleaned with 1% virkon solution before and after a protocol is performed.

In the case of unanticipated spillages and similar accidents in the lab, a dedicated GMO spill kit is provided. The Spill Kit is inspected regularly by the BSO or another competent lab user, and its use is described during the safety induction and is detailed further in its own SOP. The Spill Kit contains at least two separate disinfectants that are suitable for inactivation and disinfection of a spillage, the spill kit also contains plastic disposable aprons, gloves, shoe covers, absorbent materials, and autoclave bags, to enable efficient and complete clean up. Once the spill kit has been used to clear up a spillage, the materials that have been used are autoclaved prior to disposal.

This risk assessment was submitted to the SC and after minor modifications it was approved. The risk assessment was also reviewed by an external adviser who provided advice to the committee.

All contaminated waste and cell culture waste, including cultured cells and vessels, growth media, disposable plastics, laboratory glassware and other contaminated materials will be autoclaved at 121°C for at least 15 minutes to inactivate GMOs (100% kill) prior to disposal or cleaning and recycling. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored with autoclave indicator tape to show the target temperature of 121°C is reached. Periodic swabs will be taken from the culture media after autoclaving to ensure effective operation. Inactivated, autoclaved waste will be uplifted and disposed of by incineration by a commercial contractor.

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Project Additional Information

#### Purposes of the contained use

Biological cell potency assays

#### Recipient or parental organism

HEK293 cells - human embryonic kidney cells

#### Host/vector system

Adenovirus 5

#### Origin & function

HEK 293 is a virally transformed, stable well established human epithelial kidney cell line that is routinely used in expressing plasmid derived proteins. This cell line has been established for laboratory use only and would not survive long without specific culturing conditions. The HEK293 cells contain DNA from Adenovirus 5. The cell line will be cultured for a cell-based potency assay for a chemotactic drug product.

#### Evaluation of foreseeable effects

HEK293 cells are unable to survive outside their laboratory environments and are therefore unlikely to cause harm to other organisms

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A - full containment of the live cells will be used

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation of all plasticware and media that has come into contact with the GMM with 1% virkon solution. The liquid and/or plasticware will then be autoclaved at 121°C for 45 minutes (internal probe in the autoclave and TST test strips included in the load). The autoclave waste is then put into 60L incineration bins for incineration off site by SRCL. SRCL provide us with a quarterly notification of destruction.

#### Is an emergency plan required according to regulation 20?

No

#### Project Ref 3268/18.1

- **Date Ackn’d**: 25/01/2018
- **CU2 Project Title**: Analysis of modified adenovirus ONCOS-102 by Dynamic Light Scattering
- **Class**: Class 2
- **Culture Volume**: ≤ 1 Litre
- **Non-GMM Consent Granted**: Consent Granted
- **Project notified under transitional arrangements**: N

#### Purposes of the contained use

The organism is used as a cancer therapy, samples of the virus will be submitted to our site for analysis. The virus will be analysed by Dynamic Light Scattering (DLS), this is a non-destructive test used to determine the degree of aggregation of the virus particles. This information will be used to characterise the product to provide data to support stability and process development.
### Recipient or parental organism

Adenovirus type 5

### Host/vector system

None

### Origin & function

The virus contains three modifications these are:

i. A deletion in the E1A gene preventing the virus from replicating in none dividing cells

ii. Introduction of the gene for human Granulocyte Macrophage Colony Stimulating Factor (GMCSF), a chemokine added to enhance the immune response

iii. Replacement of the Adenovirus type 5 fibre knob sequence with than of the Adenovirus type 3 sequence.

### Evaluation of foreseeable effects

Adenovirus type 5 is an ACDP hazard group 2 pathogen which causes mild respiratory symptoms and is infectious via the aerosol and the faecal-oral routes. The modified virus contains a deletion in the E1A gene, therefore preventing transformation of infected cells. This will limit replication to cells which are already undergoing cell division, as this process will no longer be triggered by the virus.

Expression of GMCSF is expected to cause an upregulation of the immune response at the site of infection due to activation of T-cells, this would not be expected to cause a hazard. Replacement of the Ad5 fibre knob with the Ad3 fibre knob will change the cell surface receptor used for viral entry. The receptor for Ad5 is down regulated in many tumour cells, both rectors are widely expressed in normal tissues. This modification would therefore not be expected to cause a change in the hazards associated to the virus (both Ad5 and Ad3 are hazard group 2 organisms, which exhibit the same clinical symptoms).

The pathogenic traits of the virus will be reduced compared to the parent as viral replication will be limited to dividing cells, due to the E1A deletion. The construct does not contain a known mobilisable genetic element (mob elements), it is unlikely that the virus would transfer genetic material to another organism.

The virus could cause an infection, however due to the E1A deletion this would be expected to be less productive than the wild type virus. Wild type adenovirus causes mild flu like or gastrointestinal symptoms, the modified virus is highly unlikely to be more pathogenic than the wild type.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be treated over night with Virkon resulting in a least a 6 log reduction in virus titre. Contaminated plastics (pipette tips, tubes and cuvettes) will be autoclaved resulting in a 100% kill, prior to disposal as clinical waste for incineration.
Further detail requested on clean down for SSC and spill procedure, added to assessment prior to approval.

## Project Additional Information

### Purposes of the contained use
- Analytical testing to support product development

### Recipient or parental organism
- Arenaviruses, Lymphocytic Choriomeningitis Virus Armstrong strain and Pichinde Virus

### Host/vector system
- None

### Origin & function
- non-ocogenic fusion protein of Human Papilloma Virus 16 early proteins E6 and E7

### Evaluation of foreseeable effects

The parent Arenaviruses LCMV Armstrong strain and PIC are both hazard group 2 organisms. It should be noted that per the approved list of biologics the majority of LCMV strains are class 3, however the Armstrong strain is specifically named as a class 2 (this is a lab adapted strain). These organisms cause flu like symptoms with a typical incubation period of 5-21 days. The strains have been attenuated and are expected to be less pathogenic than the wild type parent organisms, however at the present time it can not be confirmed that the attenuation is sufficient to support moving to class 1. Expression of the wild type versions of the E6 and E7 proteins leads to oncogenic transformation, the constructs contain a fusion protein of E6 and E7 which has been in engineered to be non-oncogenic. This non-functional protein is expected to generate an immune response against E6 and E7 proteins.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated overnight with Virkon resulting in at least a 6 log reduction in virus titre. Contaminated plastics will be treated as clinical waste and removed from site in sealed containers for incineration.
The committee requested that a clarification was added that the majority of LCMV strains are class 3, while the Armstrong strain used is specifically named as a class 2.

**Project Additional Information**

**Purposes of the contained use**
The GMO is under evaluation as a gene therapy product. Intertek will perform biophysical analysis to provide data to support manufacturing of this product.

**Recipient or parental organism**
Adeno Associated Virus

**Host/vector system**
None

**Origin & function**
The gene encoding the human Beta-hexosaminidase subunit alpha has been introduced. The construct is designed for use in gene therapy to treat individuals with mutations in the Beta-hexosaminidase subunit alpha gene which results in Tay-Sachs disease.

**Evaluation of foreseeable effects**
A previous study using a similar construct demonstrated that intracranial injections of AAVrh8 encoding monkey i3-NAcetylhexosaminidase, resulting in overexpression of the HEXA gene caused neurotoxicity in the non-human primate brain (Golebiowski et al., 2017). However, this transgene was under control of a CSA (chicken beta actin) promoter/WPRE which may induce expression at different levels versus the promoter used in the constructs here. Of note, AAV8 does not cross the blood-brain-barrier reducing the risk of neurotoxicity for handlers of the GMO. In addition to neuronal tissue, AAV8 is capable of transducing muscle, liver, retina and pancreas the effect of expression of the transgene in these tissues is not known.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Project Additional Information**
### Purposes of the contained use

Analytical testing GMO to support product development

### Recipient or parental organism

Adenovirus serotype 5

### Host/vector system

None

### Origin & function

The inserted sequence encodes two ligands which activate the human immune system

### Evaluation of foreseeable effects

Adenovirus serotype 5 cause acute respiratory disease and occasionally pneumonia in both children and adults. Patients with compromised immune systems are especially susceptible to severe complications of adenovirus infection that can cause more systemic diseases. Unmodified Ad5 is classified in hazard group 2 under the COSHH Regulations.

While the precise identity of the transgene is unknown, the information provided states that it encodes for two ligands that activate the immune system. This may result in several undesirable effects including cytokine storm, direct activation of cytotoxic lymphocytes or other non-specific proinflammatory responses, which if untreated may be detrimental to health

The supplied vector is a first-generation recombinant adenovirus with deletions in the E1NE3A genes rendering it replication incompetent. The coding sequence of the proteins has been situated in the E3A cassette.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated overnight with Virkon resulting in at least a 6 log reduction in virus titre. Contaminated plastics will be autoclaved on site prior to being treated as clinical waste and removed from site in sealed containers for incineration.

Project Additional Information

Purposes of the contained use
Analytical testing GMO to support product development

Recipient or parental organism
Equine Infectious Anaemia Virus (EIAV)

Host/vector system

none

Origin & function

The inserted sequence encodes three human genes required for the biosynthesis of neurotransmitters under the control of the CMV promoter

Evaluation of foreseeable effects

EIAV can cause mild flu like symptoms in humans, however in this case the construct is a 3rd generation self inactivating (SIN) gene therapy vector which lacks all accessory and replication genes required for viral propagation. During production these functions were provided in trans by simultaneous transfection with multiple separate plasmids, which are not carried forward to the final construct. The vector is pseudotyped with the vesicular stomatitis virus (VSV) capsid to allow infection of multiple cell types. While the virus is expected to be infectious the infected cells would not generate any new progeny virus particles. Expression of the transgenes is not expected to cause toxicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The Biological and Genetic Modification Safety Committee meets at least quarterly but extraordinary meetings may also be held. The committee is chaired by the company's Biological Safety Officer and is composed of the Senior Health and Safety Scientist and scientists from the infectious disease, cell biology and immunology teams. All members have at least 3 years experience working in bioscience and have received formal training in biosafety. The precise composition at each meeting may vary depending on the agenda items. This is to ensure that the committee has the right level of expertise to review submissions/issues and any conflicts of interest are removed. Other specialists are invited to attend as and when required.

Project Ref  3269/15.1

Date Ackn'd  09/03/2015

Date Project Ceased

CU2 Project Title  Use of bioluminescence to quantify bacteria in infection

Class  Class 2  CultureVolClass2  < 1 Litre

Consent Granted

Non-GMM  Consent Granted
**Purposes of the contained use**

Our laboratory performs a number bacterial infection models, which are used in the investigation of novel antimicrobial agents. The ability of the novel compounds to inhibit growth of bacteria is tested. The test will be a determination of the numbers of bacteria present and the hope is that treatment will reduce these numbers.

For some of our studies, we aim to quantify the numbers of bacteria at serial timepoints through the course of infection, by using imaging methods. In order to do this it is necessary to use bacteria which have been genetically modified to produce light (bioluminescence). These light-producing bacterial strains are commercially available and the light production is due to the introduction of a gene such as luciferase, exploiting the same principle as the production of light in many species in nature, for example the firefly. By quantifying the amount of light, the number of bacteria can be determined at several different timepoints during the course of infection.

**Recipient or parental organism**

This work encompasses the following bacterial strains: *Staphylococcus aureus*, *Streptococci pneumoniae*, *Escherichia coli*, *Pseudomonas aeruginosa*, and *Acinetobacter baumannii*.

These recipient (host) micro-organisms are bacteria which are ACDP hazard group 2 and are genetically modified to render them bioluminescent (in the presence of luciferin substrate).

Acinetobacter is readily found throughout the environment including drinking and surface waters, soil, sewage and various types of foods.

*Escherichia coli* is commonly found in the intestines & faeces of humans and animals.

*Pseudomonas aeruginosa* is commonly in soil and water.

*Staphylococcus aureus* is a common coloniser of human skin and can be found on environmental surfaces around infected individuals.

*Streptococcus pneumoniae* is part of the normal human upper respiratory tract flora & has been isolated from aquatic environments such as seawater.

These bacteria do not tend to cause disease in immunocompetent individuals, but can be problematic in the immunosuppressed, neonates or the elderly. The risk assessment outlines primary containment and PPE measures which have been assessed for the handling and containment of these organisms.

**Host/vector system**

The host organisms covered by this risk assessment are bacteria which are ACDP hazard group 2 and are genetically modified to render them bioluminescent (in the presence of luciferin substrate).
The genetically modified bacteria will be obtained from a commercial source or from a scientific collaborator. This risk assessment covers the use of these genetically modified bacteria and their wild type equivalents, not the generation of genetically modified bacteria.

The vector for bioluminescent transformation was the gram-positive lux transposon cassette, Tn4001 luxABCDE Kmr. Examples of the transformation strategy are further detailed in K.P. Francis, et al, infection & Immunity 2001 (69(5)3350-3358) and J.L. Kadurugamuwa et al Infection & Immunity, 2003 (71(2) 882-890).

Origin & function

Insertion of genetic material from the luciferase gene (Photorhabdus luminescens lux operon) renders the bacteria bioluminescent (in the presence of oxygen and the enzymatic substrate, luciferin), hence allow their detection using non-invasive in vivo imaging using a Caliper-Xenogen IVIS system.

The modified bacteria can also be selectively grown on kanamycin, by virtue of a resistance gene. GMO are bioluminescent bacteria which can be used to quantify a bacterial infection by monitoring the level of light produced in the presence of the luciferin substrate.

Evaluation of foreseeable effects

The main risks of these products used relate to the risk to human health by these ACDP hazard group 2 organisms. The bacteria used are each commonly found either in the environment or in human hosts. Furthermore, the genetically modified bioluminescent strains are no more virulent than the parental strains. This project should not contribute any additional risk to the environment even if there were to be an accidental release.

The containment and disposal measures detailed will minimise any chance of release of the viable bacteria into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon is a bactericidal agent, which is used at a concentration of 1%. It has been shown to cause a 5-log reduction in bacterial counts (Hernandez, A. 2000. Journal of Hospital Infection. 46: 203-209).

In vitro GMM liquid waste will be disposed off into 1% Virkon. After 24 hours, this will be discarded to drains. Bacterial plates will be sealed and autoclaved. Contaminated tips will be soaked in 1% Virkon prior to autoclaving. Any contaminated glassware (kept to minimum) will be soaked in Virkon for 24 hours, then rinsed prior to collection for cleaning.

Other solid waste (plasticware eg homogenizing tubes, pipettes, pipette tips, flasks, tubes) will be disposed of as biohazard waste and autoclaved on site. Disposable plastic waste will be disposed of via the biological waste route. Biohazard waste will be removed from the laboratory to autoclaves for on site destruction.

Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains,
dispose of solids via the industrial (black bag) waste stream for landfill.

### Project Additional Information

**Purposes of the contained use**

medical research

**Recipient or parental organism**

Embryonal human kidney cells HEK-293FT. The following information is published by Thermo Fisher Scientific in the user guide for the 293FT cell line:

The 293 Cell Line is a permanent line established from primary embryonal human kidney transformed with sheared human adenovirus type 5 DNA (Graham et al., 1977; Harrison et al., 1977). The E1A adenovirus gene is expressed in these cells and participates in transactivation of some viral promoters, allowing these cells to produce very high levels of protein. The 293-FT Cell Line is a fast-growing variant of the HEK 293 cell line, and was originally obtained from Robert Horlick at Pharmacopeia.

293FT cells stably express the neomycin resistance gene from pCMVSPORT6TAg.neo. The pCMVSPORT6TAg.neo plasmid is derived from pCMVSPORT6, which has been modified to include the following features:

- The neomycin resistance gene for stable selection in mammalian cells (Southern & Berg, 1982). Expression of the neomycin resistance gene is controlled by the SV40 early enhancer/promoter from which the SV40 origin of replication has been removed.
- The gene encoding the SV40 large T antigen to facilitate optimal virus production (e.g., Thermo Fisher Scientific’s ViraPower™ Lentiviral Expression System) and to permit episomal replication of plasmids containing the SV40 early promoter and origin. Expression of the SV40 large T antigen is controlled by the human cytomegalovirus (CMV) promoter.

**References:**

Harrison, T., Graham, F., and Williams, J. (1977) Host-range Mutants of Adenovirus Type 5 Defective for Growth in HeLa Cells. Virology 77, 319-329

Studies have demonstrated maximal virus production in human 293 cells expressing SV40 large T antigen (Naldini et al., 1996), making the 293FT Cell Line a particularly suitable host for generating lentiviral constructs using the ViraPower™ Lentiviral Expression System available from Thermo Fisher Scientific.
References:

Host/vector system

A commercially available kit from Invitrogen. The ViraPower lentiviral expression system uses a replicon-incompetent lentivirus. Based on the lentikat system developed by Cell Genesys (Dull et al, 1998).

The ViraPower system is a third-generation lentiviral system and includes the following key safety features:

- The pLenti expression vector contains a deletion in the 3′ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes from pLP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
- A constitutive promoter (RSV promoter) has been placed upstream of the 5’ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

Various non-harmful constructs will be tested within the system.

Origin & function

The production of a reporter cell line using a previously genetically modified commercial cell line. The 293 FT cell line is a commercially available cell line that has been previously transformed using SV40 large T antigen. When a ViraPower expression vector and the ViraPower lentiviral packaging mix are co-transfected into 293FT cells, high levels of the viral RNA and the gag/pol and rev proteins required for packaging are produced.

The presence of the large T antigen within the cell line allows very high levels of protein to be expressed from vectors containing the SV40 origin.

Evaluation of foreseeable effects

The information below is published by Washington State University regarding hazards associated with HEK293 cells (the parental cell line of the cells in this study; with the exception of neomycin resistance, it is expected that 293FT cells will be highly similar). For more information, see: https://biosafety.wsu.edu/hek-293-cell-lines/
Family Adenoviridae—Genus Mastadenovirus— Human adenovirus Group C—Human adenovirus 5 (HadV-5). Non-enveloped double stranded DNA virus (1). Adenovirus has been completely sequenced and it includes a total of 35,937 nts (15 pp2359). The 1-4344 nts of HadV-5 represents approximately 12% of the full genome. This agent is unusually stable to chemical, physical and adverse pH conditions (2). Proteins transcribed from this left portion of the Adenovirus include proteins that are involved in oncogenic transformation and in positive regulation of transcription of the early genes of host infection (3), as well as cell cycle genes (4). However, Group C viruses are not known to be tumorigenic (15 pp.2379). It is well established that E1A proteins have mitogenic activity (4). In mammalian cells, the human adenovirus type 5 early region 1A (E1A) oncoprotein functions as a thyroid hormone (TH) dependent activator of the thyroid hormone receptor (TR) (5). Transcription of viral early genes leads to synthesis of some 17 early proteins, many of which perturb host cell or host physiology (4). The Adenovirus DNA genome provides it with the advantage that its DNA can persist in host cells as either a circular extra chromosome (plasmid) or by integration into the host DNA after the complete viral replication has stopped. It has been recently noted that adenoviral DNA from the E1A gene is correlated with COPD (6). The DNA segment which induces transformation is located between 1 and 6% from the left end of the HadV-5 DNA molecule (7). A 2002 study indicates that HEK-293 cells exhibit a pattern of intermediate filament expression similar to that seen in early differentiating neurons as opposed to cells derived from typical kidney epithelial or mesenchymal cells. This fact could have significant implications for experiments that use these cells as kidney cell controls or as non-neuronal control cells (8).

Primary hazards
Ingestion via the fecal oral route (9) Droplet exposure of the mucous membranes (9) Inhalation (through respiratory droplets) (10) Contact/hand-to-eye transfer (10)

Special hazard notes
Generalized infections can occur in immunocompromised individuals. Exposure to this agent can cause serious infection in the congenitally immunocompromised, in patients undergoing immunosuppressive treatment for organ and tissue transplants and for cancers, and in human immunodeficiency virus-infected patients. Adenovirus infections in these patients tend to become disseminated and severe. In all immunocompromised patients, generalized illness involving the central nervous system, respiratory system, hepatitis, and gastroenteritis usually have a fulminate course and result in death. Treatments for adenovirus infections are of little proven value (11). People who smoke may be at higher risk from exposure to HadV-5 (6). Using Adenoviral vectors in conjunction with these cell lines will result in replication-competent viruses as the portion of HadV-5 incorporated into chromosome 19 contains both the E1 and E3 regions that are generally deleted in commonly used Adenoviral vectors (12). Lab workers exposed to HEK-Cells may present an in vivo recombination opportunity between the 12% Adenovirus and latent adenoviruses in the human lab worker (host). Alternatively, poor work technique can cause propagation of adenovirus in the HEK cell lines by introduction of adenovirus from the lab worker (13)."

**Project Additional Information**
Purposes of the contained use

A baboon cytomegalovirus (BaCMV) strain originally acquired from ATCC was cloned into a bacterial artificial chromosome (BAC) to generate BaCMVBAC. BaCMVBAC harbours the entire BAC cassette that encodes several genes, including GFP. To rescue BaCMVBAC, DNA will be delivered by nucleofection into human fibroblasts (MRC-5 cells) and cells will be cultured until high titres of virus are produced. Viral stocks will be used in a variety of assays within a Bioscafet (Class II) cabinet in our BSL2 facilities.

Recipient or parental organism

Upon nucleofection into MRC-5 cells, BaCMVBAC DNA undergoes a full viral life cycle, i.e. the DNA is capable of replicating and producing virion components that assemble into infectious virus particles that are released to productively infect new MRC-5 cells. Many of the genes present in the BAC cassette serve no function in MRC-5 cells (since they are involved in bacterial cell regulation). However, GFP permits the visualisation of BaCMV-infected cells, allowing viral spread to be monitored over time.

Host/vector system

BaCMVBAC DNA will delivered into MRC-5 cells by nucleofection. Once virus is rescued, subsequent MRC-5 infection can be performed simply by culturing cells with virus-containing supernatant. BaCMVBAC carries no additional risks over BaCMV i.e. the presence of the BAC cassette does not alter the risks posed by working with BaCMV. Therefore it should still be handled as a BSL-2 agent.

Origin & function

The BAC cassette harbours genes important for maintenance and replication of the DNA in bacterial cells. These proteins provide no function when expressed in MRC-5 cells and therefore their risk to human health is essentially zero. The BAC will also express GFP, which has been widely used in thousands of studies and has never caused harmful effect in humans.

