**Project Additional Information**

**Purposes of the contained use**

Lentiviral vector packaging systems will be used to transduce cells which are otherwise difficult to modify using retroviral or other methods of transfection. This will mostly be employed within a pancreatic cancer setting, focusing on the tumour cells and surrounding stromal cells.
### Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

### Host/vector system

Lentiviral vector systems:-
Lentiviral vector packaging systems have divided the essential functions amongst multiple plasmids to reduce the risk of generating replication-competent lentivirus (RCL). The split-genome packaging system is designed so that multiple recombination events between the components are required for autonomous replication. Clinical trials using a split-genome packaging system have shown that this strategy effectively eliminates the creation of RCLs (see Levine et. al. PNAS, 103: 17372-17377, 2006). Commercially available 3rd generation lentiviral vector systems separate the viral envelope, env (e.g. VSV-G) from the gag-pro-pol, which encodes structural and enzymatic functions. We will be using pLB, pSicoR and pSLIK which lack gag, pol, env,tat, rev and other accessory viral genes.
We will also be using GIPZ shRNA Lentiviral Particles which are produced using the Trans-Lentiviral Packaging System. The Trans-Lentiviral Packaging system provides an even higher level of safety over 3rd generation packaging systems by further splitting the viral pol (reverse transcriptase (RT) and integrase (IN) functions) from gagpro. Because the RT and IN enzymes are provided in trans to gag-pro, additional recombination events are necessary to produce RCLs

Target cells:-
Cells will be cultured from primary animal or human sources or through immortalised cell lines. Cell lines of human origin will be verified using the Institute's human cell line authentication service. The source tissue of the cells includes pancreas, kidney, spleen, liver, breast, pleural effusion, lymphocyte, brain, pericardial effusion, ascites, lymph node and endothelium. Human patient material will be acquired via the MCRC Biobank. The Institute prohibits the collection of human tissue known, or highly likely, to be infected with a human pathogen. Any deviation from this rule must be approved by the Institute Director and Biosafety Committee.

### Origin & function

PKN2 (Protein Kinase N2) is a PKC-related serine/threonine-protein kinase and Rho/Rae effector protein that participates in specific signal transduction responses in the cell. Plays a role in the regulation of cell cycle progression, actin cytoskeleton assembly, cell migration, cell adhesion, tumour cell invasion and transcription activation signalling processes.
Other genes of similar function or implicated in the same cellular processes to that named may be investigated. But information as to their name and nature will be provided to the Biosafety Committee beforehand.

GFP (Green Fluorescent Protein) is a energy-transfer acceptor. Its role is to transduce the blue chemiluminescence of the protein aequorin into green fluorescent light by energy transfer. Fluoresces in vivo upon receiving energy from the Ca2+-activated photoprotein aequorin.

### Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV virus. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.
For the lentivirus, whilst the VSV-G envelope extends the celluar tropism and confers greater stability and environmental survivability it is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.
The target genes do not encode viral specific protein, nor does they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon is routinely used as per the manufacturer's recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation. Records are kept on site.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The committee agreed with the classification.

It asked for details of the target cells which were subsequently provided and incorporated in to the risk assessment.

02/03/2022
The project aims to investigate the immunomodulatory properties of factors derived from cancer cells on innate and adaptive immune cells typically found in the tumour microenvironment. Briefly, mouse cancer cell lines will be transduced using standard retro and lentiviral vector packaging systems such as pFB, pMSCV, pRevTRE or pLKO.1 to variably induced the upregulation or downregulation of candidate factors that might impact on the ability of the cancer cells to modulate inflammation and subvert immune surveillance. The factors will typically involve inflammatory and immune mediators but might also include known oncogenes or tumour-suppressors in order to examine how specific mutations impact the ability of the cancer cells to modulate the inflammatory and immunogenic properties of cancer cells.

Recipient or parental organism
Lentiviral parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.
Moloney Murine Leukaemia Virus parental organism is classified as hazard group 1.

Host/vector system
Lentiviral vector systems:
Lentiviral vector packaging systems have divided the essential functions amongst multiple plasmids to reduce the risk of generating replication-competent lentivirus (RCL). The split-genome packaging system is designed so that multiple...
recombination events between the components are required for autonomous replication. Clinical trials using a split-genome packaging system have shown that this strategy effectively eliminates the creation of RCLs (see Levine et al. PNAS, 103:17372-17377, 2006). Commercially available 3rd generation lentiviral vector systems separate the viral envelope, env (e.g. VSV-G) from the gag-pro-pol, which encodes structural and enzymatic functions. We will employ systems such as pFB, pMSCV, pRevTRE and PLKO.1. These systems are designed as described above with the gag and pol elements provided in trans using GP-2 or Phoenix cells.

Retraviral vector sytems:- GP2-293 (Clonetech@631458) is an HEK-derived cell line engineered to express the Moloney Murine leukemia Virus (MoMuL) essential viral packaging components by stably integrating, gag and pol genes. The viral envelope must be supplied in trans. High titre recombinant retrovirus particles are produced by transient co-transfection of pFB or pMSCV-based retraviral expression vector and a plasmid that expresses a viral envelope, such as pVSV-G. These commercially available vectors with proven safety profile are in use over many years for producing infectious but defective retroviral particles. These replication deficient VI Ps will be used to transduce the target cancer cells to study the impact of the encoded transgene expression on its immunogenic properties. The final genetically modified retroviral and lentiviral particles will be replication incompetent and therefore will not be able to propagate and establish a clinical infection. However, because they are infective they will be treated under containment level-2. Their properties are not expected to be altered by any of the inserts we will introduce into the vectors.

The potential route of transmission of the viral particles in the laboratory is mainly through skin contact that could arise from splashes, touching the objects or surfaces that are contaminated with culture media. Precautionary measures such as wearing laboratory coats and gloves and working in a laminar flow safety cabinet will prevent transmission through direct contact or inhalation of aerosol. Airborne transmissions are minimised since all cell culture work will be conducted in a class 2 microbiological safety cabinet and all centrifugation steps will be carried out in specialised sealed centrifuge buckets to prevent the generation of aerosols. Filter tips will be employed to prevent cross contamination of pipettes. No sharps or needles will be used so there is not risk of percutaneous transmissions. Accidental spillages will be dealt with by cleaning with appropriate disinfectant solutions (i.e. 1% Virkon). Any viral particle suspensions will be disposed of only after completely neutralising the virus using 1% Virkon for at least 24 hours. Contaminated consumables will be autoclaved prior to incineration.

Target Cells:- Well-characterised mouse cancer cell lines such as melanoma (8 16, 5555), colon-carcinoma (CT26) and breast-carcinoma (4T1), will be used in this project and are (or in the process to be) commercially available. B16 (ATCC® CRI6475™) and 5555 melanoma cells are a mixture of spindle-shaped and epithelial-like cells derived from C57BU6J mice. CT26 (ATCC® CRL-2638™) is an induced, undifferentiated colon carcinoma cell line derived from Balb/c mice. Product data sheets and certificate of analysis are available on the ATCC.

Origin & function

The specific gene that we are using in this project is mouse Cycloxygenase-2 gene that was supplied commercially by SourceBioscience. COX-2 is an enzyme that is responsible for formation of prostanooids. Other genes may be employed in this project encoding for molecules that may play a role in inflammation and immunity. In this event the Biosafety Committee will be notified beforehand.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication infection.
cycles. The probability of seroconversion is minimal. Historical Significant Changes: Transferred from GM80 Transferred to GM541

02/03/2022
Project Additional Information

Purposes of the contained use

The aim of the project is to assess the effect of blocking the expression of B-Raf and related signalling proteins on the growth of melanoma cell lines in a 3-dimensional model which more closely replicates the tumour microenvironment. We have previously shown that siRNA-mediated gene knockdown of B-Raf inhibits melanoma cell growth. However, this culture model is not compatible with siRNA oligonucleotides. Therefore, we wish to create melanoma cell lines which stably integrate shRNA sequences into their genome for long-term gene knockdown.

Recipient or parental organism

The recipient cell lines will be primary human melanocytes or immortalized human melanoma cell lines. Each of these cell lines are commercially available, have been maintained in cell culture for many years, are not known sources of human pathogens, and are unlikely to survive outside the laboratory environment.

Host/vector system

The vector to be used is a lentivirus derived from HIV-1. However the vector has been modified in several ways to ensure that the virus is replication-defective, and will not form active viral particles unless it is co-transfected into a packaging cell line with helper plasmids.

Origin & function

The genetic material that will be cloned into the lentiviral vector will be DNA that encodes a short hairpin RNA molecule directed against B-Raf or related genes which support melanoma progression. Expression of the shRNA molecule will result in gene-specific knockdown, most likely promoting growth inhibition or cell death in the transfected cells. We also propose to use a lentiviral vector encoding the bacterial Tet-repressor protein, so we can achieve inducible expression of shRNA in the cell lines under study. Once Tet-repressor and shRNA constructs have been stably introduced into cells, shRNA expression and subsequent gene knockdown will only occur if tetracycline is added to the culture medium.

Evaluation of foreseeable effects

The lentiviral vectors which we propose to use do have the potential for infecting any human cell. Through good lab practice (GLP) the risk of these vectors affecting the user or others in the laboratory is extremely low. In the unlikely event of infection, the viral particles will not replicate, as discussed above, The expression of these shRNA molecules is hypothesized to target the growth of melanoma cells, and would likely induce cell death. In the case of infection with a lentivirus encoding the Tet-repressor, expression of this protein would have little effect on human cells, as Tet-repressor promoter elements are not present in human genes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We are not requesting derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and infections of cells will be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 1% Virkon after use. Virkon is a chemical disinfectant that kills 99.999% of organisms in less than 10 minutes. The cabinet will prevent unwanted infection of the cell cultures as well as release of the viruses into the environment. Infected cells will be grown in a designated incubator. Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 1% Virkon before disposal. Cells and growth medium will be treated with 1% Virkon before disposal according to the Institute’s Waste Index and Disinfection.
protocols. HIV-1 is transmitted through blood and a limited number of bodily fluids, none of which will be encountered in the course of this work. Further, sharps will not be used. To date, no one has been identified as infected with HIV due to contact with an environmental surface (see http://www.cdc.gov/hiv/resources/qa/qa35.htm). No living material infected with HIV derived lentivirus will be transported other than between cabinet, microscope and incubator in the tissue culture room 5C10.1 (ACGM2), but cell extracts will be transported between room 5C10.1, laboratories 4N19-21 (ACGM1) and the equipment room on the 4th floor (ACGM1). Viral preparations will be double-contained and transported between room 5C10.1 and the —80°C freezer (room 4S4, ACGM1) for storage. In the event of a spillage, chlorine-releasing disinfectant granules (HAZ-TAB) or 1% Virkon will be used for immediate disinfection.

### Project Additional Information

**Purposes of the contained use**

CPMV is a plant virus with a bipartite RNA genome separately encapsidated in icosahedral particles. The 3-dimensional structure of the virus particles has revealed that the capsid proteins would be able to tolerate the addition of foreign sequences. Use of this property will be made for the display of epitopes from animal pathogens eg human immunodeficiency virus 1 (HIV-1) at the surface of CPMV capsids. The aim is to produce vaccines based on the expression of small immunogenic sequences via a macromolecular carrier that is non-pathogenic for animals.

**Recipient or parental organism**

Full-length cDNA copies of the genome of CPMV cloned downstream of the CaMV 35S promoter in pUC18-derived plasmids will be used as the cloning templates. Foreign sequences will be linked to the viral coat proteins.

**Host/vector system**

pUC18-based plasmids will be propagated in disabled E. coli strains (JM83 or DH5a). Purified plasmid DNA will be used to initiate an infection of the propagation host for CPMV, cowpea (Vigna unguiculata) cv Blackeye.

**Origin & function**

Synthetic oligonucleotides coding for peptide sequences which correspond to defined antigenic sites from animal pathogens, eg the envelope protein gp160 of HIV-1 will be inserted into the viral genome fragment coding for the CPMV capsid proteins. These inserts can vary in length between less than 10 and up to 100 amino-acids and are selected for their potential to elicit an immunological response in animals or humans, but are devoid of pathogenicity of their own. In addition given the synthetic nature of the DNA inserts, no propagation of the pathogens from which the sequence of these peptides is derived will be involved.

**Evaluation of foreseeable effects**

Alteration of the capsid proteins of CPMV by the addition of foreign sequences, which are neither plant nor plant pathogen-derived, has in past experiments not changed the virus host range; such alterations actually tend to produce virus particles which are less stable, less infectious and less transmissible by the crysomalid beetle vector than the wild-type counterpart.

The foreign sequences to be expressed via CPMV present no endogenous toxicity or allergenicity. Accidental induction of an immune response against the antigenic peptides grafted onto CPMV particles is unlikely given that this can only be achieved by deliberate exposure, via artificial methods (injection) of large doses of purified virus in the presence of an adjuvant.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the laboratory.
- the E. coli strains used to propagate plasmids bearing CPMV sequences are disabled; they constitute Class 1 GMMs which will be handled in Tontainment Level 1 Laboratory facilities, according to conditions of Good Laboratory Practice.
- residual plant material from the virus extraction procedure and disposable plasticware will be autoclaved before disposal whilst reusable centrifugation bottles and tubes will be treated with the broad-spectrum phenol-based disinfectant Hycolin and with bleach which will ensure their complete decontamination.

In the glasshouse, plants will be grown on waterproof benches that will permit collection of any water effluents; accidental spillages onto floors and all collected waters will be treated with 0.8% of the commercial disinfectant Jet5, supplied by Hortichem (final concentration 0.04% peroxyacetic acid). All materials used for virus inoculation (gloves, tips, tubes etc) as well as waste products from infected plants: pots, compost, residual plant material will be collected in plastic bags which will be sealed and placed into appropriate containers for autoclaving to ensure total virus particle destruction before disposal.

Is an emergency plan required according to regulation 20? Y

Project Ref 145/01.7

Date Ackn'd 05/09/2001
CU2 Project Title TRANSFORMATION OF VERTICILLIUM DAHLIAE AND IN PLANTA DETECTION
Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

a. To develop DNA-mediated transformation systems of the plant pathogenic fungus Verticillium dahliae  
b. Introduction and expression of established marker genes hygromycin resistance (hph), green fluorescent protein (GFP), luciferase (luc), B-glucoronidase (GUS)  
c. Monitoring infection, growth and development of marked V. dahliae on strawberry plants.

**Recipient or parental organism**

Verticillium dahliae, is a plant pathogenic, soil borne fungus causing vascular wilt in a variety of plant species including cotton, tomatoes, potatoes and strawberries. It is an imperfect asexual fungus with no sexual stage and as such does not interbreed. The pathogen infects the vascular system of various crop species and produces conidia (asexual spores) in planta that do not persist outside of the host. There is effectively no air-borne dispersal phase. Sole route of infection is through contaminated soils. This point is no better illustrated by the fact that healthy plants are routinely cultured beside infected plants without any cross-contamination. Micro-sclerotia (spore resting phase) are formed in necrotic plants, these are able to survive for many years in soil, but will not be formed in proposed experiments as plants will be destroyed at advanced stages of disease.

**Host/vector system**

Two host strains of V. dahliae will be used. These are two isolates (12008, 12009) from infected strawberry plants at East Malling, UK. Transforming DNAs will in the form of closed circular plasmid or as Agrobacterium binaries and will consist of marker genes under the regulation of the Aspergillus nidulans' glyceraldehyde-3-phosphate dehydrogenase (GPD) 5'UTR promoter sequence and tryptophan (trpC) terminator sequence. Transformation of the fungi occurs by integration into the genomic DNA; vector sequence do not replicate autonomously within the host strains.

**Origin & function**

V. dahliae transformants harbouring the GFP marker will be grown in broth cultures (100 ml) to produce conidia for strawberry plant inoculations. Broth cultures will be filtered to remove mycelium and conidial suspensions used for root tip inoculations. Up to 20 plants will be infected in an experiment. After ca. 1-week crown or petiole samples will he barvested and examined by UV microscopy. All plants and soils will be destroyed before necrosis.

**Evaluation of foreseeable effects**

All activities will be performed within and effectively 'contained' within purpose built laboratories and growth cabinets at HRI-Wellesbourne.
V. dahliae modified to express the marker genes proposed is no more likely to survive in the environment than wild type strains and is unlikely to displace other organisms.

V. dahliae is a plant pathogen and is non-pathogenic for humans. The inserted marker gene sequences have no known hazard and do not offer any substantial advantage should the transgenic escape into the wider environment.

As described above the organism is contained in plants, has no air-borne dispersal mechanism and is not able to transfer genes to other isolates/species.

The plant pathogenic fungus can be controlled by standard industry practices. V. dahliae is widespread throughout Europe and within the UK. Growers normally destroy infected crops. Primary disease control method is soil fumigation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated soil, waste water and plant materials will be sterilised by autoclaving prior to disposal.

Plant pots will be held on trays to collect any run-off water. Waste water and trays will be autoclaved and/or treated with the proprietary disinfectant Virkon. Water from the growth cabinets does not empty to a general drainage system.

All contaminated laboratory consumables and cultures will be sterilised by autoclaving prior to disposal or washing.

All laboratory surfaces will be disinfected using 70% v/v ethanol, hypochlorite (1,000-10,000 ppm available chlorine) or Virkon.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The risk assessment has been discussed and approved by the Genetic Modification and Biological Safety Committee at HRI, Wellesbourne.

Project Additional Information

Purposes of the contained use

PVX and PEBV are both single-stranded RNA viruses with a positive-sense genome, monopartite in the case of PVX, bipartite in the case of PEBV. PVX is a well-characterised widely used transient expression vector for foreign genes. It will be used to explore the properties of proteins encoded by another plant virus, cowpea mosaic virus (CPMV). In addition heterologous phytases will be expressed in plants via PVX.

PEBV is under development as an expression vector and only reporter genes giving colorimetric reactions will be used in order to be able to assess the efficiency of the system.

Recipient or parental organism

Full-length cDNA copies of the genome of PVX in either pBluescript (bacteriophage T7 promoter) or the binary Ti vector pGreen (Cauliflower mosaic virus 35S promoter) will be used as cloning templates. Foreign genes will be expressed either from a duplicated promoter for the PVX coat protein (CP) or linked to the PVX CP.

Full-length cDNA copies of the bipartite genome of PEBV are cloned downstream of the T7 or 35S promoter in pUC-derived plasmids. Transfer of these cDNAs into the binary vector pGreen is planned in order to allow infection of plants via Agrobacterium. Reporter genes will either replace viral gene products or be added to the viral genome.

Host/vector system
pBluescript and pUC-based plasmids will be propagated in disabled E coli strains (JM83 and DH5a). pGreen-based plasmids will be transformed into disarmed Agrobacterium tumefaciens strains (eg GV3101). Either in vitro transcripts (T7 promoter-driven clones), purified plasmid DNA (35S promoter-driven clones) or Agrobacterium cultures (pGreen-based clones) will be used to mediate the infection of host plants. PVX will be inoculated onto Nicotiana benthamiana plants and PEBV will be propagated in both N. benthamianas and peas.

Origin & function

The sequences to be inserted into PVX are of two kinds:
- genes derived from the genome of CPMV. Known functions of these viral proteins are encapsidated and movement of the viral particles from cell to cell. Their expression via PVX is destined to identify potential pathogenicity-determining functions.
- genes encoding phytases of bacterial or plant origin. These enzymes liberate phosphate stored in the form of phytate making it bioavailable both to the plant and to animals, who are devoid of this enzyme (eruminants excepted).

Genes to be inserted into PEBV consist in the green fluorescent protein (GFP) or B-glucuronidase (GUS); expression of these reporter genes from the viral vector can be monitored by fluorescence or an enzymatic reaction respectively.

Evaluation of foreseeable effects

CPMV-derived proteins are by nature of their plant virus origin not expected to represent a hazard to human health. As yet unidentified properties of some of these genes may consist in pathogenicity-enhancing traits. However given the nature of the PVX vector used, their expression will only be transitory; due to duplication of the CP promoter gene in the PVX vector, foreign sequences are rapidly lost as a result of homologous recombination.

No adverse effects are expected from the expression of phytases via PVX as this type of enzyme is already present in plants although often expressed at low levels. Higher levels of phytase will allow the host plant to better utilise phosphate from soil sources. As to animals their feed is already supplemented with phytases.

GFP and GUS are widely used reporter genes and are neither expected to increase the infectivity of the recipient PEBV nor known to have toxic or allergenic effects on humans and animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the laboratory, including propagation of recombinant plasmids in E coli and Agrobacterium, and analysis of infected plant material. Residual plant material and disposable plasticware will be autoclaved. Reusable items, eg glassware, will either be decontaminated with 20% bleach or 2% Hycolin by contact overnight.

In the glasshouse. Plants will be grown in waterproof trays in a facility with a concrete floor and presenting no connection to the general drains. Accidental spillages to the floor will be treated by addition of the commercial disinfectant Jet5 to a final concentration of >0.8%. Reusable items, including plant trays will be disinfected with 0.8% Jet5 overnight. Jet5 concentrate contains 5% peroxyacetic acid and is used according to manufacturer's recommendations.

Waste products from virus inoculation, and from plants following completion of the experiments, will be autoclaved at 121 degrees C for 30 mins to ensure complete virus particle destruction before disposal.
The attached risk assessments have been discussed and approved by the Genetic Modification and Biological Safety Committee at HRI, Wellesbourne.

Historical Significant Changes

Transferred to GM13 on closure of GM145

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

**CMV- 2b-GFP and CMV-GFP**

A mutant of cucumber mosaic virus (CMV) that lacks the 2b protein gene and expressing free green fluorescent protein (GFP) and the wild type CMV expressing free GFP obtained in the laboratory of Prof P Palukaitis (SCRI) will be used as a model system to determine whether 2b-less CMV isolates/mutants make better cross-protecting strains and test the hypothesis that cross-protection occurs via virus induced RNA silencing.

Virus movement in the plant will be assayed by detection of GFP under UV light.

Presence of the 2b protein will be determined by Western blotting.

Two well established markers for the silenced state in plants are 25 nt oligonucleotides (SiRNA) and increased levels of host RdRP (RNA dependent RNA polymerase) determination of whether levels of these markers are increased will be determined by Northern blotting.

**TRV-GFP**

A tobacco rattle virus (TRV) modified to remove the non-structural 2b and 2c genes and replaced with GFP driven by a second coat protein gene subgenomic promoter derived from a different tobravirus isolate provided by Dr S Macfarlane (SCRI) will be used as a control for CMV-GFP experiments. Virus movement in the plant will be assayed by detection of GFP under UV light.

Two well established markers for the silenced state in plants are 25 nt oligonucleotides (SiRNA) and increased levels of host RdRp (RNA dependent RNA polymerase) determination of whether levels of these markers are increased will be determined by Northern blotting.

**Recipient or parental organism**

CMV is one of the most important and widespread viruses of field grown horticultural crops in the world. CMV has a particularly wide host range including Cucumis sativus, Lycopersicon esculentum and Spinacia oleracea. In total it infects over 1,000 species including many weed species. CMV can be transmitted mechanically, and in few cases via seed, but the major mode of infection in vegetable crops is by aphids in a non-persistent manner.

Tobacco rattle virus belongs to one of only two genera of viruses that are transmitted by nematodes, the tobraviruses. Tobraviruses are transmitted only by nematodes belonging to the genera Trichodorus and Paratrichodorus. It can also be transmitted via seed, grafting and by mechanical inoculation. TRV has a wide natural host range including Stellaria media, Voila arvensis. Beta vulgaris. Spinacia oleracea, Capsicum annum Solanum tuberosum Narcissus pseudonarcissus. Tulipa sp. and Hyacinthus sp.

**Host/vector system**

CMV- 2b-GFP and CMV-GFP

To ensure that virus stocks are genetically uniform and satellite-free 2b-less CMV and the parental wild type CMV will be reconstituted from cDNA clones by in-vitro transcription and the resultant RNA inoculated onto tobacco to bulk up the virus for subsequent experiments.

**TRV-GFP**

Clones of RNA2 of TRV were modified to remove the non-structural 2b and 2c genes and replaced with GFP driven by a second coat protein gene subgenomic promoter, derived from a different tobravirus isolate (pea early-browning virus).

**Origin & function**

The CMV- 2b-GFP and CMV-GFP will be obtained from the laboratory of Prof P Pulukaitis (SCRI) and the TRV-GFP from Dr S Macfarlane (SCRI)

GFP will be used as a reporter gene for virus movement within the plant.
Evaluation of foreseeable effects

The 2b protein gene in virus interferes with virus induced gene silencing in plants protecting the virus against host defences. It is hypothesised that the properties of the 2b protein may play a role in the induction of cross protection. If the virus lacks a functional 2b protein and is therefore unable to prevent gene silencing it should be less pathogenic. The CMV-2b mutant is less able than the wild type virus to spread systemically and accumulates to lower levels than the wild type in inoculated and uninoculated tissues (Soards A.J. et al 2002, Mol. Plant-Microbe Interact Vol 15, No. 7 pp 647-653). There is therefore no predicted hazard arising from the deleted gene. The inserted gene GFP is well characterized and there is no evidence for it being a hazard.

TRV-GFP
The deletion of the non-structural 2b and 2c genes should not alter pathogenicity as infection can occur in the complete absence of RNA 2. The non-structural genes on RNA 2 have been shown to be necessary for transmission of tobraviruses by vector nematodes; thus constructs in which these genes have been deleted should be effectively contained in the plants under test. (Macfarlane and Popvich 2000 Virology 267 29-35). The inserted gene, GFP is well characterized and there is no evidence for it being a hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plant pots will be placed on trays or saucers in order to catch run-off water and this water will be allowed to evaporate naturally. All plant material, soil pots and labels will be autoclaved at 121 degrees C before final disposal in the skip. An autoclave is situated in the glasshouse. All trays, saucers, glass, flooring and benching will be thoroughly disinfected with Jet 5 disinfectant (8mls/L). Plant material used in the laboratory will be autoclaved at 121 degrees C along with bags, tips and any other items used during laboratory procedures. This will then be placed in the skip. An autoclave is present in the same building as the laboratory. Benches in the laboratory are impervious and will be swabbed down with 70% ethanol before and after use.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk-assessment has been discussed and approved by the Genetic Modification and Biological Safety Committee at HRI, Wellesbourne.

Project Containment

Laboratory Activities  Glass Houses  Growth Rooms

02/03/2022  

Page 4056 of 15326
Molecular basis for acquisition and transmission of aphid picornaviruses.

The main reasons for developing genetically manipulated aphid picorna-like viruses are:

1. To develop a cell-culture based system for production of aphid picorna-like viruses
2. To identify viral genes (eg regions of the coat protein(s) which are specifically required for virus acquisition by aphids.
3. To map gene(s) which determine the host range of aphid picorna-like viruses
4. To understand role of plants in the transmission of aphid picorna-like viruses (this will include checking whether aphid picorna-like viruses can replicate in plant cells in vivo and in vitro)
Aphid viruses which would be used in this study (Aphid lethal paralysis virus - APV, Rose-apple aphid virus - RAAV, and Acyrthosiphon pisum virus - APV) form spherical virus particles containing a single stranded positive RNA genomes. Genomes of those viruses encode non-structural replication proteins containing motifs characteristic of RNA-dependent RNA polymerases, chymotrypsin-like proteases, and helicases showing similarities with homologous proteins of other so-called picorna-like viruses.

The genome of ALPV contains two long open reading frames (ORFs), which are separated by an intergenic region. The deduced amino acid sequences of the 5' ORF and 3' ORF products respectively showed similarity to the non-astructural and structural proteins of members of the insect-specific family Dicistroviridae. Infectivity experiments showed that ALPV can not only infect aphid species but is also able to infect the whitefly Trialeurodes vaporariorum, extending its host range to another family of the order Hemiptera.

The APV genome contains two large open reading frames (ORFs). The 5'-proximal part of the ORF1 encodes non-structural proteins. The 34K major structural protein is encoded by the 3'-proximal part of the ORF1, while the 66K protein contains both ORF1-(34K) and ORF2-derived sequences and is probably expressed by a (-1) translational frameshift. The 23/24K proteins most likely arise by proteolytic breakdown of the 34K protein. APV was found in pea aphid (Acyrthosiphon pisum).

Gemp,e organisation of RAAV is very similar to that of APV. APV shares a high degree of nucleic acid (78%) and amino-acid similarity (87%) with RAAV. RAAV was isolated from rose-apple aphids.

Although the deduced APV and RAAV genomic organisation in some aspects resembles that of the picornaviruses, its overall genomic organisation indicates that APV is a distinct species only distantly related to the Picornaviridae. To date, no viruses with this genome organisation have been found in other hosts except aphids.

Recipient or parental organism

pCRII-Topo (Invitrogen) is a bacterial plasmid vector which will be in disabled E. coli strains (TOP10 or DH5a)

In vitro transcription will be used to infect insect cell culture (eg Drosophila S2 cells). Recombinant viruses will be recovered from infected cells and used for the inoculation of aphids using artificial liquid diets and by surface contamination of host plants.

In vitro RNA transcripts will also be used in plant protoplast transfection experiments to determine if aphid picorna-like viruses can replication in plant cells.

Host/vector system

Reporter gene for green fluorescent protein - GFP (from the jellyfish Aequoria victoria) will be used to facilitate the construction of the recombinant viruses and to study gene function by producing gene "knockouts" and GFP fusion proteins.

Origin & function

Picorna-like RNA viruses of aphids (RAAV, APV, ALPV) are pathogens of aphids and insect specific. They are not hazardous to vertebrates, including humans. The organisation of APV, RAAV and ALPV tenomes in significantly different from that of picorna-like viruses of mammals, in terms of tenome organisation and significant sequence similarity. Therefore aphid picorna-like viruses are unlikely to cause human disease and aphid picorna-like virus-derived proteins are not expected to represent a hazard to human health.

Plant and mammalian, and insect RNA viruses (even those which belong to the same "picorna-like" supergroup) share very low level of sequence similarity with no extended stretches of similarity, which are prerequisite for recombination events between RNA genomes. Such a low level of nucleotide similarity suggests that a possibility of recombination event between animal (insect) and plant viruses even in the event of simultaneous replication of both viruses in the same cell is extremely low and will not result in generation of viable viral genome which is capable of independent replication. Given that GM picorna-like viruses which will be produced in this study will be less pathogenic, the probability of such recombination event is very unlikely.

No adverse effects are expected from the expression of GFP, which is widely used reporter genes and are neither expected to increase the infectivity of the recipient aphid picornaviruses nor known to have toxic or allergic effects on humans and animals.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the laboratory, including propagation of recombinant plasmids in E. coli and analysis of infected cell culture, aphids and plant material.

All microbiological work is conducted in a class 2 cabinet and all waste eg Eppendorf tubes. Gilson tips etc is sterilised by autoclaving. Glassware is sterilised by autoclaving and microbiological cultures are destroyed by autoclaving. Sharps are collected in the appropriate bin, which is sent for incineration.

Cell culture work is carried out in a class 2 cabinet fitted with an UV sterilising lamp. Virus contaminated instruments are either autoclaved directly eg forceps and scrapers and contaminated glassware and centrifuge tubes are soaked in 1% "Virkon" for at least one hour which will inactivate the virus. Insects are infected in a virus handling room also equipped with UV sterilisation. The virus handling room is cleaned with 1% Virkon and then UV treated after use. Centrifuge rotors are washed in Virkon and placed under an UV lamp to inactivate any residual virus. All centrifuge gradients are prepared and loaded in the virus handling room.

Virus infected aphids are sealed into escape proof containers and are stored in designated incubators, glasshouses and CT rooms. These are opened in the virus handling room. Aphids will be transported between the designated areas in sealed containers.

Lab coats are segregated for use with viruses and labelled, gene cloning and insect rearing and are autoclaved and then laundered weekly. Hand wash facilities are in place in each room.

Recombinant virus will be handled in a Class II cabinet in Lab 30 PPB fitted with a UV lamp to destroy and residual virus or in the virus handling room in lab 13 TPB. Red lab coats will be worn and these will be autoclaved before being sent to the laundry.

Recombinant viruses and plasmids are stored at - 20 degrees C or -80 degrees C and their location recorded.

In the glasshouse.

Plants will be grown in waterproof trays in a facility with a concrete floor and presenting no connection to the general drains. Accidental spillages to the floor will be treated by addition of the commercial disinfectant "Virkon" to a final concentration of 1% Reuseable items, including plant trays will be disinfected with 1% "Virkon" overnight.

Waste products (plants, pots, gloves etc) following completion of the experiments, will be autoclaved at 121 degrees C for 30 minutes to ensure complete virus particle destruction before disposal.

Virus infected aphids are sealed into escape proof containers and are stored in designated incubators, glasshouses and CT rooms. These are opened in the virus handling room.

Infection of aphids by artificial feeding will be carried out in escape-proof containers (Lab 13 TPB adjacent to the cell culture room). After infection aphids will be transported in the sealed containers to Glasshouse Compartments CC8, or CC9 where they will be placed on plants grown in separate aphid-proof ventilated containers. Sampling of infected aphids and plants will be carried out in the glasshouse Compartments CC8 and CC9. Sampling procedure will involve (1) transfer of the aphid proof boxes (containers) to CC8/CC9 (2) collection of aphids and plant material (to Eppendorf tubes), placing the remaining plant material, pots, etc into an autoclave bag; (4) transfer of the emptied container and bagged plant material to the designated freezer (Compartment CC5) (5) 24 hr incubation in the freezer to kill aphids (6) cleaning of...
Aphid samples will be collected from the containers in the containment area CC5, counted and placed in eppendorf tubes. Gloves used in aphid handling will be autoclaved (autoclave is located in the same building, C), the lab coats will be kept in -20°C freezer. Aphids which will be left in the containers by the end of the experiment will be anesthetized by placing the entire containers with plants in -20 freezer (located in the handling compartment CC5 which is kept under negative pressure) for several hours prior to (1) collecting the remaining plant material (with pots) to autoclave bags for sterilisation and (ii) sterilisation of the containers with disinfectant. The material used in cleaning the boxes, including gloves, cloths, and paper tissues will be autoclaved alongside with the plant material. To ensure that there will be no contamination of clean plants (maintained in Compartments C8 and C9) with aphids and prevent escape of aphids to the environment, the unit will require negative pressure, airflow (direction C8/C0 - CC6 - CC5 - CC8/CC9 and airlock (CC$) in constant operation through the course of experiments. Negative pressure containment is a standard requirement for work with infected aphids (See the plan of building C above on CU2 form). Entry and exit air will be filtered by F7 filters to prevent escape of aphids (99% effective for particles of 10um).

Transfer of aphid and plant sanokes (placed in a sealed Eppendorf tubes) from the Building C to the virus handling laboratory 13 TPB will be carried out in a sealed box for additional security. Autoclaves are housed in both the glasshouse complex and the laboratory building and therefore waste will be inactivated locally without need to transfer between buildings.
Use of Pseudomonas syringae pv tomato (DC3000) to deliver oomycete effector genes into plant cells

Date Project Ceased

N

Historical Significant Changes
Transferred to GM13 on closure of GM145

Project Additional Information

Purposes of the contained use

a. Oomycete effector genes (from Hyaloperonospora arabidopsidis and Phytophthora infestans) will be fused to the secretory signal of the Pseudomonas syringae pv Tomato DC300 effector AvrRPS4 and transformed into Pseudomonas syringae pv Tomatoe Dc3000 isolate.

B. Arabidopsis plants will be inoculated with the modified DC300 isolate and tested to determine if the introduced effector triggers a defence response from the plant via recognition by a plant resistance gene (effector triggered immunity) or if the effector increases isolate virulence due to suppression of the plant's basal defence response (effector triggered susceptibility). The following plants may also be inoculated: Potato, Tobacco and Brassica oleracea.

Recipient or parental organism

Pseudomonas syringae pv Tomato is a gram negative, aerobic, rod-shaped bacterium, which is able to survive in soil, in debris form diseased plants and on seeds. Infection is spread by rain splash allowing entry into leaves via natural openings, such as stomata, where it multiplies in the intercellular space resulting in lesions on infected leaves.

Successful infection is dependant upon the translocation of effector molecules into the plant cell to promote disease and suppress/avoid PAMP (pathogen associated molecular patterns) triggered immunity and effector triggered immunity (Ponciano et al 2003, Jones and Dangl 2006)

Pseudomonas syringae pv Tomato is able to cause disease on Solanum Lycopersicum (tomatoe), Capsicum annuum (pepper) and Solanum melongena (aubergine) (Bradbury 1986). In addition, some strains, which include DC3000 are virulent on Arabidopsis thaliana, Brassica oleracea (cabbage, cauliflower, broccoli) and B. campestris (turnip) (Whalen et al 1991). DC3000 is also able to infect Nicotiana benthamiana (tobacco) if the effector hopQ1-1 is removed (Kvitko et al 2009). The isolate DC3000 was isolated in Ontario, Canada by Diane Cuppels and is widely used for molecular studies as it is a naturally occurring pathogen of the model plant Arabidopsis thaliana. In addition, the genomes of both DC3000 and Arabidopsis have been sequenced. Consequently, the technology we wish to use has been developed using this Pseudomonas isolate (Sohn et al 2007).

References:

Host/vector system

The host strain Pseudomonas syringae pv Tomato DC3000 will be used, which was isolated in Ontario Canada in 1986.

Oomycete effector genes will be cloned into the pEDV6 vector and transformed into DC3000. The pEDV6 vector was developed in Jonathon Jones's lab at the Sainsbury laboratory and contains the N-terminal secretory signal from the DC3000 effector AvrRPS4 and is expressed using the native AvrRPS4 promoter. This allows delivery of the oomycete gene into plants cells via the bacterium's type three secretion delivery mechanism. This vector carries gentamicin to allow antibiotic selection of transformed cells. The pEDV6 vector is a replication compromised plasmid that is unstable and lost in the absence of persistent antibiotic selection.

Origin & function

DC3000 transformants will be grown in liquid culture in volumes of no greater than 30 ml. Cultures will then be adjusted to an appropriate OD (1 - 2.5) before infiltration of leaves using a 1ml syringe (without needle) or spray inoculation using a hand held atomiser. Infected plants will be analysed after 0-7 days. All plants and soil will be autoclaved at the end of the experiment (see section 12).

Evaluation of foreseeable effects

All activities will be performed and effectively contained within purpose built laboratories and growth rooms at Warwick HRI, The University of Warwick, Wellesbourne. Pseudomonas syringae bacteria are non-sporulating and can be readily contained using good microbiological practice.

The oomycete effectors may increase, decrease or have no effect on DC3000 virulence when it comes into contact with its host plants. The modified DC3000 isolates may be able to suppress/avoid the host's basal resistance response. Conversely, the introduced effector may act as an avirulence factor and trigger an R gene mediated resistance response in a normally susceptible accession.

Whether the modified DC3000 strains could infect a new host plant has never been tested but this is unlikely to happen, as a single effector, evolved to function in a specific plant-microbe interaction, is unlikely to happen, as a single effector, evolved to function in a specific plant-microbe interaction, is unlikely to overcome the reasons why the plant is a non-host to DC3000 in the first instance. For example, where DC3000 is unable to overcome the plant's passive defence mechanisms, such as a waxy cuticle, rigid cell walls and preformed antimicrobials or effector triggered immunity.

During escape this organism could potentially transfer the oomycete effector gene to other bacteria and possibly cause the undesirable spread of resistance to gentamicin. The likelihood of these hazards occurring is extremely low due to the use of the replication-compromised plasmid that is unstable and lost in the absence of antibiotic selection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All infected/contaminated laboratory waste, discarded cultures and infected/inoculated plant material will be disposed of by autoclaving using a discard cycle at 121 C (15psi) with the centre of the load maintained at this temperature and pressure for a minimum of 30min. The autoclaved material will be emptied into a dustbin bag and taken to a dedicated skip for disposal.

Spillages or infected liquid will be absorbed using tissue and then disposed of by autoclaving (as above) and then disinfection of the area/equipment with 70% ethanol.

The Class II safety cabinets will be disinfected by spray and wiping with 70% ethanol. Growth chambers will be disinfected after use by spray wiping with 70% ethanol.

Propogator trays using in the growth chamber will be disinfected by immersion in a disinfectant solution (e.g. 10% bleach water solution) and/or spray wiped with 70% ethanol. All contaminated glassware/equipment will be disinfected after use and before cleaning by autoclaving where possible, otherwise by immersion in disinfectant solution or spray wiped with ethanol.

These measures will result in 100% kill of the pathogen

## Project Additional Information

### Purposes of the contained use

We wish to use third generation lentiviral vectors (PCDH family; Systems Biosciences) to express ion channel genes in neurons and neuronal cell lines. While these lentiviral vectors are deactivated using several approaches and are regarded as a very low risk for recombination (details at www.systembio.com) there remains a theoretical risk. For this reason, and to protect the target mammalian cells from contamination, as is usual for tissue culture experiments, we will conduct work in containment level 2 facilities. All live animal work will be done in containment level 2 as well.

### Recipient or parental organism

The GMOs will be lentiviral particles containing sequences encoding ion channel genes. These viruses will be recombination deficient, but will be capable of transducing individual mammalian cells (including handlers, if skin is broken). Any inoculation with these CMOs should be restricted to the subset of cells that come immediately in contact, but will not spread. The genes carried by the CMOs will be expressed in inoculated cells, but these genes (ion channels) are not dangerous to neighboring cells.

### Host/vector system

The vector system used will be the Systems biosciences PCDH lentiviral kit. These lentiviral vectors are third generation and represent a low risk of recombination or of infection. They are self-inactivated, Tat deleted, have the packaging genes split on to three separate packing vectors, and mature virus particles (the CMOs) will contain no original packaging genes. However as developments in lentiviral research provide safer alternatives we will continue to upgrade our choice of viral system, always in the direction of reduced ability to recombine and increased safety.

### Origin & function

The genetic material will be cloned cDNA from human tissues. These cDNAs will encode ion channels that are associated with inherited diseases in humans. We have a large collection of mutations in different ion channel genes (an expanding group including: SCNs, CACNA1A, KCNA1, and accessory subunits), that have been identified with patients presenting with various neurological disorders (including epilepsy, ataxia, and migraine). None of the ion channel genes are thought to be oncogenic or dangerous on their own or in combination with other genes. They are not secreted but remain in the membranes and cytosol of the cells expressing them. The genes encode ion H channels and their accessory subunits that allow cells, generally neurons or muscles, to respond to stimuli by passing ions across their membranes. We will analyse how the ability to pass ions across the membranes is altered when mutations associated with human diseases are expressed in the ion channels. All work with patient DNA is done under appropriate ethical approval and consent. The neurological nature of the diseases that we are studying, and the specialized nature of the ion channels we are studying requires that we explore the behavior of these genes in neurons and muscles. While much of our work can be done in vitro, the actual functioning of neurons and muscles in vivo, when expressing the target genes (wild-type vs. mutant) will be key to understanding how different ion channels are capable of causing different neurological disorders. We hope to investigate the ability of cells inoculated with viruses in vivo (in rodents only) to survive, propagate action potentials and to communicate with other neurons, especially when expressing ion channel H mutants that in humans have been shown to disrupt these processes.
We anticipate that the primary effects will be the limited expression of our genes of interest in the desired H mammalian cells. In general this will have modest effects on the infected cells behaviour, but should not lead to H changes in neighboring cells. It is possible that the virus particles could infect any human cells including those of H workers, if they contacted broken skin (i.e. with a sharp glass pipette or syringe needle). Such an infection with an H inactivated non-replicable virus is likely to present a very small risk to the worker. Individual cells infected by the H virus would express only the ion channel genes encoded in them and the effects of these genes would be limited to H the infected cells. However it has been shown in some circumstances where large amounts of virus are used to H infect emryonic or stem cells that tumors may be produced, although the mechanism has not been clearly linked to H the viruses. For these reasons, as well as to maintain the sterility of our tissue culture stocks, and the health of H animals during surgery, we will conduct all experiments with viral particles in containment level 2 cabinets. In H addition all plasticware, sharps and media that comes in contact with the virus particles will be disinfected with H bleach. Innoculated animals will be maintained in containment level 2 conditions and animal remains will be H disposed of in sealed containment level 2 clinical waste bags. No animals inoculated with viral particles will be H allowed to breed, and no GM animals will be generated.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Both liquid and solid waste will be treated with bleach solutions (degree of kill effectively 100% for both virus U particles and transformed mammalian cells). The effectivity of these solutions is monitored routinely by the the p1-I U indicating properties of the media, and bleach is stored in solid form to prevent inactivation. After disinfection with U bleach solid waste is disposed as clinical waste. U Surfaces in contact with media and virus will be sterilized with ethanol, and will be routinely (usually daily or, U exceptionally, weekly) UV irradiation. U Animal remains will be disposed of in sealed class 2 clinical waste bags. Live animals will be maintained in Class 2 U containment facilities, and used cages will be autoclaved before cleaning.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
In view of current understanding of the risk associated with this vector system the committee argued that containment level 2 precautions are appropriate for this purpose.

### Project Additional Information

**Purposes of the contained use**

The construction of libraries of random insertion mutants of C. jejuni as a tool for studying genes essential for virulence and pathogenicity.

**Recipient or parental organism**

C. jejuni is an ADCP group 2 pathogen.

**Host/vector system**

No DNA capable of extra-chromosomal replication in C. jejuni is involved.

**Origin & function**

The mini-transposons to be inserted contain specific insertion sequences derived from wild type transposons. The function of these sequences is to ensure the insertion of the mini-transposon into chromosomal DNA by the action of the appropriate transposase in vitro. These insertion sequences flank a short synthetic unique DNA tag sequence and an antibiotic resistance gene. The tag sequence allows the identification of inserted mini-transposons to be confirmed by hybridisation. The antibiotic resistance genes are present to allow for selection for mutants on antibiotic containing growth media. The antibiotic genes were originally cloned from Campylobacter coli isolates. The mini-transposons are cloned into standard pUC derived cloning vectors. These vectors are grown in E. coli to generate sufficient amounts of DNA needed for the in vitro transposition reactions. The construction and growth of these vectors has been classified as Class 1 in a separate risk assessment.

**Evaluation of foreseeable effects**

The GMM's will be resistant to either kanamycin, chloramphenicol or tetracycline depending on the resistance gene inserted. Since these antibiotics are not used to treat C. jejuni infections in humans, the GMM's will not pose any increased risk due to this phenotypic change. The inserted mini-transposons are likely to inactivate any gene into which they are inserted. In most cases such mutants are likely to be less able to either survive or cause pathogenic effects.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8. All contaminated plasticware is to be either incinerated directly, or following an overnight soak in 5% Hycolin disinfectant. Items will be double-bagged for transport to the incinerator. Hazardous waste will be collected weekly by a firm registered with the HSE as being a licensed hazardous waste incinerator. All other items, including vessels containing small culture volumes (up to 200ml) will be placed in lidded steel buckets for autoclaving.

The autoclave for waste has a chart recorder for monitoring load and drain temperatures. It is serviced quarterly and inspected for accuracy annually. Both incineration and autoclave procedures are expected to give a 100% kill of all GMMS.

The committee commented on the likelihood that a library of random mutants would contain mutants whose phenotype might be more pathogenic or virulent than the wild type if a negative regulatory mechanism was affected. It was agreed that this likelihood was low as in most cases gene inactivation mutants are less able to survive. It was also noted that this risk assessment in some way covers the construction of directed gene insertions in C. jejuni as the library may well contain random insertions into those desired genes.

The committee commented on the likelihood that a library of random mutants would contain mutants whose phenotype might be more pathogenic or virulent than the wild type if a negative regulatory mechanism was affected. It was agreed that this likelihood was low as in most cases gene inactivation mutants are less able to survive. It was also noted that this risk assessment in some way covers the construction of directed gene insertions in C. jejuni as the library may well contain random insertions into those desired genes.

Date Project Ceased: 02/03/2022
The construction of knock-out mutants of Streptococcus pneumoniae and expression of green fluorescent protein reporter, in order to investigate mechanisms of pathogenesis. S. pneumoniae is an ACDP class 2 pathogen.

Recipient or parental organism

Category 1 disabled hosts
Lactococcus lactis (for gene cloning and expression: classified by HSE as disabled host). L. lactis strains used in this work are naturally auxotrophic and in addition lack proteases and genes for required for lactose metabolism and growth in their natural environment (ie milk).

E.coli K12 laboratory strains eg DH5α (for gene cloning; classified as a disabled strains by HSE).

E. coli BL21 for expression work (considered non-pathogenic).

Class 2
Streptococcus pneumoniae (construction of knock-out mutants to investigate mechanisms of pathogenesis and expression of green fluorescent reporter gene).

Host/vector system

pTREP and pTREXnis broad host range gram-positive vectors; non-mobilisable for cloning and expression in L.lactis. replicon = pAMB1 antibiotic resistance = erythromycin.

pET series vectors for expression in E.coli BL21 strain and its derivatives. Vector is non-mobilisable and utilises the T7 RNA polymerase promoter for high level expression. Bom (nic+) mob-, tra-.

pUC based vectors for cloning in E.coli K12 strains designated as disabled.

No vectors are used in the Streptococcus pneumoniae work; genes are disrupted by natural transformation with PCR amplified DNA containing an antibiotic resistance marker (erythromycin).
Surface antigens from *S. pneumoniae* and *S. agalactiae* lacking any signal export sequence are to be expressed in the cytoplasm of disabled laboratory strains of *E. coli* or *L. lactis*. The antigens will be purified and evaluated as cross protective vaccine antigens for example using a range of assays eg opsonophagocytosis with purified human neutrophils and cross reactivity with human sera. Specific genes will also be knocked-out in wild type strains of *S. pneumoniae* in order to assess their effects on growth and virulence. The mutant strains will be investigated using a variety of approaches eg biochemical, proteomics, microarrays and physiological methods to investigate gene function.

### Evaluation of foreseeable effects

The host strains *L. lactis* and *E. coli* K12 are disabled and the vectors are non-mobilisable. BL21 (DE3) and BLR (DE3) are *E. coli* strains for use with the T7 expression system. The ACGM newsletter 23 of Sept 1998 states that these strains can be assigned to level 1 containment.

The genes to be cloned in these hosts are derived from pathogenic streptococci (ie *S. agalactiae* (group B streptococcus) and *S. pneumoniae*).

The expression of proteins from GBS or *S. pneumoniae* in disabled *E. coli* or *L. lactis* strains will not make these host strains pathogenic even if the genes contribute to virulence in their normal host. The capacity to cause disease is multifactorial and dependent on numerous other properties such as encapsulation, capacity to grow in vivo, capacity to colonise the host etc. The genotypes and phenotypes of the *E. coli* and *L. lactis* host strains are well documented ie they lack genes encoding invasins, various adhesion phenotypes, and a range of enterotoxins. All genes for expression in these hosts will be investigated by bioinformatics tools to ensure that they do not encode factors that might conceivably cause harm. The list of sequences to be expressed and the results of the bioinformatics searches will be provided to the members of the committee before the work commences. It is intended that all genes with greater than 50% amino acid identity to genes of known function that would not cause harm to humans or the environment in a worst case scenario will be handed at category 1. All other genes mentioned above would be handled at category 2 to ensure the overall risk is negligible.

Specific genes will also be knocked-out in wild type strains of *S. pneumoniae* in order to investigate their function. These mutations are highly unlikely to increase the capacity of the strain to cause diseases since a factor will be absent from the strain that may be essential for growth under certain environmental conditions such as those found in vivo.

The genes will be disrupted by recombination with a truncated gene fragment carrying an erythromycin resistance gene following natural transformation. This antibiotic is not routinely used to treat pneumococcal infections and autonomously replicating plasmid vectors will not be used.

The overall risk of these GMO's causing harm by accidental contamination of a laboratory worker is therefore effectively zero.

As the host vector systems utilise non-mobilisable vectors and host strains are disabled the risk of disseminating genetic material in the environment is effectively zero.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable.**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Not applicable.**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8.

All contaminated plasticware is to be either incinerated directly, or following an overnight soak in 5% Hycolin disinfectant. Items will be double-bagged for transport to the incinerator. Hazardous waste will be collected weekly by a firm registered with the HSE as being a licensed hazardous waste incinerator.

All other items, including vessels containing small culture volumes (up to 500ml) will be placed in lidded steel buckets for autoclaving. The autoclave for waste has a chart...
recorder for monitoring load and drain temperatures. It is serviced quarterly and inspected for accuracy annually. Both incineration and autoclave procedures are expected to give a 100% kill of all GMMs.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The committee requested further information about the genes to be expressed and of any virulence factors from GBS and S. pneumoniae that might cause harm if accidentally ingested. The requirement of multiple factors such as the capsule, capacity to grow in blood and assimilate iron in vivo etc were discussed in assessing the likelihood that the possession of any one factor could make a disabled host more dangerous. Given that these surface associated proteins will be expressed intracellularly it was considered unlikely that they will increase adhesiveness of the bacteria or reduce their susceptibility to the innate defence mechanisms of humans and animals. Indeed high level expression of recombinant protein often diminishes the capacity of the bacteria to grow competitively. Furthermore, the expressed proteins often aggregate and form inclusion bodies when expressed at high level.

CU2 Project Title

DETERMINING THE FUNCTION OF PUTATIVE TRANSCRIPTIONAL REGULATORS IN CAMPYLOBACTER JEJUNI

Class CultureVolClass2 CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements [N]
Project Additional Information

Purposes of the contained use
Construction of knockout mutants and conditional mutants in Campylobacter jejuni putative gene regulators and expression of such regulators in Escherichia coli facilitating their purification.