Evaluation of foreseeable effects

MRC-5 cells pose no risk to human health and have been classified as a BSL-1 agent. BaCMV is a cell culture adapted baboon strain of cytomegaloviruses. The fact that cytomegaloviruses are highly species-tropic combined with the adaptation to cell culture means the risk of BaCMV producing pathogenesis in humans is minimal. However, since other BaCMV strains have been shown to be transmitted following baboon-to-human liver xenotransplantation (Michaels et al, 2001), our risk assessment of BaCMV has been modelled on human CMV (HCMV) which is a BSL-2 agent. As a precaution, immunocompromised or vulnerable individuals should avoid working with BaCMV.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In vitro GMO waste will be disposed of in 1% virkon and after soaking overnight and then autoclaved. Contaminated tips will be soaked in 1% virkon prior to autoclaving. Any contaminated glassware (kept to a minimum) will be soaked in 1% virkon for 24 hours, then rinsed prior to collection for cleaning. Other solid waste (plastic ware, eg tissue culture flasks, pipettes, tips, tubes) will be disposed of as biohazard waste and autoclaved on site. Disposable plastic waste will be disposed of via the biological waste route. Chicken eggs will be processed and taken directly to the autoclave.

Autoclave programme is a make safe programme as specified in BS 2646 part 3 1993 (either 121-125 degrees C for at least 15 minutes, 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) any excess liquids after autoclaving are discarded to drains and solid waste disposed of via the clinical waste route.

Give brief details of the genetic modification safety committee

The role of BSO is taken on by the Biology Teamleader of the Biocatalysis Team. The BSO is a molecular microbiologist with over 15 years of lab experience in microbial molecular biology, recombinant protein production in E. coli, strain engineering. The BSO successfully registered as an ISTR Biological Practitioner Level 1 (Foundation) in 2014/15 and was appointed BSO by the technical director of Johnson Matthey CCT in February 2015.

Sterilisation: All liquid and solid waste will be deactivated by autoclaving at 123°C for at least 20 minutes in a Systec
autoclave. Deactivation will be monitored by using 3M Thermalog Indicator Strips for steam. An annual autoclave
servicing and UKAS validation of two waste cycles is performed, using a recognised method with temperature and
pressure sensors on a full cycle. Labcoats are sterilised in a special autoclave cycle before leaving the building for
dry-cleaning.

Decontamination: Work surfaces are decontaminated using 70% ethanol at the end of each work period. Any spills
are decontaminated with freshly prepared Virkon for 10 minutes prior to cleanup. Virkon is inexpensive, highly
effective against a broad range of microbes, and does not have the associated problems of metal corrosion or odour
compared to bleach. Both methods of inactivation are validated by standard means. Both methods give 100% kill and
there is therefore no possibility that bacteria will escape from the laboratory. Lab benches are regularly swabbed and
checked for antibiotic resistant recombinant E. coli.

Waste removal: Solid autoclaved waste of waste code EWG18-02-03 and contaminated sharps (placed in an
approved plastic biohazardous sharp container) are disposed of by a special disposal service. Liquid autoclaved
waste is treated as household waste water (a trade effluent form was approved by Anglian Water).

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

Two risk assessments for work in the field of biocatalysis are attached. One RA covers the storage and maintenance
of risk assessed strain and plasmid collections from X-Zyme GmbH in Germany (which belongs to JM) and other
external sources, the other one covers genetic engineering and small-scale production of biocatalysts undertaken at
the new premises. Both risk assessments focus exclusively on recombinant E. coli lab strains and E. coli plasmids
and standard techniques for manipulation and expression of genes of biocatalytic value. Transferred collections have
been previously assessed as classI or equivalent. In both assessments the level of risk is considered negligible and
the highest containment level to protect human health and environment is 1. The work is classified as GM activity
class 1 and requires therefore no contained use notification.

Project Ref 3273/18.1

Date Ackn'd 04/04/2018

CU2 Project Title Assessing the Dickeya dadantii recombinant microorganisms previously made at PHE for potential viability of increased asparaginase yield as a new product stream for Erwinase® manufacture

Class 2

Culture Vol

Class 2

1-50 Litres

Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

### Purposes of the contained use

The GMM is assigned Class 2 ACDP containment level. Although the host microorganism is classified as ACDP 1, the containment level is increased as the host is an APHA regulated plant pathogen.

### Recipient or parental organism

Genetically modified strains of Dickeya dadantii, formally known as Erwinia chrysanthemi will encode for Lasparaginase gene for overexpression of the enzyme, The inserted L-asparaginase enzyme is native to Dickeya dadantii thus it is unlikely to modify the host in any way. There are no harmful properties associated with the inserted gene product. Dickeya is Animal and Plant Health Agency (APHA) licensed as it is a plant pathogen, The GMOs will only be used in APHA licensed laboratories as specified below under strict guidance of such regulations.

### Host/vector system

**Host:** Dickeya dadantii (Erwinia chrysanthemi) NCPPB 1066 and SCI 193  
**Non-mobilisable vectors:** pASN32 (7.4kbp), pASN230 (13.5kbp) and pj401 :129213 (4983bp)

### Origin & function

The genetic material inserted is a gene encoding for over-expression of asparaginase enzyme that is naturally produced by the host Dickeya dadantii (Erwinia chrysanthemi). The encoded gene sequence, including signal peptides, will be synthesised and inserted into a vector incorporating a promoter sequence, antibiotic resistance and lac system for IPTG induction, L-asparagine is deaminated to aspartate in an enzymatic reaction catalysed by Lasparaginase, The enzyme also has a lesser activity towards L-glutamine for conversion to L-glutamate, The GMOs will be assessed for increased yield of asparaginase enzyme in the fermentation.

### Evaluation of foreseeable effects

The host organism is not a human pathogen and is classed as ACDP1.  
The host organism is a plant pathogen and can cause soft rot in succulent fleshy plant organs such as roots, tubers, stem cuttings and thick leaves and is controlled by APHA for handling and waste management. All the activities relating to the keeping and use of the GMO will be carried out in accordance with APHA regulation, confined within secure APHA registered containment labs.  
The inserted L-asparaginase enzyme is native to Dickeya dadantii thus it is unlikely to modify the host in any way. There are no harmful properties associated with the inserted gene product.  
The vectors to be used are non-mobilisable plasmid vector, therefore, negating the possibility of horizontal gene transfer to other microorganisms. Transfer of the sequences within the GMM to other microorganisms is extremely unlikely.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

N/A
All activities concerned with handling of the GMM will be carried out by APHA registered staff within APHA registered
labs. All samples and any associated waste will be incinerated via on-site incineration or by autoclaving at 121 °C for a
minimum of 15 minutes. All equipment and containment facilities will be disinfected using sodium hypochlorite under
validated conditions of use.

### Project Additional Information

#### Purposes of the contained use

The GMM is assigned Class 2 ACDP containment level. Although the host microorganism is classified as ACDP1, the containment level is increased as the vector is mobilisation defective with a strong promoter and the protein is a biologically active substance which is very unlikely to have a deleterious effect.

#### Host/vector system

#### Origin & function

#### Evaluation of foreseeable effects

Give brief details of the genetic modification safety committee

The department's biological safety committee serves as the genetic modification safety committee, and is composed of:
- The departmental biological safety officer (chairman)
- The local safety coordinator
- The departmental safety officer
- The bioengineering laboratory technician
- A university biological safety adviser

The committee meets three times per year. It reviews risk assessments and provides advice and training for about 20 researchers using biological agents in the department.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Maximum culture volume that could be released at any one time is less than one litre.

Disinfectant: Virkon® & Distel (formerly Trigene), following the manufacturer's guidelines for dosage and exposure time for maximum kill, pipettes will be totally immersed in disinfectant before disposal.

Solid contaminated waste is disposed in robust and leakproof containers, which are taken monthly by an approved external incineration contractor for certified disposal.

On site autoclave can be used for prior inactivation of solid waste in puncture proof containers, cycles at 121°C for 15 to 30 minutes, provides 100% kill, monitored with Browne's tube or steam tape, serviced, calibrated and validated for waste inactivation annually. Contaminated laboratory glassware and other materials awaiting disinfection will be stored in a safe manner.

The genetic modification safety committee (GMSC) consists of new people both of whom have more than 20 years experience handling GMMs. One is a member of the management who additionally has 5 years experience of being on the GMSC of a global pharmaceutical company which included reviewing over 50 GMM proposals every year. Any new pieces of work will be assessed by a written proposal which will then be reviewed and classed as either class 1 or class 2.

</table>
Disinfection and autoclaving will be carried out where required. All waste materials will be disposed of into autoclave bags, yellow clinical waste bags/bins or sharps bins as required. All contaminated solid waste (agar plates, disposable plasticware etc) will be placed in autoclave bags and will be autoclaved and disposed of via designated route. Liquid cultures will be chemically-inactivated (Virkon 1% or PeraSafe 0.16% for 30 mins) or autoclaved prior to disposal. All contaminated glassware and reusable plasticware will be decontaminated as above.

a) Disinfection.
1% Virkon will be used for disinfection. The surfaces of the microbiological safety cabinet will be disinfected with 1% Virkon after use. Laboratory benches will be swabbed with 1% Virkon after any activity.

b) Autoclaving.
Autoclaves are not present in the laboratory for waste treatment. However, a large central autoclave facility is located on site at Alderley Park (please see next section for the further details of the Waste management process and derogation request). The autoclave is subject to twice yearly servicing and annual validation using a 12-point thermocouple procedure which includes a probe placed in a representative load.

The GMSC met on 20th April to review PP - 2015-1 which had been given a provisional class 1 risk assessment. It was agreed that this was appropriate as there was no significant risk to either the environment or operator.

Give brief details of the genetic modification safety committee

The committee consists of three scientists with extensive combined experience working with genetically modified organisms. The committee hold monthly biosafety meetings.
- An senior academic with research interests in the development of viral gene delivery systems. Experienced in designing studies and supervising postgraduate students undertaking research projects with class II genetically modified viruses.
- A research scientist with 10+ years postdoctoral experience in containment level II laboratories working with genetically modified bacteria and viruses and acting as Biosafety Manager in a biotechnology company for 2 years.
- A research scientist who's recent PhD project involved regular work with class II genetically modified viruses.

Project Additional Information

Purposes of the contained use

A conditionally replicating vaccinia virus capable of lytic replication within cancer cells is planned to be used to treat cancer by either:
- improving the delivery of the virus into tumours by 'pumping' the virus into tumours using ultrasound induced cavitation;
or
- developing polymer modified vaccinia virus capable of extending the circulation time of the virus and further targetting the virus to tumours.

Recipient or parental organism

In vitro and in vivo experiments will be performed with established cell lines and primary cells of human and mouse origin. Established cell lines may include, but not limited to SKOV, HepG2, SNU-5, and HT116 and with primary cells may include human erythrocytes, human peripheral blood lymphocytes (PBL), mouse erythrocytes and mouse splenocytes.

Host/vector system

Attenuated vaccinia virus - Copenhagen and possibly, Western Reserve, Wyeth, and MVA strains. The inserted foreign genes luciferase or FCU1 (at the JR2 locus) replace the Thymidine kinase gene resulting in disruption of the thymidine kinase reducing the virulence. Further deletion of the ribonucleotide reductase gene (from the I4L locus) reduces virulence further.

Origin & function

Host cells are acquired commercially while the vaccinia virus is a gift from collaborators.

The luciferase gene from firefly is a widely used reporter gene not considered to be harmful. Luciferase is a natural oxidative enzyme, which catalyses the ATP dependent conversion of luciferin to oxyluciferin a process which results in the emission of a photon of light. Luciferase from firefly is widely used as reporter genes and not considered to have harmful properties.

FCU1 is a cytosine deaminase-phosphoribosyl transferase fusion enzyme for the conversion of the prodrug 5-fluorocytosine to the active metabolite 5-fluorouracil monophosphate F-dUMP. E. coli cytosine deaminase activates 5-fluorocytosine to 5-fluorouracil (5-FU), a well established anticancer drug. Phosphoribosyl transferase enhances the efficacy of the system, by improving the conversion of 5-FU to F-dUMP in the cell.

Cytotoxicity of these prodrug-activating systems is conditional upon the presence of prodrug.

The intended function of the genetic material is to enable the luminescent detection and quantification of virus infection (Luciferase) or the conversion of prodrug to
chemotherapeutic drug (FCU1) specifically in vaccinia-virus infected tumour cells.

**Evaluation of foreseeable effects**

Humans are not a natural host of vaccinia. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous infection, but it contains antigens that stimulate an immune response that is cross-reactive with smallpox antigens and thereby confers protection from the human disease. Serious complications occurred in less than 1 in 4,000 people, mainly in immunosuppressed and extremely young individuals. Rare complications include eczema vaccinatum, disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) [Fields, 1996]. Although Vaccinia viruses are replicating DNA viruses, they do not insert their DNA into the host genome and there has been no known transfer of viral genetic material into the host genome.

Vaccinia virus shows an inherent selectivity for cancerous tissues relative to normal tissues. This appears to be influenced by at least three underlying biological characteristics of tumours: their “leaky” blood vessels, for example due to Vascular Endothelial Growth Factor (VEGF) effects; their proliferative state and the activity of the Epidermal Growth Factor (EGF) receptor pathway. In addition to the inherent tumour tropism exhibited by vaccinia, several vaccinia strains (VVTK-RR-/FCU1) have been designed to be additionally attenuated in normal cells and tissues through a deletion of the TK gene. TK gene-deleted vaccinia viruses, are significantly attenuated in normal tissues. Virulence can be further decreased by removal of the ribonucleotide reductase (RR) gene, the product of which catalyzes the formation of deoxyribonucleotides from ribonucleotides. Deoxyribonucleotides in turn are used in the synthesis of the vaccinia DNA genome. RR gene-deleted vaccinia viruses, are significantly attenuated in normal tissues in vivo and are, therefore, less toxic whilst maintaining anti-tumoural activity. Work using polymers to modify the virus will further attenuate its ability to infect human cells as the regions which provide it with tropism for its target cell surface receptors will be covered. Selective tropism for cancer cells may then be provided by the addition of ligands targeting cancer specific receptors.

Some vaccinia strains have had genes inserted to produce FCU1. It is a cytosine deaminase-phosphoribosyl transferase fusion enzyme for the conversion of the prodrug 5-fluorocytosine to the active metabolite 5-fluorouracil monophosphate F-dUMP. E. coli cytosine deaminase activates 5-fluorocytosine to 5-fluorouracil (5-FU), a well established anticancer drug. Phosphoribosyl transferase enhances the efficacy of the CD system, by improving the conversion of 5-FU to F-dUMP in the cell. Cytotoxicity of these prodrug-activating systems is conditional upon the presence of prodrug.

Animals inoculated with conditionally-replicating vaccinia are unlikely to support a productive infection except within tumour cells and possibly in proliferating skin epithelium. There is a small risk from transfer of infected animal fluids to open wounds, and operators will be careful to protect their hands from such risks. The procedures put in place for handling and disposal of virus make escape into the environment highly improbable. The use of attenuated laboratory strains results in a modified virus that is less pathogenic than wild type strains and the inserted genes pose no foreseeable risk to human or environment in the unlikely event of loss of containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals injected with vaccinia will be housed in isolators in a Containment Level 2 wing of the animal unit. They will be handled in class II safety cabinets until/unless it is shown there is no risk from shedding of the virus. Cages and bedding will be treated according to standard Containment Level 2 procedures (inclucding autoclaving of animal bedding and chemical disinfection of liquid wastes) as detailed in the appended detailed risk assessment. All handling of live animals will be performed by people trained to do so during a prescribed Home Office training course. The greatest risk to humans will be from any percutaneous injury sustained during the inoculation procedure. This risk will also be minimised by following the procedures prescribed in the risk assessment.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

2% Virkon is used for soaking pipettes and tissue culture plates/flasks for at least 1 hour followed by transfer of solids into biological hazard bags for autoclaving. Virkon treated liquid waste will be washed down a drain. Virkon contact achieves a 100% degree of kill within 10 minutes (see www.antechh.com/virkonapps.html).

Virkon disinfection will be tested. Virus will be exposed to 2% Virkon for 15 minutes, a dialysis step will be performed to remove virkon and the sample diluted in culture media. This is then put on to cells and transgene expression, which indicates viability of the virus, is assayed after 24 hours.
The genetic modification safety committee concluded that the risk assessment is comprehensive and the equipment and processes in place to deal with the handling and disposal of this agent are appropriate.

### Project Additional Information

#### Purposes of the contained use

A conditionally replicating Herpes simplex virus -1 capable of lytic replication within cancer cells is planned to be used to treat cancer by either:

- improving the delivery of the virus into tumours by ‘pumping’ the virus into tumours using ultrasound induced cavitation;
- or
- developing polymer modified virus capable of extending the circulation time of the virus and further targetting the virus to tumours.

#### Recipient or parental organism

In vitro and in vivo experiments will be performed with established cell lines and primary cells of mouse origin. Established cell lines may include, but not limited to, A20 cells, CT-26 cells, and with primary cells may include mouse erythrocytes and mouse splenocytes.

#### Host/vector system

#### Origin & function

Host cells are acquired commerically while the modified HSV-1 is provided by collaborators (Amgen).

The Granulocyte-macrophage colony-stimulating factor (GM-CSF) is of mouse origin. GM-CSF is a glycoprotein that functions as a cytokine. It stimulates the production of immune cells, granulocytes and monocytes. GMSCF is part of the immune/inflammatory cascade.

The intended function of the genetic material is to elicit an immune/inflammatory response to HSV-1 infected tumour cells. This will be achieved by stimulation of an immune response through virus mediated GMC-SF production and a direct response to HSV-1 antigens. Further tumour destruction will be achieved through the oncolytic properties of the virus.

#### Evaluation of foreseeable effects

Wild type herpes simplex virus type 1 (HSV-1) infection causes blisters on mucosal membranes or epithelial cells of the mouth lips or genitals. Virus infection occurs through contact with wounds or infection of the mucosal epithelia. After initial infection the virus spreads to neuronal cells, it then travels along the neurone (by a process called retrograde transport) to the ganglion. In the case of herpes infections of the oral mucosa, the virus goes to the trigeminal ganglia whereas infections of the genital mucosa lead the virus entering the sacral ganglia. The virus can also travel in the opposite direction to arrive at the mucosa that was initially infected; hence the site of primary infection determines the site of blisters which can re-occur after periods of latency. Vertical transmission of HSV-1 to neonates is asymptomatic in 98.3% of cases, however, when symptoms do manifest they can be fatal. However, in this project the virus used is the JS1 strain with the neurovirulence gene ICP34.5 gene is removed from the virus in order to attenuate neurovirulence and restrict tropism to transformed or malignant cells. Furthermore the deletion of ICP47 enables antigen presentation and limits the virus’ immune evasion mechaism, and insertion of GM-CSF actively stimulates an immune response. As the HSV-1 thymidine kinase gene has not been deleted in this strategy, antiviral agents such as ganciclovir and acyclovir will still be effective against genetically modified virus variants.

Animals inoculated with this HSV-1 are unlikely to support a productive infection except within tumour cells and possibly in proliferating skin epithelium. There is a small risk from transfer of infected animal fluids to open wounds, and operators will be careful to protect their hands from such risks.

02/03/2022
The procedures put in place for handling and disposal of virus make escape into the environment highly improbable. The use of attenuated laboratory strains results in a modified virus that is less pathogenic than wild type strains and the inserted genes pose no foreseeable risk to human or environment in the unlikely event of loss of containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals injected with modified herpes simplex 1 virus will be housed in isolators in a Containment Level 2 wing of the animal unit. They will be handled in class II safety cabinets until/unless it is shown there is no risk from shedding of the virus. Cages and bedding will be treated according to standard Containment Level 2 procedures (including autoclaving of animal bedding and chemical disinfection of liquid wastes) as detailed in the appended detailed risk assessment. All handling of live animals will be performed by people trained to do so during a prescribed Home Office training course. The greatest risk to humans will be from any percutaneous injury sustained during the inoculation procedure. This risk will also be minimised by following the procedures prescribed in the risk assessment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

2% Virkon is used for soaking pipettes and tissue culture plates/flasks for at least 1 hour followed by transfer of solids into biological hazard bags for autoclaving. Virkon treated liquid waste will be washed down a drain. Virkon contact achieves a 100% degree of kill within 10 minutes (see www.antechh.com/virkonapps.html).

Virkon disinfection will be tested. Virus will be exposed to 2% Virkon for 15 minutes, a dialysis step will be performed to remove virkon and the sample diluted in culture media. This is then put on to cells and transgene expression, which indicates viability of the virus, is assayed after 24 hours.

The genetic modification safety committee concluded that the risk assessment for working with this modified HSV-1 is comprehensive and the equipment and processes in place to deal with the handling and disposal of this agent are appropriate for safe containment.
### Project Additional Information

**Purposes of the contained use**

We plan to show improved effectiveness of a conditionally replicating vaccinia virus carrying reporter genes, or immuno-stimulatory genes for tumour cells expression. The virus is also capable of lytic replication within cancer cells only. We will improve the delivery of the virus into tumours by ‘pumping’ the virus into tumours using ultrasound induced cavitation.

We also plan to study the effect of ultrasound on the shedding of viral antigens and its immunostimulatory effects. A transgenic cell line expressing ovalbumin will be used for this purpose.

**Recipient or parental organism**

In vitro and in vivo experiments will be performed with established human cell lines and mouse cell lines. In vivo experiments will be performed in mice with subcutaneously implanted/grown tumours composed of human or mouse cell lines. Human cells will include, but not be limited to, UM-UC-3 cells. Mouse cell lines may be transgenic and include (but not limited to), A20, A20 - OVA, A20 - OVA +AsRed, B16-F10, B16-F10 - OVA and B16-F10 - OVA +AsRed.

Mouse strain may be spontaneous immunosuppressive strains to enable human cell line engraftment such as (CD-1 nude) but not transgenic. Mice will be commercially sourced.

GM cell lines will be a gift from a collaborator. Human cell line will be commercially sourced.

**Host/vector system**

Both SKV-Luc and TBio-6517 are attenuated derivatives of the well established Copenhagen vaccinia smallpox vaccine genetically engineered to selectively replicate in...
Origin & function

The genetic modifications of SKV-Luc are designed to attenuate the virus and make it more selective to tumour cells and will have the effect of reduced pathogenicity potential in non-transformed cells. Insertion of the luciferase gene into this virus enables this reporter to be used to track infection and replication in tumours. The modification made to produce TBio-6517 are designed to induce an immunological response to the tumour cells.

A20-ova expressing ckOVA (clone C2), A20-ova expressing ckOVA and AsRed (clone D6), B16F10-ova expressing ckOVA (clone D7), B16F10-ova expressing ckOVA and AsRed (clone C9) will be used for this section of the project. Both genes are expressed under the EF1alpha promoter. The genes have been integrated at Rosa26 safe harbour locus using CRISPR/Cas9 system.

Evaluation of foreseeable effects

Humans are not a natural host of vaccinia. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous infection, but it contains antigens that stimulate an immune response that is cross-reactive with smallpox antigens and thereby confers protection from the human disease. Serious complications occurred in less than 1 in 4,000 people, mainly in immunosuppressed and extremely young individuals. Rare complications include eczema vaccinatum, disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) [Fields, 1996]. Although Vaccinia viruses are replicating DNA viruses, they do not insert their DNA into the host genome and there has been no known transfer of viral genetic material into the host genome.

Vaccinia virus shows an inherent selectivity for cancerous tissues relative to normal tissues. This appears to be influenced by at least three underlying biological characteristics of tumours: their "leaky" blood vessels, for example due to Vascular Endothelial Growth Factor (VEGF) effects; their proliferative state and the activity of the Epidermal Growth Factor (EGF) receptor pathway. In addition to the inherent tumour tropism exhibited by vaccinia, these vaccinia strains (SKV-Luc and TBio-6517) are additionally attenuated in normal cells and tissues through selection of strain with deletions including 16 native viral coding segments removed through a 13,767 bp deletion in the 3 prime region, and the deletion of 16 native coding segments removed through a 11,899 bp deletion in the 5 prime region. These deletions disable the ability of the virus to suppress the normal cellular anti-viral response (e.g. interferon signalling via the cGAS/STING pathway, other viral defence effector pathways, and apoptosis) that functions to suppress late viral replication in normal cells, but is absent in many types of transformed tumour cells. Two sets of expression cassettes were added to this SKV derivative strain. One of these was inserted into the native B8R coding segment, and expresses cDNAs for the human cytokine FLT3L and the membrane-bound p35 subunit of the human cytokine IL-12, using native vaccinia virus promoters (pB19R and pLate respectively). The other was inserted into the site of the 11,899 bp CpMDSp deletion and expresses cDNAs for the light and heavy chain genes of an anti-CTLA-4 antibody. This cassette also makes use of a native vaccine virus promoter (pH5R), and includes a bi-cistronic cassette where the two cDNAs are separated by a T2A ribosome skip sequence. The FLT3L protein is a hematopoietic growth factor that drives dendritic cell survival and proliferation. The IL-12 protein has pleiotropic effects on multiple components of the tumour microenvironment and promotes the T cell response. The anti-CTLA-4 antibody is included to inactivate any native CTLA-4 protein which normally serves to attenuate T cell activation. This transgene is modelled after the anti-CTLA-4 monoclonal antibody Yervoy, an agent approved by the FDA for the treatment of advanced metastatic melanoma. The viruses will be obtained from a collaborator and no further genetic manipulation will be performed.

The genetically modified cell lines are of mouse origin and pose no risk to humans. A20-ova expressing ckOVA (clone C2), A20-ova expressing ckOVA and AsRed (clone D6), B16F10-ova expressing ckOVA (clone D7), B16F10-ova expressing ckOVA and AsRed (clone C9) will be used for this section of the project. Both genes are expressed under the EF1alpha promoter. The genes have been integrated at Rosa26 safe harbour locus using CRISPR/Cas9 system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals injected with vaccinia will be housed in isolators in a Containment Level 2 wing of the animal unit. They will be handled in class II safety cabinets until/unless it is shown there is no risk from shedding of the virus. Cages and bedding will be treated according to standard Containment Level 2 procedures (including autoclaving of animal bedding and chemical disinfection of liquid wastes) as detailed in the appended detailed risk assessment. All handling of live animals will be performed by people trained to do so during a prescribed Home Office training course. The greatest risk to humans will be from any percutaneous injury sustained during the inoculation procedure. This risk will also be minimised by following the procedures prescribed in the risk assessment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
2% Virkon is used for soaking pipettes and tissue culture plates/flasks for at least 1 hour followed by transfer of solids into biological hazard bags for incineration. Virkon treated liquid waste will be washed down a drain. Virkon contact achieves a 100% degree of kill within 10 minutes (see www.antechh.com/virkonapps.html).

Regular inspections and health and safety checks will be made and records and logs of use and disinfection of waste will be maintained.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The genetic modification safety committee concluded that the risk assessment is comprehensive and the equipment and processes in place to deal with the handling and disposal of this agent are appropriate.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Contaminated Waste will be placed into sealed containers which will then be removed from the site by an independent contractor. The contractor will be a specialist waste management company who will dispose of the waste in accordance with all relevant legislation and guidelines applicable to clinical waste. The contractor will be required to provide communication confirming that the method of disposal complies with the relevant legislation.

# Project Additional Information

## Purposes of the contained use

The aim of the project is to validate a variety of cancer biomarker genes including oncogenes, tumour suppressor genes and genes encoding components of cellular signalling pathways in cancer in order to develop diagnostic immunoassays.

## Recipient or parental organism

**E. coli**

E. coli K12 strains such as:

- DH5α (F− Φ80lacZ∆M15 Δ(lacZYA-argF) U169 recA1 endA1 hsdR17 (rK−, mK+) phoA supE44 λ− thi-1 gyrA96 relA1)

will be used for propagation of plasmid DNA.

E. coli K12 strains are attenuated, non-colonising, non-pathogenic strains, unlikely to survive outside the laboratory and have a long history of safe use, and are regarded as non-hazardous.

**Cell lines**

Primary and established human cell lines and mammalian cell lines.

The cell lines used are not capable of survival outside the laboratory and are non-transplantable due to immuno-incompatibility. They are therefore considered to be highly disabled hosts. Established cell lines with a history of safe use may be considered hazard group 1, however primary cell lines may contain endogenous pathogens and are treated as hazard Group 2.

## Host/vector system

The following will be delivered to target mammalian (including human) cell lines:

1. cDNAs encoding wild-type or mutant known candidate biomarkers including oncogenes, tumour suppressor genes and other genes involved in cell signalling, apoptosis and/or development of cancer. Expression is under the control of cloned human promoter sequences, constitutive viral promoters (such as CMV or SV40 early promoters)).

   cDNAs may also be expressed as fusions with GFP and derivatives to allow fluorescent detection or with epitope tags such as haemagglutinin (HA) or FLAG or with poly-histidine tags to facilitate protein detection and purification.

2. shRNA or siRNA (interfering RNA) molecules under the control of human or viral promoters targeted to genes thought to be involved in cancer.

**DNA**

Human/mammalian DNA isolated from tissues, primary or established cell lines; cloned cDNA or shRNA/siRNA from collaborators or commercial sources.

## Origin & function

**Evaluation of foreseeable effects**

This work involves the use of vectors to allow targeted over-expression or knock-down of genes of interest in human and mammalian cell lines and the growth of mammalian cell lines which have been transduced with viral vectors containing expression cassettes that harbour:

- cDNA
- short hairpin RNAs

(Viral transductions will be carried out by collaborators carried out under local GM rules and risk assessments and only transferred to our facility upon testing to confirm lack of viral activity).
GMOs created would consist of:

Modified cell lines – The inserted genes/interference RNAs include those that code for/target known or potential oncogenes or tumour suppressor genes and could potentially lead to cellular transformation if expressed in an operator’s cells although several further genetic changes would be required for progression to malignancy.

E. coli K12 strains - These strains are attenuated, non-colonising, non-pathogenic strains, unlikely to survive outside the laboratory and have a long history of safe use, and are regarded as non-hazardous therefore an genetic modification should not have any effects.

In addition work to be carried out is small-scale thus there is no chance of major release of any GMO. and therefore the work is non-hazardous to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No Larger GMOs to be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None of legal controls will be derogated.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with Virkon granules or an equal volume of 10% Virusolve+ (shown to be effective in killing all known pathogens in independent tests) and left for at least 12 hours before disposal down the drain with copious amounts of water.

Solid waste (plastic ware or cells) will be treated with appropriate concentrations of Virkon or Virosolve+ for at least 12 hours before being destroyed as clinical waste.

Liquid spills

Wearing appropriate gloves, liquid spills will be treated with Virkon granules until deep pink, or with an equivalent volume of 10% Virusolve+. The treated area will be left for at least 30 minutes and the area will then be mopped with plenty of water.

Solid spills

Wearing appropriate gloves, solid spills will be gathered into an autoclave bag and the area affected will be wiped liberally with 2% Virkon. The treated area will be left for 30 minutes and the area will then be mopped with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Give brief details of the genetic modification safety committee

Neem Biotech Ltd's Quality, Health & Safety Manager is qualified with the NEBOSH H&S National General Certificate (Sept 2009) and ISTR-accredited Biosafety Professional Certificates (Jul 2009 and May 2010). The SHE Manager is also registered as a Biosafety Professional (BSP) with the ISTR in the UK and is a Registered Biosafety Professional (RBP) with ABSA in the USA. The SHE Manager previously served as the Biological Safety Officer for the University of Southampton from 2009 - 2011 where he also served on the University's GM & Biosafety Committee.

### Project Additional Information

**Purposes of the contained use**

Experiments involving biofilm reporter strains with various genetic modifications will be used to demonstrate the efficacy of various antimicrobial compounds. These strains may involve plasmid or chromosomal genetic modification. Quorum sensing inhibition is a key target in novel antimicrobials for the disruption of biofilm infections and may be explored using GMMs. Another key area of target is urease inhibition with may be studied with various GMMs.

**Recipient or parental organism**

- *Pseudomonas aeruginosa*
- *Staphylococcus aureus*
- *Salmonella enterica*
- *Ureaplasma*

**Host/vector system**

- lacZ, lux, gfp, phoA, gus
- Fluorescent proteins
- ure

**Origin & function**

All genetic material will be standard as published in peer reviewed journals or available commercially from reputable sources.

**Evaluation of foreseeable effects**

Plasmids used may carry antibiotic resistance genes for selection purposes. Genes being used are primarily used as reporters to indicate a specific metabolic activity or ability. Occasionally mutations may be introduced to knock out the function of a specific gene.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GMM liquid waste is sterilised prior to disposal (down drain) using a standard benchtop autoclave (121°C for 15 minutes) or with 10% sodium hypochlorite (final concentration). Disposable plastic or
glass is autoclaved where possible or soaked in 10% sodium hypochlorite solution prior to disposal by
registered third party waste handler.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid Class 1 GMO waste can be disposed of directly into tiger-stripe bags which are sent off site for incineration as Non-Infectious Healthcare Waste (EWC 18 01 04). Liquid waste will be treated with 1-5% Virkon for at least 30 minutes.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All risk assessments attached to this application have been discussed and amended under the guidance of those involved with the GMO process at MedImmune.

**Project Additional Information**

**Purposes of the contained use**

We undertake drug discovery research to generate therapeutic antibodies against rare cancers so as 1) to provide diagnostic tools, 2) to generate potential cancer therapeutics, and 3) to provide tools to the academic collaborators to deepen our understanding of the disease. This necessitates extensive use of mammalian cells in our research. To generate disease relevant models, these cell lines often need to undergo genomic modification (GM) as part of the process. This GM includes over-expression of target proteins, knock-down or knock-out of certain genes, intentional activation or interference of certain genes, insertion of marker proteins, and mutagenesis to include cancer relevant mutations.

The process involves introduction of nucleic acid materials (DNAs or RNAs) into chosen mammalian cell lines. This can be achieved by using a range of techniques, from traditional chemical or lipid based transfection, electroporation, to lentiviral transduction (using 3rd or later generation of lentiviral vectors). Following the above process, the genes are inserted randomly into the genome, and by selecting for a marker (often antibiotic resistance) and/or desired traits, we could obtain the pools and/or clonal cell lines. More controlled insertion and interference can be achieved by CRISPR-Cas9 technology which uses a single-stranded, hairpin-forming guide RNA (sgRNA) to introduce a modification at a specific site on DNA. Due to the nature and objectives of our research, the genetic targets are often genes linked to cancer development, including oncogenes and tumour suppressor genes.

**Recipient or parental organism**

Mammalian cells (recipient cell lines):

Parental mammalian cell lines are usually of commercial origin, e.g. ATCC or ECACC, and are from hazard group 1 or 2. The cell lines of interest would not knowingly contain (or being contaminated by) infectious human pathogens such as HIV or HepB. However, they might have integrated fragments of viral genome, e.g. HPV (which is often the case of HG2 cancer cell lines). Primary cells obtained from reputable sources should have been pre-screened for the presence of some of the blood-borne viruses, bacteria, yeast and fungi. Hazard Group 1 and Hazard Group 2 mammalian cell lines in continuous culture have been found unable to establish colonies in healthy/immuno-competent human adults following intradermal inoculation, ingestion or inhalation. Many of the cell lines have long history (some 40-50 years) of safe use. These cells are unlikely to infect or harm any living things in the environment, as they are unlikely to survive outside of laboratory culture conditions for any duration of time without required nutrients and temperature.
Lentivirus and producer cells:
Lentivirus particles are generated in a host mammalian cell line. The producer cells (e.g. HEK293T) have a long history of safe use and unlikely to be pathogenic to humans or environment. Lentivirus, generated from 3rd generation lentivirus vectors, is, while infectious, self-inactivating and replication incompetent. While an accidental infection of another cultured cells in a laboratory is possible, it is unlikely for virus to survive the harsh environment outside the laboratory to infect any living things.

Bacterial strains:
Health and Safety
Executive
The DNA plasmid vectors will be propagated during the molecular cloning stages. This process is done usually by transforming K-12 derivative strains of E. coli (Hazard Group 1 E. coli, e.g. DHSalpha and Top1 0) and purifying DNA from them. These strains are disabled, and have been demonstrated to be non-pathogenic and have well-understood, stable genetic lesions in the bacterial chromosome. These lesions often render the microorganism auxotrophic and dependent upon nutrients that must be supplied in the culture media. Furthermore, these strains are often rendered incapable of colonising mammalian hosts, either due to introduced biological restrictions or sensitivity to common agents.

Host/vector system

DNA plasmids:
All the plasmids used are non-mobilizable.

Lentiviral particles:
The plasmid containing the gene of interest is transfected along with plasmids containing viral packaging genes into the host producer cells. For 3rd or later generation of lentiviral systems, there should be at least 3 vectors required to generate packaged viral particles. The viruses are self-inactivating and replication incompetent, and enhanced safety feature of later generation of LVs ensures that the potential for multiple recombination events to revert to replication competent viruses are extremely rare.

Viral particles themselves are easily inactivated using a common laboratory disinfectant (e.g. Virkon, TriGene, Distel), and are susceptible to inactivation by dehydration or other environmental insults outside of controlled cell culture conditions. They require close contact with body fluids or percutaneous inoculation for transmission. The virus could, in principle, in the unlikely event of it being introduced to the cells of a worker, give genomic modification of cells of the worker.

Origin & function

Genes of interest:
The sequences of the genes of interest could be the full length or fragments of a gene from open reading frames (ORFs), cDNAs, genomic DNA or designed synthetic DNA sequences. The sequences can contain intended mutations. RNA interference and CRISPR-Cas9 sgRNA materials are single stranded RNAs (in case of CRISPR, it could be encoded in DNA plasmid), which has specific target sequences within the genes or in the regulatory elements.

The types of genes include 1) Non-hazardous genes encoding proteins which are soluble, membrane bound or secreted, including exogenous proteins to add functions e.g. reporter genes, 2) 'Target genes' known to have close link to cancer, or 3) known 'hazardous' genes, e.g. oncogenes, tumour suppressor genes, DNA repair genes and their regulatory elements. However, we do not intend to use any immediately toxic genes, e.g. toxin and proteins which cause neurodegenerative disorders of humans (Transmissible Spongiform Encephalopathies or TSEs)

CRISPR-Cas9 systems:
There are two major components, Cas9 (CRISPR associated protein 9) and single guide RNA (sgRNA), involved in this technology. The machinery is used in an RNA-guided manner for genome editing, e.g., knock-in, knock-out, artificial transcriptional activation and inhibition.

Genes from the viral vectors:
Five viral genes are present in the host and/or virus particles from lentiviral packaging:
Gag, pol, tat, rev, and an envelope protein (most likely VSV-G, Vesticular Stomatitis Virus glycoprotein G, replacing HIV's own envelope proteins).
These genes are encoded over 3 separate vectors in 3rd or later generation of lentiviral systems. The accessory genes from original HIV genome (v if, vpr, vpu, nef) are deleted from the packaging vectors.

Evaluation of foreseeable effects

**Mammalian cells:**
The final products are the mammalian cell lines (parental cell lines from Hazard groups 1 and 2) which have altered levels of expression of certain gene(s) of interest, or mutation(s):
A cell line might overexpress one or more gene(s) of interest
A cell line might have lowered (or no) expression of one or more genes of interest
A cell line might have one or more mutations in the gene of interest or in the regulatory element(s).
In most cases, resulting cell lines should not be any more hazardous than the parental cell lines. Even in the event of directly injecting them into a human subject or contaminating open cuts and wounds with the cells, a person's immune system should quickly mount a defensive immune response. Cell lines themselves are usually not known to be allergenic or toxic. There is no evidence to suggest that the host or genetically modified cell line will be able to propagate outside of a controlled laboratory environment without defined growth media and temperature requirements.
However, genetically modified cells, especially when manipulation was performed on known oncogenes, tumour suppressor genes, DNA repair genes, or signalling molecules i.e. cytokines, could have potential to impair normal biological pathways and systems if they are introduced directly into a human subjects. Again, in most cases, the immune system would quickly clear those cells by recognising them as foreign. However, in some rare cases, the risk might be increased due to the characteristics of the parental cell line, or the expressed gene(s):
Some parental and resulting cell lines are tumorigenic, and they might pose higher risk to immune-compromised individuals (note: experiments showing tumorigenicity are often done in nude mice, which have compromised immune system).
Some Hazard Group 2 cells contain genetic material from human papillomavirus (HR-HPV). In the normal 2-D culture condition, cells cannot produce HPV. However, in 3-D cultures, co-culturing or genetic modification could potentially allow production of HPV particles.

**CRISPR-Cas9:**
There is a slight risk if all the components of CRISPR machinery are injected into the operator, especially in conjunction with a lentiviral vector delivery system:
DeSigned CRISPR effects: The changes originally designed for in vitro tissue culture could occur within the operator’s cells.
Potential for insertional mutagenesis: The original viral particles generated in producer cells can infect human cells and integrate the genome in the host human cells from the accidental introduction (e.g. needle sticks). This could potentially lead to 1) integration and expression of Cas9 and sgRNA genes, 2) insertional mutagenesis depending on the site of integration of Cas9 gene and subsequently oncogenesis. The risk rating becomes higher if 1) high viral titre, 2) large volume and 3) directly injected/contaminating via open cuts/wounds.
To minimise risk, avoid route of direct infection, e.g. needle sticks and/or spills onto open wounds. Take caution when dealing with CRISPR-Cas9 machinery, especially if lentiviral vector delivery system is used. Resulting cell lines should not pose an increased risk to the operator over their parental cell lines.
Lentiviral particles:
The highest risk of infection is when virus particles are generated and handled: The resulting virus particles are infectious, although self-inactivating and replication incompetent (i.e., cannot increase the viral load after being taken out of virus producing cells). Because of engineered pseudotyping, the virus will have a broad array of cell types and species it can infect. The viral particles require close contact with body fluids or percutaneous inoculation for transmission. If the virus is introduced directly (e.g. Injection or spill over broken skin), chances of infection could be conceivable. Exposure to other mucus membrane (e.g. Splash to the eyes, nose, mouth, or inhalation of airborne particles) might have some risk of infection, although at much reduced rate. An accidental contact of the cultured cells or viral particles to intact skin should not have hazardous consequences given the affected skin is washed immediately with copious amount of water.

There are several potential risks if accidental exposure of the virus particles to human occurs:
Potential for insertional mutagenesis: The original viral particles generated in the producer cells (e.g. HEK-293) can infect human cells and integrate their genome in the host human cells from the accidental introduction (e.g. needlesticks). This could potentially lead to 1) integration and expression of insert gene (which could be an oncogene), 2) insertional mutagenesis depending on the site of integration (which could potentially change the gene or regulatory elements) and subsequently oncogenesis. The risk rating becomes higher if 1) oncogenes are inserted, 2) high viral titre, 3) large volume and 4) directly injected/contaminating via open cuts/wounds.

Potential for generating replication competent virus: the later generation of lentiviral vectors are self-inactivating and replication incompetent. The complex safety features, e.g. deleted accessory genes and ‘split-genes’ into separate vectors, requires at least 3 recombination events to generate reverted, replication competent viruses, which is extremely rare and highly unlikely.

The lentiviral particles cannot survive outside of closed controlled cell culture conditions and are rapidly inactivated by dehydration or other environmental insults. Once the virus particles are internalised, remaining virus particles washed away, and the viral genome integrated into host's DNA, the resulting established cell lines should not be any more harmful than the parental mammalian cell lines.

Bacteria cells:
The bacterial strains used to produce the plasmid vectors are attenuated non-colonising strains that are harmless to Humans and cannot survive outside culture conditions, and are therefore harmless to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon and Distel are broad spectrum virucidal disinfectants effective in against blood borne viruses, including GM lentivirus - which are the main microbial hazards in this project. They also destroy DNA and RNA, making them suitable reagents for destroying GMOs. 2% Virkon or Distel (v/v) will be used to treat liquid waste (30 minutes) and to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste will be poured down the sink after treatment with 2% Virkon or Distel. Work surfaces will be wiped down with Distel and 70% ethanol at the end of work and when contamination is suspected. After treatment, solid waste (e.g. flasks) will be bagged in biological waste bags. This waste will then be destroyed by high temperature incineration using a reputable waste contractor, such as Grundon. High temperature incineration is a validated means used to provide assurance of complete GMO kill.
CMAL has an agreement with waste management CRO, Grundon, whose operational site is located within 6-miles of the laboratory. Building management team assists us with transportation of laboratory waste to the designated bins. The team also operates the autoclave instruments in the building.