Recipient or parental organism
Campylobacter jejuni is an ADCP group 2 pathogen

Host/vector system
Non-mobilisable E. coli vectors pBluescript II SK+ (Stratagene), pCR2.1 (Invitrogen), pCRT7NT-TOPO (Invitrogen), pCRT7CT-TOPO (Invitrogen) will be used for cloning, propagation, mutagenesis and expression of Campylobacter genes in E. coli K12 strains JM109 (Promega), TOP10F' (Invitrogen), BL21(DE3)pLysS (Invitrogen)

Origin & function
pBluescript and pCR2.1 will be used as standard cloning vectors to facilitate cloning, propagation and mutagenesis (by inverse PRC) of Campylobacter genes in E. coli. pBluescript is a standard cloning vector derived from a variety of sources and includes an origin of replication derived from the E. coli plasmid ColE1, a portion of the E. coli lacZ gene, a synthetic multiple cloning site, a gene conferring resistance to ampicillin and the origin of replication derived from the E. coli phage f1. pCR2.1 is another general purpose cloning vector that has been developed by Invitrogen to facilitate direct cloning of PCR products. In addition to the elements described above for pBluescript it, additionally, contains a promoter derived from the E. coli phage T7 and a gene encoding resistance to kanamycin. After mutagenesis an antibiotic resistance element (of Campylobacter coli origin) encoding resistance to either chloramphenicol or kanamycin will be introduced into the mutated genes and these constructs will be used to mutate the Campylobacter genome by allelic replacement. Plasmids pCRT7NT-TOPO and pCRT7CT-TOPO will be used to clone and express Campylobacter regulators. They are derivatives of pCR2.1 and, in addition to the elements described for that vector, contain a synthetic ribosome binding site, ATG initiation codon, additional codons including 6 histidine codons to facilitate purification of fusion proteins and an epitope (the Xpress epitope) that can be used to identify fusion proteins immunologically. In cases where knockout of a particular gene is not possible due to its being essential for cell viability a chloramphenicol resistance gene of Campylobacter origin, in which a synthetic iron-responsive operator sequence has been inserted will be cloned upstream of the gene of interest allowing for the controlled expression of the gene.

Evaluation of foreseeable effects
The genetically modified Campylobacter will be resistant to either chloramphenicol or kanamycin. Neither of these agents is used to treat Campylobacter infections in either man or farm animals and so this does not pose any additional risk. The mutants will, additionally, be unable to express particular regulators, which will have unpredictable effects on genes that are normally regulated either positively or negatively. It is assumed to be highly unlikely that such changes in gene expression will result in an increase in the virulence of the organism or its ability to survive in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid C. jejuni and recombinant E. coli cultures will be transferred in sealed containers to be autoclaved before disposal. Solid media on which modified C. jejuni or E. coli has been cultured will be double-bagged and sealed before being incinerated. Contaminated plastic ware will be double bagged and incinerated. A firm registered with the HSE as being a hazardous waste incinerator will collect hazardous waste weekly. Other items including glassware will be placed in lidded metal buckets for autoclaving. The autoclave has a temperature recorded (chart recorder) for monitoring load and drain temperatures. It is serviced quarterly and inspected for accuracy annually. Both incineration and autoclaving are expected to kill 100% of all genetically modified E. coli and C jejuni.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

All the initial review of this proposal, the GMSC asked for a list of the genes encoding the putative regulators to be attached to the risk assessment. It was also requested that vector maps should be supplied, together with details of their origin of replication. The possibility of knocking out a negative regulator was discussed (thereby increasing transcription levels of unknown genes), but this would not necessarily cause the recombinant strain to become more hazardous, and in any event it was considered that the proposed containment level would still be adequate.

Project Ref 155/01.4

Date Ackn'd 17/08/2001

CU2 Project Title MOLECULAR GENETICS OF GRAM POSITIVE FOOD PATHOGENS

Class 2

CultureVolClass2 < 1 litre

Class VolumeClass3-4
This project will concentrate on changes in gene regulation of Listeria monocytogenes in response to its environment. A plasmid with a constitutive Listeria promoter controlling green fluorescent protein (gfp) expression in Listeria will allow detection protocols of this reporter gene to be optimised. A vector derived from this will be used to clone promoters that are environmentally regulated in Listeria. These plasmid derivatives will be introduced into the Listeria monocytogenes strains in the study. Plasmids based on this system can be present in Listeria and replicate as a plasmid or under temperature induced chromosomal integration resulting in gfp expression under the cloned promoter on the chromosome. The gfp expression from the various promoters will be monitored under different environmental conditions.

**Hosts:** E.coli MC1002, MC1061 and S17-1 strains, Listeria innocua and Listeria monocytogenes EDGe, ScottA and 10403S strains. 10403S is streptomycin resistant. E.coli strains used for ease of laboratory manipulation before cloned fragments such as promoters are transferred into Listeria. Listeria monocytogenes strains EDGe, ScottA and 10403S are established laboratory strains.

**Vectors:** pMJ153 is a listerial promoter probe plasmid which encodes for ampicillin and kanamycin resistance in E.coli and just kanamycin resistance in Listeria. pMJ161 is pMJ153 with an insert in the BamHI site that gives constitutive expression of gfp and chloramphenicol. The constitutive promoter is very strong and gives resistance to 100g/ml of chloramphenicol. Both of these plasmids have a temperature sensitive RepA protein and so will only replicate at 30C in Listeria. At higher temperatures pMJ161 and other pMJ153 derivatives will integrate into the chromosome at the position of the cloned promoter resulting in a single copy of gfp under the control of the promoter and an uninterrupted copy of the promoter and its listerial gene. These plasmids will replicate in both E.coli and Listeria. They are not temperature sensitive in E.coli and they can conjugate from E.coli into Listeria.

**Inserts:** Green fluorescent protein gene from Aequoria victoria mut1 allele F64L, S65T (Cormack et al.(1996) Gene 173:33-38) with promoters for the expression of green fluorescent protein (GFP) including listerial promoters such as the constitutive promoter in pMJ161, acid and oxidative stress responsive promoters cloned randomly, sigB the sigma factor that responds to general stress and the virulence promoters for internalin and haemolysin.

Listeria monocytogenes is defined as a ACDP class 2 organism requiring its growth and manipulation at containment level 2.
non-mobilisable. This will be used to investigate promoter expression, as indicated by gfp activity, in response to different environmental conditions (e.g. food preservation techniques). Gfp activity will be assayed by FACS analysis and by visual fluorescent microscopy.

Evaluation of foreseeable effects

Listeria monocytogenes is defined as an ACDP group 2 organism requiring its growth and manipulation at containment level 2.

The treatment of choice for listeriosis is ampicillin/penicillinG combined with an amino glycoside such as gentamycin. The second choice for patients who are allergic to penicillin is trimethoprim with a sulphonamide e.g. sul famethoxale. Neither of these treatments is affected by the manipulations envisaged so the GMMs should not have a selective advantage over the wild type in the event of environmental release.

The pMJ derived plasmids can replicate in E.coli and Listeria and transfer from E.coli to Listeria because there is an E.coli oriT on the plasmid. This plasmid and its derivatives do not carry Listeria mobilization functions so transfer between Listeria is highly unlikely. The antibiotic resistance genes used for vector selection do not code for antibiotics used in the treatment of listeriosis. Environmental antibiotic resistance in Listeria is generally low except for tetracycline.

The expression of reporter genes such as green fluorescent protein gene is highly unlikely to cause increased pathogenicity. So the GMMs should not be considered more pathogenic than the wild type.

However this study is designed to determine whether environmental conditions can influence gene regulation including virulence; this will be taken into consideration when handling both the wild type Listeria monocytogenes and the GMM cultures that have been exposed to stressful conditions.

Transmission to people within the laboratory is most likely by the ingestion route. Listeria monocytogenes and other GMMs generated during this study will be handled in accordance with Good Microbiological Practice and with awareness of high risk groups. The risk of contracting listeriosis is higher in certain groups such as pregnant or immunosuppressed people. Access to the laboratory will be restricted and pregnant women will not be permitted to enter. Transport to and from the laser laboratory (where gfp is assayed) will be in closed containers marked with Danger of Infection tape.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8. All contaminated plastic ware is to be either incinerated directly, or following an overnight soak in 5% Hycolin disinfectant. Items will be doubled-bagged for transport to the incinerator. All other items, including vessels containing small culture volumes (up to 100ml) will be placed in lidded steel buckets for autoclaving. Small bioformentors (volume up to 1.7 litres) will be sealed, transported in a suitable secondary containment vessel and autoclaved separately. The autoclave for waste has a chart recorder for monitoring load and drain temperatures. It is serviced quarterly and inspected for accuracy annually. Both incineration and autoclave procedures are expected to give a 100% kill of all GMMs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
Members of the GMSC asked for maps of the vectors that were to be used. After enquiries had been raised about the mobilisability of these plasmids, they were satisfied that the final classification and containment measures are adequate for the proposed project.

Project Additional Information

Purposes of the contained use

Mutations in the nucleoid-associated DNA-binding protein family of genes will be created in four enteropathogenic bacterial strains. These mutations will be complemented by transformation of these strains with a low-copy plasmid containing the gene deleted from the chromosome. Linear fragments of DNA will also be integrated into the pathogenic strains, in order to introduce mutations or reporter-gene constructs, together with antibiotic resistance markers. Promoters of several Salmonella virulence genes will be fused to a green fluorescent protein reporter (GFP) gene, and these constructs will be introduced into the two...
Salmonella serovars either by integration into the bacterial chromosome, or on a low-copy number plasmid. GFP expression will be measured during invasion of cultured mammalian cells and in the tissue of infected animals. Specific mutations affecting regulatory proteins will be introduced into the Salmonella strains harbouring the gfp fusions, and their effects upon virulence gene expression determined by measuring GFP production.

Recipient or parental organism

Salmonella enterica serovars Typhimurium LT2a and Enteritidis, and enteropathogenic (EPEC) Escherichia coli E2348/69 (O127:H6) are classified as group 2 pathogens, as determined by the ACDP. Normally, Escherichia coli O157:H7 (VTEC) is classified as group 3, requiring more stringent containment conditions. However the strain that we are proposing to work with, NCTC 12900, lacks the prophage encoding the shiga-like toxin and therefore satisfies the requirements for consideration as a group 2 pathogen. E. coli K-12 (strains DH5a and MG1655) are classified as ACDP hazard group 1, since these strains are not considered pathogenic and are not expected to survive in the environment due to having several auxotrophic requirements.

Host/vector system

1) In all 4 strains, we will be mutating genes encoding members of the nucleoid-associated DNA-binding protein family such as hns, stpA and fis. We will complement the mutations by transforming the strains with a low copy-number (5-10 copies per cell), pSC 101-derived, non-mobilisible, ampicillin-resistant plasmid, pWKS30, containing the gene that has been deleted from the chromosome. Whilst cloning the various DNA fragments, we will initially employ the widely available general-purpose cloning vectors pUC18 and 19. These vectors are non-mobilisible, as they lack a bom site.

To introduce mutations or reporter-gene constructs into the chromosomes of the pathogenic strains, we will transform linear fragments of DNA containing the mutated allele / reporter-gene construct (containing kanamycin or chloramphenicol antibiotic-resistance markers) into the strain of interest, harbouring an oriR101-based temperature-sensitive plasmid (pKD46) encoding the ?Red recombinase, ampicillin and/or chloramphenicol resistance and araC (Datsenko and Wanner, 2000). This plasmid encodes a recombinase and proteins required to inactivate the host's RecBC exonuclease V system, allowing efficient recombination of the linear DNA fragments into the host chromosome, and is induced by adding L-arabinose to the culture medium. The plasmid also encodes a temperature-sensitive RepA protein, only allowing replication of the plasmid at temperatures up to 30C.

2) We will be fusing the promoters of Salmonella virulence genes to gfp, the gene encoding green fluorescent protein (GFP) and introducing the resultant constructs in to the puPA locus, encoding a proline permease and proline dehydrogenase, located on the Salmonella chromosome. The promoters that will be fused to gfp will include ssaG, prgH, invF, spiC, spvB, nirB, rpsM, htrA, waaN and other gene promoters of future interest. Virulence gene promoters and the promoterless gfp gene will be amplified by PCR and fused by a recombinant PCR approach, and will not involve plasmid based cloning. Linear DNA constructs will be introduced into the chromosome using the oriR101-based plasmid system described above in (1).

In instances where the introduction of mutations by the RED system proves unsatisfactory, allelic exchange will be performed using the suicide vector pCVD442 (Donnenberg and Kaper, 1991). The fusions can also be cloned onto a ColE1 or pMB1 replicon such as pBR322. The pBR322 vector is mobilisation defective and will only contain the promoter sequences for virulence genes.

Origin & function

All genetic material will derive from the four enteropathogenic strains listed above, or from the vectors/reporter genes described. The overall intended function of manipulations in both sets of experiments is to study the regulation of virulence in these strains. In all cases genes of interest will be mutated, or their promoters will be fused to the gfp reporter gene.

We will be performing detailed phenotypic analyses to determine the consequences of the mutations. We will perform in vitro tissue-culture based assays to study the interactions of the wild-type and the mutant strains with cultured cell lines, isolate RNA from the bacteria to measure gene expression by micro array and multiplex primer extension analysis, and use protein-based techniques such as SDS-PAGE and Western blotting to confirm results obtained by RNA analysis.

In project (2), the phenomenon of non-genetic variation (NGV), a poorly understood mechanism whereby non-genetic differences between sister cells enables strain survival under adverse conditions, will be studied using both gfp fusions and an additional reporter gene encoding an easily distinguishable phenotype, that can be correlated with the GFP expression. This additional gene will probably encode a salmonella outer membrane protein. Cellular differences in the level of GFP expression will be studied by fluorescence microscopy and Fluorescence Activated Cell Sorting (FACS).

We will be using some of the promoter-GFP fusions, to investigate the effects of growing Salmonella in simulated food environments. This will be done by fluorescence ratio imaging microscopy (FRIM).
Genetically modified strains will be used to measure the levels of virulence gene expression in vivo in mice, by fluorescence microscopy and FACS. The regulatory mutations that will be investigated are hns, stpA, fis, and hilA. Mutations in these genes have previously been shown to attenuate virulence in Salmonella. The promoters that will be fused to gfp will include ssaG, prgH, invF, spiC, spvB, nirB, rpsM, htrA, waaN and other gene promoters of future interest.

**Evaluation of foreseeable effects**

In all 4 strains, we will be mutating genes encoding members of the nucleoid-associated DNA-binding protein family such as hns, stpA and fis. These genes are also found in all non-pathogenic strains of Escherichia coli. As such, they do not contribute to pathogenesis in the absence of other factors and are therefore not considered to be virulence factors. Although subsequent complementation, by transforming with clones of hns, fis and stpA in pWKS30, will increase the copy-number of the genes and could conceivably result in higher levels of the cognate proteins, significant over expression is unlikely, since these genes are subject to negative feedback regulation.

The system for introducing linear DNA constructs into the bacterial chromosome involves the presence of the temperature-sensitive plasmid, pKD46. None of these genes encoded by the plasmid are considered likely to enhance the virulence of the strains harbouring them.

Since plasmid pKD46 and its derivatives cannot replicate at 37 degrees C, the plasmid would normally be lost following ingestion of the bacteria by a mammalian host. We are not aware of any potential for this plasmid to be mobilised and transferred to other strains although the theoretical possibility does exist whilst the strains harbouring the plasmid are in the gut. Thus, there is a minimal risk of antibiotic resistances encoded by this plasmid being transmitted to other strains.

The alternative allelic exchange system proposed in both projects will be performed using the suicide vector pCVD442. The fusions can also be cloned onto a ColE1 or pMB1 replicon such as pBR322. The pBR322 vector is mobilisation defective and will only contain the promoter sequences for virulence genes. Although pBR322 is not conjugable itself, the plasmid could be mobilised in the presence of a helper plasmid. The risk is considered very low. Moreover, the contents of the plasmid would not increase the pathogenic potential of a recipient strain.

Plasmid pCVD442 is an ampicillin resistant, RP4-based replicon and can only be maintained in strains containing the pir gene. It lacks most of the genes necessary for its mobilisation and thus, will neither replicate nor be mobilised unless the strain harbours another RP4-based plasmid, which could complement the deficiencies in pCVD442. This plasmid also contains the sacB gene from Bacillus subtilis, conferring toxicity to the bacteria in the presence of sucrose. This will have no harmful effect upon animal hosts.

There is no reason to believe that strains harbouring pWKS30-derivatives expressing nucleoid-associated proteins will be more hazardous than the original wild-type strain. Indeed, over-expression of nucleoid-associated proteins frequently reduces fitness and growth rate. It has not been previously reported that cloning and increasing the copy-number of genes encoding nucleoid-associated proteins enhances the virulence of pathogens. Indeed, we have previously shown that increasing the copy number of fis actually represses the expression of certain virulence genes (see preprint supplied).

The mutants defective for any of the nucleoid-associated DNA-binding proteins will be, at best, attenuated for virulence and at worst, equivalent to wild-type. Although H-NS acts a repressor of virulence gene expression, the consequent derepression of several virulence factors in the hns mutant will not enhance the organisms' pathogenic potential as it has already been previously shown that such mutants are avirulent in animal models. This is believed to be largely due to the inability of the mutants to respond appropriately to the environmental stresses that are encountered in the host. Moreover, because these organisms tend to express some of their virulence determinants inappropriately, they alert the host of their presence, enabling the host to mount an early response. For this reason, we will be investigating the possibility of using these strains for the development of vaccines. Since these proteins are required by the bacteria to assist in adapting to environmental changes and stresses, these strains should have a selective disadvantage.

The mutants will contain kanamycin and/or chloramphenicol resistance genes; these are not the drugs of choice for the treatment of infections by these infectious agents and thus would present no selective advantage in the event of an accidental release. Complementation of the mutants with pWKS30-derived plasmids encoding ampicillin resistance would similarly not present a selective advantage. Likewise, ampicillin is not the choice of antibiotic for the treatment of such infections.

All in vitro work will involve standard laboratory procedures at small scale. Given the level 2 containment and control measures, it is unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory.
Transmission to laboratory personnel is most likely via the oral route. Good laboratory practice and implementation of the recommendations outlined in Schedule 8 will minimise risks. This will include restricting access to authorised workers, ensuring that all areas that have been in contact with potentially hazardous microorganisms will be routinely swabbed with a recommended disinfectant, no laboratory clothing will be allowed outside the laboratory and all outdoor clothing will be stored in offices. All contaminated waste will be autoclaved and/or incinerated.

Highly qualified staff, in special category 2 containment animal research facilities, will conduct all in vivo work involving animals. Once infected, the animals will not be moved from the designated area until the end of the experiment. At the end of the experiment, the animals will be dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to the laboratory for further processing. The remains of the animals and any material in contact with the infected animals will be autoclaved and incinerated. This approach reflects "best practice" used at the Cambridge University Veterinary School, the Hammmersmith Hospital, London and the Veterinary Laboratory Agency, Weybridge.

Salmonella is pathogenic to animals and humans, although it causes only limited gastro-intestinal infection in health individuals. Therefore, the consequence of hazard is restricted.

The Salmonella strains containing the promoter-gfp fusions are anticipated to have virulence characteristics close to wild-type levels. Introduction of the fusions are not expected to enhance the virulence properties of these strains because they only contain virulence gene promoters, not the entire structural genes.

S. enterica serovars Typhimurium and Enteritidis, EPEC and E. coli 0157 VT are classed as ACDP group 2 organisms. It is considered that the GMM strains resulting from our work will not be more pathogenic than the wild type. This would indicate a biological hazards group 2 for all strains, requiring containing level 2 precautions and hence a provisional classification of Class 2. The above precautions will reduce the likelihood of a hazardous event to negligible levels. Thus, the overall risk is effectively zero given the proposed containment and control measures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8.

All in vivo work involving mice will be conducted in special category 2 containment animal research facilities. Once infected, the animals will not be moved from the designated area until the end of the experiment. During experiments, animal waste and bedding will be autoclaved before being incinerated. At the end of the experiment, the animals will be dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to the laboratory for further processing. The whole cage will be autoclaved; its contents will be autoclaved and incinerated. The remains of the animals will subsequently be incinerated. This approach reflects "best practice" used at the Cambridge University Veterinary School, Hammersmith Hospital, London and Veterinary Laboratory Agency, Weybridge.

All contaminated plastic ware is to be either incinerated directly, or following an overnight soak in 5% Hycolin disinfectant. Items will be double-bagged for transport to the incinerator. A firm registered with the HSE as being a licensed hazardous waste incinerator will collect hazardous waste weekly.

All other items, including vessels containing small culture volumes (up to 100 ml) will be placed in lidded steel buckets for autoclaving. The autoclave for waste has a chart recorder for monitoring load and drain temperature. It is services quarterly and inspected for accuracy annually.

Both incineration and autoclave procedures are expected to give a 100% kill of all GMMs.
The original version of the risk assessment submitted to the committee lacked information on the VTEC E.coli strain NCTC12900, (ie exactly how the shiga-like toxin was no longer produced); this was supplied at a further assessment meeting (the prophage encoding the toxin is not present).

The GMSC also asked for more details on the regulation of virulence genes by the nucleoid-associated DNA - binding proteins, as the claim was made that mutants of the latter were likely to be attenuated. The modified risk-assessment states that mutations in at least three known members of this family (hns, stpA and fis) have been shown to attenuate virulence in Salmonella, and a mutation in fis markedly attenuates virulence in the EPEC strain of E.coli.

Finally, maps of the key plasmid vectors to be used were requested.

PROJECT TITLED USE OF ADENOVIRUS TO EXPRESS TIMP’S IN A MURINE ARTHRITIS MODEL

Class 2

Consent Granted not applicable

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

The purpose of this project is to test the efficacy of tissue inhibitors of metalloproteinases (TIMPs) in a murine model of arthritis (collagen-induced arthritis). Delivery will be by intraarticular injection of a recombinant adenovirus expressing either TIMP-1 or TIMP-2. Early experiments will use virus expressing β-galactosidase as a marker to range find for dose and length of expression. TIMPs are inhibitors of the matrix metalloproteinase (MMP) family of enzymes. These enzymes, and particularly those that have collagenolytic activity, are strongly implicated in cartilage destruction in both osteo- and rheumatoid arthritis.

Recipient or parental organism

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (McGrory, W. J. Bautista, D. S and Graham, F. L: A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target infected cells. It is generally accepted that the adenovirus will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenavirus will pose less of a threat once in the animal than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

Host/vector system

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans), replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr Frank Graham (McGrory, W J Bautista, D. S and Graham, F L: A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. All transgenes have been constructed from full length TIMP cDNAs obtained from other research institutes and verified prior to subcloning into the relevant vectors.
Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the adenovirus will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the animal than most expression vectors as they will definitely not replicate or integrate into the host genome.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during aliquotting, or diluting replication-defective adenoviruses, all solid waste (plastics etc) is autoclaved prior to disposal. All liquid waste is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.

ANALYSIS OF EFFECT ON STREPTOCOCUS PNEUMONIAE VIABILITY FOLLOWING INDUCTION OF THEIR BACTERIAL APOPTOTIC SYSTEMS (TOXIN/ANTI-TOXIN SYSTEM & IDENTIFICATION OF THE BACTERIAL CELLULAR TARGETS)

Streptococcus pneumoniae is an ADCP group 2 pathogen.

Recipient or parental organism
Streptococcus pneumoniae R61 strain is a non capsulated strain and research has shown this strain to be non pathogenic in mice. Using homologous recombination the chromosomal relB gene has been deleted and replaced by a chloramphenicol resistance gene. The BAS relE type toxin gene(s) are cloned in the non-mobilisable S. pneumoniae plasmid vector, pLS1 (Nieto et al 2000, Plasmid 43,205-213), originally derived from the S. agalactiae natural replilicon pMV158. The plasmid vector pLS1 contains a gene for erythromycin resistance.

Origin & function
The RelE type BAS toxin gene(s) from S. pneumoniae strain R61 were cloned into the plasmid vector pLS1 by our EU project partners in Spain. The toxin gene9s) are under the control of the MalR gene and are inducible by the addition of maltose to the media. Induction of the BAS toxin genes has been demonstrated to reduce bacterial host viability. Following maltose induction of S. pneumoniae R61 containing the plasmid borne BAS toxin genes, culture samples will be taken at specific time points over a period of several hours. At the time of sampling the bacterial culture aliquots will be mixed immediately with a chilled solution of ethanol/phenol. This procedure has previously been demonstrated to kill S. pneumoniae. The cell material will be stored at -80°C until required for RNA or protein isolation prior to microarray or proteomic analysis.

Project notified under transitional arrangements N
analysis. The cellular target of the toxins will be identified using biophysical, immunological and biochemical techniques.

**Evaluation of foreseeable effects**

Streptococcus pneumoniae R61 strain is a non capsulated strain and research has shown this strain to be non pathogenic in mice. Using homologous recombination the chromosomal relB gene has been deleted and replaced by a chloramphenicol resistance gene. The presence of the chloramphenicol resistance does not necessarily increase the hazard level as third generation cephalosporins and alternative antibiotics are typically used to treat human infections. Precautions will be taken to prevent accidental ingestion or inhalation of the bacteria, containment will be provided by the use of a Class II cabinet for handling of all S. pneumoniae strains. When centrifugation is required, aerosol retaining caps will be used. After centrifugation the centrifuge vials will be opened in the Biological Safety Cabinet.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8. All contaminated plastic waste and small culture volumes will be placed into autoclave bags contained within lidded polypropylene buckets and autoclaved prior to incineration of the contents. All contaminated glassware will be autoclaved in lidded steel buckets. The larger volumes of culture media supernatant, generated during the time course experiments and containing ethanol/phenol mix are not suitable for autoclaving. However treatment of the samples with ethanol/phenol solution has been demonstrated locally to kill S. pneumoniae. The treated culture supernatant will be dealt with as toxic chemical waste.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N

The committee accepted the risk assessment for the project work involving streptococcus pneumoniae, and suggested the proposal include any potential future work (e.g. the generation of gene mutations and the production of overexpressing strains), that may be undertaken on the material described in the proposal. However due to financial and time constraints the proposer thought it highly unlikely that further work would be undertaken.

**Project Containment**
**Project Additional Information**

**Purposes of the contained use**

Microarray experiments will be performed upon Shigella flexneri, Salmonella enterica (excluding S. Typhi, S. Paratyphi A and S Paratyphi B) and category II pathogenic strains of E. coli to observe how these organisms respond 1) to different environmental conditions and 2) to the presence of a range of mutations. To confirm the results obtained, defined mutations will be made in selected genes and a range of experiments conducted to investigate how the mutants respond to different environmental conditions and in some cases, how virulence is affected, using tissue culture - based techniques and animal models. In most instances, linear fragments of DNA will be integrated into the pathogenic strains, in order to introduce mutations or reporter-gene constructs, together with antibiotic resistance markers. On some occasions, suicide-vectors will be used to introduce mutations into a strain. Mutations or reporter genes will sometimes be moved between strains by generalised transduction. Mutations will be complemented by cloning functional copies of the genes of interest into low copy-number vectors.

Promoters of several genes will be fused to reporter genes, and these constructs will be introduced into a variety of strains either by integration into the bacterial chromosome, or on a low-copy number plasmid. Reporter gene expression will be measured during invasion of cultured mammalian cells and in the tissue of infected animals. Specific mutations affecting regulatory proteins will be introduced into the Salmonella strains harbouring the reporter gene fusions, and their effects upon virulence gene expression determined by assaying the activity of the reporter gene product or by a range of microscopic examinations.
**Recipient or parental organism**

S. enterica (except serovars Typhi, Paratyphi A and Paratyphi B). S. flexneri, category II strains of E. coli such as ETEC and EPEC are classified as group 2 pathogens, as defined by the ACDP. Normally, Escherichia coli 0157:H7 (VTEC) is classified as group 3, requiring more stringent containment conditions. However, the strains that we are proposing to work with, NCTC 12900 and EDL933 either lack the prophage encoding the shiga toxin or have had the toxin genes specifically deleted and therefore satisfy the requirements for consideration as group 2 pathogens. E coli K-12 is classified as ACDP hazard group 1, since this group of strains is not considered pathogenic and is not expected to survive in the environment due to having several auxotrophic requirements.

**Host/vector system**

We will be employing a range of plasmids and vectors, many being based upon the pUC family and are designated as disabled. As such, these vectors are non-mobilisable.

To construct some mutants, we will utilise suicide vectors based upon plasmid pCVF442 (Donnenberg and Kaper (1991) to perform allelic exchange. This vector is based upon an ampicillin resistant, RP4 - replicon and can only replicate in strains containing the pir gene. It lacks most of the genes necessary for its mobilisation and thus, with neither replicate nor be mobilised unless the strain harbours another RP4-based plasmid which could complement the deficiencies of pCVD442. This plasmid also contains the sacB gene from Bacillus subtilis, conferring toxicity to bacteria in the presence of sucrose. This will have no harmful effect upon an animal host.

Construction of most of our bacterial mutants will utilise a non-cloning strategy (Datsenko and Wanner, 2000). We will transform S. enterica, E. coli and S. flexneri with linear fragments of DNA, generated by PCR, containing the mutated allele/reporter-gene construct, flanked by two FRT recombinase sites and ~50bp DNA homologous to the sequences either side of the target gene(s). The linear DNA fragments will contain a selectable marker (kanamycin or chloramphenicol resistance). During the mutagenesis procedure, this strain will be harbouring an oriR101-based temperature-sensitive plasmid (pKD46) encoding Red recombinase under the control of the tightly regulated arabinose-inducible ParA promoter. The plasmids also encode ampicillin and/or chloramphenicol resistance and araC. The use of an arabinose-inducible recombinase and proteins (required to inactivate the host's RecBC exibyckease V system) avoids unwanted recombinatorial events under non-inducing conditions, allowing efficient recombination of the linear DNA fragments into the host chromosome. The plasmid also encodes a temperature-sensitive RepA protein, only allowing replication of the plasmid at temperatures up to 30 degrees C. None of the genes encoded by the plasmid are considered likely to enhance the virulence of the strains harbouring them. The 50 bp of DNA sequence designed to permit homologous recombination into the host chromosome are too short to encode any functional genes, are identical to the normal sequence of chromosomal DNA and will therefore not affect the virulence of the strain.

Once the gene of interest has been successfully replaced by the antibiotic resistance marker, if desired, the marker can be excised to leave a clean deletion. This achieved by transforming the strain with another temperature-sensitive plasmid, pCP20, encoding a flip-recombinase that deletes the DNA sequence between the two FRT sites (Datsenko and Wanner, 2000). Like the Red recombinase, the flip-recombinase is induced by the addition of arabinose to the culture medium. The plasmid is easily eliminated from the host strain by incubating at 37 degrees C. None of the gene products encoded by pCP20 are considered likely to affect the virulence of the host strain.

To complement the mutant phenotypes, we will be cloning wild-type copies of the gene(s) of interest into single/low-copy-number cloning vectors. These plasmids are non-transmissible and are intended to mimic the conditions within the wild-type background i.e to simply replace the missing gene functions within the strain. Cloning genes into these vectors will in some cases raise the number of copies of these genes. However, the increase in gene dosage would be modest and is considered unlikely to significantly alter the virulence properties of the host strain.

On occasions, we will use expression vectors that use a variety of inducers such as arabinose or isopropyl-B-D-thiogalactopyranoside (IPTG) to induce en of the cloned gene of interest. In the absence of the inducer, expression of the cloned gene is normally undetectable. These vectors are designed to give moderate levels of expression following induction. The copy number of the plasmids is low to medium and these vectors lack mobilisation functions.

**Origin & function**

All genetic material will derive from the strains listed above, or from the vectors/reporter genes described. The overall intended function of manipulations in all experiments is to study the regulation of virulence in these strains. In all cases, genes of interest will be mutated, or their promoters will be fused to reporter genes.
We will be performing detailed phenotypic analyses to determine the consequences of the mutations. We will perform in vitro tissue-culture-based assays to study the interactions of the wild-type and mutant strains with cultured cell lines, isolate RNA from the bacteria to measure gene expression by micro array and other RNA-based techniques, and use protein-based techniques such as SDS-PAGE and Western blotting to confirm results obtained by RNA analysis. In addition, we will perform in vivo assays in mouse models to 1) compare the virulence of different mutants, 2) measure gene expression using reporter genes fused to promoters of selected genes and 3) extract the bacteria from different organs to isolate and purify the bacterial RNA for microarray analysis.

**Evaluation of foreseeable effects**

Many genes in *S. flexneri, S. enterica* and *E. coli* encode proteins of unknown function. Microarray analysis enables us to identify many of these genes that may be expressed under specific conditions. We anticipate that whilst some mutants will retain virulence characteristics close to the parental strain, many will display attenuated phenotypes. Since all work will be formed under class 2 conditions that are already deemed satisfactory for the handling of the wild-type strains, it is therefore considered that no additional risk is likely to be posed by the mutants derived from these strains.

Plasmids pKD46 and their derivatives cannot replicate at 37 degrees C. Following ingestion of the bacteria by a mammalian host, the plasmid will eventually be lost. Apart from pCVD442, none of the plasmids that we are proposing to work with contain genes that would enable mobilisation into another strain. Plasmid pCVD442 and its derivatives lack most of the genes necessary for their conjugal transfer. The plasmids also lack the pir gene necessary for their replication and would thus be rapidly lost if acquired by another strain. Whilst the theoretical possibility exists, that the plasmids could be acquired by bacteria in the gut harbouring functional RP4-based plasmids, which would permit replication of pCVD442 and its derivatives, there will be nothing cloned into the plasmids that would enhance the virulence properties of the strain.

The antibiotic-resistance genes that we will be using encode resistance to kanamycin, chloramphenicol, tetracycline, ampicillin/carbenicillin and occasionally gentamycin. Since these antibiotics are not the drugs of choice by clinicians for the treatment of infections by these infectious agents, the presence of these resistance genes within the strains would not present a selective advantage in the event of an accidental release.

The salmonella strains containing promoter-reporter-gene fusions are anticipated to have virulence characteristics close to wild-type levels. Introduction of the fusions will not enhance the virulence properties of these strains because they only contain virulence gene promoters fused to well-characterised proteins/enzymes, known to catalyse specific, assayable, biochemical reactions. When assaying the reporter enzymes, a cell lysate will be prepared from the strains and will not contain viable organisms that could be accidentally released.

All in vitro work will involve standard laboratory procedures at small scale. Given the level 2 containment and control measures, it is unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory.

Transmission to laboratory personnel is most likely via the oral route. Good laboratory practice and implementation of the recommendations outlined in Schedule 8 will minimise risks. This will include restricting access to authorised workers, ensuring that all areas that have been in contact with potentially hazardous microorganisms will be routinely swabbed with a recommended disinfectant, no laboratory clothing will be allowed outside the laboratory and all outdoor clothing will be stored in offices. All contaminated waste will be autoclaved prior to leaving the site and incinerated by authorised contractors.

All in vivo work involving mice will be conducted in special category 2 containment animal research facilities. Once infected, the mice will not be moved from the designated area until the end of the experiment. At the end of the experiment, the mice will be humanely killed and then dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to the laboratory for further processing. The remains of the animals and any materials in contact with the infected animals will be autoclaved and incinerated. This approach reflects "best practice" used at the Cambridge University Veterinary School and the Hammersmith Hospital, London.

Culture of mammalian cells will be prepared in a dedicated tissue culture incubator in a Category 2 pathogen laboratory. Bacterial cultures will be grown in approved Category 2 pathogen laboratories. Once the mammalian cells are infected with Salmonella strains, they are to be considered as class 2 hazardous material and the containers in which they are grown will only be opened in Category 2 containment laboratories for further processing. The tissue-culture plates containing the hazardous material will be transported between the tissue-culture incubator and other Class II laboratories in sealed containers. Lysis of cultured mammalian cells harbouring
Intracellular Salmonella cells will be quickly transferred to sealed tubes for bacterial cell harvest. Tissue culture and bacterial culture waste will be collected in appropriate bags/containers and autoclaved prior to incineration.

The above precautions will reduce the likelihood of a hazardous event to negligible levels. Thus, the overall risk is effectively zero given the proposed containment and control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8.

All in vivo work involving mice will be conducted in special category 2 containment animal research facilities. Once infected, the animals will not be moved from the designated area until the end of the experiment. During experiments, animal waste and bedding will be autoclaved before being incinerated. At the end of the experiment, the animals will be dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to the laboratory for further processing. The whole case will be autoclaved; its contents will be autoclaved and incinerated. The remains of the animals will subsequently be incinerated. This approach reflects "best practice" used at the Cambridge University Veterinary School, Hammersmith Hospital, London and Veterinary Laboratory Agency, Weybridge.

All contaminated plastic ware is to be either incinerated directly, or following an overnight soak in 5% Hycolin disinfectant. Items will be double-bagged for transport to the incinerator. A firm registered with the HSE as being licensed hazardous waste incinerator will collect hazardous waste weekly.

All other items, including vessels containing small culture volumes (up to 200 ml) will be placed in lidded steel buckets for autoclaving. The autoclave for waste has a chart recorder for monitoring load and drain temperatures. It is services quarterly and inspected for accuracy annually.

Both incineration and autoclave procedures are expected to give a 100% kill of all GMMs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This notification arose as a result of submitting internal Risk Assessment amendments to the local GMSC, which we assumed would be covered by our original class 2 notification to the HSE (GM 155/01.5 'Regulatory mechanism affecting virulence in Salmonella enterica serovars typhimurium and enteriditis, enteropathogenic E. coli and E. coli 0157:H7 VT, by nucleoid proteins').

However, the GMSC advised us that

1) analysis of genes that are not directly connected to virulence,
2) the construction of any mutants in these micro-organisms, and
3) the use of any reporter gene other than GFP, constituted a significant change in the direction of the research project. We were therefore obliged to submit this document as a new notification.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The complex microbiota of the gastro-intestinal tract plays a vital role in human health but its analysis by conventional microbiology is hampered by the fact that many bacterial components are difficult to culture or currently unculturable. Metagenomics offers an alternative molecular approach based on the analysis of genomic DNA extracted from the entire complex microbial community. This can be used to make clone libraries to be screened for specific sequences (by PCR and hybridisation) or functional properties. Conventionally E. coli is used as a background host for metagenomic libraries and we will make libraries with E. coli fosmids. However the main purpose of this study is to investigate the use of the Gram positive bacteria Lactococcus lactis and Lactobacillus as background hosts. We will develop the genetic tools for library construction in Lactococcus lactis and Lactobacillus. The metagenomic libraries generated will NOT be expression libraries with cloned genes expressed from a plasmid derived promoter. Expression will be from the native cloned promoter and relies on its compatibility with the transcription/translation machinery of the background host bacteria.

Metagenomic libraries derived from GI tract bacteria will be subject to a series of functional screens to identify genes that are relevant to microbiota dynamics and/or the role of the microbiota in the maintenance of health. Specific targets could include antimicrobial compounds and enzymes involved in microbial catabolism and transformation of glycosyl and glucuronyl conjugates of dietary phytochemicals. They are involved in human health maintenance but many conjugates are only active when released from their bound form in the diet by the action of gut bacteria.

**Recipient or parental organism**

E. coli 1(12 and derivatives, Lactococcus lactis MG 1363 and Lactobacillus and their derivative strains including mutants. E. coli K12 is compromised and it is unable to colonise the human gut. Lactococcus lactis and Lactobacillus are recognised as Generally Regarded As Safe (GRAS) organisms. Lactococcus lactis MG 1363 does not colonise the gut but passes through as a transient component of the microflora. The colonising ability of Lactobacillus is dependent on the species and strain used. (continued on additional comments sheet)

**Host/vector system**

Hosts will be the bacterial species described above. The vectors include E. coli fosmid and cosmid systems available commercially and a pLP712 derived vector system for use in Lactococcus. If an alternative vector was required for library construction in Lactobacillus this could be based on native plasmids or the broad host range pAMBI vector. The vector systems that we have chosen to use are NOT expression vectors. Expression of cloned genes will be reliant on their own promoter activity and compatibility with the transcription and translation machinery of the host.

**Origin & function**

icDNormetagenomic libraries will be sourced from both specific individual strains (1) and mixtures (2).

1. Specific individual strains Individual cultivated bacterial species will be obtained from the IFR or Rowett culture collections or other strain collections including commercial type strains. These strains will have been characterised to different extents ranging from primary isolation and cultivation from faecal samples up to and including the availability of full genome sequence information. We are unlikely to want to make a clone library of a known pathogenic strain. 2. DNA fragments directly from uncultured gut bacteria to generate library of GI tract bacteria DNA for library construction will be isolated from a variety of samples as appropriate :-

   a. Animal faecal samples (mice, pig, chicken, turkey)
   These samples may be collected from healthy animals or animals previously inoculated with lactic acid bacteria, commensal bacteria or infected with pathogens (eg. Salmonella, Clostridia). This will include gnotobiotic mice (germ-free) inoculated with selected organisms and mice with a defined gut flora.

   b. Human faecal samples (healthy and unhealthy)
   Healthy humans (absence of identified clinical symptoms) and human volunteers taking part in the study of gut disorders in both active and remission states (IBS, IBD, Crohn’s disease, diarrhoea). Faecal samples will be provided, stored and used as agreed with the Human Ethics Committee and the in-house IFR Code of Practice for
work with Biological Samples.
c. Samples taken from the in vitro colonic gut model.
The in vitro colonic gut model comprises a closed 3 vessel fermentor system that mimics the human colon. It is inoculated with fresh faecal material and the bacterial population stabilises. This gut model system is then maintained as a “control” or exposed to an environmental change by addition of another bacterial species or media component.
Samples taken from the gut model will be used as the source of the genomic DNA for library construction.
Screening of libraries can be sequence based and utilise PCR and hybridisation to identify homologues of known proteins. In no case will this be for genes that include functions that are thought to be potentially harmful (eg. toxin genes). Our primary aim is to use function based screening incorporating a) Activity based selection for antibiotic and bacteriocin resistance, b) Enzyme screening methods utilizing colour and fluorescence assays (eg. CMCase carboxymethyl cellulase activity) and possibly c) Antibodies specific for known proteins to detect protein expression. These approaches will be used to screen the metagenomic libraries for other genes beside those already mentioned. Lactococcus, Lactobacillus and E.coli are non pathogenic and classed as ACDP group 1 organisms. Due to the possibilities of cloning detrimental genes as described elsewhere the GMMs should be placed in a higher category (Class II) and the metagenomic library strains will be handled under category 2 laboratory conditions.

Origins and intended functions of genetic material involved
One potential problem with a metagenomic library is the scarcity of clones. We will increase our chances of finding a particular clone by the selection of active clones by activity or complementation. If the library is transformed into a mutant strain we can select for a particular activity. Selection is more efficient than screening. Alternatively, we may enrich the genomic DNA prior to library construction. Methods available include % CC DNA fractionation and enrichment for the metabolically active bacteria (growth on xenobiotics, sugars etc., stable isotope labelling with 13C (SIP) or 5-bromo-2-deoxyuridine BrdU to label DNA).

Evaluation of foreseeable effects
From a mixture of faecal bacteria we run the risk of cloning known and unknown genes which can be harmless or harmful. Potential detrimental genes include toxins, virulence and bacteriophage genes and viruses (human and animal dependent on DNA source).

The aim of these metagenomic libraries is to isolate large fragments of genomic DNA and the level of risk will vary with the source of the genomic DNA used for metagenomic cloning. In the absence of cloning biases, the frequency with which genes will be present in the metagenomic library is a reflection of their prevalence in the starting material. Relatively uncommon pathogenic bacteria are unlikely to be represented within the library whereas abundant bacteria will be well represented. However even the healthy gut (human or animal) as defined by the lack of defined clinical symptoms is a potential source of pathogenic bacteria and hence genes. In the case of animals infected with pathogens or human subjects with gut disorders the relative percentage of potentially harmful bacteria may be higher so the likelihood of cloning deleterious genes will also increase. However virulence is often multifactorial and is unlikely to be cloned in its entirety on one plasmid and be active in the library host.

Where we are cloning the genome of an individual strain the amount of prior information or characterisation available will vary. Within a metagenomic library the individual plasmids will be extremely varied so it is impossible to predict the characteristics of any given GMM.

Exact foreseeable effects are hard to determine as would be the case in the cultivation of faecal bacteria under appropriate conditions and media. Within a metagenomic library the individual plasmids will be extremely varied so it is impossible to predict the characteristics of any given GMO.

For all these reasons the gut metagenomic libraries will be cultivated under category 2 laboratory conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC required confirmation that the activity screens rely on successful promoter and transcription/translation control in the library host, but also on having all the necessary processing and transport/secretrion mechanisms as well. We are looking to capitalize on the ability of Lactococcus to express heterologous genes that come from other low GC Gram positive bacteria (eg. Firmicutes) and have no plans to use expression vectors in the future. The committee felt that It is quite likely that faecal samples will contain some bacteria with potentially harmful genes and are happy that we are assessing the probability of hazard. However the chance of producing a virulent GMM is unlikely as this would require the heterologous expression of many different genes. As we are using a system built on a native lactococcal plasmid with a cos site we are limited to DNA fragments of around 50-60kb and this will be maintained at the relatively low copy number of the parent plasmid. Although different strains/species of Lactobacilli display different gut colonisation abilities, they will all have GRAS status and many of them will be probiotic strains. The genetic modification safety committee agreed with the assessment of this research as Class 2.

02/03/2022
The activity involves the introduction of reporter gene and knock out mutant complementation sequences into a conserved pseudogene in Campylobacter jejuni using suicide vectors.

Recipient or parental organism

Campylobacter jejuni is a ACDP class II pathogen. The expression of reporter genes in this will not alter the hazard associated with this organism. Expression of genes complementing existing knock out mutants should merely restore the wild type phenotype.

Host/vector system

The suicide vectors are constructed in Ecoli K12 using pUCI8 derived plasmids

Origin & function

The suicide vectors contain flanking sequences derived from the Campylobacter pseudogene to allow homologous recombination to occur and commonly used antibiotic resistance marker genes to allow selection of transformants. The reporter genes to be inserted are:

- Green fluorescent protein (gfp) from Aequorea victoria
- Beta-Galactosidase (B-Gal) from E.coli
- Beta-Glucuronidase (GusA) from E.coli

The promoters used to control the expression of genes complementing knock out mutants will either be the native promoter associated with the gene to be complemented or Campylobacter derived sequences with known levels of expression.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Appropriate disinfection and waste management procedures will be carried out in accordance with Schedule 8. Good Microbiological Practice (GMP) and the in-house Code of Practice for Biological Waste Disposal will be followed. All biological waste including GMO waste is double bagged, collected from the laboratories and autoclaved. Following autoclaving, the bags are sealed prior to transport to the incinerator. Hazardous waste is collected weekly by a firm registered with the HSE as a licensed waste incinerator. All other items, including small culture volumes (up to 200ml) are placed in lidded steel buckets for autoclaving. All contaminated plasticware and solid media is bagged with the rest of the biological waste, autoclaved then incinerated as described above. Where plasticware is to be used again (eg. some centrifuge tubes and pots) it is soaked in chlorine-based detergent at an appropriate concentration overnight after which it is washed up. The autoclave is used exclusively for waste and has a chart recorder for monitoring load and drain temperatures. Additional indicator strips are put in with each load and checked at the end of every autoclave run. The autoclave is serviced quarterly and inspected for accuracy annually. Both autoclave and incineration procedures are expected to give an 100% kill of all GMMs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC had few comments about the risk assessment, concerning the prevalence of the pseudogene target in other Campylobacter strains, for which there is little or no evidence, and a request for further details of the pseudogene target with regards to possible problems with transcription read through. Both of these issues were addressed in the final approved risk assessment.

Project Ref 155/08.3
The aim of the research is to determine how microbial pathogens invade the body and in particular the routes they take to cross boundary cells that line tissues exposed to the environment. For example, epithelial and endothelial cells that line the gastrointestinal tract and blood vessels, respectively, act as barrier cells to pathogen invasion. Using model pathogens genetically engineered to express reporter genes allows them to be "visualised" by for example, microscopy so that we can track and define their migration in living cells and tissues.

Microorganisms used will be representative of enteric pathogens (Salmonella typhimurium, campylobacter jejuni, Toxoplasma gondii) and systemic pathogens (listeria monocytogenes) engineered to express chemiluminescent (e.g luciferease) or fluorescent (e.g green/yellow and flavin mononucleotide-based fluorescent proteins) reporter genes. The reporter genes have no known effect on virulence and the GM forms will be no more harmful than parental strains.

Origin & function
The reporter genes are derived from diverse species including the firefly( luciferease), sea pansy (renilla luciferease), click beetle (fluorescent proteins), bacteria (e.g bacillus subtilis and pseudomonanas puida as sources of flavin mononucleotide-based fluorescent proteins and Vibio spp. For luciferease), algae (fluorescent proteins) and jelly fish (GFP-YFP). In the event that additional fluorescent genes (e.g Blue light photosensor (LOV) genes) are inserted into these backgrounds the IFR GMSC will assess any amendment. The genes encoding these reporter proteins which are invariably single polypeptides have been cloned and the coding sequences optimised for expression in bacteria,
The committee had some questions specially related to the Toxoplasma.
1. Will you just be using the asexual forms, tachyzoites and bradyzoites? How do you propagate your stocks in tissue culture?
2. Is toxoplasma a particular risk to pregnant women like Listeria is?
3. Are Toxoplasma gondii oocysts resistant to disinfection with Virkon? Will Toxoplasma never be in this form or is there evidence that Virkon is effective against protozoa in all stages of the life cycle?
Other general questions included classification of transport and conditions of use within special imaging facilities. Also which antibiotic resistance markers were in use?
The GMRAs related to the CU2 were approved following the satisfactory response to the committees comments.

### Project Additional Information

**Purposes of the contained use**

Defining the molecular mechanisms underlying the interactions of intestinal Bacteroides ssp. with the host and with other members of the gut microbiota and development of commensal bacteria as heterologous expression hosts.

**Purpose of research:**

Our overall aim is to develop or use established genetic tools to study the physiology of gut commensal bacteria with a particular interest in their relationship and interactions with the host. Furthermore, we would like to develop these gut commensals into heterologous expression hosts. This work will involve the expression of heterologous genes and operons (e.g., bacterial such as sseB from Salmonella; viral such as synthetic h5f stem form influenza; antigenic protein coding genes from Yersinia such as v1 and caf1 and eukaryotic genes (e.g. microRNAs and cytokine genes)) in both Gram-negative (E. coli, Bacteroides) and Gram-positive (Lactococcus, Bacillus and Lactobacillus) bacteria and the introduction of point mutations or the generation of deletions into several genes of the commensal bacteria.

- **Gene deletion:** using site-directed mutation as well as other mutagenesis strategies. These experiments will be performed with the aim to remove native gene functions that might interfere (regulatory or metabolically) with the successful expression of heterologous genes and biosynthetic gene clusters.
- **Gene insertion:** we will introduce heterologous DNA, both in the form of replicating plasmids as well as stable chromosomal insertions with the aim to identify the
products of the inserted genes and their biological function.

Recipient or parental organism

E. coli (derivatives of K12 and other laboratory strains)
E. coli strains will be used for subcloning during the construction of gene integration vectors, expression vectors or for plasmid isolation. Derivatives of K12 are crippled and will only survive under laboratory conditions. These strains are unlikely to colonise and establish a persistent infection in the gut of a healthy individual. E. coli strains such as DH5α and BL21 do not carry the well-recognized pathogenic mechanisms required by strains of E. coli which cause "the majority of enteric infections" and therefore they are "considered to be non-pathogenic and unlikely to survive in host tissues and cause disease."

Lactobacillus are generally regarded as safe (GRAS) organisms. As natural residents of the gut they should be considered to have the potential for colonisation. All of the strains mentioned are obtained from strain collections and have been characterised by others.

Lactococcus lactis (derivatives of MG1363)
Lactococcus lactis is a generally regarded as safe (GRAS) organism used in food and feed fermentation. Lactococcal strains in use for this project will include derivatives of L. lactis MG1363 including strain UKLC10 in which the nisR and nisK regulatory genes of the nisin operon have been inserted in the bacterial chromosome. This enables nisin regulated control of heterologous genes under the control of the nisA promoter in expression vectors such as pUK200. In addition UKLC10 was engineered to be a peptidase-deficient mutant of MG1363.

Lactobacillus isolates of GI tract origin (human or animal).
Lactobacillus are generally regarded as safe (GRAS) organisms. As natural residents of the gut they should be considered to have the potential for colonisation. Strains used will be type strains of these organisms (e.g. Lb. gasseri NCIMB 11718) and/or isolates of GI tract origin (human and animal, held in the IFR collection) and may include Lb. Johnsonii F19785.

Bacillus subtilis is not a human pathogen, nor is it toxigenic like some other members of the genus. The virulence characteristics of the microorganism are low. According to Edberg (1991) either the number of microorganisms challenging the individual must be very high or the immune status of the individual very low in order for infection with B. subtilis to occur. This microorganism also falls under the Class 1 Containment under the European Federation of Biotechnology guidelines.

L. lactis (derivatives of MG1363), laboratory strains of E. coli (derivatives of K12), B. subtilis and Lactobacillus isolates of GI tract origin (human or animal) are all classified as ACDP Hazard Group 1.

Bacteroides
The Bacteroides spp. used in this study are commensal in the colon and as such should be considered to have the ability to colonise. The characteristic of this genus is that its members are anaerobes. They occur in the alimentary tract of humans and animals. These organisms are classified by ACDP as Hazard Group 2 but are generally considered non-pathogenic and have generally not been shown to have any toxic or allergenic properties. Exception is represented by some strains of Bacteroides fragilis that have been associated with wound infections, especially after surgery. Several B. fragilis virulence factors have been shown to be implicated in the development of these infections. This work will be carried out under Class II conditions.

Host/vector system

E. coli: colE1, pACYC, R↓Δori, pBBR1, pSC105
The pCR2.1 and TA type systems for the cloning of PCR fragments into E.coli are commercially available and the associated plasmids are non-mobilisable.

Lactococcus: pSH71, pWV01, pGhost, pAM↓1, pOrI,

Lactobacillus: Plasmids will be based in the replicons, listed in the Lactococcus section above, that replicate in Lactobacillus. In addition, this work will take advantage of
vectors based on intrinsic lactobacillus plasmids (e.g. p9785S and p9785L from Lactobacillus johnsonii FI9785) including the derivative expression plasmid pFI2560.

Plasmids may carry one or more of the following resistance genes: chloramphenicol (cmR), erythromycin (emR), ampicillin (ampR), kanamycin (kanR), spectinomycin (spcR), trimethoprim and tetracycline (tetR).

Additional genes may be present on some plasmids as part of a controlled expression or integration system.