Joint Cancer Research UK Therapeutic Discovery Laboratory and Cancer Research UK Biological and Genetic Modification Safety Committee:
This committee agreed that the proposed project falls within the activity assigned (activity class 2) and approved the project with a minor comment:
- Incubation of cultures involved in lentiviral work should be incubated in a separate incubator from other cultures.

The recommendation from the committee was reflected in the final version of the risk assessment, typographical errors were corrected, and approved by CMAL, Shurene Bishop Simon (Health and Safety Manager and secretary of the safety committee) and Lorna Stewart (chair of the safety committee).

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

GMM liquid waste will be disposed off into appropriate disinfectant (2% sodium hypochlorite, 1% Virkon or a 1:10 dilution of Distel or Chemgene) within a Class II Microbiological Safety Cabinet (MSC) where all work using these organisms will be carried out. After 24 hours, this waste will be discarded into the drains. Bacterial culture plates will be sealed, double-bagged inside the cabinet before being autoclaved on site (see attached Risk Assessment for details of cycles). Contaminated tips will be soaked in appropriate disinfectant (see above) and disposed of in a sharps container. Any contaminated glassware (kept to minimum) will be soaked in appropriate disinfectant for 24 hours, then rinsed prior to normal cleaning. Other solid waste (plasticware) will be autoclaved on site prior to disposal via the clinical waste route. Autoclave logs will be monitored and waste will only be disposed of if the run is successful. Fresh dilutions of each disinfectant will be made weekly.

Virkon is a bactericidal agent, which is used at a concentration of 1%. It has been shown to cause a 5-log reduction in bacterial counts (Hernandez, A 2000. Journal of Hospital Infection. 46: 203-209). Low concentrations of sodium hypochlorite (bleach) have a biocidal effect on mycoplasma and vegetative bacteria in seconds in the absence of high amounts of organic material (Dychdala GR Disinfection, sterilization, and preservation. 2001 :135-157). S. aureus, Salmonella choleraesuis, and P. aeruginosa have been shown to be inactivated in <10 minutes by sodium hypochlorite (Rutala WA et al Infect Control Hosp. Epidemiol. 1998;19:323-7). Distel I Chemgene are bactericidal and effective in destroying type strain cultures of P. aeruginosa, S.aureus, MRSA and VRE with contact time of 1-5 minutes.

Project notified under transitional arrangements

**Historical Significant Changes**

Tick if notifying a connected programme of work

**Project Additional Information**

**Purposes of the contained use**

Bacterial infection models will be used to characterise the activity of novel antimicrobial agents. Specifically, the ability of the novel compounds to inhibit bacterial growth will be tested. These experiments aim to quantify and monitor infection at serial timepoints by using bacteria that have the green fluorescent protein (gfp) gene inserted into their genome. Monitoring GFP production will allow the visual detection of infection as well as quantification of the amount of bacteria present. Mutant bacterial libraries with deletions in non-essential genes, will also be used to characterise pathways that are targeted by the antimicrobial agents being assessed.

**Recipient or parental organism**

The following bacteria will be used in the proposed work:

- *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Salmonella typhimurium*, *Acinetobacter baumannii*, *Bacillus subtilis* and *Escherichia coli*.
- These micro-organisms are classified as ACDP hazard group 2 (or 1 in the case of B. subtilis) and are found in the environment or human host.
- *E.coli* is commonly found in the intestine and faeces of humans and animals as a commensal organism.
- *S.aureus* commonly colonises human skin and nasal passages and is found on environmental surfaces in hospitals and in community settings.
- *Acinetobacter* is found in the environment in water (including drinking and surface waters) as well as in sewage and soil.
- *Pseudomonas aeruginosa* is commonly found in soil and water.
S. typhimurium is predominately found in the intestinal lumen of humans and animals. Bacillus subtilis is classed as non-pathogenic. These bacteria do not tend to cause disease in immunocompetent individuals or cause a self-limiting disease, but can be problematic in the immunosuppressed, neonates or the elderly. Risk assessments are in place outlining the safe handling of these organisms. J-Iat cells originate from the Jurkat cell line, which are designated as biosafety level 1.

Host/vector system

The host organisms are ACDP hazard group 2 or below and are described above. The genetically modified bacteria and cells will be obtained from commercial sources or from a scientific collaborator.

Origin & function

Non essential bacterial genes are disrupted by the insertion of an antibiotic-resistance cassette or a transposon cassette. Fluorescent bacteria have a gfp gene inserted. The modified bacteria can be selectively grown, by virtue of a resistance gene. The genetic material is stably inserted into the bacterial genome and is not known to result in more virulent bacteria.

Evaluation of foreseeable effects

To human health and environment:
Any risk using these GMOs relates to them being ACDP hazard group 2 organisms. The modified strains have not been shown to be more virulent than their wildtype equivalent. Control measures will be in place when using these GMOs, as outlined in the attached risk assessment. Therefore there are no additional risks to humans or the environment as a result of any of the identified modifications. The containment and disposal measures outlined in the risk assessment below will minimise the chance of infection to the worker or release of these organisms into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM liquid waste will be disposed of into appropriate disinfectant (2% sodium hypochlorite, 1% Virkon or a 1:10 dilution of Distel or Chemgene) within a Class II Microbiological Safety Cabinet (MSC) where all work using these organisms will be carried out. After 24 hours, this waste will be discarded into the drains. Yes

Give brief details of the genetic modification safety committee

The site BSO attends the bi-annual GM committee at pfizer Cambridge site for peer review of GM risk assessment.

Biological Safety Officer attends the local bi-weekly Leadership Team meeting including a section for raising any safety and biological safety issues.

All lab representatives attend a 3-monthly health and safety local meeting to raise issues and disseminate information to lab users including Bio safety issues and information.

Risk assessments are created in an electronic registration system and are circulated to registered GM users with appropriate expertise and experience, before final approval by BSO and discussion at safety meeting.

Solid Waste:
Any biological or potentially infectious waste must be autoclaved to sterilise prior to disposal. Waste for autoclaving should be collected in clear, autoclave bags placed inside autoclavable bins or in autoclavable Bio-bins. Once full, the bins should be sealed and labelled for disposal. All autoclave waste must be left in the appropriate collection point for collection by LBIC staff. The waste will be collected on a daily basis. Laboratory waste which does not require autoclave sterilisation should be bagged in a yellow, clinical waste bag or an appropriate Bio-bin. Once full, the bag or bin should be sealed using cable ties and labelled and left in the appropriate collection point.

Liquid Waste: Liquid waste for disposal to foul drain should be disinfected with approved method of disinfection e.g. Virkon, Chern Gene or precept. All waste material and residues will be disposed of according to the LBIC hazardous waste disposal guidelines.

Biohazardous waste is emptied daily.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Attached biohazard risk assessment has been reviewed and approved.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

To engineer, design and develop rAAV vectors as well as develop rAAV manufacturing process and analytical methods to support the research and development of gene therapy medicinal products. The work involves culture of laboratory strains of non-pathogenic transmission immobilized bacteria, rAAV, produced using tissue culture methods in established mammalian or insect cell lines (supplied from external sources) in conjunction with plasmid DNA or recombinant viruses. Plasmid and viral lots will be analysed using biochemical, biological, molecular and physical characterisation methods. The biological methods include the use of HeLa RC32 (RG2ICl2) cell line (HeLa cells containing Rep/Cap Genes from AAV2) for infectious titer assay of rAAV lots and use of Adenovirus type 5 (Ad5) reference standard and HEK293T (both RG2ICl2).

**Recipient or parental organism**

Non-pathogenic transmission immobilised Bacteria (E.Coli DH5Alpha and SURE bacteria) are used to generate and engineer plasmid DNA through molecular biology techniques (cloning) and amplify stock of plasmids for further use. rAAV are derived from a non-pathogenic and replicative defective human virus (AA V) and generated using human embryonic kidney cells (HEK293T, HEK293), Chinese Hamster Ovary (CHO) or insect (SF9) cell lines in conjunction with either plasmid DNA, recombinant baculoviruses (AcMNPV) generated through cloning and transfection through SF9 cells, or recombinant baculoviruses (from external sources).

**Host/vector system**

rAAV are generated within HEK cells (HEK293, HEK293T), CHO cells or SF9 cells. AAVs are non Pathogenic, replication deficient human viruses. Characteristic of the AAV Systems to be used:

- **Virus Free System:** The rAAVs will be manufactured using a helper-virus free system by transient transfection of 2 or 3 plasmids in HEK293 or HEK293T cells (RG2ICl2):

  - The 2 plasmids System is composed of a Helper/Packaging Plasmid coding for the 5 minimum required adenoviral helper Genes/proteins, the Rep proteins of the AA V2 and the Cap proteins (VP1, VP2, VP3) of different rAAV serotypes and engineered variants (depending on the specific of each project the different serotypes use will be...
AAV-1, 2, 3, 4, 5, 6, 7, B, 9, rh10 and Variants derived/engineered from AAV 1, 2, 3, 4, 5, 6, 7, 8, 9, rh10). The second plasmid contains the expression cassette flanked by AAV2 ITR sequences. The third plasmid system is composed of a Helper plasmid containing the 5 minimum required adenoviral helper genes/proteins, the packaging plasmid containing the Rep gene from AAV V2 and the Cap gene of dille rent AAV serotypes and engineered variants (as above) and the third plasmid contains the expression cassettes flanked by AAV2ITRs.

**Origin & function**

The expression cassettes intended to be used are either reporter genes (YFP, GFP, luciferase etc...) or a therapeutic transgene (for gene therapy strategy evaluation, usually based on human genes) under the control of tissue specific promoter or constitutive ones (CMV, CAG etc...). Each Therapeutic transgene will be risk assessed separately on a project to project basis.

Nature and origin of inserts including possibility of inserted material, altering the characteristics of the recombinant AAV: rAAV genomes produced contain the 2 ITRs from AAV 2 (inverted terminal repeats) flanking an expression cassette composed of either reporter genes such as YFP, GFP or luciferase or therapeutic transgene (risk assessed separately on a project by project basis) under the control of tissue specific human promoters or constitutive promoters such as CMV or CAG promoters.

The helper functions coding for the 5 minimum required adenoviral helper Genes/proteins E1A-E1B, E2, E4, and VA RNA will be brough by the helper plasmids in the transfection system.

rAAV variant engineering, by modification of the AAV Cap sequences, generates rAAV with modified capsid resulting in increased transduction efficency, increased or modified biodistribution, modified tissue tropism and/or reduced immunogenicity.

**Evaluation of foreseeable effects**

Due to the production systems using separated entity for the expression of Rep/Cap genes and the ITRs and Genome, recombination events leading to a replication competent AAV (wtAAV) are considered very low. In the event of this recombination occurring the resulting species would be as replication deficient as the wild type AAV and nonpathogenic.

rAAV genome integration in human genome is considered extremely low risk due to the deletion of the Rep gene (involved in the site specific integration mechanism) from the rAAV genome. Rare events of random integration of rAAV genome have been reported but the probability of such an event is considered very low.

HEK293, HEK293T, Hela, Hela RC32 all carry biohazard associated with the partial viral genome they contains and potential adventitious agent, however the risk is considered low considering the controls in place.

Baculovirus does not infect humans or animal but causes hazard to environment (as is insect pathogene) however the Baculovirus expression system is based on a deleted strains for the polyhedrin gene rendering the virus sensitive to environmental factors and insect gut condition resulting in a low risk for the environment and human health.

Accidental exposure routes are determined to be:

Ingestion, Inhalation, Inoculation/Injection, Contact e.g. eyes, dermal
The likely sources of accidental exposure are due to aerosol inhalation, exposure to contaminated liquids or via sharps.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Solid Waste**

Any biological or potentially infectious wastes are handled through the LBIC waste management route via autoclaving. Biohazardous wastes are collected in clear biohazard bags or in autoclavable Bio-bins. Once full, the bins are sealed and labelled for disposal.

All autoclave waste are left in the appropriate collection point for collection by LBIC staff. The waste are collected on a daily basis.

Laboratory waste which does not require autoclave sterilisation are bagged in a yellow or orange waste bag or an appropriate Bio-bin. Once full, the bag or bin is sealed using cable ties and labelled and left in the appropriate collection point for collection by LBIC.

**Liquid Waste**

- Liquid waste for disposal to foul drain are disinfected with approved method of disinfection e.g. Virkon 1% (w/v) or Chern Gene (1:20 v/v) for a minimum period of 2 hours.

All waste material and residues will be disposed of according to the LBIC hazardous waste disposal guidelines.

Biohazardous waste is emptied daily.

**Project notified under transitional arrangements** N

### Purposes of the contained use

The project involves the design, production and analysis of HBoV/AAV vector composed of a HBoV1 capsid and a rAAV genome encoding for either reporter genes (Luciferase, mCherry, GFP, YFP) or the human or ferret CFTR gene, under the control of CMV, CAG or F5 promoters. Design will involve molecular biology cloning techniques and DNA amplification in E.Coli lab strains, production will involve amplification of cell line (HEK293 or HEK293T), transfection with an Helper, packaging, transgene and replication plasmids. Clarification through microfluidisation, centrifugation, ultracentrifugation, filtration; purification by chromatography. Analysis of the vector will involve nucleic acid amplification techniques (PCR, qPCR, dPCR), protein analysis, (HPLC, SDS PAGE, WesternBlot, ELISA), Genome analysis (alkaline AGE, AGE, HPLC) and other methods for potency and purity determination.

### Recipient or parental organism

Non-pathogenic transmission immobilised Bacteria (E.Coli DH5Alpha and SURE bacteria) are used to generate and engineer plasmid DNA through
molecular biology techniques (cloning) and amplify stock of plasmids for further use. rAAV genomes are derived from a non-pathogenic and replicative defective human virus (AAV), Packaged into the caps of HBoV1 (human boca virus 1), a member of the Parvoviridae virus family has been suggested to cause human disease (has been associated with lower respiratory tract and gastrointestinal infections, predominantly in children) generated using human embryonic kidney cells (HEK293T, HEK293), or insect (SF9) cell lines in conjunction with either plasmid DNA, recombinant baculoviruses (AcMNPV) generated through cloning and transfection through SF9 cells.

**Host/vector system**

rAAV/HBoV vector are generated within HEK cells (HEK293, HEK293T) or SF9 cells. Characteristic of the rAAV/HBoV1 Systems to be used: Virus Free System: The rAAV/HBoV1 will be manufactured using a helpervirus free system by transient transfection of 4 plasmids in HEK293 or HEK293T cells (RG2/CL2): o The 4 plasmids system is composed of a Helper plasmid containing the 5 minimum required adenoviral helper genes/proteins, the packaging plasmid containing the early terminated non structural gene (NS) and Structural (VP1, VP2 and VP3) gene of HBoV1 under the control of CMV promoter, the Replication plasmid containing the Rep gene from AAV2 and a 1.3Kb deleted version of the Cap gene of AAV2 (disrupted capisid gene) flanked by ITRs fro Adenovirus 5 and the fourth plasmid contains the expression cassettes flanked by AAV2 ITRs. Baculovirus (AcMNPV) /Insect Cells System (RG1/CL1) for rAAV/HBoV1 production: rAAV/HBoV1 production is allowed by infecting SF9 Cell culture by 2 Baculovirus expressing Rep from AAV2, VP gene of HBoV1 gene and The expression cassettes flanked by AAV2 ITRs. HEK293 are transformed with Adenovirus 5 DNA and HEK 293T express the SV40 large from the Simian Virus 40 in addition, both cell line are handled at CL2..

**Origin & function**

The expression cassettes intended to be used are either reporter genes (YFP,GFP, Luciferase, mCherry etc..) or a fCFTR (ferret CFTR) or hCFTR (human CFTR) therapeutic transgenes under the control of tissue specific promoter or constitutive ones (CMV, CAG or F5). Nature and origin of inserts including possibility of inserted material, altering the characteristics of the recombinant AAV/HBoV1: rAAV genomes produced contain the 2 ITRs from AAV 2 (inverted terminal repeats) flanking an expression cassette composed of either reporter genes such as YFP, GFP, Luciferase or mCherry or therapeutic transgene (fCFTR or hCFTR) under the control of tissue specific human promoters or constitutive promoters such as...
CMV, CAG or F5 promoters.
The helper functions coding for the 5 minimum required adenoviral helper
Genes/proteins E1A-E1B, E2, E4, and VA RNA will be brought by the helper
plasmids in the transfection system.

rAAV/HBoV1 vector are regenerated using a HBoV1 capsid and a rAAV
genome increasing tissue tropism to the Lung.
The resultant rAAV/HBoV1 vector would be, as all rAAV (since the genome
is based on AAV), replication incompetent, and once introduced into human
cells result in CFTR expression. There is none expected harmful properties
to human as rAAV is non-pathogenic, additionally CFTR is normally expressed
in normal individuals and is not expected to be harmful in the population, at
least overexpression of CFTR in healthy animal is not known to be harmful or
toxic. rAAV are also safe for the environment (infect only mammalian) and in
the unlikely accidental infection of environmental species, AAV is not known to
cause any animal diseases and the expression of human CFTR gene in

Evaluation of foreseeable effects

animal is not know to be harmful or toxic. has the only component from
HBoV1 is the proteic capsid surrounding the rAAV genome it is not expected
to display any of the pathological effect of the wild type HBoV.

Due to the production systems using separated entity for the expression of
Rep genes, the ITRs and Genome, and the HBoV1 capsid, recombination
events leading to a replication competent AAV (wtAAV) are considered not
possible since the rAAV capsid gene in the system is disrupted.

Recombination event leading to a replication competent HBoV1 is considered
very low since most of the NS proteins, essential to HBoV1 replication, have
been removed from the system. recombination event leading to a replication
competent rAAV/HBoV1 would only be possible if AAV Rep protein could
support the replication, assembly and packaging of rAAV/HBoV1, and this
multiple recombination is considered of low risk, and it is unknown whether
AAV Rep could support all these function in a cross species system. In the
event of any of this recombination occurring the resulting species would be as
replication deficient as the wild type AAV and non-pathogenic. rAAV genome
integration in human genome is considered extremely low risk due to the
deletion of the Rep gene (involved in the site specific integration mechanism)
from the rAAV genome. Rare events of random integration of rAAV genome
have been reported but the probability of such an event is considered very
low.

HEK293, HEK293T, HeLa, HeLa RC32 all carry biohazard associated with
the partial viral genome they contains and potential adventitious agent,
however the risk is considered low considering the controls in place.
Baculovirus does not infect humans or animal but causes hazard to
environment (as is insect pathogen) however the Baculovirus expression
system is based on a deleted strains for the polyhedrin gene rendering the
virus sensitive to environmental factors and insect gut condition resulting in a
low risk for the environment and human health.
Accidental exposure routes are determined to be:
Ingestion, Inhalation, Inoculation/Injection, Contact e.g. eyes, dermal
The likely sources of accidental exposure are due to aerosol inhalation,
exposure to contaminated liquids or via sharps.

Off-site treatment by High Temperature Incineration will be used. Solid and liquid waste will be separated and stored for collection by Grundon (waste contractor) and sent for High Temperature Incineration. Provisions for inactivation on-site will also be available; an autoclave on-site (serviced annually and each run will be monitored with print out of temperature/time profile) using standard methods of inactivation with a 100% degree of kill expectation will be used to inactivate solid waste.

Virkon powder to disinfect liquid waste with 1% Virkon solution. Inactivated liquid waste will be disposed of to drain once this has been approved and included in ATDBio’s Thames Water Trade Effluent Notice.

For activities involving GMMs, describe the waste management measures which will apply to the activity

<th>Virus Type</th>
<th>Description</th>
<th>Relevant Studies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Herpes Simplex Type 1 (HSV-1) or Type 2 (HSV-2)</td>
<td>The project will use strains disabled by deletion of the ICP34.5 or ICP34.5 and ICP47 genes. Each of the deletions in ICP34.5 and ICP47 have been shown individually to generate a non-pathogenic, though still replication competent virus.</td>
<td>Burgos et al. (2006) J Neurovirol 12: 420-27; Goldsmith et al. (1998) J Exp Med 187:341-348; Perng et al. (1995) J. Virol. 69:3033-41; Perng et al. (1996) J Virol 70:2883-93. This virus is designed to replicate selectively in tumors as compared to surrounding tissue.</td>
</tr>
<tr>
<td>Vesticular stomatitis virus (VSV)</td>
<td>This virus is a member of the Rhabdoviridae family. It is inherently tumor specific as replication is strongly suppressed in Interferon gamma (IFNy) response-normal tissues, but activated in IFNy pathway-defective tumor cells. Strains which have mutations in the matrix (M) protein have increased IFNy sensitivity which has been shown to increase tumor specificity.</td>
<td>Huang et al. (2003) Mol. Ther. 8: 434-440; Balachandran and Barber (2000) rUBMB Ufe 50: 135-138; Stojdl et al (2000) Nat. Med. 6, 821-825. 80th wild type and strains strains containing mutations in the matrix (M) proteins will be used in this project. Clinical trials are underway with VSV as an oncolytic agent (Clinicaltrials.gov identifier: NCT01628640)</td>
</tr>
<tr>
<td>Maraba virus</td>
<td>This virus is also a member of the Rhabdoviridae family and is also inherently tumor specific due to suppression of replication by IFNy. Like VSV, mutant strains with deletions in the M protein sequence which show increased IFNy sensitivity have been identified.</td>
<td>Brun et al. (2010) Mol Ther 18: 1440-1449. 80th wild type and strains containing mutations in the matrix (M) protein and G protein will be used in this project. Clinical trials are underway with Maraba virus as an oncolytic agent (Clinicaltrials.gov identifier: NCT02285816). Both Maraba virus and VSV may be pseudotypes with the envelope glycoprotein of lymphocytic choriomeningitis virus (ICMV), which has been shown to reduce neutralizing antibody induction in vivo (Muik et al. (2014) Cancer Research 74: 3567-3578).</td>

#### Host/vector system

See above. The Green fluorescent protein (GFP; jelly fish) and/or bacteriallacZ marker genes will be inserted into each of the viruses under CMV, RSV or endogenous viral promoter control. Therapeutic genes may then be inserted which will be the subject of separate submission(s).
Origin & function

Green fluorescent protein (GFP: jelly fish) and lacZ marker genes. CMV and RSV viral promoter sequences.