Bacteroides: Plasmids will be based on Bacteroides replicons as is the case detailed in GM559/05.2. Dependent on the bacterial host these plasmids will be low or high copy for plasmid replication alternatively they could be suicide or temperature/antibiotic permissive selection vectors for chromosomal integration. Promoters will be used to express genes encoding proteins either by inducible (e.g. L. lactis; lac or nisin promoters, Bacteroides; xylanase chromosome. The reporter gene plasmids will be further adapted to act as promoter isolation vectors for the selection of stronger or inducible promoters from chosen bacterial species. Choice of promoters will be by random selection or selected using genome analysis where the genome sequence is available.

Origin & function

Selected genes (e.g. B. thetaiotaomicron lipoprotein genes mini-library, relaxase genes or phosphatase genes) will be cloned into suitable vectors and transformed into the bacterial hosts using standard transformation, electroporation, conjugation or transposon-based methods as appropriate. The decision whether to express the gene on a plasmid or to integrate into the chromosome will be dependent on the strength of expression of the gene i.e. the relative dosage effect. Further development of the system may include the use of a reporter gene for the isolation of stronger and/or inducible promoters. This may lead to the identification of better sites for chromosomal integration strategies.

PCR, splicing and cloning will be used to introduce these genes into appropriate vectors for Bacteroides, E.coli, B. subtilis, L. lactis and Lactobacillus.

Evaluation of foreseeable effects

Bacteroides spp. are generally susceptible to a variety of antibiotics including metronidazole, carbapenems, beta-lactams and chloramphenicol; moreover since they are anaerobic, their environmental survival is expected to be very limited. Lactobacillus spp. are generally susceptible to imipenem, piperacillin-tazobactam, erythromycin and clindamycin. Escherichia spp. are generally susceptible to nitrofurantoin, norfloxacin and gentamycin. Lactococcus lactis is susceptible to erythromycin, chloramphenicol, ciprofloxacin and vancomycin.

All gene products are potentially non-toxic and should not make these GMOs more harmful than the unmodified hosts. However, although most of Bacteroides spp. have generally not been shown to have any toxic effect, there is a low risk that overexpression of some of the proteins could exert some toxicity.

Lactococcus and Lactobacillus are GRAS organisms and the E. coli strains are K12 derivatives for laboratory use. B. subtilis is also routinely used in category 1 sites. The antibiotic resistance genes are all in routine use in other vectors used with these host bacteria. Bacteroides spp. organisms are classified by ACDP as Hazard Group 2 and are generally considered non-pathogenic and have generally not been shown to have any toxic or allergenic properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Bacteroides ssp., B. subtilis, L. lactis, Lactobacillus spp., and E. coli and the GMM’s generated during the study will be handled in accordance with Good Microbiological Practice and the correct Hazard Category. …

Appropriate disinfection and waste management procedures will be carried out in accordance with Good Microbiological Practice (GMP) and the Institute Code of Practice for Biological Waste Disposal will be followed. …

Highly qualified staff, in special category 2 containment animal research facilities, will conduct all in vivo work involving animals. Once infected, the animals will not be moved from the designated area until the end of the experiment. At the end of the experiment, the animals will be dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to the laboratory for further processing. The remains of the animals and any materials in contact with the infected animals will be autoclaved and incinerated. This approach reflects “best practice” used at the Cambridge University Veterinary School, the Hammersmith Hospital, London and the Veterinary Laboratory Agency, Weybridge. …

Initially the RA was considered to be too generic and lacking detail - examples of the types of genes to be investigated were requested.

The committee asked for statements regarding the risks associated with the genes to be investigated to be included.

All of these points were addressed in the final RA

### Project Additional Information

#### Purposes of the contained use

Human opportunistic pathogens, and genetically modified variants of human opportunistic pathogens, are to be used to characterise the lifestyle of said pathogens, in the pursuit of novel strategies for treatment.

#### Recipient or parental organism

The recipient organisms are all Hazard Group 2 human opportunistic pathogens. Such organisms are generally ubiquitous in the environment and/or form part of the human commensal flora, and rarely pose a problem to the immunocompetent. However, these organisms are major nosocomial infections and are a significant cause of morbidity and mortality in the immunocompromised, such as post-surgical patients, chemotherapy patients, the very young and the elderly. Examples of these organisms include: Pseudomonas aeruginosa; Staphylococcus aureus; Enterococcus faecalis; Enterobacter spp.; Acinetobacter baumannii; non-tuberculoid Mycobacterium; Haemophilus influenzae; Klebsiella pneumoniae; and, the Burkholderia cepacia complex.

Initial studies will be performed in laboratory strains of these organism which have been extensively characterised. It will be necessary to validate these findings in clinical isolates. Such isolates often have increased virulence and antimicrobial resistance. Any undertakings with clinical isolates will only be performed when sufficient characterisation has occurred to ensure that any genetic modification does not increase the virulence or significantly decrease the available treatment and disinfection options. All species will be checked against the COSHH and any work will be performed as per the precautions stipulated in that assessment.

Treatment of these organisms is limited due to the high prevalence of multi-drug resistant strains and more effort must be made to further characterise the lifestyles of these organisms so as to develop innovative and effective treatments. The laboratory strain Escherichia coli K12 (and derivatives) is often used as an intermediary, expression or cloning vector for research. They are well characterised and non-pathogenic strains of E.coli and are routinely used in research.

#### Host/vector system

Vectors will be used to introduce homologous recombination, incorporate markers and express proteins. Many vectors...
will be used over the course of this project, however non-conjugative vectors will be used and vector exchange can only be achieved through established laboratory protocols, the use of accessory plasmids, and/or the incorporation of the strain into a conjugative E. coli K12 derivative. Such exchange is therefore extremely unlikely without knowledgeable intervention. Such vectors include (but are not limited to): pGem-T and derivatives; PME based plasmids and derivatives; pUC18/19 and derivatives; pUCP18/19 and derivatives; MiniCTX and derivatives; pME3087 and derivatives; pBlueScript and derivatives; pET and derivatives and pG19 and derivatives. Transposon-based genetic modification will also be used and will include the use of the Tn7 transposon system, the Tn5 transposon system, the Himar transposon, and the Mariner transposon.

E. coli K12 derivatives will be used as intermediaries, donor organisms or protein expression vehicles.

Origin & function

In most cases the host DNA is being altered by deletion and the deleted genes restored under the control of a native, inducible or constitutive promoter. Exogenous genes may be added as a marker or created as a genetic fusion for protein characterisation or localisation. These genes include, antibiotic resistance genes, fluorescent protein genes, luminescent protein genes or, genes for enzymes that catalyse a quantifiable phenotypic change, such as β-galactosidase (lacZ). These genes are very well characterised and are used frequently by those in the art and come from a variety of different sources. Such genes would not convey any selective advantage to the host organism or increase the virulence or pathogenicity of the organism, or significantly alter treatment options.

Evaluation of foreseeable effects

Gene deletions will be made in the host organism. Such deletions will be made in genes involved in virulence and pathogenicity and as such the resulting GMO is expected to be less virulent than the wildtype. The gene defect will be restored by the inclusion of the gene under the control of a native, inducible or constitutive promoter, such that the resulting GMO will have no increased virulence or pathogenicity when compared to the wildtype.

It is possible that an unknown regulatory promotor will be deleted leading to a rise in the overall virulence of the GMO. This is not the aim of this project and such regulatory proteins often require multiple changes or deletions in metabolic pathways to significantly alter the virulence of an organism or increase the resistance of the organism to antimicrobials or disinfection procedures. It is highly unlikely that such a GMO will occur but if it does, the organism will be immediately destroyed.

Genes encoding toxins may be introduced and produced. Individual risk assessments will be carried out on each toxin as and when appropriate. For the purposes of protein expression, these toxins will only be produced by laboratory attenuated bacterial hosts and as such would not survive outside of the carefully controlled laboratory environment. They will only be made on non-conjugative vectors so that the toxin producing gene will not spread to other microorganisms. Wherever possible toxin production will be controlled using inducible promoters so that toxin production can not occur without specialised intervention.

Antibiotic resistance genes will be incorporated for the use as a selection marker for genetically altered strains. Antibiotics resistance genes used as selection markers are for antibiotics not used or not preferred for clinical treatment, such as kanamycin. No GMO will be created that render the organism resistant to current treatment options.

The GM strains generated by this work are extremely unlikely to pose any significant threat to human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No genetically modified plants and animals will be created.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid biological waste will be sterilised by autoclaving at 121 °C for 20 minutes, or 30 minutes for dense loads. Liquid biological waste will be sterilised by autoclaving at 121°C for 20 minutes. Any chemically contaminated biological waste will be sent for incineration by a licenced waste contractor.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Date Project Ceased  02/03/2022
Purposes of the contained use

The aim of the research is to identify how the gut protects the body from invasion and disease caused by bacteria that either normally live in the gut or those that gain entry via contaminated food. Specifically, we will determine the role intestinal epithelial cells play in preventing microbes from invading the body by determining what the consequences of interfering with the expression of genes known to be important in protecting other cells of the body from invasion are on the ability of intestinal epithelial cells to prevent infection by different types of bacteria. A type of virus, Lentivirus, will be used to deliver toxic molecules to epithelial cells that will interfere with the expression of genes involved in microbial defence.

Recipient or parental organism

Lentivirus based vectors have been chosen for this study since of all available gene delivery vehicles they are most suited to the delivery of genes into primary, non-dividing, cells. The vectors to be used are replication defective, HIV-1 based, recombinant lentiviral vectors that can only be generated using a transient triple transfection system. Since all HIV coding sequences have been deleted no viral genes can be transferred to the target cells. Due to the transient and reversible effects of the Lentivirus delivered genes, the final modified cells are expected to be more harmful than the unmodified cells.

Host/vector system

The Lentivirus has been significantly modified for biosafety. Use is made of self-inactivating (SIN) vectors, which prevent promoter activity in the viral 5' LTR in the integrated provirus from in target cells, reducing the probability of insertion activation. To minimise the possibility for homologous recombination, the HIV genome is divided into three parts, cloned into separate expression plasmids and extensively modified. The following modifications have been made to prevent viral replication.

1. Packaging vector lacks both LTRs and has no viral packaging signal (y).
2. The env, tat, rev, vpr, vpu, vif and nef gniral genes have been deleted from the packaging vector.
3. Rev is supplied in trans on a different vector.
4. The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene product.
5. Envelope (VSVG) is expressed on a separate vector.

Relevant references:
Packaging vectors:

Self inactivating LTR:
The inserted synthetic sequences will encode interfering RNA (RNAi) or short hairpin RNA (shRNA) species that will result in reduced or no expression of the target genes (eg NOD2, alkaline phosphatase, B-galactosidase) in intestinal epithelial cells. The effect of the NRAi/shRNA is expected to be transient and non-lethal and will only interfere with the cells ability to produce certain cytokines in response to challenge with infectious and non-infectious stimuli.

Origin & function

Since all HIV coding sequences have been deleted from the Lentivirus vectors to be used no viral genes can be transferred to the target cells. Due to the transient and reversible effects of the Lentivirus delivered genes, the final modified cells are expected to be no more harmful than the unmodified cells.

Evaluation of foreseeable effects

Evaluation of foreseeable effects

Since all HIV coding sequences have been deleted from the Lentivirus vectors to be used no viral genes can be transferred to the target cells. Due to the transient and reversible effects of the Lentivirus delivered genes, the final modified cells are expected to be no more harmful than the unmodified cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

There is very little risk associated with the "escape" of the Lentivirus vectors which alone or in combination cannot produce replication competent virus. Cultured primary intestinal epithelial cells cannot survive outside the culture medium and have a finite life span. (<2 weeks) in vitro. It is expected that Lentivirus-transduced cells will not survive any longer than non-transduced cells (<2 weeks).

The likelihood of the escape of treated cells is remote. Virus-transduced cells are kept in tissue culture incubators in a category 2 designated tissue culture room within a research laboratory to which only authorised laboratory personnel have access. Access to this laboratory is via locked doors that have a coded keypad locking system and access to the tissue culture room within is restricted to designated personnel and is locked when not in use. A Class 2 cabinet to BSEN 12469 specification will be used to contain virus-producing cell lines and vector-transduced cells. Sharps will be eliminated from all aspects of the laboratory work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Routine disinfection will be carried out using 1% Virkon spray.
Liquid waste will be diluted with an equal volume of 2% Virkon and left for a minimum of 16h prior to drain discard.
Solid waste will be disposed of by autoclaving at 121 degrees C followed by incineration.

Historical Significant Changes

Historical Date of Additional Info

Transferred from GM559 October 2008

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

The modified B. ovatus will be used to assess zylan-inducible expression of the genes described in Section 5. Recombinant organisms will then be used in experiments as novel immunotherapies to try and treat and prevent disease.

Recipient or parental organism

B. ovatus is ACDP Hazard Group 2. The final modified organism will be tetracycline resistant. Although a gut commensal, the likelihood of the GMM colonising humans or persisting in the environment is minimal. Expression of the genes described in Section 5 by this organism should not pose a hazard.

Host/vector system

E. coli vector pGEM is non-mobilisable. Vector pBT-2 is an E. coli-Bacteroides mobilisation-defective shuttle vector requiring E. coli strain J53/R751 for transfer. This is a suicide vector in Bacteroides, requiring integration into the genome for maintenance.
E. coli DH5a and J53/R751 are ACDP Hazard Group 1. B. ovatus is Hazard Group 2.

**Origin & function**

The zylanase promoter originates from B. ovatus. They cytokine/growth factor and antagonist genes will be cDNA copies that will be transcribed in a zylan-inducible manner in the final GMM.

**Evaluation of foreseeable effects**

The final GMM will be tetracycline resistant. Expression of genes described in Section 5 should be regulated and the modified organism must compete with resident microflora to colonise. Release of the number of viable organisms required to colonise other animals or humans is unlikely. Survival in the environment is likely to be limited. Expressed gene products are unlikely to be produced in large enough quantities to have a significant effect on humans. The modified organism should pose no greater hazard than the wild type.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All pipette tips, slides and small disposable plasticware will be disposed of in discard pots containing 2% (v/v) Tego prior to being autoclaved and discarded.
All waste cultures, media and larger plasticware will be autoclaved prior to discarding.
All glassware will be autoclaved before being washed and returned for use.
Sharps will be disposed of in a cin bin which will then be autoclaved and incinerated.
All culture spills will be mopped up with Trigene and tissue that will then be autoclaved prior to discarding.
No viable GMMs will be left after treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

Following consideration of this application by the Microbiology GM Safety Committee at its meeting on 16 August 2004, the Committee requested some very minor, mostly typographical changes to be made. These changes have been completed to the satisfaction of the BSO.

**Project Additional Information**

02/03/2022
### Purposes of the contained use

To protect laboratory works and the environment from any potential harm.

### Recipient or parental organism

Cultured mammalian cells. These are characterised cell lines with strict growth and temperature requirements and will be incapable of growth outside the culture flask.

### Host/vector system

Different retroviral vectors will be used with a range of selectable markers. In all cases the vectors are non-mobilisable ie defective for replication with no gag, pol or envelope genes. Expression of the inserts is not expected to be harmful since they are expressed in normal human cells.

### Origin & function

The repair/checkpoint genes encode proteins known to function in damage response pathways. The genes may contain mutations engineered into them.

### Evaluation of foreseeable effects

The human genes are not harmful and are non-oncogenic. Packaging lines are non-mobilisable. Expression not expected to be harmful since they are expressed in normal human cells. Human cells, to which they will be transferred, have strict growth requirements and are incapable of growth outside the culture vessel. Therefore, risk to the environment and laboratory workers is negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be destroyed using Virkon. Disposable plastics destroyed by autoclaving. See attached risk assessment for further validation. Virkon has been shown to be effective against retroviruses and we consider will inactivate our low litres.

### Project Additional Information

#### Purposes of the contained use
To protect the laboratory workers and the environment from any potential harm.

#### Recipient or parental organism
Cultered mammalian cells. These are characterised cell lines with strict growth requirements and are incapable of growth outside the culture flask.

#### Host/vector system

---

02/03/2022
Retroviral vectors or transfection vectors (e.g., pcDNA3).
The retroviral vectors are defective for replication with no gag, pol or env genes.
All vectors are non-mobilisable.

Origin & function

cDNA libraries derived from human or mouse cells. Hopefully the libraries will be representative of all human cDNAs. Our interest is in those expressing DNA repair and cell cycle checkpoint genes.

Evaluation of foreseeable effects

The human cDNA library could potentially include harmful genes such as oncogenes. These will however represent a low percentage of the total cDNAs in the library.
The packaging line contain no helper virus and helper functions are encoded by separate segments. The vectors are non-mobilisable and defective for replication. The inserts are however under strong promoters. The insert will not change the host range of the vector.
The mammalian recipient lines have strict growth requirements and are incapable of growth outside the culture flasks.
Taken together the environmental and human risks are minimal.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be destroyed using Virkon. Disposable plastics destroyed by autoclaving.
See attached risk assessment for further validation.
Virkon has been verified to be effective against retroviruses and we consider will inactivate our low litres.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volume that could be discarded is 10 litres. All cultures whether in glass or disposable containers should be autoclaved before disposal or recovery of containers. Liquid medium from which micro-organisms have been recovered should be sterilised either in the autoclave or by treatment with a suitable disinfectant before being discarded. Place Pasteur pipettes into 2.5% chlorosan in a beaker; rinse and discard after 24 hours in an appropriate container for waste glass.

The autoclave should operate at 15 lbs/ in 2 for 20 minutes following the maker's recommendations for use. Regular monitoring should be undertaken once a week using Thermolog S to confirm that the desired autoclave temperatures are attained. The autoclave should be regularly serviced.

Historical Significant Changes

Historical Date of Additional Info
**Project Additional Information**

**Purposes of the contained use**

To research the molecular structure and function of the pneumolysin protein from the human pathogen Streptococcus pneumoniae in the formation of oligomeric complexes during membrane pore formation.

**Recipient or parental organism**

The GMM will express at high levels the virulence determinant protein pneumolysin of the human pathogen Streptococcus pneumoniae. While the purified toxin protein will be a hazardous material, the GMM itself should not directly cause harm to human health or other organisms.

**Host/vector system**

The host: E.coli K-12 derived strain, M15 [pREP4], this is a multiple auxotroph. The vector: pKK233-2 [discontinued by Pharmacia PLC. in 1991] is a derivative of pBR322 which contains the colE1 replicon which renders the vector mobilisation defective. The combination of a disabled host and a mobilisation defective vector greatly reduces the transfer risk with this GMM to other hosts.

**Origin & function**

The host/vector system has been produced and characterised by the group of Professor Peter Andrew at the Department of Microbiology and Immunology at the University of Leicester. This GMM will be provided for culture at a small scale [6 litres maximum volume] and the expressed toxin purified for structural analysis.

**Evaluation of foreseeable effects**

Although the GMM carries a vector which will express the pneumolysin toxin in a soluble form, there are no known or recorded harmful effects to humans, animal or plants anticipated from the growth and use of this host/vector system.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

At the meeting of the genetic modification committee held on 9th May 2001 the proposed category 2 risk assessment was considered. The suggested GM risk level of category two was discussed and indicated that the GMM itself was unlikely to lead directly to harm to humans or other organisms. It was proposed that the risk assessment be forwarded to the Notifications Office at the HSE for their consideration and comments.

**Project Ref** 159/10.1

- **Date Ackn'd**: 22/04/2010
- **CU2 Project Title**: Structural studies of the Type IV secretion system
- **Class**: Class 2
- **Culture Volume**: 1-50 Litres

- **Non-GMM Consent Granted**
- **Project notified under transitional arrangements**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim is to produce the component proteins comprising the Type IV secretion system in E. coli together at high levels for structural studies. This will make the
host/vector(s) system self-mobilising at this point and probably conjugation competent. However the expressed proteins should have no adverse biological effects. The Type IV secretion system is found widely in nature, but as we will be effectively reducing the biological containment level while undertaking protein expression, we consider this as a Category 2 experiment.

Recipient or parental organism

The GMO will express the components of the Type IV secretion system. The GMO itself will not in our assessment cause harm to human health or other organisms.

Host/vector system

The recipient strain of E. coli acting as host for expression will be BL21 (DE3), TOP10. The vectors include: pASK-IBA3c_virB1-11, pRSF oriT, pHis17_tralHJK, pKM101.

Origin & function

All sequences will be PCR amplified from the plasmid pKM101.

Evaluation of foreseeable effects

Although the GMO will be expressing the complete Type IV system, there are no known or recorded harmful effects to humans, animals and plants. There are no anticipated harmful effects from the growth or the use of these host/vector systems to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Negative pressure relative to the pressure of the immediate surrounds - not required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The systems in place are designed to ensure that all contaminated waste is efficiently sterilised and only GMO's killed. There are two main routes for the sterilisation of laboratory waste to be used in this notification. All liquid and solid laboratory waste will either be incubated with 1% Virkon for at least 30 minutes using validated conditions, or will be autoclaved on the same day. Each autoclave cycle is validated with the inclusion of a thermolog S strip to monitor that the target temperature for killing the GMOs has been successfully achieved. The sterile, solid autoclaved material can then be disposed of via our normal waste route. Treated sterile liquid waste would go down the sink route.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The risk assessment was circulated to all members of the College GM safety committee. All responses were positive. Some minor corrections were made. It was recommended to be forwarded to the HSE for consideration and duly signed by the Clerk of the College on 15th April 2010.

**Project Additional Information**

**Purposes of the contained use**

The aim is to express and purify the individual component proteins comprising the Type IV secretion system in Agrobacterium tumefaciens at high yields for both structural and electron microscopic studies. The production of these proteins requires the transformation of a strain of Agrobacterium tumefaciens (A348) that is not disabled, and so we consider this as a Category 2 experiment. As this is a plant pathogen, we have also obtained an import licence to work with Agrobacterium tumefaciens.

**Recipient or parental organism**

Molecular cloning of the virB operon proteins into the pBADM-11 vector using E. coli hosts in this project are assigned to GM class 1. The growth of transformed A. tumefaciens for the production of virB operon proteins in both liquid and solid cultures, and storage of frozen cell pellets in this project are assigned to GM class 2. For the...
latter work neither the pathogenicity, nor the host range or tissue tropism will be altered from wild type A. tumefaciens.

Project Ref 159/13.2

Date Ackn'd 31/10/2013

cu2 Project Title Bacterial Plasmid Expression

Class 2

CultureVolClass2 1-50 Litres

Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**

The aim is to express and purify full-length pili from E. coli for use in both structural and electron microscopic studies. Expression will be undertaken in both a standard disabled host and the Uropathogenic E. coli strain YT189_LON. The production of these pili from engineered Uropathogenic bacterium, known to cause cystitis in humans, causes us to classify these experiments as requiring GM category 2 containment.

**Recipient or parental organism**

Full-length pili are to be expressed in two different hosts; Pili are to be expressed from pPAP5 plasmid in the commercial strain HB101 for expression, and Top10 for plasmid propagation. pPAP5 carries a 9.8-kilobase (kb) EcoRI-BamHI chromosomal fragment previously constructed from isolated E. coli J96 that encodes for the production of an adhesive P pilus. This has the ability to grow a pilus and hence cause hemagluttination of human erythrocytes. Full-length pili are also to be expressed and purified from the Uropathogenic E. coli strain U189_LON phase locked on resulting in the fim promoter being constitutively on. The UT189_LON is a wild type isolate and can cause cystitis in humans. However, apart from the need for a higher level of containment and laboratory hygiene, it is not expected to have any additional harmful properties beyond its ability to cause treatable cystitis in humans.

**Host/vector system**

Recipient vector for HB101 and Top10 is pPAP5 (Lindberg et al., (1984), EMBO Journal vol. 3 no. 5 pp. 1167 - 1173).

**Origin & function**

In terms of human health risk, the expression in hosts (HB101 and TOP (both are E. coli standard laboratory strains), these are not known to be infectious. A functional pilus can be formed using this plasmid, causing hemaglutination of human erythrocytes. However these bacteria lack many other essential components for a successful urinary tract infection (Type I fimbriae, siderophores, hemolysins) and requires ampicillin in order that the plasmid is maintained in the bacteria. Expression products will be accumulated in the periplasm or the outer membrane of bacteria. The products are not oncogenic. So there is minimal risk to human health.

For the environmental risk, the E. coli standard laboratory strains show low viability outside controlled environments. Non-pathogenic strains are used. Plasmids used are mobilization defective and are lost without selection. Inserted genes do not give competition advantage to host. These pili perform an adhesive function for the bacteria, they are not conjugative pili, or an injectosome organelle and as such do not increase the chance of DNA transfer between bacterial species.

For human health, UT189_LON was derived from Uropathogenic E. coli UT189, this is an isolate from a patient with cystitis, and therefore would have the capability to cause urinary tract infection. However all standard laboratory procedures in place will keep this to a minimum risk, i.e. informing the laboratory workers, high levels of personal hygiene, use of gloves and other personal protection, regular swabbing of benches, and the daily autoclaving of waste by validated means. These control measures should therefore ensure minimal risk to human health.

For the environmental risk, UT189_LON would be a viable competitor to the wild type UT189 in infecting humans and so offers no additional risk beyond that characterised...
previously (ref: Kostakioti et al. 2012, Infect Human.; 80 (8): 2826-2834). Containment controls in place within the laboratory will minimise any potential escape to the environment and wider population.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Negative pressure relative to the pressure of the immediate surrounds - not required

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The control systems in place are designed to ensure that all contaminated waste is efficiently sterilised and any GMOs killed. There are two main routes for the sterilisation of laboratory waste to be used in this notification. All liquid and solid laboratory waste will either be incubated with 1% Virkon for at least 30 minutes or will be autoclaved on the same day using validated conditions. Each autoclave cycle is validated with the inclusion of a thermolog S strip to monitor that the target temperature for killing the GMOs has been successfully achieved. The sterile, solid autoclaved material can then be disposed of via our normal waste route. The 1% Virkon treated sterile liquid waste would go down the sink route.

Is an emergency plan required according to regulation 20?

**Project Ref**  159/15.1
The obligate intracellular bacterium Chlamydia trachomatis has been considered genetically intractable. However, there have been multiple recent reports of transformation from different laboratories using recombinant plasmids based on hybridisation of E.coli and the endogenous Chlamydia trachomatis plasmids. We intend to use these vectors to express epitope-tagged or fluorescent fusion proteins in Chlamydia trachomatis to investigate the localization of virulence effectors and components of the type III secretion system biochemically and using imaging techniques.

Recipient or parental organism

The following aspects of this project are assigned to Class 1.
- Cloning and manipulation of the vectors and their propagation in E.coli strains

The following aspects of this project are assigned to Class 2.
- Transformation and propagation of transformed C. trachomatis within cultured mammalian cells.

Host/vector system

Wild-type Chlamydia trachomatis (this is a Biosafety level 2 organism and not disabled)
E.coli DH5a and XL-1 Blue will be used for plasmid propagation and sub-cloning procedures. These are E.coli K12 derivatives and are classified as 'disabled and non-colonising' by the ACGM.