Evaluation of foreseeable effects

HSV-1 is universally prevalent virus (approximately 50-80% of the human population are seropositive for HSV-1). HSV-1 rarely causes severe symptoms. The final vectors should only be capable of replicating in rapidly dividing eukaryotic cells. The viruses to be generated will be disabled by the deletion of ICP34.5 and ICP47 which has been shown to significantly reduce the pathogenicity of recombinant HSV-1 viruses compared to wild type virus and has been shown to be safe in a number of clinical trials (Andtbacka et al. (2015). J Clin Oncol. 2015 May 26. pii: JCO. 2014.58.3377; Harrington et al. (2010). Clin Cancer Res 16: 4005-15; Hu et al. (2006), Clin Cancer Res 12: 6737-47; MacKie et al. (2001). Lancet 357:525-6; Markert et al. (2000). Gen Ther 7:867-7). HSV-2 is closely related to HSV-1 and is also a universally prevalent virus although infections levels are lower than those for HSV-1 (approximately 20% of the human population are seropositive for HSV-2). The final vectors will have the same characteristics as those shown displayed by ICP34.5 and ICP47 deleted HSV-1 viruses.

VSV mainly infects horses, cattle, pigs, sand flies (Fang et al. (2012). Vaccine 30: 1313-21) and is non-lethal. The virus is passed on by insect bite or direct contact with an infected animal. Zoonotic infection of humans can occur either by directly exposed 10 infected livestock, or following an insect bite. Most human infections appear to be mild or subclinical (Letchworth et al. (1999). Vet J 157: 239-260; Lichty et al. (2004). Trends in Mol Med 10: 210-216). A clinical trial with a modified form of the virus containing IFN-13 (VSV-IFN-13) for the treatment of liver cancer is currently ongoing in the US. Oncolytic VSV has also been shown to be well tolerated in dogs (leBlanc et al. (2013) Hum. Gen. Ther. Clin. Dev. 24: 174-181) by intravenous dosing at up to 10 x 10^{10} TCID50. Maraba virus is related to VSV but is only found in insects and does not naturally infect mammals (Pauszek et al. (2011). Arch Virol 85: 9346-9358). A clinical trial with a modified form of the virus containing transgenic MAGE-A3 (MarabaMAGE-A3) is currently ongoing in Canada.

No expected effects of human exposure to any of these viruses are expected due to the attenuating deletions included (HSV1/2) or as the viruses do not naturally cause human disease (VSV, Maraba virus). Where oncolytic viruses have been tested in clinical trials, by direct injection into tumors, side effects are generally limited to mild fevers and local inflammation. However, this is at far higher doses than could occur following accidental exposure during this project.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A 1% Virkon solution will be used for the disinfection of HSV vectors. 70% IMS and DistelTM will be used for general cleaning purposes.

All liquids that come into contact with virus will be treated with 1% Virkon solution for a minimum of 20 minutes prior to disposal.

All tissue culture plastics, tips and pipettes that come into contact with virus will be treated with 1% Virkon solution for a minimum of 20 minutes prior to disposal. After disinfecting, plastics will be drained of any excess liquid and then
placed in clinical waste bags. Once full, the bags will be sealed with biohazard tape before being removed by a regulated contractor.

Historical Significant Changes

Historical Date of Additional Info
The aim of this project is to develop oncolytic virus based on herpes simplex virus type 1 (HSV-1) or herpes simplex virus type 2 (HSV-2) which express proteins which may be beneficial for cancer treatment.

Herpes Simplex Virus Type 1 (HSV-1) and Type 2 (HSV-2): the project will use strains disabled by deletion of the ICP34.5 or ICP34.5 and ICP47 genes. Each of the deletions in ICP34.5 and ICP47 have been shown individually to generate a non-pathogenic, though still replication competent virus (Burgos et al. (2006) J Neurovirol 12: 420-27; Goldsmith et al. (1998) J Exp Med 187:341-348; Perng et al. (1995) J. Virol. 69:3033-41; Perng et al. (1996) J Virol 70:2883-93). This virus is designed to replicate selectively in tumours as compared to surrounding tissue.

The following genes (in various combinations) will be used to construct the viruses. These proteins are being inserted to aid in the promotion of an antitumor immune response and/or spread of the virus through tumours. Immune stimulatory proteins to be expressed will include ICOS-L, GITR-L, CD40-L, OX40-L, 4-1BB-L, FLT3-L, IL12, IL2, IL18, IL5, IL21, IL-28, IL-29, GM-CSF and TNFa. Anti-sense and/or RNAi to be expressed will include RAAi for TGFb2, IFNa and IFNg. Single chain antibodies to be expressed will include antibodies to CTLA-4, PD1, LAG-3, TIM-3 and VISTA PATENT. Molecules to aid viral spread will include viral membrane fusogenic glycoproteins from VSV-G, measles virus H or F, GALV-R-1, metalloproteinases and collagenases chondroitinases, and secreted DNAse.

One to four of these proteins will be expressed from a single virus to identify optimal combinations. Viruses expressing of marker genes (GFP, LacZ) in addition to the genes listed above. In all cases mouse or human versions of the genes may be used. These genes will be under the control of the human cytomegalovirus immediate early promoter (HCMV IE), the Rous sarcoma
virus promoter (RSV), the Simian Virus 40 (SV40) promoter, the Moloney murine leukemia virus (MMLV) LTR promoter, promoters from HSV itself or mammalian promoters such as the EF-1α/eIF4g hybrid promoter.

**Evaluation of foreseeable effects**

HSV-1 is a universally prevalent virus (approximately 50-80% of the human population are seropositive for HSV-1). HSV-1 rarely causes severe symptoms. The final vectors will selectively replicate in tumors as compared to normal tissue through the deletion of ICP34.5 or ICP34.5 and ICP47. These deletions have been shown to significantly reduce pathogenicity compared to wild type virus and have been shown to be safe in a number of clinical trials, including with the additional expression of GM-CSF (Andtbacka et al. (2015). J Clin Oncol. 2015 May 26. pii: JCO. 2014.58.3377; Harrington et al. (2010). Clin Cancer Res 16: 4005-15; Hu et al. (2006). Clin Cancer Res 12: 6737-47; Mackie et al. (2001). Lancet 357:525-6; Markert et al. (2000). Gen Ther 7:867-7).

HSV-2 is closely related to HSV-1 and is also a universally prevalent virus although infections levels are lower than those for HSV-1 (approximately 20% of the human population are seropositive for HSV-2). The final vectors will have the same characteristics as those shown displayed by ICP34.5 and ICP34.5/ICP47 deleted HSV-1 viruses.

No expected effects of human exposure are expected due to the attenuating deletions made in the viruses. Where oncolytic viruses based on HSV-1 have been tested in clinical trials by direct injection into tumors, side effects are generally limited to mild fevers and local inflammation following direct injection of up to 1e8 pfu/ml virus stocks into tumors. These are far higher doses than would be expected to occur following any accidental exposure to the viruses to be constructed in this project. In all cases, even following accidental exposure at high dose, only very localised expression of the encoded gene(s) would be expected as viruses to be constructed in the project will not replicate productively in normal tissue and would also be expected to be rapidly inactivated following any systemic exposure by immune responses to HSV.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Tick to confirm that it is attached to this form

Is an emergency plan required according to regulation 20? N
RP1 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. RP1 has a particular utility in combination with immune co-inhibitory pathway blockade. Intended indications to study include soft tissue sarcoma, breast cancer including triple negative breast cancer (TNBC), lung cancer including non-small cell lung cancer (NSCLC), melanoma, non-melanoma skin cancers, head and neck cancer, primary liver and kidney cancer and colorectal cancer. The initial clinical trial protocol intends to test RP1 in several indications as a monotherapy and in combination with anti-PD-1 therapy.

RP1 (rHSV-1hGM-CSF/ GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the Rsequence deleted (R-) [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PiT-1 receptor for GALV. This results in the death of the cells by membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an anti-tumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

RP1 (rHSV-1hGM-CSF/ GALV-GP) is derived from the RH018 strain of Herpes Simplex Virus-1. RP1 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.
RP1 was constructed using a new strain of HSV-1 (strain RH018). Replimune obtained and compared 30 clinical strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018) for further development. RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the PIIT1 receptor, which is widely expressed on mammalian cells including human tumour cells. PIIT1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immune-mediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an anti-tumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1% Virkon solution). As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol (day 1, day 3/7/10, day 14, day 21, day 28, day 35, day 42, day 49, day 56 and as part of the follow up, 30 days after the last dose). Blood will be collected after the first, second and third RP1 injections at the following time-points: 1 (±15min), 2 (±15min), and 4 (±15min) hours and also immediately prior to dosing at the second and third dose. RP1 DNA levels and virus from saliva/oral mucosa, injection sites, injection site dressings, and lesions that appear to be herpetic will be determined on the same days.

Purposes of the contained use

RP1 will be administered to subjects as an anti-tumour therapy, as part of a phase II clinical trial to treat patients with advanced cutaneous squamous cell carcinoma. RP1 has a particular utility in combination with immune coinhibitory pathway blockade. The clinical trial protocol intends to estimate the clinical benefit of cemiplimab monotherapy versus cemiplimab in combination with RP1 for patients with locally advanced or metastatic (nodal or distant) cutaneous squamous cell carcinoma (CSCC), as assessed by overall response rate (ORR) according to central review.

Recipient or parental organism
RP1 (rHSV-1hGM-CSF/GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the Rsequence deleted (R-) [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PiT-1 receptor for GALV. This results in the death of the cells by membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an anti-tumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Host/vector system

RP1 (rHSV-1hGM-CSF/GALV-GP) is derived from the RH018 strain of Herpes Simplex Virus-1. RP1 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.

Origin & function

RP1 was constructed using a new strain of HSV-1 (strain RH018). Replimune obtained and compared 30 clinical strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018) for further development.

RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity.

GALV-GP-R- binds to the PiT1 receptor, which is widely expressed on mammalian cells including human tumour cells. PiT1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigencontaining exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immune-mediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy.

As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1% Virkon solution).

As part of phase II of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol. Blood, urine, oral swabs, injection site and exterior of dressing samples will be collected at the first, second and third RP1 injection at the following timepoints: pre-dose (excluding dressing), and also immediately prior to dosing at the fourth through to the eighth dose (Cycle 3 Day 1). Samples on injection days will be done prior to any injections and handling of RP1. Samples will also be collected at Cycle 3 Day 43 and Cycle 4 Day 43 (note exterior of dressings will not be obtained at these timepoints). For patients who withdraw from treatment or due to PD, prior to Cycle 4 Day 43; samples will be collected at the EOT visit. NOTE: Samples will also be taken at 6 hours (+/-2hr), 21 hours (+/-3hr) and 48 hours (+/-6hr) post dose in 24 patients following the first, second and third RP1 doses.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All glassware, plasticware and tips that have been contaminated with GMO material will be de-activated in 2% Chemgene before disposal. Solid waste agar plates will be placed into clear Biohazard bags for onsite autoclaving followed by incineration. Liquid waste will be deactivated with 4% Chemgene solution (minimum of 2% final concentration) for at least 2 hours prior to disposal down the sink. Further information about the onsite autoclave

Validation testing on a regular monitoring schedule has been designed to comply with Environment Agency guidance: 'How to comply with your environmental permit. Additional Guidance for: Clinical Waste (EPR 5.07)' Annex 2 and 'standard rules SR2008 No 25 clinical waste and healthcare waste treatment and transfer station'. This includes daily chemical indicator tests and temperature reports, quarterly biological indicator tests and annual validation.

Further information on Chemgene

According to the manufacturer, ChemGENE has been proven to denature DNA and RNA. "Dr Martin Moncrieffe of the Department of Biochemistry, Cambridge University has certified that "Formulation HLD4 at dilutions of 1:200 or lower is very effective at precipitating/denaturing DNA and RNA". (0.5% final). In addition ChemGENE has proven virucidal activity including the ability to inactivate "Adenovirus, Hepatitis B, Herpes Simplex, Human Immunodeficiency Virus (HIV) and Norovirus". For inactivation of HIV ChemGENE is effective at a 1:50 dilution (2% final)

ChemGENE works by inducing apoptosis in the target cells at concentrations less than 1:100 (1% final).

Please enter comments of the GM safety committee on the risk assessment

The risk assessment was reviewed in detail, and the below changes were requested to be made:
- Removal of HG2 cell lines
- Potential for and risk from any aerosols generated.
- Addition of further information on the onsite autoclave facility.
This risk assessment will cover genetic manipulation of cell lines and bacterial strains to investigate drug targets for immunology disease areas. The work is to primarily to investigate cell signalling pathways and drug interactions with the cell lines. This is to validate and screen various drug targets in these disease areas.

This specifically will include:
- The use of commercially available Hazard Group 1 & 2 and Activity Class 1 & 2 GMO cell lines.
- Transient transfection of Activity Class 1 & 2 GMO’s in Hazard Group 1 & 2 cell lines.
- Generation and propagation of plasmid expression vectors including lentiviral expression plasmids.
- Plasmid transfection of Hazard Group 1 & 2 and Activity Class 1 & 2 cell lines with expression vectors to modulate gene expression by either overexpressing open reading frames (ORFs), cDNAs or specific gene sequences and/or knocking down gene expression by RNAi using siRNAs.
- Generation of stable cell lines using plasmid transfection
- Generation of third generation, recombinant, self-inactivating (SIN) lentiviral particles using HEK293T packaging cell line, using the commercially available third generation packaging system from Systems Biosciences.
- Transduction of Hazard Group 1 & 2 and Activity Class 1 & 2 cell lines with lentiviral particles to
modulate gene expression by either overexpressing open reading frames (ORFs), cDNAs or specific gene sequences and/or knocking down gene expression by RNAi using shRNAs.
- Protein production in bacterial strains.
- Protein production in mammalian cell lines.

Recipient or parental organism

Mammalian cell lines including Hazard Group 1 and 2 and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.
Bacterial hosts will be for plasmid propagation or for protein expression.
Expression hosts contain a chromosomal copy of the T7 RNA polymerase gene under lacUV5 control to allow inducible expression of the gene of interest. All strains will be covered by appropriate risk assessments.

Host/vector system

This assessment will cover various vector systems:
Lentiviral vectors:
The vector system used will be the commercially available third generation packaging system for example from Systems Biosciences.
The aim is to use lentiviral transduction to produce cell lines that express cDNAs, ORFs and gene sequences encoding potential drug targets and/or shRNAs (designed to knockdown the expression of these targets). The genes of interest will be expressed by 3rd generation self-inactivating (SIN) lentivirus.
Lentiviral vectors (LV) are viral-based gene delivery systems that can stably deliver genes or shRNA into cell lines with up to 100% efficiency. LV particles bind to target cells using an envelope protein that allows for release of the LV RNA containing the gene or gene silencing sequence into the cell. The LVs RNA is then converted into DNA within the target cell line and the DNA preintegration complex enters the nucleus and integrates into the target cell’s chromosomal DNA. Gene delivery is stable because the target gene is integrated in the chromosome and is copied along with the DNA of the cell every time the cell divides. The experimental work proposed here involves the generation of lentiviral particles and the addition of lentivirus particles encoding gene sequences to mammalian cell lines in vitro. Following the transduction of the mammalian cell lines with gene specific lentivirus, RNA and protein will be extracted from the cells to determine expression levels of target gene or gene product and functional assays will be performed.
Bacterial vectors:
For bacterial protein expression the E. coli strains to be used for this work include, but not exclusively: BL21, BL21(DE3), BL21(DE3) pLysS, Lemo21 (DE3), BL21 Star pLysS, Tuner, Tuner pLysS, Origami, Origami B, Origami pLysS, Rosetta, Rosetta pLysS, Rosetta-gami-pLysS. Work with any additional strains will be reviewed internally by the GMSC.
Expression hosts contain a chromosomal copy of the T7 RNA polymerase gene under lacUV5 control to allow inducible expression of the gene of interest.
gene under lacUV5 control to allow inducible expression of the gene of interest.

**Origin & function**

These vectors will be used to generate disease model cell lines for assessment of target biology for use in the immunology therapeutic areas and to identify and/or validate open reading frames (ORFs) / cDNAs or specific gene sequences as potential drug targets and for screening assays. Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of ORFs, cDNAs and gene sequences (encoding potential drug targets or therapeutic proteins) will be expressed in self-inactivating (SIN) lentiviral expression vectors.

The genetic material cloned into the viral expression vectors before being used to generate lentivirus for transduction of various cell lines.

Of particular note:

**Overexpression of Oncogenes** (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9).

Genes encoding known proto-oncogenes or genes with known oncogenic mutations can contribute to cellular transformation. Any use of lentiviral particles encoding oncogenic inserts will require appropriate controls and operator training. The expression of the majority of genes is predicted to generally have little or no adverse effect. Cells expressing these gene products pose no greater risk than Hazard Group 2 cancer cell lines, many of which harbour mutations within these genes.

**Knockdown of tumour suppressors** (ref: SACGM compendium of guidance part 2-2, p42, paragraph 24).

Knockdown of genes encoding known tumour suppressors can contribute to cellular transformation. However, shRNA expression systems rarely completely silence the targeted gene. shRNAs targeting these types of genes or gene sequences with tumour suppressive functions will only be expressed in third-generation SIN lentiviral vectors. Any use of lentiviral particles capable of reducing tumour suppressor expression will require appropriate controls and operator training.

In addition to the genes/shRNAs the lentiviral vectors will encode selectable antibiotic resistance markers for example (but not limited to): ampicillin resistance, blasticidin resistance, puromycin resistance, neomycin resistance and hygromycin resistance.

**Evaluation of foreseeable effects**

These will vary depending on the cell type and can be known or unknown. Potential common pathogens might
be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are typically screen for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

Note: Hazard Group 2 cells and Activity class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

Regarding lentiviral particles, the only potential for harm to human health could be through direct exposure to or injection of the recombinant lentiviral particles. A no sharps policy will be in place to mitigate the risk of inoculation. However even with injection of lentiviral particles, the immune system would most likely recognise this as foreign and mount an immune response. Though lentiviral particles can infect almost all human cells, the recombinant lentiviral vectors used to generate viral particles are self-inactivating and replication deficient, so they are unable to replicate and do not express any of their endogenous genes. Once within the mammalian cell no viral particles would be produced. There is therefore no risk of viral gene transfer to another host. Precautions should be taken to avoid working on one’s own cells or those of colleagues to mitigate any transmission risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be disinfected with a suitable detergent (e.g. 10% Distel or 5% Chemgene) then autoclaved using an autoclave cycle (held at a minimum of 125 degrees C for at least 15 minutes). The inactivated waste will then be sent for incineration by a waste management contractor. Liquid Waste will be disinfected by incubating with equal volume of suitable detergent (e.g. 10% Distel or 5% Chemgene) for a minimum of 2 hours before disposing to drain.

Autoclave monitoring and validation:
1. Daily Efficacy Monitoring is achieved by Chemical Indicator strips used in each cycle every day and each container of waste is sealed with colour reactive autoclave tape.
2. Alongside this are printout report checks which are used to determine if a successful cycle has been achieved in terms of temperatures and times. The printer report will also be checked to see if any alarms have been recorded.
3. Biological indicator testing is completed monthly for the first 6 months of autoclave operation and quarterly thereafter.
4. Servicing is to be completed twice a year and Validation Testing annually by an authorised, competent recognised 3rd party contractor.
The risk assessment was discussed by the GMSC on 5th February 2016. All committee members agreed that Class 2 is the appropriate classification for this work and that GMM_RA_IM002 is approved.

Please enter comments on the GM safety committee on the risk assessment

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

The Phoremost Ltd genetic modification committee will consist of:
1. The Biosafety Officer (J. Dillon), who has extensive experience of genetic modification issues. The biosafety officer will chair all genetic modification committee meetings.
2. The Manager & Chief Operating Officer (J. Roix), who has 15 years experience of genetic modification and has supervised research groups both in industry and academia. His function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.
3. Investigator & Lab Head (J. Dillon), who has 20 years experience of genetic modification in E. coli and mammalian cells. She will provide advice and ensure the actions arising from the committee meetings are implemented.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting reviewed the existing risk assessments.

02/03/2022
All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class 1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".

Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The safety committee was convened on 3 August 2015. The scope and particular aspects of safety risks described in this risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols for enablement of further work, pending notification and acknowledgement by relevant authorities.
The generation and use of lentiviral particles for mediating gene modulation in mammalian cells and their subsequent use in vitro for screening and target identification and validation.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To enable the generation and use of recombinant self-inactivating third generation lentiviral particles (by commercial research organisations or in house using commercially available 3rd generation lentivirus systems) encoding:

- Open Reading Frames (ORFs), cDNAs, peptides
- Specific gene sequences
- Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of:

- Determining peptide activity in disease relevant screening platforms
- Efficiently generating cell and disease relevant models lines for assessment of target biology and target validation
- Validating data from other experiments
- Identifying and / or validating ORFs / cDNAs / or specific gene sequences as potential drug targets.

Recipient or parental organism

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues.
The mammalian cell lines fall into two types: a packaging/helper cell line into which plasmids containing lentiviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

The lentiviral vectors which will be used are derived from HiV-1, which is an ACDP Hazard Group 3 biological agent. However, "Third Generation" lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety. These include the vif, vpr, vpu and nef accessory genes which are not required for in vitro replication. The tat gene is also deleted and the Tat responsive promoter present in the 5’ LTR is replaced with heterologous promoters, for example with the Rous sarcoma virus U3 region. An additional biosafety feature is achieved by deletion of the rev gene from the viral transfer vector. Viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences (figure 1).

An additional biosafety feature is that these vectors are self-inactivating (SIN), whereby the U3 region of the 3’ LTR (which contains the major viral promoters and enhancers) is copied to the 5’ end of the provirus during reverse transcription. Deletion of enhancer and promoter elements from the 3’ U3 region in the vector construct will result in a provirus that is entirely devoid of U3 enhancer sequences, therefore reducing the potential for transactivation of cellular genes as a result of insertion. Furthermore, such vectors are not easily mobilisable as a result of a superinfection with wildtype virus.

Third generation Lentiviral Expression Systems include the following key safety features:

The Lenti expression vectors contain a deletion in the 3′ LTR (−U3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.

The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).

Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have...
been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998). Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced. Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

**Origin & function**

Selectable markers – examples (but not restricted to);
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
- Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger
- Reporter proteins such as (but not restricted to);
  - Fluorescent proteins as reporters;
  - GFP derived from the jellyfish Aequorea victoria and variants of this
  - Luciferase – class of oxidative enzymes used in bioluminescence renilla luciferase derived from the Sea pansy (Renilla renifomris) firefly luciferase derived from the firefly Photinus pyralis.
- Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins
  - and / or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) – all human derived.