X1-Blue recA1 endA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [F' proAB lacIqZΔM15 Tn10 (TetR)]
DHSalpha F- phi80lacZ::M15 delta(lacZYA-argF)U169 deoR recA1 endA1 hsdR17 (r-, m+) phoA supE44 thi-1
gyrA96 relA1 lamdapASKGFPL2
pTRL2-GFP
pCDSSKO
placZ-CD55KO
Origin & function

We plan to study the localisation and function of C. trachomatis proteins encoding components of the type III secretion system (inner and outer membrane protein, ATPase, translocan and needle) and the substrates, which are delivered into the boundary membrane of the replicative vacuole (hydrophobic inclusion proteins), host cytosol or nucleus. These genes will be amplified by PCR from chromosomal DNA of C. trachomatis held in our laboratory or by gene synthesis (as some genes are exceptionally difficult to amplify by PCR). Epitope tags will be added to the sequence as part of the PCR primer or synthesised product (e.g. FLAG, Myc) when required. In the case of fusion proteins to MBP, GFP, mKate2 these will be amplified from existing commercial vectors (e.g. pEGFP-C2; Clontech) or obtained from collaborating laboratories where necessary.

Evaluation of foreseeable effects

E.coli. will be used to make the expression constructs. The Chlamydia trachomatis will be used to express the various components of the epitope-tagged or fluorescent fusion proteins to investigate the localization of virulence effectors and components of the type III secretion system biochemically and using imaging techniques. The GMOs themselves will not, in our assessment, cause any additional harm to human health above the virulence of the wild-type organism. Chlamydia elementary bodies survive for only a very short time outside their host cells (30 minutes to 1 hour), so risks from environmental release do not significantly exceed those of the wild-type organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Purposes of the contained use**

The aim is to produce the component proteins comprising the Type IV secretion system in E. coli together at high levels for structural studies. This will make the host/vector(s) system self-mobilising at this point and probably conjugation competent. However the expressed proteins should have no adverse biological effects. The Type IV
secretion system is found widely in nature, but as we will be effectively reducing the biological containment level while undertaking protein expression, we consider this as a Category 2 experiment.

Recipient or parental organism

The GMO will express the components of the Type IV secretion system. The GMO itself will not in our assessment cause harm to human health or other organisms.

Host/vector system

Page 4152 of 15326
**Project Additional Information**

**Purposes of the contained use**

Purpose of this project is to optimise and assess the ability of hTERT to extend the proliferative lifespan of primary cultured fibroblasts.

**Recipient or parental organism**

Primary fibroblasts.

**Host/vector system**

The retroviral vectors, pBabehTERTloxP and pBabeCreHygro, based on Moloney Murine Leukemia Virus (MuLV) and were designed to be replication defective by deleting trans-acting viral structural genes pol and env. The vectors contain open reading frame of hTERT, which is flanked by loxP sites, or Cre gene as well as selecting markers, puromycin or hygromycin resistant genes. Packaging cell lines (both ecotropic and amphotropic) are required for infecting host cells.

**Origin & function**

The retroviral vectors, pBabehTERTloxP and pBabeCREHygro, are gift from Dr. Shay, Dr. Wright and Geron Corp. (Steinert et al 2000). In these vectors, hTERT cDNA and Cre gene are under the control of the viral LTR. Expression of hTERT in the primary cultured cells is expected to extend proliferative lifespan in these cells. Cre recombinase is going to be transiently expressed in hTERT stable-transfected cells to excise the floxed hTERT cDNA from the cells so that the cells no longer express...
hTERT protein after Cre expression. Selectable makers, puromycin or hygromycin are applied for selecting transfected cells.

Evaluation of foreseeable effects

The retroviral vectors used in this work are modified MuLV which are only able to replicate in a retroviral packaging cell line. The vector RNA genome is packaged into virus particles which bud off into the culture medium. The virus stocks produced by the packaging cells are also replication-defective.

However, even if containment of the virus failed, infection of human and animals is expected to cause very limited damage as the retroviruses require close contact for their transmission and their survival in the general environment is poor. Reports suggest that hTERT alone can only extend the lifespan of human primary cells but not transform them (Bodnar et al 1998; Jiang et al. 1999; Morales et al. 1999). Cre, puromycin and hygromycin do not have cytotoxic effects. The literature/data will be checked regularly for the changes in the risk associated with the inserts (e.g. hTERT) and the risk assessment will be updated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

a) Contaminated Pasteur pipettes and tips will be disposed into a plastic sharps-safe bin located in the tissue culture hood. On a daily basis, bins will be sealed, level 2 labelled, autoclaved and incinerated, 100% kill.
b) Contaminated plastic pipettes will be placed in tripled, clear, plastic biohazard bags. These will be sealed with tags and level 2 labelled, autoclaved and incinerated as a).
c) Aspiration of all fluids used within the dedicated tissue culture hood will fed directly into a flask with haz tabs tablets, such that the maximum dilution will be 1 tablet/litre fluid, producing 2500 ppm available chloride. Biological material will be inactivated overnight (100% kill), before discarding down the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee has reviewed the risk assessment of the proposed activity and concurs with the assignment of the activity class 2. The laboratory identified is appropriate for the application of full level 2 containment and the use of a class 2 tissue culture cabinet will further reduce the hazard to the personnel involved. In addition, the waste management arrangements will ensure that risks to other workers and to the environment are reduced to negligible levels.

02/03/2022  Page 4154 of 15326
The MoMuLVsup-1 will be used to measure the effect of HP1 deletion on the De Novo methylation machinery. Briefly, ES cells, which have been deleted for HP1 gene products, will be infected with the MoMuLVsup-1. The viral DNA will integrate into the host genome. In wild-type ES cells the viral DNA becomes De Novo methylated, which can be measured by Southern Blot analysis. We aim to determine the effect of deleting HP1 function on De Novo methylation of the introduced MoMuLVsup-1 viral DNA.

Recipient or parental organism
Mouse embryonic stem (ES) cells.

Host/vector system
The retroviral vector, MoMuLVsup-1 is based on the Moloney Murine Leukaemia Virus (MoMuLV). In this vector, the bacterial sup-F gene has been integrated into the LTR (Reik et al., PNAS USA 82, 1141-1145, 1987) which allows its detection in mouse genomic DNA. The virus is replication competent so makes its own coat proteins that are required for infecting cells.
Origin & function

The MoMuLVsup-1 vector is a gift from Dr En Li (See Hong et al., Development, 122, 3195-3205, 1996; Okano et al., Cell 99, 247-257, 1999). The vector will be used, as documented in Dr Li's papers above, to measure the De Novo methylation activities in ES cells. Briefly, 3T3 cells, which express the MoMuLVsup-1 virions, will be cultured in ES cell medium. Supernatants from these cultures will be used to infect ES cells whereupon the MoMuLVsup-1 DNA will integrate into the host genome. In wild-type ES cells the viral DNA becomes De Novo methylated, which can be measured by Southern Blot analysis.

Evaluation of foreseeable effects

The MoMuLVsup-1 retrovirus is replication-competent and the vector RNA genome can be packaged into virus particles that can bud off into the medium. Appropriate procedures (see 12) will be used to contain the virus. However, even if the containment of the virus failed, infection of animals is expected to be very limited, as the retrovirus requires close contact for transmission: their survival in the general environment is also poor. With the method described, this virus has been used in different laboratories for over 15 years without deleterious effects (Reik et al., PNAS USA 82, 1141-1145, 1987; Hong et al., Development, 122, 3195-3205, 1996; Okano et al., Cell 99, 247-257, 1999).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(a) Contaminated Pasteur pipettes and tips will be disposed into a plastic sharps-safe bin located in the tissue culture hood. On a daily basis, bins will be sealed, level 2 labelled, autoclaved and incinerated. 100% kill.
(b) Contaminated plastic pipettes will be triple sealed in clear plastic biohazard bags. These will be sealed with tags and labelled, autoclaved and incinerated as in (a). 100% kill.
(c) Aspiration of all fluids used within the dedicated tissue culture hood will feed directly into a flask with haz tab tablets, such that the maximum dilution will be 1 tablet/litre fluid, producing 2500 ppm available chloride. Biological material will be inactivated overnight (100% kill), before discarding down the sink.

Project Containment

02/03/2022
USE OF ADENO- (AD) AND ADENO-ASSOCIATED VIRAL (AAV) VECTORS TO INTRODUCE AND EXPRESS TRANSGENES IN CULTURED HUMAN AND MOUSE EMBRYONIC STEM (ES) CELLS.

We intend to use the B-galactosidase marker to optimise the ability of Ad and AAV to transfect human and murine ES cells. We then plan to investigate the possibility that the preferred integration site for AAV will prove to be an appropriate site for the expression of further transgenes by integrating a 'floxed' marker gene and replacing it with a second histological marker. In the event that Ad or AAV are useful for the reliable expression of transgenes then we will use this route for the introduction of genes which direct the differentiation of ES cells to provide therapeutically useful cell types. We also plan to establish if AAV carrying homology to endogenous genes will lead to integration by homologous recombination.

We will obtain replication incompetent viral vectors as follows:
(i) adenoviral (Ad) vectors designed to deliver and express marker genes to cultured cells
(ii) adeno-associated viral vectors (AAV) designed to deliver and express marker genes and/or genes designed to cause directed differentiation to cultured cells
(iii) Ad or adeno-associated viral vectors carrying a 'floxed' marker to facilitate integration of subsequent transgenes by site-specific recombination.
Adeno-associated vectors designed to target endogenous genes

Recipient or parental organism
Human and murine embryonic stem (ES) cells.

Host/vector system
Recombinant adenovirus - Ad 5
Non enveloped, icosahedral virions of 75-80nm diameter with double stranded 37kb DNA linear genome. Replication defective recombinants have E1 and E3 deletions and can only be produced in cell lines where E1 genes are supplied in trans, such as the 293 line, which contains 17% of the left-hand side of the adenovirus genome. There is a risk of recombination events between the virus and integrated DNA fragment during scale-up, leading to production of replication competent adenovirus (RCA). Therefore, preparations of the vector are checked for RCAs. In these vectors the transgene is under the control of the CMV promoter. These recombinants fall into ACGM containment level 2.

The virus is stable and can retain biological activity after extraction with ether and/or chloroform, or withstand exposure to room temperature for 3-8 weeks. The virus can be inactivated by heat inactivation (56 degrees C/1 hour) or exposure to Mikrozid solution (A. J. Beveridge, Cat: 2A63) for 30 minutes.

Health concerns
Adenovirus does not need to be replication competent to cause symptoms such as corneal or conjunctival damage. Symptoms may also include acute respiratory illness (cold-like symptoms), pneumonia, conjunctival infection (red eye), and corneal infection leading to scarring. Skin contamination should be washed repeatedly with soap and water, with eye infections being thoroughly washed in water.

Origin & function
Selectable marker transgenes are bacterial in origin and confer resistance in culture to drugs such as G-418. Their presence is to facilitate the cloning of colonies of transfected cells. Histological markers are either bacterial (B-galactosidase) or eukaryotic in origin (luciferase, GFP). Histological markers are used to visualise transfected cells in order to track their differentiation following engraftment. Transgenes likely to affect the pattern of differentiation of ES cells are predominantly of human or murine origin and may be under inducible transcriptional control. For example certain muscle regulatory factors (myogenin, myf5 myoD) are known to direct the differentiation of some cell types to muscle.

Evaluation of foreseeable effects
Drug resistance markers may include neo, puro, hyg or cat genes. Expression markers may include GFP, luciferase, B-galactosidase or dsRed. These reporter genes have been evaluated in transgenic mice, which express the markers without showing a phenotype. (For example, see Capecchi, M.R (1989) Altering the genome by homologous recombination. Science 244:1288-1292 and Okabe M. et al. (1997) Green mice as a source of ubiquitous green cells. FEBS Lett. 5: 407, 313-9). Other transgenes may include hTERT or hTR (RNA subunit of telomerase). These transgenes are expected to extend life span in transfected tissue culture cells and the consequence of viral release to the environment must be considered. If release occurs, which should be unlikely given the working practices described below, infection of humans and animals is expected to cause very limited damage. Reports suggest cultured human fibroblasts have extended life soabs vyt are bit trbsfrined as denibstrated vt ckassucak assats sygc as faukyre if cekks ti griw ub sft agar ir ub byde nuce (Morales, C. P. et al (1999) Absence of cancer-associated changes in human fibroblasts immortalised with telomerase. Nature Genetics 21:115-118 and Bodnar, A. G. et al (1998) introduction of telomerase into normal human cells. Science 279:349-352). None of these transgenes is expected to affect cell function or survival under normal culture conditions. Some modifications will be designed to affect cell survival or survival under normal culture conditions. Some modifications will be designed to affect cell survival in vivo. In some instances such as the expression of xenogeneic surface markers, the effect will be to reduce viability. In others, such as the expression of angiogenic factors, the effect may be to enhance cellular engraftment. In both cases however, the likelihood of cells gaining access to the human body accidentally is small and would be expected to elicit a rapid immune response that would destroy the contaminating cells. The possibility of infectious virus carrying these transgenes as a consequence of accidental co-transfection with wild type virus is small but must be considered. The particular concern would be the case of transgenes encoding factors to enhance engraftment which could, in principle, lead to phenotypic consequences.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

a) Contaminated Pasteur pipettes and tips will be disposed into a plastic sharps-safe bin located in the tissue culture hood. On a daily basis, bins will be sealed, level 2 labelled, autoclaved and incinerated, which gives 100% kill.

b) Contaminated plastic pipettes will be placed in tripled, clear, plastic biohazard bags. These will be sealed with tags and level 2 labelled, autoclaved and incinerated as (a).

c) Aspiration of all fluids used within the dedicated tissue culture hood will fed directly into a flask with haz tab tablets, such that the maximum dilution will be 1 tablet/litre fluid, producing 2500 ppm available chlorine. Biological material will be inactivated overnight (100% kill), before discarding down the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee has reviewed the risk assessment of the proposed activity and concurs with the assignment of the activity to class 2. The laboratory identified is appropriate for the application of full level 2 containment and the use of a class 2 tissue culture cabinet will further reduce the hazard to the personnel involved. In addition, the waste management arrangements will ensure that risks to other workers and to the environment are reduced to negligible levels.

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**
To assess the uptake of anti-tumour drugs by acute myeloid leukemia (AML) cell lines by measuring light output of virally transformed cells.

**Recipient or parental organism**
Well characterised human AML cell lines, including THP-1 and KG1a

**Host/vector system**
A third-generation lentiviral vector, such as pLenti6/V5-DEST (Invitrogen)

**Origin & function**
Genes encoding bacterial luciferase enzymes and a fatty acid reductase
Genes encoding fluorescent proteins, such as GFP.

**Evaluation of foreseeable effects**
The lentivirus produced with the pLenti 6/V5-DEST system is able to transduce primary human cells and therefore poses some risk (classified as hazard group 2). However, the packaged virus lacks viral structural genes and cannot produce replication-competent virus. The genes to be inserted are widely distributed in fluorescent organisms in the environment. The products are well-characterised with a history of safe use as reporters and no harmful biological activity has been reported. The modified virus is thus not expected to be more harmful than the unmodified vector.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All culture material, reusable glassware and disposable waste will be inactivated by autoclaving at 121°C for a minimum of 30 minutes. Each load will be monitored by the use of test strips. Autoclave function is independently monitored by an external contractor on an annual basis.

**Is an emergency plan required according to regulation 20?**

Y

**Tick to confirm that it is attached to this form**

N
The risk assessment is required for a new part of an ongoing project which will involve the use of lentiviral vectors […] explained the background to this new area of work and the reasons for using these viral vectors. […] commented that the vectors described could not produce viable virus. They would be able to produce the DNA provirus, but not viral RNA. […] asked for clarification of the description of the packaging cell line. The risk assessment submitted did not fully described the E. coli strains to be used in this work; these should be included. […] questioned a sentence under disposal of waste that described the use of settle plates to monitor for contamination. It was agreed that this was not necessary or appropriate as a routine procedure. Since the project involves collaboration with another institution, it was felt that transport of materials should be considered and the procedure(s) to be followed should be detailed under section 2(d). The committee approved the risk assessment subject to the suggested changes being made to the satisfaction of the chair.

### Project Ref 164/07.1

**CU2 Project Title**

Silencing and over-expressing hormone-and stress-related genes in potato (Solanum tuberosum L.).

**Non-GMM** Grant

Consent Granted: Not Applicable

**Project notified under transitional arrangements**

N

**Project Additional Information**

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
### Purposes of the contained use

To study the effect of silencing or over-expressing genes involved in hormone- or stress-signalling in potato plants grown in sterile culture.

### Recipient or parental organism

- Laboratory strains of *Escherichia coli* K12
- Laboratory strains of *Agrobacterium tumefaciens*
- *Solanum tuberosum* plants grown in vitro

### Host/vector system

Plasmids pGR106/7, which are non-mobilisable binary vectors for transformation of plants using *Agrobacterium tumefaciens* and which obtain sequences derived from *potato X* (PVX) isolate UK3.

### Origin & function

Initially, we intend to silence brassinosteroid signalling genes from potato, but in future we wish to use other hormone- and stress-related genes where no change in PVX host range or pathogenicity can be predicted and where no altered interaction with toher plant pathogens is expected. These might include: plant genes encoding proteins involved in phytohormone biosynthesis, perception, signal transduction and metabolism, for example, enzymes that catalyse phytohormone biosynthetic reactions, phytohormone receptors, positive and negative regulators of phytohormone signal transduction, plant genes encoding proteins involved in stress perception, signal transduction and responses, for example, heat shock proteins, proteins up- or down-regulated after stress.

Genes encoding GFP (Green Fluorescent Protein) and PDSas (Phytoetene Desaturase) will be used as controls.

### Evaluation of foreseeable effects

The *Agrobacterium* constructs to be produced will be capable of generating modified potato Virus X (PVX), (derived from strain UK3) when they infect a susceptible plant. PVX is a plant pathogen that infects solanaceous crops such as potatoes and occurs naturally in the UK. Plants deliberately infected with *Agrobacterium* constructs in the laboratory will produce viable PVX, which could be transmitted mechanically to other susceptible plants in the absence of control measures. However, potato crops are not grown in the immediate vicinity of the laboratory or growth rooms. In the case of gene-silencing constructs, expression of endogenous plant genes might be altered in recipient plants. It is possible that this might affect the growth or survival of the infected plant, but the predominant effect is likely to be the disease caused by the virus.

There is no reason to suppose that the host range or infectivity of the modified virus will be altered compared to the recipient strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The plants will be cultured in vitro, in tissue culture vessels maintained in growth cabinets in a restricted access area within the faculty. When needed, the GM plants inside tissue culture vessels will be transported to the laboratory in sealed boxes via a specified route. A class 2 laminar flow hood will be used when formicpropogating the plants. This is required to ensure sterility during tissue culture and will be sufficient to control the risk to the environment. Disposable gloves and sterile material will be used when manipulating the plants. All non-disposable materials will be autoclaved before re-use. All plants will be transferred to autoclavable bags and autoclaved before disposal. All waste, including gloves, that has possibly been in contact contaminated plant material will be autoclaved before disposal. Used tissue-culture vessels will be autoclaved before cleaning. The working surfaces will be disinfected with Virkon S after the manipulation of infected plant material.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All plant material, bacterial cultures, re-useable glassware and disposable waste will be inactivated by autoclaving at 121°C for a minimum of 30 minutes. An autoclave is situated in the building and waste will be transported to the autoclave in autoclave bags contained in robust containers with lids. Each load will be monitored by the use of
test strips. Autoclave function is independently monitored by an external contractor on an annual basis.

(…) gave a short summary of the proposed work. The committee agenda agreed the main hazard was the possibility of the virus escaping and infecting another plant. The virus can be mechanically transmitted, but (…) explained that this was not a very efficient process. The transgenic plants would be grown in tissue culture vessels and would be likely to die unless very carefully transferred to soil due to humidity change. The most likely route of transmission of virus was thought to be via escape of the Agrobacteria containing viral sequences. The committee felt that the overview did not adequately explain how the virus was produced. Another point raised by members of the committee was whether the Agrobacterium strain was disarmed. (…) told the committee that it does not have the genes to cause crown Gall. (…) then went on to explain that although sharps wont be used with bacteria as stated on the risk assessment, scapel will be used when manipulating the plants. This was thought not to be an issue as PVX does not infect humans. The Chair went on to raise the issue of transporting the plants from the undercroft to the labs. This should be in sealed boxes via the route described for the transport of hazardous materials in the faculty. The Chair suggested that the risk assessment should say that a class 2 sterile hood would be used when opening the tissue culture vessels and handling the plants. The committee agreed that the work could be carried out safely under class 2 containment and approved the risk assessment subject to the changes noted and correction of typographical errors.

**Project Additional Information**

**Purposes of the contained use**

To build a lenti-viral knock-down rescue systems to study metabolic signalling mechanisms in health and disease.

**Recipient or parental organism**

| a. | IMR-32 neuroblastoma cells. Human cells. Widely used and considered biosafety level 1. |
| b. | SH-SYSY neuroblastoma cells. Human cells. Widely used and considered biosafety level 1. |
| c. | hCMEC/D3 immortalized endothelial cells. Human cells. Widely used and considered biosafety level 1. |
| d. | L6 myocytes. Rat cell line. Widely used and considered biosafety level 1. |
| e. | MIN6/INS1. Mouse insulinoma cell lines. Widely used and considered biosafety level 1. |
| f. | HEK293TN. Human cell line. HEK293TN producer cell line is optimized for effective, high titer production of pseudoviral particles. The cell line has been transformed with the SV40 large T antigen to promote robust growth. The Neomycin resistance marker is also featured in the 293TN cell line for stable propagation. Biosafety level 2. |

**Host/vector system**

| a. | Tet-pLKO-puro – third generation lentivirus backbone plasmid. This plasmid cannot produce lentiviral particles without co-transfection with a minimum 2 packaging plasmids in mammalian cells. The plasmid confers resistance for mammalian cells to puromycin/neomycin with the Pac gene. Plasmid also contains Amp gene for bacterial ampicillin resistance. The risk of spontaneous viral generation is very low with the 3rd gen system as: |
| i. | HIV-1 gene number is reduced and separated (requires 4 recombination events for spontaneous generation); to date there have been no reports of spontaneous expression. The National Gene Laboratory (NGVL) has produced over 60 liters of HIV-1 vector and has screened supernatant and cells from different vector systems, using different assays, without detecting recombination events. |
| ii. | The expression vectors are not self-replicating - TAT is removed totally. |
| b. | pXLG3 – a third generation lentivirus backbone plasmid. This plasmid cannot produce lentiviral particles without co-transfection with minimum 2 plasmids in mammalian cells. The plasmid confers resistance for mammalian cells to puromycin/neomycin with the Pac gene. Plasmid also contains Amp gene for bacterial ampicillin resistant. |
| i. | The vector is self-inactivating – it contains a 400bp deletion in the 3'LTR, removing the TATA box and promoter activity, in common with other 3rd generation plasmids. |
c. pCMVR8.91, the packaging plasmid, in which the cytomegalovirus (CMV) immediate early gene promoter controls the expression of HIV-1 genes gag, pol (necessary for the nuclear transport of the HIV-1 pre-integration complex), tat and rev (both required for viral expression by transcriptional and post-transcriptional mechanisms).

d. pMD.G2, encoding the VSV-G coat protein, flanked by β-globin regulatory sequences, under the control of the human CMV immediate early promoter.

Note that the transfer vectors (pLKO, pXLG) are 3rd generation, whereas the packaging and envelope vectors are 2nd generation. This compromise allows the high efficiency of virus production of the 2nd generation system, whilst also maintaining the safety of the self-inactivating 3rd generation transfer vectors.

**Origin & function**

The function of the genes to be expressed or knocked down is as follows: BCAT1 or BCAT2 gene (branched chain amino acid metabolism); UBC9, SENP1-7, SUMO1-3 (regulators of protein SUMOylation); syntaxin-1/3/4, SNAP-25, Munc18 (secretory proteins); GLUT4 (glucose transporter); Neto1/2 (K+ channel regulators), GFP, mCherry, SyGCamp (fluorescent marker proteins).

**Evaluation of foreseeable effects**

The most hazardous GMO are the lentiviral particles generated. These will only be generated during a closely monitored set timepoint; spontaneous generation is extremely unlikely to occur by accident as vector formation requires transfection of an additional 2 plasmids. Random formation and recombination events resulting in infectious virus have yet to be reported despite extensive attempts.

When lentiviral particles are generated full PPE (class 2 microbiological safety cabinet, nitrile gloves, and a lab jacket) will be worn and a class 2 biological safety environment will be maintained throughout the experiment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Full PPE (class 2 microbiological safety cabinet, nitrile gloves, and a lab coat) will be used. All GMM viral manipulations will be contained within a class 2 microbiological safety cabinet. All microbiological safety cabinets are serviced and calibrated by British Clinical Services on a 6th monthly interval. All work will be performed in accordance to Biological Containment Level 2.

All work surfaces will be sprayed with 70% ethanol before work commences. All bottles and gloves when introduced or removed from the biological safety cabinet will be sprayed with 70% ethanol.

Discard containers containing 1% virkon will be used in the microbiological safety cabinet for discard of pipette tips and microcentrifuge tubes. Users will ensure all pipette tips and microcentrifuge tubes are fully submerged into the 1% virkon. Discard containers will be left overnight to ensure 100% kill and changed each morning before work commences.

Liquid waste generated will be discarded into clean duran bottles and autoclaved using a standard, calibrated discard programme (121 degrees Celsius, 15psi for 15 minutes) ensuring 100% kill.

Solid waste (pipettes and plastic cell culture flasks, bacterial agar plates) will be deposited in a biohazard autoclave bag, placed in a biohazard bin and autoclaved. A fresh autoclave bag will be used for each experiment involving lentiviral material. At the conclusion of each experiment waste will be autoclaved immediately.

All surfaces will be disinfected with 1% virkon at the end of the procedure to achieve 100% kill of any remaining microorganisms and viral particles. Small spillages will be treated with 1% virkon. A large volume (excess of 50ml) spill kit is available containing powdered virkon, absorbant material, face mask and gloves.

Cell lines transduced using the lentiviral protocol will be monitored for the presence of remaining virus by pipetting cell media onto un-transduced cells and visual monitoring (active viral products produce GFP) and ELISA assays. This will ensure the absence of active virus from transduced cells used in subsequent experiments.
The GMSC met to consider the risk assessment entitled ‘Lentiviral induction of mammalian cell lines’ submitted by Dr Tim Craig (TC). The RA was presented by TC and the committee asked for clarification on a number of points. Overall although the GMSC considered most aspects of the RA to be class 1, because some 2nd generation lentiviral packaging and coat protein plasmids being used the conclusion was to assign this RA as class 2. TC had completed part 2 of the RA identifying any potential risks and describing the measures taken to reduce these and the GMSC were satisfied with this.

After some minor corrections were addressed the RA was accepted as class 2 and the UWE RA number 2016.1 assigned to it.

Prof. Dawn Arnold, GMSC chair.

**Project Additional Information**

**Purposes of the contained use**

To generate professional antigen presenting cells which process thyroid peroxidase (TPO) via the endogenous rather than the exogenous pathway, to examine the repertoire of TPO epitopes presented by these cells, and their interactions with TPO-specific T cells.

**Recipient or parental organism**

Baby hamster kidney (BHK-21) cell line. This cell line is permissive for the replication of the MVA vector, and will be used for large scale preparation of recombinant MVA-TPO vector. Dendritic cells established from anonymous donor blood packs. EBV-transformed B cell lines (LM and CX81).

**Host/vector system**

The vector system is Modified Vaccina Ankara strain (MVA), a highly attenuated strain of vaccinia virus which is unable to replicate in most mammalian cells, and has a history of safe use as a smallpox vaccine. MVA is regarded as a single round expression vector with little potential to spread.

**Origin & function**

Thyroid peroxidase (TPO) is a membrane-bound protein expressed by thyroid epithelial cells, and is a common autoantigen in auto-immune thyroiditis. Mouse TPO cDNA will be introduced into the MVA vector by means of homologous recombination in BHK-21 cells. Recombinant vector will be prepared by sequential plaque purification, followed by ultracentrifugation of BHK-21 cell lysates. The vector will be used to induce the expression of full length TPO protein in professional antigen presenting cells (either primary human dendritic cells or established B cell lines).

**Evaluation of foreseeable effects**

There is a hypothetical possibility that the accidental infection of an operative with the recombinant TPO-expressing vaccinia virus might provoke an autoimmune reaction targeting the thyroid. In a worst case scenario this could lead to hypothyroidism. The MVA vector is highly attenuated, so that there is no means of propagation of an infection. MVA alone provokes a relatively poor immune response to exogenously expressed antigens, and current vaccinations protocols combine MBA with a DNA immunisation step. The local rules for the use of vaccinia virus expressly forbid the use of sharps, and impose strict conditions for the prevention of aerosol release. The possibility of harm to human health is therefore regarded as remote. No infection of animals with recombinant virus is proposed, and contaminated waste will be disinfected in a manner known to inactivate the virus. There is therefore no significant risk to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Disinfection by exposure to Microsol3 at a final concentration of >2% for a period greater than 2 hours. The disinfecting reagent is certified by the manufacturers to inactivate pox-viruses under these conditions (effectively 100% kill). Disinfected liquid waste is washed down the sink.

Solid waste: Solid waste (in double thickness biohazard bags) is collected from the contained use site each day and autoclaved immediately at 134oC for 15 minutes. These conditions will achieve 100% kill. The autoclave is subject to a maintenance contract with the manufacturers, with 2 maintenance visits and 1 full KI discus test per year. Autoclaved waste is collected and disposed of by a licensed waste disposal company.
The risk assessment has been rigorously examined by the local Genetic Modification Safety Committee over a period of several months, and during this time has undergone extensive modification. The GMSC was concerned about the possibility of thyroid auto-immunity following accidental infection with the recombinant virus. Ultimately, it was agreed that the risk of this occurrence was small, but could not be discounted entirely. On the grounds of this theoretical risk it was agreed that the work should be classified as a Level 2 operation, and that local rules should provide sufficient protection for operatives and the environment. The local rules for vaccinia virus work are appended.

Project Ref 165/05.1

Date Ackn'd: 27/09/2005
CU2 Project Title: Developing viral vaccines to protect against microbial disease.

Class

Consent Granted

Non-GMM: Not Applicable

Project notified under transitional arrangements: N

Historical Significant Changes

Withdrawn: N

Tick if notifying a connected programme of work: N
The principal goal of this project is to develop a vaccine to protect against microbial diseases. Vaccination is suboptimal for several diseases, such as viral infections (Influenza) and cancer. Several previous approaches to vaccination have only been effective in a percentage of the population. To fully immunise the elderly, young children and other susceptible populations, new approaches to vaccination must be explored. Vaccination with a non-replicating adenoviral vector provides the opportunity to induce strong protective immune responses while remaining relatively safe to the vaccinee. Therefore, this approach may provide the opportunity to develop an effective vaccine that will induce good immune responses across all members of the population.

Through the use of these GM Adenoviruses we may be able to develop a vaccine that is effective against disease in all target populations.

A non-replicating adenovirus will be used for vaccination.

The virus is genetically modified with commercially available and laboratory constructed vectors from the gateway system of cloning (Invitrogen). All adenoviral constructs are deleted at both the E1 and E3 regions, and are hence replication deficient. Recombinant adenovirus genomes, purified from a K12 strain of E. coli, are transfected into the packaging cell line HEK293, virus will replicate and then plaque purification is performed. A large scale grow-up is carried out, the construct is validated by PCR and western blotting, and the presence of replication competent adenovirus is checked by a plaque-forming assay using human skin fibroblasts.

These adenovirus constructs will express an antigen from a disease causing microorganism, such as influenza. The function of the genetic material from the microorganisms is to induce an immune response, but will not include toxins or other molecules that can be directly detrimental to the health of humans and other animals.

The normal tropism of adenovirus is for the upper respiratory tract; however, it is able to infect a variety of other cell types in vivo and in vitro. This virus can cause minor respiratory disease but because of the mechanisms of viral attenuation it cannot form a pool of replicative virus. Therefore disease in humans is minor. The principal routes of accidental infection are needlestick injury or aerosol production. The microbial antigenic determinants may generate an immune response in humans if exposure occurs, but this response will likely be beneficial rather than detrimental.
The antigens have a remote possibility of causing allergic responses if the recipient has been exposed previously and has become allergic. There are no direct hazards arising from the alteration of existing traits of the adenovirus. However if mobilisation of the genome between adenovirus strains occurs these inserts could be expressed by other replicative adenoviruses. These new replicative viruses could then affect immune responses through the expression of the inserts as detailed above and in 17, however this is unlikely. Mobilisation of adenovirus requires the complementation of the deleted E1 and E3 functions or recombination with endogenous adenoviral sequences to restore these to the genome. Complementation of the virus could theoretically occur following the infection of the adenovirus into hosts. However if recombination does occur, the inserted gene products will most likely be deleted due to the packaging restraints of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste
Treated by: Addition of Microsol3 to a final concentration of 10%, incubation for >1hr.
Kill is effectively 100%
This treatment is used as per the manufacturers instructions, the effectiveness of the reagent is checked on any change in procedure.
Disposal by: Sinks (down the drain after inactivation).

Solid waste
Treated by: autoclaving at 134°C for 3 minutes under vaccuum.
Kill is effectively 100%
This treatment is used as per the manufacturers instructions. A temperature recorder is attached to assure that the optimal temperature is achieved for each run. In addition, the manufacturer checks the operating parameters of the autoclave yearly by contract.
Disposal by: Waste is collected for incineration by PHS.

Animal waste
Treated by: Waste is soaked in 1% Virkon overnight and are stored at 4°C before maceration.
Kill is effectively 100%
This treatment is used as per the manufacturers instructions, the effectiveness of the reagent is checked on any change in procedure.
Disposal by: Macerated waste is disposed of down an approved drain.

Date Project Ceased 21/07/2011
Project notified under transitional arrangements N

CU2 Project Title
Lentiviral expression systems as a tool for studying intracellular signalling pathways in cells of the immune system

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 ≤ 1 Litre
Non-GMM Consent Granted

Purposes of the contained use
This is a study undertaken in order to investigate the mechanisms of pro and anti-inflammatory signaling in immune cells such as macrophages, dendritic cells and lymphocytes.
We have previously generated lentivirus particles using 3rd generation transfer vectors and a 3rd generation packaging system. This system is designed to minimise the
possibility of replication competent virus particles arising during lentivirus production, where the gag/pol and rev gene products are expressed from separate plasmids that are co-expressed with the envelope (VSVg) vector following co-transfection with the lentiviral backbone vector into packaging cells (KEK293T/17). Substitution of the HIV-1 envelope protein with the Vesicular Stomatitis Virus envelope glycoprotein (VSV G) not only results in the production of a higher virus titre with a significantly broadened host cell range but also contributes to an enhanced safety of the system. The resulting retrovirus is replication-defective. However, the improved safety features of 3rd generation packaging systems are off-set by considerably lower virus titre yields obtained with this configuration. Therefore to improve viral titres we obtained a 2nd generation packaging system from the Trono Lab (Switzerland). In this case, all the auxilliary genes are expressed from one plasmid, which also incorporates the transactivator gene tat (absent in the 3rd generation system), namely psPAX2 or PDCMV8.91. Together with the envelope protein encoding plasmid (pMD2.G) these 2nd generation packaging systems are compatible with packaging of 3rd generation lentiviral transfer vectors containing SIN LTRs and are widely used to produce small scale amounts of lentiviral particles of in vitro transduction of primary mammalian cells.

Viruses will be assembled and packaged in the HEK293T/17 cell line and the conditioned supernatants (containing mature lentivirus) will be concentrated by centrifugation and titred prior to use in experiments. Virus titres will be determined using a FACs-based assay using either GFP fluorescence assay or labelled tNFGR (truncated nerve growth factor receptor) marker genes to calculate the amount of lentivirus infectious units. This will be carried out in HT1080, Jurkat and SupT1 for 3-6 weeks and monitoring the culture supernatants for p24 expression by ELISA. A positive control for p24 protein will be incorporated in this assay.

Once generated, lentiviruses will be used to infect a range of cell lines and primary cells over a range of MOI (multiplicity of infection). In the first instance we plan to study innate immune receptors, including TREM-1, DAP12, CD38, CD164, transmembrane protein123 (TMEM123), TLRs, tyrosine kinases., IRF family membesrs, NFKB signaling components (e.g. Myd88), p38 MAP kinase, and reporter genes such as TNF-luc, IL-6-luc, Stat3-luc. All these targets represent non-oncogenic, non-secreted cell components.

Recipient or parental organism

- 293T/17 cells (highly transfectable cell line derived from the 293T cell line established from human embryonic kidney cells)
- RAW 264.7 (murine macrophage line)
- HeLa (human epithelial carcinoma cell line)
- HT1080 (human fibrosarcoma cell line)
- MonoMac6 (monocytic cell line)
- SUP T-1 (human T Lymphoblast cell line)
- HUVECS (Human Umbilical Vein Endothelial Cells)
- Primary human monocytes, acrophages, dendritic cells osteoclasts & lymphocytes derived from elutriated blood packs
- Cells derived from dissociated human synovial membrane tissue taken from rheumatoid arthritis or osteoarthritis patients (primarily fibroblasts, monocytes, macrophages, dendritic cells & lymphocytes)
- Alveolar macrophages from sarcoid patients

Host/vector system

- pENTR/U6 vector
- pENTR/4.1 vector
- pRRLsin.PPTshCMV.GFPpre vector
- pCMV-GIN-ZEO gateway vector
- pCMV-GIN-ZEO gateway rc vector
- pCMV-GIN-ZEO 234 gateway
- pLentiPPT-DEST
- p156RRsinPPT.hCMV-GFP.WPRE (LV#5)
- LV#5GR (gateway adapted LV#5)
- pLenti6/BLOCK-IT-DEST vector
- pLP1 (packaging vector)
- pLP2 (packaging vector)
The gene and promoter sequences used are of human and rat origin. We have constructed lentiviral transfer vectors encoding (1) reporter genes (e.g. TNF-luciferase); (2) cDNAs (e.g., human Foxp3, p38) and; (3) shRNAs (p38):

(1) Reporter genes will be used to measure promoter activities of the TNF, IL-6 and Stat-3 genes in primary human immune cells (monocyte/macrophages, T cells). Constructs will contain the promoter(s) and deletion mutants thereof in the presence and absence of the 3' UTR (untranslated region). These experiments will be short-term and result in destruction of target (infected) cells. We will also perform short-term (8-hour) co-culture experiments with adenovirus-infected primary human macrophages (expressing TNF-luciferase reporter genes) and primary human CD4 T cells transduced with Foxp3-expressing lentivirus. Macrophages will be infected with adenovirus for 1 hour and cultured for 24 hours in the absence of virus. Similarly, VD4 T cells will be transduced with lentivirus 14 days prior to co-culture and washed extensively prior to co-culture. The end-points for these experiments will necessitate cell lysis, resulting in destruction of the target (infected) cells. Lysates will be frozen prior to subsequent luciferase activity determination.

(2) Short-term (<4 weeks) transgene expression in human and rat immune cells using lentiviral vectors will be employed to study the role of human genes Foxp3, TREM-1, DAP12, CD38, CD164, transmembrane protein 123 (Tmem123), TLRs, tyrosine kinases, IRF family members, NFKB signaling components (e.g. Myd88), p38 MAP kinase and rat CD16A.

Immortalized human cell lines will be transduced and selected for stable expression of Foxp3. Such cell lines will be tested for replication competency using the p24 ELISA method, and all handling and disposal will be as outlined in the associated GM risk assessment.

(3) Lentiviral vectors expressing shRNA sequences (targeting the same genes as in (2) - above) and embedded in the miR30 backbone will be employed to perform specific gene knockdown in target cell populations.

The above-mentioned gene sequences will be inserted into lentiviral vectors in order to infect human and rat cells of the immune system.

Evaluation of foreseeable effects

None of these gene inserts transfer vector(s) should present a hazard. One of the transgenes, Jund, is a member of the proto-oncogene Jun family however it is an atypical
member as it has a negative effect on cell proliferation and thereby poses little risk (Hernandes et al., 2008; PGM081, section2).

The WPRE sequence located in transfer vectors encodes the potentially oncogenic X-protein sequence. There is a risk of recombination with other viruses and/or latent viral sequences in the target cells although the lentivirus produced is replication incompetent. Routine testing for replication competency of all virus produced will be performed to assess for this possibility and any such virus will be destroyed.

The use of Class II microbiological safety cabinets for II procedures involving the handling of lentivirus vectors will minimize the risk of accidental exposure to workers should a replication competent lentivirus arises during virus production and/or use.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: inactivation by the addition of Microsol3 to a final concentration of 10%, or 1% (final concentration) Trigene/Virkon, as per manufacturers’ instructions. The effectiveness of each reagent is checked on any change in procedure. Inactivated waste will be disposed of via sink into the drains.

Solid waste: plasticware such as plates, culture flasks, are double bagged and either autoclaved at 136º C for 6 minutes under vacuum. The run number is recorded and chart paper traces and printouts kept. The autoclaves are serviced bi-annually and validated yearly by contract using representatives dummy loads in order to check that all areas of the load are reaching the required temperatures. Autoclaved waste then proceeds via the Imperial College clinical waste route.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Part 1: PI CID number missing and the GM Centre is: GM165.
1.22: Change last strain to: Murine bone-marrow-derived cells.
1.24: State clearly which of the vectors contain the WPRE elements.
1.25: Third before last paragraph, Typo: 'tehse'
1.3: Please answer the questions in this section
2.1.1.2: Associated hazards: The WPRE element has oncogenic potential and then there is the risk of recombination with other viruses. Although the vectors are replication incompetent.
2.1.1.3: Explain why the answer is 'no'
2.1.1.4: Answer is 'n/a'
2.1.1.5: Answer: not altering existing traits.
2.1.1.6: Answer: None associated.
2.2.1.1, 2.2.1.2 and 2.2.1.3: Explain why the answer is 'none'
2.2.1.4: Answer: None, recombination incompetent
2.3.1.1: Change answer to "Working with handling of viral vectors containing WPRE".
2.3.2.2.b: Change answer to Yes. Also provide details.
2.3.3.2.b: Question is unanswered
2.3.3.3.b: Explain answer
2.3.3.3.d: Leave aerosols to settle first, then disinfect and finally use soapy water.
2.3.3.4.a: Typo: 'tehn'
2.3.3.5, 2.3.3.6 and 2.3.3.7: Questions are unanswered.
2.3.3.8.b: Remove 'Latex gloves'
2.3.3.8.c: Change answer to "No other PPE is used".
2.3.6: Tick box: 2
Part 3: Fill in Tick box.
3.1.1.a: Waste container should be 'sealed' and remove reference to sharps.
3.1.1.b: Change Autoclave cycle details to 136°C for 6 minutes.
Change 'temperature recorder' to 'print out'
Location of backup is: Basement and BSU, in event of a breakdown list the secondary autoclave.
3.2.a: Change answer to, "tubes carried in a rack".
3.31.a: Answer is 'None', delete the answers in rest of the section.
3.32: Answers are: n/a
4: Answer is 'no'
3.5.a: Spillage during transport: disinfect first.
3.5.b: Skin surface contamination: Use microsol wipe, then soapy water.
Medical intervention/prophylaxis: Change answer to section 2.3.5 of the form.
3.7.1: Remove staff that have left and add the CID numbers of those missing.
3.7.2: Question is unanswered: cleaners etc...
Agreed Class 2, Containment Level 2. This project is notifiable to the HSE.

All of the comments of the two committees have been addressed and the requested amendments incorporated into the risk assessments forwarded with this form.

Historical Date of Additional Info 14/12/1999, 24/07/2002

Project Additional Information

Purposes of the contained use

Recipient or parental organism

Host/vector system

Origin & function
Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [ ]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

## Project Additional Information

### Purposes of the contained use

The aim of this project is to determine the role of macrophages in tumour angiogenesis, particularly the role of HIF in the hypoxic induction of the pro-angiogenic activity of macrophages. It is not possible to transfect human macrophages using conventional techniques but these cells have been efficiently transduced with adenovirus.

### Recipient or parental organism

Replication-defective adenovirus will be produced in the human kidney endothelial cell line HEK-293 after conventional transfection. The virus will then be used to transduce primary macrophages which will be co-cultured with tumour cells growing as spheroids.

### Host/vector system

This work will make use of a commercially available adenovirus transduction kit sold by Stratagene. This is an adenovirus type 5 (Ad5) derived vector system comprising the transfer vector, either pShuttle or pShuttle-CMV (the former lacks a promoter which is then inserted along with the gene of interest, the latter includes the CMV promoter to maximise expression of the transduced gene) and a plasmid, pAdEasy-1, which contains the Ad5 viral genome deleted in the E1 and E3 regions. These are recombined in E.Coli to yield the adenoviral vector containing the gene of interest (Group 1, Containment level 1, therefore non-notifiable). The latter is then transfected into the packaging cell line HEK-293, which contains the E1A and E1B Ad5 viral genes, permitting the production of replication-defective adenovirus containing the gene of interest. The recombinant adenovirus will then be used to infect primary macrophages. The laCZ gene has been inserted in the MCS site of the pShuttle-CMV to produce pshuttle-CMV-laCZ and is provided with the AdEasy kit. This construct enables transduction efficiency to be monitored by expression of β-galactosidase.

### Origin & function

The HIF sense and anti-sense oligonucleotides will be produced commercially by TCS

The effect of the expression of these genes will be determined via a variety of functional assays following viral transduction of the primary cells and co-culture with tumour spheroids.

Assays will be performed up to 3 weeks after transduction and then the resultant cells destroyed.

### Evaluation of foreseeable effects

All of the adenoviral vectors to be used are Ad5-derived. Wild-type Ad5 infection may lead to mild upper-respiratory tract infections in children. However, Ad5-derived vectors lack the early region 1 (E1) genes so that replication-competant viral particles can only be produced where these genes are supplied in trans by the complimentary packaging cell line (HEK-293 - see above). The adenoviral vectors are therefore "unlikely to cause human disease" and are assigned to Hazard Group 1 with containment level 1 as the minimum level of containment (ACGM Compendium of Guidance Part 2b).

The vectors supplied with the AdEasy kit also lack E3 genes. This increases the size of the insert that can be introduced into the vector but at the same time also "reduces the likelihood of a GMM causing harm as a consequence of making the virus less able to establish and maintain an infection" (ACGM Compendium of Guidance Annex III).
This is a theoretical possibility that recombination events (between the recombinant virus and the viral sequences in the 293 cells or between the recombinant and wild-type virus) could lead to the occurrence of replication-competent adenovirus. This can be monitored for. HIF is a transcription factor binding to DNA recognition sites known as hypoxia responsive elements (HRE). HIFs are expressed in many cell types and although produced continuously by normoxic cells, they are unstable and rapidly broken down. Under hypoxic conditions the breakdown pathway is inhibited thus upregulating the expression, stability and DNA-binding of HIF. Thus any contamination of the body would be disposed of by the normal breakdown pathway for these proteins. The protein -galactosidase, expressed by the lacZ gene in the control virus, is a widely used reporter with no known deleterious properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be treated, by incubation for several hours, with concentrated hypochlorite or Virkon, before disposal to the public sewer. All solid waste will be autoclaved and then disposed of via incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

At a meeting of the Local Genetic Modification Safety Committee on January 23rd 2001, the risk assessment was felt to be suitable and satisfactory to allow this work to proceed as a designated Class 2 project under Level 2 containment.

Project Ref 168/01.15
CREATION OF BACTERIAL EXPRESSION CONSTRUCTS, STABLE MAMMALIAN TRANSFECTED CELL LINES FOR THE INVESTIGATION OF THE FUNCTION AND MOLECULAR INTERACTIONS OF PROTEINS IN SIGNAL TRANSDUCTION PATHWAYS

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Date of Significant Change

Project Additional Information

Purposes of the contained use
Investigation of the function of eukaryotic signal transduction components.

Recipient or parental organism
Laboratory E.coli strains BL21 (DE3), DH5a and XL 1 blue.
Defective third generation retrovirus vectors
Mouse, rat, hamster, monkey or human-derived cells in tissue culture.

Host/vector system
Bacteria will be of attenuated laboratory strains of E.coli, primarily BL21(DE3), DH5a and XL1 blue. Plasmids will be derived from the mobilisation-defective pUC vector. All amphotrophic retroviruses will be prepared from third generation packaging lines in which the helper virus lacks packaging signals and the rival genome is divided into at least two non-contiguous components.

Origin & function
The genes of interest will be from mouse, human and other mammalian species, chicken zebrafish or drosophila. Fusion proteins may also be created in some cases with the fluorescent proteins from Coelenterates or with other reporter proteins from insects (such as luciferase) or bacterial chromogenic enzymes.

The natural function of the genetic material will be under investigation, but will fit broadly into the processes of intracellular signalling responses to extracellular signals. Typical molecules of interest will be cell surface receptors, receptor associated protein kinases, small G protein (the ras superfamily), adaptor molecules, scaffolding proteins, non-receptor protein kinases, phosphatases, caspasases and other apoptotic effector proteins and transcription factors.
Mutated genes, either derived from natural sequences or as a result of site-directed mutagenesis, will be expressed in many cases. Some of these mutated genes will encode proteins that have activated or dominant negative functions.
Experimental constructs will be designed to allow biochemical investigation of the functions of the gene products, the raising of anti-sera in appropriate animals for the detection of the endogenous proteins.

### Evaluation of foreseeable effects

#### Health of the Worker

Cytoplasmic and nuclear signalling components are generated within the cytoplasmic phase of the cell. They are not secreted by overexpressing bacteria or cell lines. If cells do rupture and are simultaneously presented (as a result of an accident, with injury, for example) to the tissues of an individual handling the materials, the components will not be available to the normal cellular compartments in which they are functional without passing through the cellular endosomal pathway, where they are likely simply to be degraded. Routine exposure is minimised by good laboratory practice, but if it occurs is likely to result from the inhalation of aerosols containing overexpressing bacteria, cells or supernatants containing retroviruses.

Replication-defective amphotrophic retroviruses will be used for the efficient expression of genes within non-rodent cells, such as human or monkey-derived lines. On infection of the human cells, the defective virus is unable to perform more than a single round of infection, because capsid proteins and reverse transcriptase are not present within the recombinant viral genome, but are provided only by the packaging cell line. In third generation packaging lines, which will be used here, the viral proteins are provided by a segmented retroviral genome that lacks the viral packaging signals. It is thus extremely unlikely that a recombination event could restore either the packaging virus. If it did, though, then it would be able to facilitate the transfer of the defective virus between cells. To ensure that such recombinations are not occurring, amphotrophic packaging cell will be tested monthly while in use for the presence of reverse transcriptase activity.

Bacterial used for the expression of eukaryotic signalling molecules will be of attenuated laboratory strains of E.coli, primarily BL21 (DE3), DH5a and XL1 blue. They are unlikely to colonise the gut in competition with the endogenous flora. All expression systems will rely on inducible promoters and will use non-mobilisable vectors (derived from pUC) and therefore will not be transferred efficiently to endogenous flora. On lysis within the gut, expression products will be exposed to the destructive gut contents and will not be available to act in the cytoplasm where they must be present in order to function. The risks to the worker are therefore extremely low.

#### Environmental Implications

There is no anticipated release either of bacterial agents or retroviruses to the environment. The bacteria are laboratory strains and will be unable to compete in the environment. In the absence of selective pressure, plasmids, which are burdensome to replicate, will tend to be lost. Expression of eukaryotic intracellular proteins by bacteria in the environment will have no foreseeable consequences. The consequences of accidental release would therefore be negligible.

Yields of retroviruses are quantitatively very small, (typically 10,000-100,000 per ml of culture) and quantities of medium used in establishing stable cell lines is typically 10 ml. Retroviruses have a short biological half-life (less than 24 hrs) and are destroyed by drying. the likelihood of the retrovirus reaching an unintended biological target is therefore extremely small. The retrovirus is unable to sustain further cycles of replication after release from the packaging cell line. Should there be accidental release, the implications would be negligible.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not relevant

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None required

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Retrioviral packaging lines will be tested monthly, while in use, for the presence of reverse transcriptase in their cell supernatants according to Pyra et al (1994) Proc Natl. Acad. Sci. (USA) 91, 1544-8.

Retrovirus contaminated waste will be disposed of by mixing medium with sodium hypochlorite at least 1% or will be treated with virusolve, as described by the manufacturers, and disposed of via the drains or will be incinerated. A complete kill is expected.
Bacterial cultures will be treated with sodium hypochlorite solution at >1%. Cultures will be disposed of to the drains after standing for 30 min. A complete kill is expected as this is a standard microbiological practice.

This project was presented to a meeting of the Local Genetic Modification Safety Committee on 23 January 2001. The risk assessment was held to be suitable and satisfactory to allow it to be forwarded to the ACGM as a Class 2 project under level 2 containment.

Historical Significant Changes

Withdrawn N
Purposes of the contained use

To construct replication deficient, recombinant viral vectors (Adeno-X and Sindbis) containing ion channel genes for gene deliveries into cultured mammalian cells, particularly non-dividing cells, for the study of the properties of the expressed ion channel genes.

Recipient or parental organism

The recipients in this study are different types of mammalian cells (e.g., Human Embryonic Kidney cell lines and Baby Hamster Kidney cell lines) and cultured mammalian cells/tissues (e.g., rat and mouse neural cells, rat and human macrophages).

Host/vector system

Both the Adeno and Sindbis vectors used in this study are replication deficient derivatives available commercially. Both require packaging cell lines to make complete virus particles. The viral particles can undergo only one round of infection.

The Adeno virus vector is available from CLONTECH as linear DNA (Adeno-X). The DNA of this virus has a deletion removing most of the Early region 1 (E1) (which is responsible for cell transformation and tumourigenicity) and E3. The deletion ensures that recombinant adenovirus is not infectious and replication incompetent. The Adeno-X virus is unable to replicate in cells other than the complementing cell line, HEK292, which expresses the proteins required for viral assembly. The replication deficient Adeno vectors have no mechanism for long-term maintenance in the cells.

The Sindbis system used in this study is a replication-deficient derivative of the alphavirus Sindbis commercialised by Invitrogen in a proviral plasmid form, pSinRep5.

pSinRep5 is a plasmid DNA vector used to generate recombinant RNA molecules, by in vitro transcription. The RNA thus produced will be used for transient transfection of a packaging cell line, baby hamster kidney cell line (BHK), commercially available from Invitrogen. The Sindbis structural protein genes have been deleted from the vector to make the virus replication-deficient.