**Evaluation of foreseeable effects**

The lentiviruses are, at worst, amphotropic or pseudotyped with VSVG protein, either of which confers a broad host tropism including human cells. However, infectivity is unstable and infection is only obtained by cocultivation
of the packaged viruses with the recipient cells. The retrovirus is self-inactivating and therefore exhibits a low possibility of further transfer.

Since some of the inserted DNA codes for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.18-20).

Even for the nononcogenic inserted DNA, there is a slight but nonnegligible risk due to the presence in the lentiviral vector of the Woodchuck Posttranscriptional Regulatory Element. The WPRE-containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.13)).

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.

The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

Third generation or Self-inactivating vectors retrovirus vectors will be used in all experiments.

Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. our 3rd generation SIN lentivirus vector system), gloves should be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits invasion of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 1% (w/v) Virkon
solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1. Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

The generation and use of lentiviral, retroviral and adenoviral particles for mediating gene modulation in mammalian cells and their subsequent use in vitro for screening and target identification and validation.

Project Additional Information

Purposes of the contained use

Following from our previously approved clearance of a Class 2 activity (GM3294 / 15.1), we plan to expand the repertoire of genetically engineered viral vectors used in our research: we aim to employ additional virus types, and expand the collection of GMO transgene inserts:

Specifically, these protocols will enable the generation and use of lentiviruses, retroviruses and adenoviruses encoding:

1) Open Reading Frames (ORFs), cDNAs, peptides
2) Specific gene sequences
3) Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

These genetically modified agents are used in vitro to generate and use stable mammalian cell lines to:

1) Determine peptide activity in disease relevant screening platforms
2) Efficiently generate cell and disease relevant models lines for assessment of target biology and target validation
3) Validate data from other experiments
4) Identify and / or validate ORFs / cDNAs / or specific gene sequences as potential drug targets.

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues. The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which plasmids containing lenti-, retro- and adenoviral DNA will be introduced,
and from which infectious virus will be secreted into the medium to high titre. Media extracted from these cell-lines present a risk of infection to personnel, as they typically contain high titres of infectious viral particles.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines are proven to not actively produce infectious virus particles, and therefore are unlikely to present greater risk than uninfected, parental cells.

**Host/vector system**

Transgene function or mutagenesis, our overall risk assessment category and risk mitigation plan are not significantly changed from protocols we previously approved for using genetically modified lentiviruses (GM3294 / 15.1). All new virus types employed here each have proven history of safe use by other parties, following from multiple viral attenuation and risk mitigation strategies employed in their construction; the methods we will employ do not differ from those established protocols.

**Lentiviral**

As described in our previously accepted protocols, we will employ second generation or later versions of self-inactivating (SIN) lentiviral vectors. Similar to our intended retroviral use, these systems confer risks of potential human infection, but the viruses employed have also been multiply attenuated to strictly limit viral propagation and infectious risk. Our anticipated protocols use established reagents, and our methods do not vary significantly from those employed with a historical record of safe use by third parties [see: SACGM containment level 2 (ref: SACGM compendium of guidance part 2-11 P119 sections 8-30)].

**Retroviral**

We will employ several retroviral vectors, including those derived from Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTV), Feline Leukaemia Virus (FeLV), or Murine Embryonic Stem Cell virus (pMSCV). While all vectors are ACDP Hazard Group 1 biological agents, we will utilise virus preparations that have expanded tropism and potential infectious risk in humans. All vectors are multiply attenuated to strictly limit viral propagation and infectious risk for the intended use (see SACGM compendium of guidance part 2, section 2.11 (Retroviruses) pp117).

**Adenoviral**

We will use several adenoviral vector systems, of which the commercially available AdEasy vector system is an example. As with our retroviral and lentiviral intended uses, we will employ standard reagents and protocols similar to those proven through historical use by third parties. The multiply attenuated variants of adenovirus vectors we will employ all fall within SACGM 2 criteria due to infection risks from self-replicating viruses formed via recombination or risk of insertional mutagenesis. [see SACGM containment level 2 (ref: SACGM compendium of guidance part 2 pg. 78, Section 2.7)]

**Origin & function**

Selectable markers – examples (but not restricted to);
Ø Ampicillin resistance: E.coli derived
Ø Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
Ø Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to);
Ø Fluorescent proteins as reporters;
• GFP derived from the jellyfish Aequorea victoria and variants of this
Ø Luciferase – class of oxidative enzymes used in bioluminescence
• renilla luciferase derived from the Sea pansy (Renilla reniformis)
• firefly luciferase derived from the firefly Photinus pyralis.
This work involves the use of DNA fragments that, when delivered into mammalian cells and integrated into the cell genome, will abrogate the ability of one or more genes to generate a complete and functional protein product that would otherwise normally be produced by the cell.

**Evaluation of foreseeable effects**

All viral vectors employed in this protocol exhibit broad tropism and potential to infect human. Risks conferred following infection are identified as:

i) genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will employ transgene promoters and other viral sequences that may affect host gene function in a wide range of cell types (e.g. CMV promoter). We assess retro-, lenti- or adenovirus infection might induce permanent changes in infected cells including a risk for tumorigenesis. Risks conferred are previously described and categorised under Class 2 risks [SACGM compendium of guidance part 2, page 121]: “…The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression.”

ii) expression of human-derived or homologous transgenes with potentially deleterious effects: various transgenes may be employed, wherein intrinsic function of the transgene confers potentially deleterious effects. For example, expression human oncoproteins could induce transformation of infected cells. Beyond endogenous homeostatic mechanisms that may lessen this risk (e.g. apoptosis and other host tumor suppression responses), we assess that standard precautions under Class 2 risk mitigation procedures are adequate to address such risks.

iii) expression of exogenous transgenes directed to host genes with potentially deleterious effects: multiple transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to modify the function of endogenous genes with potentially deleterious effects. For example, RNAi or antisense RNA could reduce the function of genes necessary to control cell apoptosis, potentially resulting in tumorigenesis. As above, we assess that Class 2 risk management procedures adequately address these risks.

iv) expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse collections of non-human derived, exogenous transgene sequences that carry potential risks following infection. Risks from expression of these collected transgene sequences are mitigated and attenuated through several means. First, known pathogenic transgenes systemically removed, and other exogenous gene products are fragmented or rearranged, such that potentially pathogenic or other biologically deleterious genetic functions are not recapitulated in their complete endogenous configuration. Second, potentially deleterious transgenes in any infectious viral preparation are highly titrated, such that any single deleterious sequence comprises less than 1 part in 100,000 parts of an inoculum with infectious potential. In total, we assess these risks are adequately managed via the same Class 2 risk precautions employed above.

We assess environmental hazards are adequately addressed through the proposed personnel risk management measures. We employ multiple attenuation strategies and protocols to severely limit independent virus propagation beyond the intended use, and therefore anticipate minimal risks of GMM release.
Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.

Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".

Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

The data sheets describing inactivation by Virkon are attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The members of the GM safety committee include the Managing Director and the Research Director of the Company. Both of them have appropriate scientific qualifications and extensive prior experience of working with the type of GMMs to be used. In addition, the committee includes a scientifically-qualified representative from Oxford Innovation (the landlord and facility manager). The committee members are based at the laboratory where the work will be carried out. Meetings are held when a new project is to be initiated and at least once a year to review all projects.

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info
The aim of the project is to develop stable mammalian cell lines that can be infected by virus but do not allow replication of the virus.

1) HEK-293T. The stable cell line HEK-293T is a very widely used human embryonic kidney cell line which has been transformed with adenovirus E1a and carries a temperature sensitive T antigen co-selected with neomycin. The cell line was first described in 1977 and is Class 2 because of the incorporation of adenovirus genes.
2) BSC1. The stable cell line BSC1 is a very widely used Cercopithecus aethiops (African green monkey) kidney cell line and was first characterised in 1963. The cell line is Class 1.
3) HELA. The stable cell line HELA is a very widely used human cervical adenocarcinoma cell line. In 1955 HeLa cells were the first human cells successfully cloned and were used to propagate poliovirus. HELA carries genes from human papillomavirus 18 and therefore is Class 2.
4) A549. The stable cell line A549 is a very widely used human lung carcinoma cell line and was first described in 1972. The cell line is Class 1.
5) SK-Mel-28. The stable cell line SK-Mel-28 is a very widely used human melanoma cell line. It was created with a large number of other melanoma cell lines by passaging primary tumour cells in nude mice and was first described in 1972. The cell line is Class 1.

1) pRS. The commercially available pRS vector is to be used for transient transfection of recipient cells with shRNA. The plasmid contains standard elements including a bacterial origin of replication, ampicillin resistance gene, human U6 promoter and puromycin antibiotic resistance gene under the control of an SV40 early promoter.
2) pGFP-C-shLenti and pLenti-C-mGFP. These are commercially available third-generation lentivirus vectors for stable integration of genes coding for shRNA and TetR in recipient cells. The vector is multiply disabled and incapable of autonomous replication.
3) lentivirus packaging and envelope plasmids. These three commercially available trans-active plasmids code for rev and the rev response element and an envelope protein from vesicular somatitits virus, all of which are essential for expression and packaging of the lentivirus in HEK-296T cells.

1) shRNA. The shRNA genes do not code for protein, but for RNAs which will putatively specifically inhibit the replication of virus if it were infecting the recipient cell. They are not expected to have any pathological effect either in humans or animals.
2) TetR. TetR codes for tetracycline repressor protein, a component of the tetracycline-controlled transcriptional activation system, widely used since 1992. TetR is capable of binding to a bacterial tetracycline operator (TetO) which may be placed upstream of a gene which it is desired to control. Binding of TetR to TetO reduces transcription of the associated gene. TetR is not expected to have any pathological effect either in humans or animals.

The GMOs resulting from this project will be stable mammalian cell lines which have been modified to express shRNA specific for silencing genes of a virus and TetR, the
tetracycline repressor protein which is able to repress the transcription of genes which are preceded by the tetracycline operator TetO. TetO is not expected to be found in the recipient cells. The foreseeable effects of the genetic modification are that if the modified cells were to be infected with the virus, then the replication of the virus could be inhibited, and if the modified cells were to be infected with a virus that had genes controlled by TetO, then the expression of those genes could be inhibited. There is no reason to expect that these foreseeable effects are likely to have an adverse impact on human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste material which might be contaminated with the GMM will be disposed as follows:
Cell culture ware, plastic ware etc will be immersed in 10% bleach or 1% Virkon for at least 1 h. Aqueous liquid will be discarded to the laboratory drain, solid waste will be securely bagged and taken for incineration by an approved contractor (Select Environmental Services Limited, Prosper Park • Bennet Road • Reading • Berkshire RG2 0QX)
Culture medium, other liquids will be treated with bleach to final concentration of 10% or Virkon to a final concentration of 1%, for at least 1 h and discarded to the laboratory drain.
Sharps, pipettor tips, broken glass etc will be stored in sealed sharps container and taken for incineration by the approved contractor.
Our risk assessment indicates that these proposed waste management measures are at least as effective, and overall less inherently hazardous than inactivation by autoclaving, and therefore the availability of an autoclave within the facility is not considered necessary.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The aim of the project is to develop a modified vaccinia virus. Vaccinia virus, strain Lister. ACDP hazard group 2. This is the vaccine strain which was developed in the UK and widely used in the eradication of smallpox. Vaccinia infection is mild and typically asymptomatic in healthy individuals, but it may cause a rash and fever. Certain complications and/or vaccine adverse effects occasionally arise. The chance of this happening is significantly increased in people who are immunocompromised. Approximately one in a million individuals developed a fatal response to vaccination.

(1) Host cells will be selected from following the widely used mammalian cell lines: HEK-293T. (human embryonic kidney transformed with adenovirus E1a, class 2), BSC1 (African green monkey kidney, class 1), HELA (human cervical adenocarcinoma cell line, class 2), A549 (human lung carcinoma cell line, class1), SK-Mel-28 (human melanoma, class 1), Vero (African green monkey kidney, class 1). No risks to human health are expected to be associated with the use of these cells.

(2) The vector will be derived from pUC13-EcoGPTEGFP, a shuttle vector widely used for insertion of genes into vaccinia by homologous recombination. No additional risks to human health are expected to be associated with the
**Origin & function**
The genetic material to be inserted is not expected to be expressed and does not have any intended or expected functions in the final GMO as used in this project.

**Evaluation of foreseeable effects**
The GMOs resulting from this project will be modified vaccinia virus which have been attenuated by disruption of the thymidine kinase (TK) gene and therefore likely to be significantly less virulent than the original virus. They will incorporate inserted genetic material which is not expected to be expressed in the host cells. There is no reason to expect that these foreseeable effects are likely to have an adverse impact on human health or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Activity**

---

**Project Containment**

Laboratory Activities | Glass Houses | Growth Rooms

02/03/2022
The aim of the project is to develop a modified vaccinia virus that expresses immunoglobulins from infected cells.

Recipient or parental organism

1) Vaccinia virus, strain Lister. ACDP hazard group 2. This is the vaccine strain which was developed in the UK and widely used in the eradication of smallpox. Vaccinia infection is mild and typically asymptomatic in healthy individuals, but it may cause a rash and fever. Certain complications and/or vaccine adverse effects occasionally arise. The chance of this happening is significantly increased in people who are immunocompromised. Approximately one in a million individuals developed a fatal response to vaccination.

Host/vector system

(1) Host cells will be selected from widely used mammalian cell lines which will include: CV1 (african green monkey kidney, class 1), BSC1 (African green monkey, class 1), A549 (human lung carcinoma cell line, class 1), HEK-293 (human embryonic kidney transformed with adenovirus E1a, class 2) and HELA (human cervical adenocarcinoma cell line, class 2). Other mammalian cell lines of class 1 or 2 biosafety may also be used. No risks to human health are expected to be associated with use.
of these cells. (2) One vector will be derived from pUC13-EcoGPTEGFP, a shuttle vector widely used for insertion of genes into vaccinia virus by homologous recombination. Another vector will be pUC57, a widely used general purpose cloning plasmid, that will have DNA inserted into it homologous recombination with vaccinia virus. No additional risks to human health are expected to be associated with the vector.

Origin & function

The resulting modified Vaccinia viruses will be attenuated as the inserted transgenes will disrupt genes in the vaccinia virus genome including Thymidine Kinase (TK) and Vaccinia Growth Factor (VGF) and may include disruption of other vaccinia virus genes. The transgenes themselves will be immunoglobulins specific for human or analogues of human proteins in animals. The immunoglobulins will not target proteins present in the GMO and are not expected to affect the host cells described above.

Evaluation of foreseeable effects

The GMOs resulting from this project will be modified vaccinia virus which have been attenuated by disruption of the thymidine kinase (TK) and/or the Vaccinia Growth Factor (VGF) gene and therefore likely to be significantly less virulent than the original virus. They will incorporate inserted DNA code for immunoglobulins which will be expressed in the host cells, though there is no reason to expect that these immunoglobulins are likely to have an adverse impact on human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Guidance has been taken from the GMO Safety Committee from a major London academic institution specifically experienced in the use of GMOs planned for use by Autolus. Also from previous experience working with GMOs in a large pharmaceutical company (GSK).

Please refer to attached risk assessments - briefly:
Gloves, laboratory coats and safety glasses are routinely used in the labs. No needles/glass sharps will be used.
Solid GMM waste will be placed in autoclave bags and sent for incineration.
No sharps (such as glass pipettes or needles) will be used - pipette tips will be placed in a sharps container prior to
disposal in autoclave bags.
It is not possible to estimate a degree of kill of virus. However, autoclaving or incineration is sufficient for 100%
inactivation of viruses.
Liquid waste will first be disinfected with 1 % Vircon for a minimum of 30 minutes (or Presept overnight - 1x2.Sg
tabletsSOOml waste to give 2S00ppm available chlorine) before being disposed down the sink. This is a standard
procedure and enveloped viruses are known to be fully inactivated this way.
Surfaces such as hoods or benches will be disinfected with 70% ethanol - again a procedure known to inactivate
enveloped viruses.
In the case of spillages - virkon will be added at at least 1 % for 30 minutes, the area will then be wiped, wipes placed
in autoclave bags, and then surfaces treated with 70% ethanol.
* Note: For GMM work using human blood samples as starting material work will be CL2 (see specific RA for
additional measures and disposal procedures and completed CU2 form).

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Dr Ekaterini (Nina) Kotsopoulou holds a DPhii in Gene Therapy using lentiviral vectors (obtained 2000) and has 19
years experience working in laboratories using GMOs. She has authored a number of risk assessments, has reviewed
and approved a number of risk assessments while at her previous employment (Director in R&D, at GSK), received
extensive training while at GSK (employed there 2005-2015) and was part of the biological safety committee for a
year.
Generation of replication-deficient retroviral vectors and use to transduce mammalian cell lines and human and rodent primary cells.

**Purposes of the contained use**

Research and Development towards the generation of novel ex vivo gene therapy based treatments for cancer

**Recipient or parental organism**

Disabled bacterial strains (E. Coli derivatives), continuous mammalian cell lines (such as HEK293) - host lines and cell lines expressing retroviral vectors, primary cells of human and rodent origin - host cells and primary cells expressing retroviral vectors

**Origin & function**

Replication deficient retroviral vectors (mainly MoMLV based), expressing CAR genes.

*See risk assessments for full details.*

**Evaluation of foreseeable effects**

The retroviral vector could theoretically transduce a broad range of cell types of multiple species and theoretically express the CAR and/or suicide gene within those cells. Expression of these proteins is unlikely to cause harm if accidentally transferred to humans. Due to the inherent instability of the virus outside of the cell the risk of this is extremely low.

The viral vector only contains the minimal elements required for genome packaging, integration and transgene expression and is replication deficient, hence in the unlikely event of accidental transfer to human, it will not propagate. Accidental insertion of the vector genome in human cells though could theoretically lead to insertional mutagenesis in the transduced cells, although the likelihood of the latter is extremely low.

The retrovirally transduced cells are not expected to be of any greater hazard than the original unmodified cells.
Human primary blood cell samples carry the risk of bearing human pathogens/viruses such as HIV-1 and/or Hepatitis S. It is possible this could lead to infection of personnel working with these samples. The risk is low as (a) samples will come from pre-screened donors where possible, (b) all personnel will be vaccinated against Hepatitis S, (c) appropriate procedures and training will be in place for work involving human blood samples and (d) the use of sharps will be avoided where possible.

Please see attached risk assessments for further details.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For any work excluding the use of human blood material (classified as CL 1):
- Solid GMM waste will be placed in autoclave bag, and sent for incineration.
- No sharps (such as glass pipettes or needles) will be used - pipette tips will be placed in a sharps container prior to disposal in autoclave bags.
- It is not possible to estimate a degree of kill of virus. However, autoclaving is sufficient for 100% inactivation of viruses.
- Liquid waste will first be disinfected with 1% Virkon for a minimum of 30 minutes (or Presept overnight -1x2.5g tableU500ml waste to give 2500ppm available chlorine) before being disposed down the sink. This is a standard procedure and enveloped viruses are known to be fully inactivated this way.
- Surfaces such as hoods or benches will be disinfected with 70% ethanol- again a procedure known to inactivate enveloped viruses.
- In the case of spillages - virkon will be added at at least 1% for 30 minutes, the area will then be wiped, wipes placed in autoclave bags, and then surfaces treated with 70% ethanol.

For any work where human blood material is used (classified as CL2) additional measures are:
- All solid waste will be soaked in a final concentration of 1% Virkon overnight before being disposed of by incineration.
- All liquid waste will be made up to at least a final concentration of 1% Virkon overnight before being disposed down the sink.
- All glassware and plastics will be soaked in at least a final concentration of 1% Virkon for at least 1 hour, rinsed thoroughly and placed into the washing-up bowls or yellow bins as appropriate.
- Stripettes will be rinsed in Virkon 5% prior to disposal by incineration. Vacutainers with minimal blood residues will be disposed of by incineration.
- Tubes with blood residues from Ficoll separation will be disposed of by incineration (or autoclaving if known infected) or liquid waste is inactivated by 1% (v/v) Virkon for a minimum period of 1 hour and then discarded down the drain.

In case of spillages the following instructions will be followed (disinfectant = 1% Virkon):

ACCIDENTAL SPILLAGE: Do not bend down to inspect the damage, as this will immediately expose you to the concentrated aerosol. If the spillage is not too big, cover promptly with paper towels or an inert binding material and gently pour disinfectant over the paper, working from the outside towards the centre of the spill. After 30 mins, the towels can be removed to solid waste. The area can then be cleaned with disinfectant.
SPILLAGE IN CABINET: Cabinets must be left switched on, and minor spillages (<10ml) absorbed onto paper towels, and the sprayed with disinfectant and left for 20-30 minutes to inactivate the spillage, then mopped up with absorbent paper, which will then be disposed of as solid waste. The grill will be checked to determine if the spillage has contaminated underneath the MSC work surface. If so, it must be decontaminated as described above. For larger spills (>10mls) the work will be made safe and advice sought from laboratory manager or departmental safety adviser to assess if fumigation is required.

SPILLAGE IN CENTRIFUGE: Failure of the centrifuge run or if a spill or leak is suspected. The centrifuge will be switched off or disconnected from the power supply, and left for 30 minutes before opening to allow any aerosol generated to settle. During this time a note will be placed on the centrifuge to inform other users of the situation and to prevent anyone else using it. Any sign of a leak/spill inside the centrifuge will be cleared up with disinfectant and paper towels.

cell lines and human and rodent primary cells in both research and clinical environments

Disabled bacterial strains (E. Coli derivatives), continuous mammalian cell lines (such as HEK293) – host lines and cell lines expressing retroviral vectors, primary cells of human and rodent origin – host cells and primary cells expressing retroviral vectors

Replication deficient retroviral vectors (mainly MoMLV based), expressing CAR genes. See risk assessments for full details.

The retroviral vector could theoretically transduce a broad range of cell types of multiple species and theoretically express the CAR and/or suicide gene within those cells. Expression of these proteins is unlikely to cause harm if accidentally transferred to humans. Due to the inherent instability of the virus outside of the cell the risk of this is extremely low.

The viral vector only contains the minimal elements required for genome packaging, integration and transgene expression and is replication deficient, hence in the unlikely event of accidental transfer to human, it will not propagate. Accidental insertion of the vector genome in human cells though could theoretically lead to insertional mutagenesis in the transduced cells, although the likelihood of the latter is extremely low.

The retrovirally transduced cells are not expected to be of any greater hazard than the original unmodified cells.

Human primary blood cell samples carry the risk of bearing human pathogens/viruses such as HIV-1 and/or Hepatitis B. It is possible this could lead to infection of personnel working with these samples. The risk is very low as (a) samples will come from pre-screened donors where possible, (b) all personnel will be vaccinated against Hepatitis B, (c) appropriate procedures and training will be in place for work involving human blood samples and (d) the use of sharps will be avoided where possible.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None - standard CL2 measures applicable (and none additional identified from risk assessments)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid GMM waste will be placed in autoclave bag, and sent for autoclaving.

Sharps will be placed in a sharps container prior to disposal in autoclave bags/incineration.

It is not possible to estimate a degree of kill of virus. However, autoclaving is sufficient for 100% inactivation of viruses.

Liquid waste will first be disinfected with 1% (minimum) Vircon (or equivalent) for a minimum of 30 minutes (or Presept overnight – 1x2.5g tablet/500ml waste to give 2500ppm available chlorine) before being disposed down the sink. This is a standard procedure and enveloped viruses are known to be fully inactivated this way.

Surfaces such as hoods or benches will be disinfected with 70% ethanol – again a procedure known to inactivate enveloped viruses.

In the case of spillages – virkon will be added at at least 1% for 30 minutes, the area will then be wiped, wipes placed in autoclave bags and sent for incineration/autoclaving, and then surfaces treated with 70% ethanol.

### Premises Conditions

**Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities**

**Give brief details of the genetic modification safety committee**

The competent person that has reviewed the risk assessment has had 17 years academic experience working in laboratories involved in biochemistry and stem cell research. The individual has attended the Newcastle University GMO training course. The individual runs a large laboratory research group and is responsible for all SH&E aspects of the group.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

For activities involving GMMs, describe the waste management measures which will apply to the activity

I have assessed the activities that will be carried out within in the premises that are the subject of this notification and am satisfied that the appropriate protocols and controls are in place to satisfy the requirements of the Class I activities.

All waste is soaked in 10% bleach solution overnight and discarded in clinical waste bags for uplift and incineration by an authorised waste contractor (LabWaste). In addition, any spillages of CL2 materials are cleaned with Microsol/IPA and all waste materials autoclaved and discarded as described above.

Storage of CL2 GMO materials

For activities involving GMMs, describe the waste management measures which will apply to the activity

Disposal of any waste which has come into contact with the cells is disposed of in biohazard bins. Waste is double bagged before removing from the lab for off-site incineration. This method gives 100% kill.
Liquid waste is treated with Virkon and left for 24 hours. This could be monitored by removing a sample of liquid, spinning it down and culturing to look for viable material. This method is sufficient to kill any living material left in contact with it (100% kill)

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

This is an initial risk assessment to cover propagation of class 1 cells. We ultimately expect to be undertaking work requiring class 2 containment. Therefore, containment level 2 containment measures will be adopted from the outset.

Date Ackn'd 18/12/2015
Date Project Ceased

CU2 Project Title

Use of plasmid-based mammalian expression vectors and lentiviral vectors for the generation of stably-modified mammalian cell line for pre-clinical drug discovery applications (e.g. target identification/validation, cell-based screening, etc).

Class CultureVol Class 2 CultureVolumeClass3-4

Class 2 1-50 Litres
Non-GMM Consent Granted

Project notified under transitional arrangements
**Project Additional Information**

**Purposes of the contained use**

The development of cell lines (primarily as a contract research service, but also for in-house research):

1. To evaluate gene function under normal and disease conditions by overexpression or RNAi-mediated knockdown of the relevant gene function in established mammalian cell lines.
2. To generate stable cell lines (derived from established cell lines) expressing wild-type and mutant genes of interest to be used in the development of cell-based screening assays and disease-relevant in vitro cell models. These assays will be used to explore gene function and to screen compounds for activity at drug targets. In many cases, the gene products will be expressed as fusion proteins encompassing an epitope tag or fluorescent/luminescent reporter.

**Recipient or parental organism**

The recipient cells will be established, well-characterised mammalian cell lines (both immortalised cell lines and induced pluripotent stem cell lines) that will be, to the best of our knowledge, free of adventitious agents.

**Host/vector system**

Two types of vector system will be used (with gene expression typically being controlled from the immediate early Cytomegalovirus (CMV) promoter or, where required, via an inducible Tet-based system):

1) Standard, non-mobilisable mammalian expression vectors including Pcdna3.1 and derivatives. Vectors frequently contain the SV40 origin which enables episomal replication in mammalian cells that contain the SV40 large T antigen. Where this is the case, the recipient cells to be used in these procedures will be negative for the SV40 large T antigen.

2) Third generation (or later), replication-defective lentiviral vector systems based on HIV. Only gag, pol and rev genes from HIV will be employed and these will be supplied in trans to facilitate virus packaging. All other HIV genes have been deleted. Examples of commercially available vectors with these properties include Invitrogen’s ViraPower (pLenti vectors), and Sigma’s pLKO.1 vector systems. High titre virus stocks will be generated by co-transfecting a 293T packaging cell line with transfer and packaging vectors.

**Origin & function**

The genes of interest will typically be mammalian genes encoding for major classes of cellular proteins e.g. receptors, ion channels, kinases and other enzymes. The sequence of the coding regions will be known and provided by the client and gene expression will typically be under the control of a constitutive promoter (e.g. CMV). These genes will have putative or established roles in regulating cellular signalling and will often play a role in modulating cell proliferation and/or apoptosis. As such, these genes will almost always be regarded as being potentially oncogenic. Genes will either be provided by the client or obtained from commercial sources.

Inhibitory RNA sequences will be targetted to genes considered to be of potential relevance in disease processes. Targeted genes will include those encoding cell receptors, ion channels, kinases and other enzymes. Inhibitory RNA sequences will be obtained from commercial sources.
Evaluation of foreseeable effects

The risk associated with overexpression or knockdown of individual genes will be considered on a case by case basis and reviewed locally by the GM safety committee prior to work commencing. Particular consideration will be given to genes that may be oncogenic or immunomodulatory.

When developing cell lines using plasmid-based mammalian expression vectors, a range of commercially-available, non-mobilisable eukaryotic expression vectors will be used including pEGFP-derived and pcDNA3-derived vectors. Many of the genes of interest that will be carried by these vectors will be regarded as being potentially oncogenic. Expression of such sequences in mammalian cells may, in some instances, enhance the malignant properties of the cells. However, neither the DNA, encoded protein, or mammalian transfectants are likely to have any deleterious effect on the worker or the environment. No primary cultures will be used and all recipient cells will be "non-self". Therefore, in the unlikely event that a worker is infected with a transfected cell (e.g. via inadvertent percutaneous inoculation), the cells will be recognised as non-self and cleared by the workers immune system. Nevertheless, in order to minimise the potential for exposure, and given the potentially oncogenic nature of the genes of interest, the generation of cell lines using this approach is assessed as requiring level 2 containment (see below). The GM microorganisms are incapable of surviving outside of the laboratory environment, particularly in the context of the level 2 containment procedures being adhered to, effectively reducing the environmental risk to zero (see below).

When developing cell lines using lentiviral transduction, VSV-G pseudotyped lentivirus strains will be used and these strains will have the ability to infect human cells and cells from other mammalian species. However, because these strains are replication defective, the virus can only carry out a single round of infection. Structural genes and other components required for packaging the viral genome are separated onto three plasmids and have been engineered so as not to contain any homologous sequences to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. When prepared lentiviral particles are not available from the client, lentiviral production will be carried out on-site using HEK293T cells with harvested supernatants being filtered using a 0.45 um filter before either being dispensed as aliquots or further purified by chromatography and/or concentrated by ultrafiltration.

Cells that may contain virus sequences able to mobilise the lentivirus vectors by providing structural genes in trans will be excluded from these experiments. Provirus integration into the host genome will occur with high frequency and while this is unlikely to generate a harmful phenotype in the cultured mammalian cell (and host cells from workers will not be used), there is a low probability of infection of a worker e.g. through accidental inoculation with packaged virus via inadvertent percutaneous inoculation. Integration and long term expression of the recombinant gene or cDNA encoding inhibitory RNA could occur. There is a theoretical risk of transformation of cells by insertion of oncogenes or by knock-down of tumour suppressor genes. Because of the replication-defective nature of these vectors, this could only occur at low frequency and therefore unlikely to have a detrimental effect as a single event is unlikely to result in cellular transformation. Lentiviruses can also act as insertional mutagens. The likelihood of this occurring is reduced by the use of a self-inactivating vector which disables the LTR regions in the integrated vector and thus reduces the risk of oncogene activation at the site of insertion. Additionally, because the vector is replication-defective, the level of exposure that might occur following accidental introduction of the virus will be low and thus reduces the probability of virus insertion at a site likely to promote tumourigenesis. However, because these vectors incorporate strong heterologous promoters and because provirus insertion is a feature of lentivirus biology, work with these vectors is assessed as a class 2 activity and the use of appropriate containment is used to minimise exposure.

To summarise, whilst many of these genes will be regarded as being potentially oncogenic, the hazards to workers and the environment posed by the vector, insert and GMO are considered negligible due to the containment level 2 measures employed. All work will be carried out in access-controlled laboratories. Skin contact with the vectors or the transfected cells will be avoided by minimising aerosols (by keeping cells in sealed vessels that are only opened in a Class II biosafety cabinet), and by use of gloves and Howie-style lab coats. Two pairs of gloves will be worn when preparing and handling viral particles, to allow disposal of possibly contaminated outer gloves whilst retaining a protective barrier. Sharps (e.g. needles or glass pipettes) will not be used. If a worker does accidentally infect themselves with the virus, it is likely that it will be rapidly destroyed by the workers’ immune system. In the extremely unlikely event of transfected cells gaining entry to the worker, the cells in all likelihood would be rapidly destroyed by the workers’ own immune system by virtue of being "non-self".

Transfected mammalian cells are highly unlikely to survive in the environment in the absence of strict osmotic, buffering, temperature, and nutrient conditions. Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein-buffered media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus cannot replicate and so the consequences of escape are considered negligible, therefore
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

GMMs derived using non-mobilisable, non-viral expression vectors from cell lines that are normally designated as requiring Biosafety Containment Level 1 will be considered as being Class 1 once stable pools have been selected (provided the cells are unable to support episomal replication - e.g. cells negative for the SV40 large T antigen).

Similarly, following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus we propose to be able to use these cells at Biosafety Containment Level 1 based on the application of the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as requiring Biosafety Containment Level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The majority of waste will be in liquid form (e.g. spent tissue culture medium, media in microtitre plates), but some solid waste will also be generated (e.g. stripette tips, reagent vials).

All solid waste will be sealed in double autoclave bags, removed by a specialist waste-management company (Medisort) for autoclaving with steam. Effectively 100% kill.

All liquid waste will be inactivated by treatment with Virkon at a final concentration of 1% for 12 hours before disposal via the drains. Effectively 100% kill as determined by the manufacturer (DuPont).

*Virkon
Rely+On : Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1. The solution is generally stable for five to seven days and there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
The GMO risk assessment has been presented to the genetic modification safety committee. Summary findings: The health and environment risks with the handling of GMOs has been reduced to low, acceptable levels by the use of trained staff, procedural and containment controls and personal protective equipment.

The GMSC has agreed the production, handling and use of the lentiviral siRNA stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using third generation (or later), self-inactivating, 3 or 4 plasmid expression systems, and cells that may contain virus sequences able to mobilise the lentivirus vectors by providing structural genes in trans will be excluded from these experiments, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. The proteins targeted for expression or knock-down will be assessed by the GMSC (meeting as and when required, but at least every three months) on a case by case basis to ensure their potential risk is minimal. The request to derogate the Biosafety Containment Level 2 from 2 to 1 post-transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus.

The majority of labware that will come into contact with GMMs will be disposable. All such material will be deposited in autoclave bags, and will be autoclaved at a minimum of 126 degrees centigrade for a minimum of 15 minutes, rebagged and tagged before disposal by London Bioscience Innovation Centre (LBIC) central autoclaving services. GMM waste in non-disposable containers will be autoclaved in the same way, before being disposed of as aqueous waste. LBIC is part of the Royal Veterinary College London, which is a registered hazardous waste producer, and all waste is disposed of in accordance with the Waste Regulations 2005.

Autoclaves at LBIC are serviced on an annual basis, and a temperature probe is placed at the centre of the waste to ensure all material reaches the required temperature for the sterilization period. All autoclaving will be verified with the use of autoclave indicator strips.
The formation of the Synthace Genetic Modification Safety Committee (GMSC) has necessitated a review of the procedure for risk assessments and seeking GMSC approval for genetic design and assembly work.

The GMRA workflow will follow a sequence based on:

i. Design of genetic constructs,
ii. Formal Risk Assessment (RA),
iii. Identification of genetic technical details and requirements,
iv. Preparation of GMSC submission,
v. Order of DNA ‘parts’ from external sources,
vi. Construct assembly and testing.

The GMSC will convene and review submitted proposals during phases iv / v above, and before:

- The Synthace GMSC will meet at least monthly.
- The use of the term ‘origin’ is taken to mean origin of sequence as well as potentially the origin of DNA, the full name and of an originating species together with the assessment of the associated biological class of risk will be determined and recorded.
- To facilitate future gene assembly studies gene sequences relating to standardised ‘parts’ will designated by an internal reference number and part name.
- Managerially, Synthace will establish a Safety and Quality Compliance Committee (SQCC) and it has been determined that the GMSC will constitute a subcommittee of this key function. Dr Markus Gershater is designated as company Safety Officer (SO) and Biological Safety Officer (BSO) until such time permits the appointment of a full-time employee to oversee these roles.

### Project Additional Information

#### Purposes of the contained use

To perform cell culturing, handling and transfection of HEK293 and 293T cells with 4 plasmids for transient overexpression of fluorescent proteins (TagBFP, mKO2, neonGreen, mKate2) and synthetic transcriptional regulators (L7Ae, Tet-3-G) acting on the promoters for the fluorescent proteins, with the aim of optimizing transfection procedures using design of experiment (DOE) protocols.

To perform cell culturing, handling and infection of HEK293 cells with AAV particles containing a GFP transgene, with the aim of quantifying percentage of GFP-positive cells by flow cytometry.

#### Recipient or parental organism

HEK-293 (ATCC CRL-1573™) and 293T (ATCC CRL-3216™) cell lines. These are considered BSL-2.

#### Host/vector system

The plasmids are all pCMV-containing Tetracycline, Ampicillin and Kanamycin for cloning and transfection selection in E. coli. No vectors to be transfected confer any selection cassette for cell line selection (antibiotics are only expressed under bacterial promoters.)

AAV8 particles carrying GFP transgene (obtained from commercial sources).

#### Origin & function

Genetic inserts for the plasmids will either be fluorescent proteins or synthetic transcriptional regulators, and do not carry harmful biological activity. Full list and origins for inserts and DNA parts can be found below:

- **TREG** (Inducible promoter (by Tet3G)) Ref sequence: pLVX-TRE3G [https://www.takarabio.com/products/genefunction/tet-inducible-expression-systems/tet-on-3g-systems/tet-on-3g-lentiviral](https://www.takarabio.com/products/genefunction/tet-inducible-expression-systems/tet-on-3g-systems/tet-on-3g-lentiviral)
- **Tet3G** (Transcriptional activator (of pTREG)) Ref sequence: pLVX-Tet3G [https://www.takarabio.com/products/genefunction/tet-inducible-expression-systems/tet-on-3g-systems/tet-on-3g-lentiviral](https://www.takarabio.com/products/genefunction/tet-inducible-expression-systems/tet-on-3g-systems/tet-on-3g-lentiviral)

Plasmid transfection will be performed through lipid-based transfection systems, cells will be discarded following assessment of gene expression (flow cytometry).

In the case of infection with AAV8-GFP particles, cells will be used for the assessment of AAV titer and as a measure of infectivity (flow cytometry) and not cultured further.
The sequences being overexpressed are highly unlikely to alter the pathogenicity or properties of the mammalian host cells. Neither the DNA, encoded protein, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment.

The GM microorganisms are incapable of surviving outside of the laboratory environment. All laboratory procedures will follow good microbiological practice. GM microorganisms will be manipulated in a Class II Microbiological safety cabinet. Written records of staff training will be obtained and checked before commencement of work by individuals. All handling and manipulation of mammalian cell cultures will be carried in a Class 2 cabinet within a containment level 2 facility. Personal protective equipment (PPE) such as disposable gloves, laboratory coat and lab safety spectacles will be worn for all applications.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For preparation of plasmic DNA/protein, bacteria will be collected by centrifugation and lysed. Liquid waste material will be rendered non-viable by decontamination with Chemgene for at least 30 minutes prior to sink disposal and autoclaving.

Any contaminated solid waste (e.g. contaminated disposable plasticware, agar plates, DNA) will be bagged and autoclaved prior to disposal as normal solid waste in accordance with laboratory practice in the laboratory. Disposal and decontamination of materials used in mammalian cell culture will be done essentially as described above for bacteriological work.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment has been reviewed to have been carried out correctly and sufficiently with control measures in place that are appropriate to minimise personnel and environmental risks associated as well as being in line with the regulatory requirements.

The internal Health & Safety committee acknowledges that this contained use excludes the use of working with any sharps or harmful genetic inserts. If the stated project needs change with regards to these exclusions then it is acknowledged that a full review of the contained use be carried out.

**Give brief details of the genetic modification safety committee**

Advice has been obtained from the Safety Officer of our sister company Agalimmune prior to submitting this application and writing applicable risk assessment for Altermune. The Agalimmune safety officer is an experienced GMO(CU) scientist who has worked with class 2 GMOs for >10 years. A GMSC has now been set up for Altermune comprising of 3 individuals with extensive GMO experience who will meet on a monthly basis. This include the following:

- Head of the Translational Research Group and past manager of the containment level 3 facility at Pfizer, Sandwich.
- The laboratory steward of the Altermune laboratory with >10 years experience working with class 2 GMOs and cat 3 pathogens.
- Experienced Scientist within the laboratory with >10 years experience working with class 2 GMOs.

### Project Additional Information

#### Purposes of the contained use

Use of biosafety level 2 designated mammalian cell lines in experiments to determine the efficacy and mode of action of novel therapeutics.

#### Recipient or parental organism

Not Applicable

#### Host/vector system

Mammalian cell line and primary human cells.

#### Origin & function

The origins of the biosafety level 2 designated cell lines are mammalian and are all available from commercial sources such as Public Health England. In most cases these cells have been transformed with a viral vector to immortalise them or they may have been demonstrated to be infected with a pathogen. This requires them to be handled and disposed of under containment level 2 conditions. Human primary cells such as peripheral blood mononuclear and natural killer cells will be obtaining from commercial sources where they have been tested from the presence of pathogens. However the cells still need to be treated as potentially infectious and will therefore be handled under containment level 2 conditions. The cell lines may be transiently or stably transfected with human proteins using non viral methods in order to express the protein on the cell surface for functional studies. These protein will be non infectious.

#### Evaluation of foreseeable effects

The cell lines are potentially infectious, although with organisms that do not cause serious human disease and have been designated BSL-2 by ATCC and ECACC. The pathogens and their risks are well documented and all cell lines will be purchased from commercial sources. The risk to human and environmental health are therefore low. The primary human cells to be purchased from commerical sources are potenitally infectious, although they will have been screened for the serious human pathogens HIV, Hep B and Hep C. The risk to human and environmental health is therefore moderate, but warrants use under containment level 2 conditions. The protein that may be transfected to the cell lines will be naturally occurring human wild-type or mutant variants of human protein and are not infectious.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All solid genetically modified waste (e.g. plasticware) will be removed by contractors and incinerated on site according to validated methods.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (e.g. plasticware) will be discarded in designated GMM waste bins containing Biohazard waste bags. The waste will be collected and removed for incineration at Discovery Park by Augean, an onsite contractor that specialises in the handling and disposal of hazardous biologcal waste. All liquid waste will be completely inactivated by adding Virkon to make a 1% solution and incubating for >15 minutes before disposal down a sink, likewise pipettes and glassware will be soaked in 1% Virkon solution for >15 minutes before disposal. Areas where GMM work has taken place will be disinfected with a 1% Virkon solutions once completed. Staff will receive full traning on the handling and disposal of GMM waste.
The committee deems that containment level 2 conditions will be suitable for the use of both BSL-2 designated cell lines and potentially infectious human cells, providing that they are procured from a source that has been prescreened the primary cells for the presence of HIV, HCV and HBV. Staff must be fully trained in the requirements for working under containment level 2 conditions as laid out if the risk assessment and local and HSE guidelines. Written records of this training must be kept on record.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

The Genetic Modification Safety Committee (GMSC) at York St John University was formed in July 2015 as a sub-committee of the Faculty Health, Safety and Well Being committee. The Head of Programme for Biomedical Science, University Health and Safety Advisor and the Biological Safety Officer form the GMSC. The GMSC at York St John University will meet regularly (each semester) and may also include the Dean of the Faculty of Health and Life Sciences and Deputy Vice Chancellor who also have experience of working with GMO and HSE guidelines and legislation.

Both the University Health and Safety Advisor and Biological Safety Officer have undertaken the Biological Safety training course from Edinburgh University (June 2015). The Biomedical Science academic staff, Head of Programme and Dean of the Faculty of Health and Life Sciences have experience from previous institutions of working with GMO and complying with appropriate legislation. The Head of Programme has liaised with colleagues from their previous institution who were members of their GMO committee and have extensive relevant experience in this area. Additionally, advice has also been sought from HM Specialist Inspector at the Health and Safety Executive, Biological Agents Unit, by email.

The work will be carried out in compliance with good laboratory practice and local safety rules for GM work in a containment level 2 facility. The category 2 laboratory will be regularly monitored by academic members of staff and the Biological Safety Officer to ensure good housekeeping and hygiene is regularly maintained with particular emphasis on treatment and disposal of infectious biological waste.

Protective clothing will be worn as necessary and laboratory coats will remain in the laboratories when in use and will be laundered regularly. GMM contaminated material and liquid waste will be inactivated in 1-3% Virkon and disposed after 24 hr, as per manufacturer's validated instructions; or autoclaved at 121 degrees C for 30 minutes 1 BAR (100% Kill) or 130 degrees C for 15 mins 2 BAR (100% Kill) prior to incineration by validated means through licensed contractor.

Autoclave:
- Liquid sterilisation 120 degrees C for 30 minutes
- Equipment/Glassware sterilisation 121 degrees C for 15 mins
- Solid waste 130 degrees for 15 mins

</table>

For activities involving GMMs, describe the waste management measures which will apply to the activity
Probe in position to determine that the correct temperature has been reached internally. If required the autoclave performance can be validated by a 12-point thermocouple test on an annual basis.

Records will be kept on site.

All autoclaved solid waste will enter the yellow bag clinical waste route and goes for incineration. This will be autoclaved prior to leaving the building to be incinerated as per clinical waste.

It is unlikely that any viable GMMs would remain after this treatment, and in any case would require specialist conditions for growth.

The licensed contractor for all Biohazard waste and sharps is currently Phs Wastemanagement Head office located at PHS Group Caerphilly, Wales.

Spillages:

Virkon is routinely used as per the manufacturers recommendations:

- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% for 1hr prior to cleaning.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).
- Liquid waste will be treated, for at least 12 hours with Virkon to a final concentration of at least 2%. This will then be discarded to drain.
- Contaminated clothing where autoclaving is not possible/appropriate soak in 1% then rinse well in water and wash.

The licensed contractor for all Biohazard waste and sharps is currently Phs Wastemanagement Head office located at PHS Group Caerphilly, Wales.

The licensed contractor for Chemical Waste Disposal will be SLS Chemical Waste Disposal Service.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment.
The Biological Safety Officer and Head of Programme have worked together to compose the risk assessment document, based on an initial risk assessment and Health and Safety considerations outlined in an internal document for the Faculty Health, Safety and Well Being committee required by the meeting in July 2015. The internal document has been considered by the University Health, Safety and Well Being committee in October 2015.

Risks associated with the general use of the undergraduate Biomedical Science teaching laboratories are outlined in the attached risk assessment form and the persons responsible for taking action are identified.

The risks from using mainly category 1 micro organisms and well characterised cell lines are low and the normal health and safety considerations outlined in forms CU1 and CU2 should reduce these risks further. Any GMO will be used only under the supervision of the Biological Safety Officer and the trained academic staff and all students will receive bespoke training before they commence any activities using category 1 or category 2 micro organisms, GMO or cell lines: including safe use; sterile technique; handling of any spillages and correct disposal routes.

Disinfection of the equipment and laboratory benches, inactivation of all cells in virkon and autoclaving of liquid and solid media before incineration will be overseen by the Biological Safety Officer to minimise the risk of any contamination. The Biomedical Science laboratory facilities are locked and have card access. Only authorised and trained staff and students will be allowed access to the facilities and a record of laboratory users will be maintained.

Based upon our review of the techniques and procedures to be carried out in the Biomedical Science laboratories, we consider the facilities and procedures are adequate to control the level of risk presented to humans and the environment by these genetically modified Hazard Group 2 bacteria.

---

**Project Ref 3304/15.1**

**Date Ackn'd**: 11/11/2015

**CU2 Project Title**: Generation of recombinant antibody binders using a human synthetic scFv (Tomlinson I+J library) or peptide (PhD 12) phage display library etc

**Class**: Class 2

**Culture Vol**: < 1 Litre

**Project notified under transitional arrangements**: N

**Historical Significant Changes**: NOTIFICATION WITHDRAWN 13/04/2016

**Project Additional Information**

**Purposes of the contained use**

- Project 1 - For the production of in vitro recombinant binders as replacement for animal-derived antibodies.
- Project 2 - Production of recombinant proteins in prokaryotic or eukaryotic expression systems
<table>
<thead>
<tr>
<th>Project 3</th>
<th>Production of alternative splice variants using microarray/RT-PCR in a number of well characterised (immortalised) cell lines of human origin (see Appendix 2)</th>

</tr>
<tr>
<td>Project 5</td>
<td>Production of specific point mutations or deletion mutants in the beta-2-microglobulin gene</td>
</tr>
</tbody>
</table>

Recipient or parental organism

- Standard laboratory E. coli strains including K12 derivatives TG1, HB2151 BL21, BL21 (DE3), DH5alpha, Stbl2, dam-/dcm-and XL10-GOLD (see Appendix 1).
- Saccharomyces species such as cerevisiae/boulardii.
- A number of well characterised (immortalised) cell lines of human origin (see Appendix 2).

Host/vector system

Project 1 - Well characterised systems with a history of safe use will be used, for example, non-mobilisable plasmid and bacteriophage.

- A bacteriophage, or phage, is a virus that solely infects bacteria (e.g. E. Coli). Infection is mediated by binding of a phage surface protein (pII) to the bacterial F pilus. It is possible to genetically insert genes encoding antibody fragments (Tomlinson I+J) or peptide binder sequences (New England Biolabs) into the phage gene III which encodes pIIl capsid protein. The Tomlinson I+J system uses a plasmid (phagemid) to produce these virus recombinants on site whereas the peptide library supplies phage previously genetically modified at commercial source.

Project 2 - The bacterial hosts will be E coli K12 derivatives such as BL21, BL21 (DE3), DH5alpha, Stbl2, dam-/dcm-& XL10-GOLD. Also DH10Bac™, which contains a baculovirus shuttle vector (bacmid bMON14272) and a helper plasmid (pMON7124). All of these strains are disabled and unable to survive in the environment outside the lab.

- No hazard to human health or the environment.
- Bacterial plasmids are pUC-based (e.g. pUC19 DNA) pCR-Blunt, pCR-TOPO, pDONR.
- Recombinant baculovirus will be received from collaborators (Baylor College of Medicine, Houston, Texas) ready modified using the plasmid backbones pFastBac™ Dual, pBAC4x, pDEST8, pDEST10, and pDEST20, pGEX-2T. pFastBac and similar baculovirus vectors containing bacterial promoters driving expression of antibiotic resistance and a baculovirus polyhedron promoter driving expression of the inserted sequence, which is only active in the presence of insect baculovirus in insect cells.

Project 3 - The mammalian cell lines to be used in this project will include a number of well characterised (immortalised) cell lines of human origin (see Appendix 2).

Project 4 - Conditional cell wall mutants will be generated by replacing key cell wall genes with an MX cassette using long flanking homology-PCR. Several mutants will be generated in order to achieve the optimum lysis under alkaline conditions. Aptamers will be identified to specific allergens. These aptamers once optimised will be introduced into the Yeast cell wall mutants produced above. The aptamers will be placed under the control of promoters key to the stress response, again using an MX cassette for selection and long flanking homology-PCR to replace the genes. Several mutants will be produced to optimise production of aptamer before yeast cell lysis under alkaline conditions.

Project 5 - Bacterial strains used will be E. coli JM109 for DNA analysis and BL21DE3 for protein analysis, both are standard lab cloning strains. The plasmid (pET23a) will be used to insert the beta-2-microglobulin gene and express the point mutations and it contains no mobile elements.

Origin & function

Project 1 - (Tomlinson I+J) Phagemid genes encode human antibody fragments (scFv) which are used to produce recombinant antibodies.

Project 2 - Recombinant baculovirus will be received from collaborators ready modified (Baylor College of Medicine, Houston, Texas, USA). Bacterial strains will be purchased from commercial sources such as Novagen, New England Biolabs and Invitrogen technologies.
Project 3 - Immortalised cell lines will be received from collaborators from the University of Huddersfield (see Appendix 2.

Project 4 - The Saccharomyces species will be received from collaborators at Manchester University or purchased from the Saccharomyces gene deletion project. Aptamers will be purchased from a commercial source, for example Aptamer Solutions Ltd, York

Project 5 - The pET23a plasmid containing the wild type and mutated beta-2-microglobulin genes will be received from storage from the University of Bradford. Bacterial strains will be purchased from commercial sources such as Novagen, New England Biolabs and Invitrogen technologies

Evaluation of foreseeable effects

Projects 1 - 5 - None of the vectors are harmful to the environment and do not supply a survival advantage to any microorganisms. The cloning and expression vectors are also not a hazard to human health. The bacterial strains to be used are non-colonising and incapable of surviving in the environment or causing human infection. They pose minimal risk to users or the environment.

The genetically modified micro-organisms are likely to cause similar effects on human health and the environment as the wild type parent. Therefore, the containment measures for the parental micro-organisms reflect this risk and come in 2 forms:

1. Containment Level 2 conditions including use of negative pressure class 2 fume hood (sealability for fumigation, HEPA filters on extract air).

2. If working at the bench then this should take place within 18 inches of a blue flame-Bunsen burner. All reusable instrumentation in contact with GMOs (e.g. metal inoculating loops) or the mouths of open bottles containing GMO will be flame sterilized before and after use to prevent contamination of the worker or environment with GMO.

Methods 1 and 2 will be required to reduce the risks to research and support staff and to the broader environment to an acceptable level. It is extremely unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability, host range and/or response to prophylaxis/treatment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work will be carried out in compliance with good laboratory practice and local safety rules for GMO work in a containment level 2 facility. The category 2 laboratory will be regularly monitored by members of staff and the Biological Safety Officer to ensure good housekeeping and hygiene is regularly maintained with particular emphasis on treatment and disposal of infectious biological waste.

For preparation of plasmid DNA/protein, bacteria and / or cell culture will be collected by centrifugation and lysed. Liquid waste material will be decontaminated overnight with Virkon (1%) and autoclaved prior to sink disposal. Any contaminated solid waste (e.g. contaminated gloves, paper towels, disposable plastic ware, agar plates) will be bagged and autoclaved before disposal as normal solid waste. All materials in contact with bacteriophage will be soaked overnight in 2% trigene disinfectant. 2% Trigene (Distel) will be used to treat spills and wipe down surfaces and equipment after work. Trigene is used in strict accordance with the manufacturer's guidelines and efficacy.
data. 2% Trigene and 70% alcohol sprays will be kept to hand at all times for cleaning purposes and for decontamination of spillages.

The efficacy of autoclaving procedure will be validated as follows:
From the electronic schedule of autoclave cycle parameters to ensure successfully completed autoclave cycle on each occasion. If any cycle is unsatisfactory, it will be repeated. Following autoclaving, liquid waste will be disposed of as standard laboratory waste. Solid waste such as agar plates will be autoclaved inside plastic bags within a metal container at 121 degrees C for at least 15 minutes. Autoclave run records will be checked following each run, and if unsatisfactory the cycle will be repeated. During the first four years after installation an annual 12-point validation test, employing independent thermocouples, will be used to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time. Thereafter, autoclaves will be serviced every 6 months by an engineer from the provider and calibrated annually to ensure the validation criteria are met.

Spillages:
Virkon is routinely used as per the manufacturers recommendations:
Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% for 1hr prior to cleaning.
Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).
Liquid waste will be treated, for at least 12 hours with Virkon to a final concentration of at least 2%. This will then be discarded to drain.
 Contaminated clothing where autoclaving is not possible/appropriate soak in 1% then rinse well in water and wash.

The licensed contractor for all Biohazard waste and sharps is currently Phs Wastemanagement Head office located at PHS Group Caerphilly, Wales.

The licensed contractor for Chemical Waste Disposal will be SLS Chemical Waste Disposal Service

Inspections: Safety inspections are carried out regularly to ensure local health and safety rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Advisor and Biological Safety Officer.
The Biological Safety Officer and Head of Programme have worked together to compose the risk assessment document, based on an initial risk assessment and Health and Safety considerations outlined in an internal document for the Faculty Health, Safety and Well Being committee required by the meeting in July 2015. The internal document has been considered by the University Health, Safety and Well Being committee in October 2015.

Risks associated with the general use of the undergraduate Biomedical Science teaching laboratories are outlined in the attached risk assessment form and the persons responsible for taking action are identified.

The risks from using mainly category 1 microorganisms and well characterised cell lines are low and the normal health and safety considerations outlined in forms CU1 and CU2 should reduce these risks further. Any GMO will be used only under the supervision of the Biological Safety Officer and the trained academic staff and all students will receive bespoke training before they commence any activities using category 1 or category 2 microorganisms, GMO or cell lines: including safe use; sterile technique; handling of any spillages and correct disposal routes.

Disinfection of the equipment and laboratory benches, inactivation of all cells in virkon and autoclaving of liquid and solid media before incineration will be overseen by the Biological Safety Officer to minimise the risk of any contamination. The Biomedical Science laboratory facilities are locked and have card access. Only authorised and trained staff and students will be allowed access to the facilities and a record of laboratory users will be maintained.

Based upon our review of the techniques and procedures to be carried out in the Biomedical Science laboratories, we consider the facilities and procedures are adequate to control the level of risk presented to humans and the environment by these genetically modified Hazard Group 2 bacteria.

  - Yes
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees Celsius for at least 15 minutes or 126-130 degrees Celsius for at least 10 minutes or 134-138 degrees Celsius for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees Celsius for at least 15 minutes or 126-130 degrees Celsius for at least 10 minutes or 134-138 degrees Celsius for at least 3 minutes), discharge to drains, or chemical disinfection with Virkon using manufacturer’s instructions under standard conditions, discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees Celsius for at least 15 minutes or 126-130 degrees Celsius for at least 10 minutes or 134-138 degrees Celsius for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) and glassware (disposable or broken) - dispose via clinical waste stream for incineration.

Degree of kill
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical disinfection with Virkon, used according to manufacturer’s instructions under standard conditions, manufacturers validation [eg4.79] log reduction ([eg99.998]% kill).

The project involves the preparation of mutants of enzymes of cytochrome P450BM3

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Purposes of the contained use

Improving the purification of viral vectors

### Recipient or parental organism

HEK-293 cells and HEK-293T cells

### Host/vector system

Lentivirus, Adeno Associated Virus and Adenovirus. The proprietary versions of these vectors have been modified from the wild type to make them safe for use in human therapeutics. They have been altered to be replication incompetent and contain a benign reporter transgene (green florescent protein or beta galactosidase) - minimising concerns for both operator and environment.

### Origin & function

Proprietary Lentivirus, Adeno Associated Virus and Adenovirus material will be obtained from 3rd parties. This material will be purified using Puridify’s material at the premises outlined. Samples of purified viral material will be used to infect HEK 293 or HEK 293T cells and the reporter transgene quantified (green florescent protein or beta galactosidase). Other samples of purified viral material will be used to analyse the purification e.g. protein gels.

### Evaluation of foreseeable effects

All of the vectors used in this project are being developed for human therapies and thus have been significantly engineered to alter parts of the genetic code to create proprietary vectors that have a better safety profile than wild type.

The key alteration is that all vectors have been altered to be replication incompetent. This means that they pose a minimal concern to the environment should they be released as they cannot replicate in any cell or organisms they are able to infect. The vectors used also pose minimal to no chance to infecting plant or livestock as they are developed/chosen to transfect human cells.

These vectors have the ability to infect humans via a number of methods e.g. direct contact with skin, mucous membrane of the eye, nose and mouth, ingestion, or injection. Infection could lead to the expression of the transgene; insertional mutagenesis or an immune response.

However the transgenes of the vectors used express do not encode for oncogenes, growth factor receptors or toxin molecules. The reporter transgenes used in this work will be green florescent protein and beta gal to minimise the chance of harm to either the environment or personnel. If an individual is infected the vectors are replication incompetent and so will be unable to propagate throughout an individual.

There is the possibility that if an organism is also infected with a replication competent wild type vector that that transgene vector will also gain this ability. However control measures implemented as outlined below make this a highly unlikely event.

**HEK-293 cells and HEK-293T cells**

HEK 293 cells were generated in 1973 by transformation of cultures of normal human embryonic kidney cells with sheared adenovirus 5 DNA. As this cell line includes adenovirus genes it allow the propagation of the viral vectors used which have been engineered to become replication incompetent. The HEK-293 line has been further engineered to contain the SV40 Large T-antigen for the use of retroviral propagation.

The HEK cell lines pose minimal potential damage to the environment as they have been adapted to an artificial cell culture environment under laboratory conditions and so are unlikely to thrive in the external environment if released. It is not the aim of this project to propagate virus for experimentation but rather use these cell lines to test the
infectivity of the purified vectors via quantification of successfully transfected reporter transgene. Therefore the adherent cultures will be grown in multiwall plate formats of well columns less than 5mL (<500,000 cells per well). And not more than 1L of cell culture volume total. These wells will be infected with low viral concentrations (anticipated to be less than 10E6 per well). This makes handling and destruction of the viral infected cells easier to control, therefore minimising risk to operator or environment.

Rational of Class 2 classification for all vectors

• After a review of the information sources and discussions with experts in the field there was a mix of opinion as to which of the proprietary vectors should be considered Class 1 and which should be considered Class 2 – these opinions differed between the sources consulted for the same vector variants. The case for Class 1 classification often being argued under the rational that the vectors are replication incompetent and express what were considered to be biologically benign transgenes.
• However, due to the disparities in classification of the vectors from the information sources it was decided that all vectors should be treated as Class 2 materials and appropriate control measures for Class 2 materials applied to the entire project.

Control measures to be adopted:

Records and tracking of materials used are kept as part of Puridify’s good lab practice which involves both hard copy and electronic copies of lab books. All materials are clearly labelled and stored in specific safe storage areas within the facilities.

• PPE: lab coats, gloves and goggles to be worn at all times. This is to reduce the possibility of any physical contact with the vector.
• To avoid exposure to aerosol/droplets viral manipulations should be conducted in biosafety Level 2 (BSL2) cabinets to prevent release and possible inhalation.
• No sharps to be used – removes the possibility of introduction into the blood stream
• Centrifugation must be conducted in closed containers and using sealed rotors. Rotors must be opened in a Biosafety cabinet.
• Once the vector has been disrupted during preparation for nucleic acid or protein analysis it is safe to be used outside of the cabinet (PPE as outlined above should still be used).
• All wastes treated to destroy GMO material (see disposal section below)
• Volumes of dilute virus material to be kept under <1L of 1E13 virus particles to make waste handling and disposal easier and to reduce the severity of any adverse events
• Volumes of concentrated virus material to be kept under 20mL of 1E15 virus particles. This allows easy handling in the biosafety hood.
• HEK 293, HEK 293T cell lines (volumes less than 1L). Once cells have been transfected they should only be handled in closed containers or in the BSL2 cabinet
• All vector material when stored in fridge/freezer will be clearly labelled as to its contents.
• All experiments take place in the Stevenage Bioscience Catalyst which is on a secure site as part of the Glaxo Smith Kline Campus. All areas where the virus is stored are only accessible by employees (via keycard or lock and key). Visitors are supervised and wear badges to identify them.
• Training for use of the vector material will be conducted by users who have prior experience of handling the vector material. The completion of training will involve the adding of the individuals name to this risk assessment. The signature will serve as a record of the training and be kept on file as part of the Puridify training records.
• Where vector material is transported this will only be done in sealed containers which are labelled and placed inside sealed plastic packaging. These in turn will be put into larger boxes, sealed and the box labelled with Puridify’s name, address and contact details with the instruction not to open unless authorised.
• There will be no lone, out of hours, work for this project.
• The Purifidy Health and Safety Policy covering lab practice and use of COSHH is to be followed at all times.

Protein Purification in the AKTA Avant system
• The AKTA Avant system has an enclosed fraction collector meaning the virus is not in contact with the external environment
• Viral material loaded to the loop inside the BSL2 cabinet;
• Parafilm should be wrapped around the connections;
• Delta pressure alarm should be less than 2 MPa;
• To avoid the formation of aerosols, 10 minutes should be the minimum of time between the last fraction collected and before opening the drawer.

Protein Purification in the AKTA Pure system
• The AKTA pure system does not have an enclosed fraction collector therefore all work must be completed inside a BSL2 cabinet

Together the implementation of these control measures make this project “LOW” risk

First Aid:

EYE EXPOSURE FROM SPLASH OR AEROSOLS: Rinse a minimum of 15 minutes in eye wash available at all sink hand wash areas or flush area with water. Seek medical attention.
CONTACT WITH SKIN: wash thoroughly with disinfectant. Hand sinks available in all labs for washing.
INHALATION EXPOSURE FROM AEROSOLS: Seek medical attention.
NEEDLESTICK AND/OR SHARPS EXPOSURE: No sharps are to be used

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
• Vikon is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations
• Hard surfaces: A solution containing 1% Virkon for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
• Safety cabinets: 1% Virkon (10mins)
• Discard jars, plastic tissue culture flasks, glassware: A solution containing 1% Virkon.
• Ensure all surfaces are in contact with the disinfectant (10mins). Added to sealed bags for autoclaving at a minimum of 1210C, 1.15bar, 15 mins hold.
• Supernatants/liquid waste: 3% Virkon diluted 2:1 in culture medium
• All autoclaved solid waste is to be placed into hazardous waste bags. There are 2x autoclaves available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method. Chart recorder or display screen is attached to autoclave to monitor treatment.
• Full bags are to be transported to Purifidy’s hazardous waste bins in the SBC storage area
• Bins are collected for off site incineration by Grundons waste management

Accidental Release:
In a contained area Virkon powder should be applied all over the split area. This solid waste is then to be autoclaved
as above.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed.
Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
The floor is sealed and the lab is built to CL2 level

Interest an emergency plan required according to regulation 20?  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The Stevenage Bioscience Catalyst (SBC) is an incubator hub for small and emerging biotechnology start-up and spin-out companies. It is a UK Government backed (Innovate UK) enterprise in collaboration with the Wellcome Trust and GSK. The SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety compliance. It has set up a GMO committee to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice among researchers. Dr Deonarain is the chairman of this committee and has 25 years experience working with GMO in academic and commercial settings and was Chairman of Imperial College Life Sciences GMO committee for 4 years. The SBC committee has reviewed and advised Puridify on its GMO risk assessment and are satisfied that they have considered the risks in terms of GM organisms and scale of work. They have appropriate control measures to contain the work and appropriate procedures for the class of GMO activity for waste disposal.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities [Y]

Give brief details of the genetic modification safety committee

The GMSC will be comprised of the Chief Scientific Officer/Safety Officer, two Scientific Officers and an administrator. Note that we are a small company, and the Chief Executive Officer is also the Safety Officer. A quorum for the meeting is a minimum of three individuals. The Committee will meet a minimum of once per year to discuss routine matters, review all existing risk assessments and audit the existing procedures. The GMSC will meet more frequently to discuss risk assessments etc. that require more urgent attention.