DH-BB (Defective Helper, deleted between BspM 11 and Bam H1) is a plasmid NDA template that contains the genes for the four structural proteins required for packaging of the Sindbis viral genome.

Origin & function

Known ion channel genes will be inserted into the viral genome for transient expression in a target host cell. These genes present no risk to human or animal health or to the environment.

Evaluation of foreseeable effects

The level of exposure of workers to infectious viral particles will be low (no handling of large volumes, no aerosol generation). Neither the recombinant nor the non-recombinant viral particles is likely to have any pathogenicity. In the extremely unlikely event of viral particles infecting a worker through a cut or lesion, the area infected will be very limited as the infection will not spread to the rest of the body and will be without any consequences as the expression of viral and recombinant proteins is transient.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment Level 2 required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All culture vessels and objects (mainly disposable plasticware) coming into contact with viral particles will be immediately immersed in fresh 3% Virkon for at least 3 hours and autoclaved at 121 degrees C for 25 minutes. All disposable solid waste will then be packaged for disposal by the University's normal route.

Virkon will be added to all waste culture media to a final concentration of 5%. All liquid waste will then be autoclaved at 121 degrees C for 25 minutes. The liquid waste will then be disposed of down the laboratory sink.

These procedures will result in a 100% kill of cells.

Appropriate disinfectants (Bleach or Virkon) will be used to decontaminate exposed work areas.

### Purposes of the contained use

The aim of the contained use is to identify genes in Aeromonas and Vibrio spp. that are involved in pathogenesis, adherence, motility and LPS biosynthesis. These genes may be involved in the colonisation process of these organisms.

### Recipient or parental organism

- **Escherichia coli K-12**
  - Aeromonas spp. Including (Aeromonas caviae, Aeromonas hydrophila, Aeromonas veronii bv sobria)
  - Vibrio spp. Including (Vibrio parahaemolyticus, Vibrio cholerae)

### Host/vector system

- **Escherichia coli K-12:** CC118 (pir) containing derivatives of the suicide plasmid pKNG101, pUTminiTn5 derivatives.
- **E. coli K-12:** DH5a and XL-1 Blue containing derivatives pBBR1MCS.
- **E. coli K-12:** BL21-DE3 containing derivatives of pET28
E. coli K-12: HB101 (pRK2013)
Aeromonas spp. and Vibrio spp. containing derivatives of pBBR 1MCS, pUTminiTn5 and pKNG101.

**Origin & function**

The genetic material will be obtained from primarily Aeromonas spp. (A. caviae) and Vibrio spp. (V. parahaemolyticus). Initially the whole genomes of the Aeromonas spp. will be represented, as plasmid libraries will be constructed in E. coli (multi-copy). Therefore all gene functions present in Aeromonas will be represented in the library, provided that they can be expressed, which is not always the case.

Homologues of the specific genes identified in Aeromonas, will be isolated from the chromosome of V. cholerae (or other Vibrio spp.) using PCR and information gained from the genome sequence, therefore genomic libraries of these organisms will not be constructed.

**Evaluation of foreseeable effects**

There are no foreseeable harmful effects resulting from the construction of the recombinant E. coli K-12 strains, as they already carry a number of mutations that leave them disabled.

Aeromonas spp. and Vibrio spp. cause a variety of diseases in humans and animals, including fish amphibians and reptiles. Both are considered to belong to ACDP hazard group 2. There is no foreseeable significant increase in harmful effects resulting from the construction of the previously mentioned recombinant Aeromonas spp. or Vibrio spp. in comparison with their wild-type parental strains. There is a possibility that plasmid complemented strains may express certain genes at a higher level than the wild-type. However, as the pathogenicity of these organisms is a complex multi-factorial process requiring many genes, it is extremely unlikely that any clone will have a significant increase in its ability to cause harm or to the survive in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- **Project notified under transitional arrangements**: N

#### Purposes of the contained use

Specific gene expression in prostatic cell cultures will be modulated using recombinant DNA technology. Initially, cDNAs will be generated as RT-PCR products and cloned. The amplified sequence will then be sub-cloned, either in the sense or anti-sense configuration, into a retroviral expression vector. The retroviral expression constructs will be cloned into a packaging cell line to produce replication incompetent virus particles expressing the gene of interest in either the sense or anti-sense
configuration, under control of the Tet operon. These retroviral particles will then be used to obtain stable transformation of human cell lines expressing the sequence of interest under tetracycline control.

Recipient or parental organism

HOST
RetroPack PT67 retroviral packing cell line (third generation packaging cell line)
The packaging cell line is capable of producing replication incompetent retrovirus (see below for effects) after transfection with the aforementioned plasmids.

Replication incompetent retroviruses
The replication incompetent retroviruses are capable of transfecting a wide range of mammalian cells, inducing the target cells to constitutively express the insert sequence in either the presence, or absence of tetracycline (depending on whether Tet on or Tet off vectors are used). The constitutive expression of cloned sequences could potentially have deleterious effects (see list below)

Human cell lines
Human cell lines that have been infected with replication incompetent retroviruses will constitutively express the cloned sequence, either in the presence, or absence of tetracycline (depending on whether Tet on or Tet off vectors are used). These cells are not able to produce retroviruses. The transfected cells are cell culture dependant, and therefore do not pose a health and safety risk over the untransformed parental cells, with the exception of the theoretical risks associated with recombination.

Host/vector system

The pRev vectors will be transfected into the packaging cell line producing replication incompetent virus particles expression the gene of interest. The pRev plasmid contains only the packaging signal and the packaging cell line contains genes required for non-replicating virus particle formation. These genes are present within the packaging cell line as several independant sequences, reducing the probability of recombination events producing replication proficient virus particles (third generation packaging cell line). These replication incompetent retroviruses will then be used to produce stable transformed human cell lines expressing the sequence of interest.

Origin & function

All expressed sequences will be normal, human cDNA sequences obtained by cloning of human cDNA. Sequences will be expressed in the sense or anti-sense configuration, to either increase expression of, or to abolish endogenous expression of the protein of interest.

Sequences that are likely to render the replication incompetent retroviruses to be replication competent, will not be cloned. In addition, no known transforming oncogene sequences will be used, and no more than one sequence will be transfected into any cell population. The sequences of interest are a heterogeneous group of molecules including growth factors and their receptors, intracellular signalling molecular and proteins involved in the production or degradation of extra-cellular matrix. Lists of sequences that come under these headings, in addition to a small number of miscellaneous sequences are shown below.

LIST OF GENE SEQUENCES TO BE CLONED AND EXPRESSED
Growth factors and receptors, including:
Transforming growth factor (TGF)a
TGFb1-3
Epidermal growth factor (EGF)
Fibroblast growth factor (FGF)1-23
Insulin-like growth factor (IGF)1-2
Connective tissue growth factor (CTGF)
Interleukin-6 (IL-6)
Tumour necrosis factor (TNF)a
Tumour necrosis factor receptor superfamily, member 11 (TNFRSF11) (Osteoprotegerin (OPG))
Colony stimulating factor (CSF)1-2
Bone morphologic protein (BMP)1-9

Cellular signalling proteins, including
Growth factor receptors (see above)
SMA and MAD-related protein (SMAD)1-7
Receptor activator of NK-Kappa-B Ligand; (RANKL)
Androgen receptor (AR)
Estrogen receptor (ESR)1-2
Glucocorticoid receptor (GR)
Retinoid X receptor (RXR) a,b and y
Retinoic acid receptor (RAR) a and B
TNF-related apoptosis-inducing ligand (TRAIL)
TNF-related apoptosis0inducing ligand receptor 1; (TRAILR1)
Apoptosis-related cysteine protease; (CASPASE)1-14

Other proteins, including
Matrix metalloproteinases (MMP)1-26
Tissue inhibitors of metalloproteinases (TIMP)1-4
Plasminogen activators (tPA and uPA)
Plasminogen activator inhibitor (PAI)1-2
A disintegrin and metalloproteinase domain (ADAM) 1-20
A disintegrin-like and metalloproteinase with thrombospondin type 1 motif, (ADAMTS)1-7
Latent transforming growth factor-beta-binding protein (LTBP)1-4

Extracellular matrix proteins, including
Collagen type 1 and IV
Fibronectin

**Evaluation of foreseeable effects**

The replication incompetent retroviruses are capable of infecting a range of mammalian cells, resulting in constitutive expression of the cloned sequence under the control of tetracycline. Transforming oncogene sequences, and viral sequences that will allow production of replication competent viruses will not be expressed. Transient infection with replication incompetent sequences would allow stable transformation of the user. The most likely route of infection would be needle stick injury, or aerosol inhalation. The risks of aerosol inhalation or needle stick injury will be minimised by the use of class II biological safety hoods and by not using any sharp instruments or disposables (syringe needles, scalpels etc.) In both situations, the resulting transformation would be expected to be identical to injectionm or inhalation of naked plasmid DNA. The efficiency of stable transfection via retroviral infection, however, would be substantially higher than with naked DNA. If an infection was to occur, resulting in stable expression of one of the aforementioned sequences, serious effects would not be expected. The expressed sequences are normal gene products. It must be stressed that the modulation of expression of many genes are required for transformation of normal cells to a neoplastic, or malignant phenotype. Therefore the risks of serious effects of infection, if it were to occur, are small.

The use of third generation packaging cell lines ensures that the risk of recombination, producing replication competent retroviruses is a remote and theoretical risk. However, all infected cells will be checked for the presence of replication competent virus in stable transformed cell lines and transfection reactions using a reverse trascriptase activity assay.

The intended genetically modified organisms (human cell lines) are not likely to have any increased health and safety risk associated with modification over the parent cells, other than the theoretical risk of recombination. The cells are dependent on cell culture conditions and modification is therefore unlikely to confer an increased health and
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially contaminated waste will be precept treated, autoclaved and disposed of in sealed waste bins for incineration. Treated waste will be tested for the presence of retroviral activity using a reverse transcriptase activity assay. Combined precept treatment and autoclaving would be expected to achieve 100% kill.

Project Ref 168/02.3

Date Ackn’d 08/10/2002
CU2 Project Title ANALYSIS OF GENE FUNCTION IN THE OPPORTUNISTIC PATHOGEN
Class 2
CultureVolClass2 1-50 litres
CultureVolumeClass3-4
The aim is to learn more about the biology of this fungal pathogen using a genetic approach based on the genome sequence. This follows on from work in progress to sequence the whole genome of this species in the US and the UK. Work currently proposed will focus on genes of secondary metabolism.

Aspergillus fumigatus is a saprophytic filamentous fungus, found commonly in the soil/rhizosphere, with similar metabolic properties to other soil aspergilli such as A nidulans and A niger, growing on organic debris. Its asexual spores (conidia) are amongst the most ubiquitous of airborne fungal spores. Since inhaled spores are dealt with effectively in healthy individuals, its main threat is to immunocompromised hosts. Its prevalence as a pathogen has therefore increased in recent years amongst patients undergoing cancer treatment (especially leukaemia), bone marrow transplants and solid-organ transplants.

Recipient or parental organism

Aspergillus fumigatus is a saprophytic filamentous fungus, found commonly in the soil/rhizosphere, with similar metabolic properties to other soil aspergilli such as A nidulans and A niger, growing on organic debris. Its asexual spores (conidia) are amongst the most ubiquitous of airborne fungal spores. Since inhaled spores are dealt with effectively in healthy individuals, its main threat is to immunocompromised hosts. Its prevalence as a pathogen has therefore increased in recent years amongst patients undergoing cancer treatment (especially leukaemia), bone marrow transplants and solid-organ transplants.

Host/vector system

Host: Aspergillus fumigatus AF293 (wild-type)
Aspergillus fumigatus AF293-1 (uridine-requiring auxotroph)
Vectors: derivatives of pBluescript and pUC19 carrying the pyr-4 gene of Neurospora crassa as a selectable marker to complement the host pyrG mutation, or the hygromycin phosphotransferase gene (hph) of E coli under the control of a fungal promoter as a selectable marker to transform the wild-type strain.

Origin & function

Genetic material will be from extracted Aspergillus fumigatus genomic DNA, or from cosmid libraries of A fumigatus obtained from sequencing centres.

Gene disruption and increased gene expression will be sought in order to analyse gene function in A fumigatus. Initial work will be with genes encoding biosynthetic steps for secondary metabolites. Mutant strains will then be analysed for changes in gene product(s) by small scale fermentation and chemical analysis of culture material. The main aim of the research is to learn more about the biosynthesis of secondary metabolites by filamentous fungi, using A. fumigatus as a model system because of the imminent completion of its genome sequence, giving access to all of its genes.

The preferred route is to look for loss of a compound following disruption of a gene.
Where the gene product is made in very small amounts, as is often the case for secondary metabolites, overexpression of a gene may aid identification of its product.

In some cases, mutant strains with characterized changes in metabolism will be sent to other laboratories for pathogenicity testing, since the possible role of secondary metabolites in pathogenicity is not yet understood.

**Evaluation of foreseeable effects**

Gene disruption/overexpression is likely to result in changes in the amount of secondary metabolite produced by the modified fungal strains.

Secondary metabolites are not usually essential for growth and reproduction of a species, but do include biologically active compounds such as antibiotic and toxins (e.g. gliotoxin, fumitremorgins).

Some of these may play a role during infection, since they may have inhibitory activity against animal cells. Gene disruption is likely to lead to a strain which would still grow, but has lost one of its non-essential functions. Strains with increased expression of a toxin could lead to increased pathogenicity, but since pathogenicity is likely to depend on a combination of many factors, it is unlikely that single change, which could also arise by spontaneous mutation, would have a major effect on pathogenicity or persistence of the modified strain in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

As with unmodified A fumigatus, the main risk for infection or environmental contamination is via airborne conidia. Only dry spores (e.g. on sporulating agar plates) are easily dispersed in the air. Once wetted and converted into conidial suspensions in tween 80/Saline, they are unlikely to become airborne. Harvesting of spores (used for inoculation of liquid and solid media) and inoculation of cultures will be carried out in a Biohazard Cabinet. Outgoing air from the cabinet is filtered, and the cabinet is serviced every 6 months. Prior to servicing, the system is fumigated with formaldehyde (60% formaldehyde in water, overnight fumigation) as recommended by the manufacturers). After routine use for handling spores, the Biohazard Cabinet is swabbed with 20% sodium hypochlorite solution.

Since shaken liquid cultures (mycelial growth) do not conidiate, they do not present the same risk of airborne dispersal. Flask cultures of up to 1 litre culture per flask (up to 1 litre culture per flask) will be grown to extract protein for enzyme assays, and to extract culture supernatant and filtered mycelium to detect metabolites. Mycelium will be harvested by filtration, and disrupted to obtain soluble protein. Culture supernatant and dried mycelium will be used for analysis for metabolites.

After use, plate cultures, mycelium and spent culture medium will be sterilized by autoclaving with the Department of Molecular Biology and Biotechnology. The central autoclave used for sterilization is validated at least every 12 months.

In the event of spillage, the area will be effectively disinfected using sodium hypochlorite (20% solution).

100% kill is obtained by all 3 methods of waste management.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The risk assessment was considered by the local genetic modification safety committee on 22/1/02, who suggested inclusion of further details of environmental risks in the initial risk assessment. This has now been incorporated in the attached risk assessment.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**
Overview or aim of the project: The aim of this project is to determine if the infection of cells by RSV is via the recognition of a specific surface antigen. Previous studies have demonstrated that RSV infects a proportion of cells in vitro. In these studies the fixing and permeabilising of the cells to detect intra cellular RSV antigens modified the detection of other cell surface antigens. Using rg-RSV will allow the sorting of the RSV infected cells by flow cytometry. It would then be possible to stain both the infected and uninfected cells for surface antigens to determine whether a specific phenotype predisposes a subset of cells to RSV infection. This technique can be carried out without disrupting the surface antigens. The identification of a specific antigen required for RSV infection would be a major stepping-stone in the development of RSV treatment and vaccines. The project will require the propagation the laboratory A2 strain and the genetically modified viruses in HeLa cells. RSV encodes 3 transmembrane surface glycoproteins in the viral envelope, G (glycoprotein), F (fusion) and SH (small hydrophobic). It is proposed that at least one of these proteins is essential for RSV infection. Cells will be infected with RSV mutants lacking of these proteins to assess the importance of each for efficient RSV infection. RSV infection will be determined by fix-permeabilising the cells and staining for RSV antigens. Rg-RSV and the deletion mutants will also be used.

The construction of the virus is described in Hallak et al (2000) and a full description of the rescue system is in Collins et al (1995) both papers are attached. The modified virus strains have been developed in the laboratory of Rush-Presbyterian-St Luke's Medical Centre, Illinois. The rg-RSV is the same as the standard A2 RSV laboratory strain, except that it expresses an additional gene (GFP) when it replicates. The rg-RSV and the deletion mutant (described in Techaarpornkul, 2002) are to be kindly donated and no further genetic modifications will be made in our laboratories for the proposed studies.

The infectivity of the virus declines over time so it is necessary to propagate the virus to increase both the infectivity and titre of virus for use in the experiments. The virus will be propagated in HeLa cells. The infected cells will carry no hazards beyond those infected with the laboratory A2 strain of RSV.

HeLa cells: The A2 laboratory RSV, and the modified RSVs will be propaged in HeLa cells. Cells infected with the modified RSV will carry no hazards greater than cells infected with the laboratory A2 strain of RSV. It is expected that titre of infectious virus will be lower than the A2 strain. Cells are unable to survive outside of the tissue culture environment. Good cell culture practice, within a class II laboratory, will be followed when handling the infected cells. Infected HeLa cells will be cultured in a designated experimental incubator.

(Secondary host) human cells: Cells infected with A2 laboratory RSV or modified RSV will carry no hazards greater than cells infected with the laboratory A2 strain of RSV. It is expected that titre of infectious virus will be lower than the A2 strain. Cells are unable to survive outside of the tissue culture environment. Good cell culture practice, within a class II laboratory, will be followed when handling the infected cells. Infected cells will be cultured in a designated experimental incubator. Cells will not be isolated from the researcher for use in these experiments.

The modified RSVs are to be kindly donated by Rush University, Illinois. The rg-RSV is the same as the standard A2 RSV laboratory strain, except it expresses a reporter gene when it replicates. The virus construction and rescue is described briefly below and in detail in Hallak et al, 2000 JViro/ 74:10508-10513, Collins et al., 1995 PNAS 92:11563-11567.

Transfection and Recovery of recombinant RSV: Monolayer cultures of Hep-2 cells were infected with 1 focus-forming unit per cell strain MVA vaccinia virus recombinant expressing T7 RNA polymerase (MVA-17) and transfected with antigenome, N and P plasmids and L and M2 (ORF1) plasmids using LipofectACE.

Preparation of rg-RSV: Full length RSV cDNA clone MP224 used to rescue rgRSV was constructed to contain green fluorescent protein as its first gene by inserting a BstX1 fragment containing the gene start, the NS1 region, the Green Lantern Protein gene and the L gene end.
This BstX1 fragment was generated by transferring the BstX1/BamH1 fragment from the minigenome C41-GFP into another minigenome MP129 to create MP166 and transferring the Xhol/NCOI fragment from MP166 into MP90 a bipartite minigenome containing the GFP flanked by BstXI sites and followed by the luciferase gene, to create MP169. The BstXI fragment from MP169 was moved into the full-length RSV cDNA clone, D46, to generate MP224. MP224 was recovered by transfecting it along with four plasmids expressing the N, P, L and M2-I support proteins into Hep-2 cells transcription from these plasmids was driven by T7 RNA polymerase provided by the recombinant vaccine virus MVA-T7.

Evaluation of foreseeable effects

The laboratory A2 RSV strain is routinely used in RSV studies due to the difficulty in propagating wild type isolates in the laboratory. The virus could potentially infect humans. Infection in adults results in mild-cold-like symptoms including running nose and coughing. The virus will be handled whilst wearing a howie coat and gloves and in a class II cabinet, and cultured and stored with within a contained area using good handling, cell culture and laboratory practice (as described in COSHH assessment). Virus stocks will be contained in a designated area of a -80 degree C freezer.

The addition of the reporter gene on the RSV will not carry hazards greater than the laboratory A2 strain. The deletion mutants will be less hazardous than the A2 strain. The reporter gene does not alter the pathogenicity of the A2 strain. The deletion mutants will have reduced pathogenicity. The reporter gene is unlikely to confer extra pathogenicity to other related organisms.

There is unlikely to be any risk to human health or the environment. The virus does not readily survive outside culture conditions, but can be transferred by aerosola. Good laboratory practice will minimise these risks. The virus is required at high titres for efficient infection. The virus rapidly degrades even at -80 degree C. Beyond passage 7 titres of the modified virus decline.

We will ensure that hazards are contained by implementing good working practice (aseptic techniques) and by regular servicing of the class II safety cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment for this project will be at level 2. We will ensure that hazards are contained by implementing good working practice (aseptic technique) and by regular testing of the disinfected cultures and by regular servicing of the class II safety cabinets.

Infected and uninfected cells will be disinfected with bleach for 24 hours. The disinfected culture supernatant will be checked for viable virus using the plaque assay. Aliquots of disinfected culture supernatant will be added to cultures of HeLa cells and the formation of viral plaques will be checked by staining with RSV antibody. The containment procedure will be reviewed annually.

We will ensure that hazards are controlled by containment by implementing good working practice (aseptic technique) and regular servicing of the class II safety cabinets.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
A risk assessment for this project was presented to a meeting of the Local Genetic Modification Safety Committee on Tuesday 20 January 2004. It was agreed by the committee that this proposal should be forwarded to the ACGM as a Class 2 project, as soon as a cheque could be raised.

Project Ref 168/05.1

Date Ackn'd 10/02/2005

Date Project Ceased

Date of Significant Change

Project Additional Information

The aim of this project is to achieve both efficient and stable delivery of lentiviral vectors to vascular cells allowing either over-expression of SERT, IL-1ra and S100A4/Mts 1 or gene knock-down via delivery of short hairpin RNA constructs targeting BMP-RII, SERT, IL-1ra and S100A4/Mts 1 that will induce specific RNA interference and assess their role on signalling pathways and phenotype.
# Parental Micro-organism to propagate Lentiviral DNA

*Escherichia coli STBL3* (invitrogen) are purchased commercially.

# Parental Organisms to propagate replication deficient lentivirus

*Human Embryonic Kidney 293* packaging cells.

# Recipient Organism

*Human and Rodent primary vascular cells.*

---

## Host/vector system

**Hosts:** Human Embryonic Kidney 293 packaging cell line transformed with pCMVSPORT6T.neo plasmid to express the SV40 large T antigen/human and rodent endothelial and smooth muscle cells (primary cells).

**Vector:** pLenti6/V5 Dest (Invitrogen) & pLenti6-CMV/V5 Dest (Custom made by removing the CMV promoter for pLenti6/V5 Dest).

**Over-expression Insert:** human Serotonin transporter (hSERT), human S100A4/Mts1, human Interleukin 1 receptor antagonist (IL-1ra).

**shRNA Insert:** Human SERT, Human Bone morphogenetic protein receptor 2 (BMP-RII) and IL-1ra.

---

## Origin & function

### siRNA

pLenti6/V5 and pLenti6-CMV/V5 produce a replication-incompetent HIV-1 based lentivirus, which can be used to deliver and express the gene/shRNA cassette in mammalian cells.

Lentiviral containing supernatant will be collected from the 293FT (Invitrogen) packaging cells and used to infect both human and rodent primary vascular cells.

**Over-expression Vectors**

- **Over-expression of the full length human serotonin transporter (SERT) cDNA - sequence attached.**
  The function of SERT is to transport the neurotransmitter serotonin into and out of the cell, a mechanism that regulates extracellular levels of serotonin via breakdown by monoamine oxidase following transport. Serotonin transport and signalling has been linked to proliferation and contractility in vascular cells.

- **Over-expression of the full length Interleukin 1 receptor antagonist (IL-1ra) cDNA - sequence attached.**
  The function of IL-1ra is to compete with the pro-inflammatory cytokine IL-1 for the binding of the IL-1 receptor on the cell surface.

- **Over-expression of the full length S100A4/Mts1 cDNA - sequence attached.**
  S100A4/Mts1 is a small calcium binding protein that promotes motility in cancer cells, smooth muscle cells and endothelial cells.

**shRNA Cassettes**

- **Expression of U6-BMP-RIIshRNA to induce specific RNAi-induced knock-down of BMP-RII expression.**
  The bone morphogenetic protein receptor 2 (BMP-RII) signalling pathway has been linked to inhibition of proliferation in pulmonary vascular cells via the SMAD and/or p38 signalling pathways. Knock-down via RNAi should result in a more proliferative phenotype.

- **Expression of U6-SERTshRNA to induce specific RNAi-induced knock-down of SERT expression.**
  The function of SERT is to transport the neurotransmitter serotonin into and out of the cell, a mechanism that regulates extracellular levels of serotonin via breakdown by monoamine oxidase following transport. Serotonin transport and signalling has been linked to proliferation and contractility in vascular cells.

- **Expression of U6-IL-IrashRNA to induce specific RNAi-induced knock-down of IL-1ra expression.**
  The function of IL-1ra is to compete with the pro-inflammatory cytokine IL-1 for the binding of the IL-1 receptor on the cell surface. Knock-down of IL-1ra should allow for
Evaluation of foreseeable effects

Infection of primary human and rodent vascular cells will be relatively short lived, due to the antibiotic selection issue of primary cells. The typical experimental time course will be 3-10 dyas, after which the cells will be destroyed.

The expected effects of these vectors on transduced cells are described above. Although the risk of homologous recombination with wild type virus is low (human vascular cells are purchased from Cascade Biologics and are screened for infectious agents prior to shipping), caution will be observed and therefore handled in a class II Microbiological Safety Cabinet in a dedicated category II suite in the Clinical Sciences Centre.

Likelihood of hazards is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon is used according to manufacturer's instructions (5% w/v) to inactivate liquid waste from viral infections. All glassware/plasticware will be soaked in Virkon. Glassware will then be rinsed and then soaked in bleach. Disposable plasticware and all other waste from the Category II suite is autoclaved before being placed in sealed omnibins and incinerated.

The autoclave is SCS is tested on a 6 month basis with full probe set. These data are displayed in the Category II suite for inspection.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The proposal was presented at the local GMSC at a meeting on 18 January 2005. The local GMSC agreed that this was a Class 2 proposal overall and therefore it would be forwarded to ACGM together with the administration fee for notification/approval.

### Project Additional Information

**Purposes of the contained use**

The project aims to express RANKL, OPG, TRAIL and related cytokines and their receptors, or components of the Wnt-signalling pathway, and to express anti-sense and si-RNA for these genes in mouse and human bone or tumour cell lines, to assess their effect in models of bone biology, or metastasis to bone, in mice. We intend

* to test whether various human and mouse bone and tumour lines can be infected with retroviral constructs that will lead to the expression of marker molecules such as Aequoria green fluorescent protein (GFP) or E.coli LacZ
* To raise or reduce RANKL, OPG, TRAIL, their receptors, or components of the Wnt-pathway, by transducing their genes, siRNAs or antisense constructs and controls into murine and human bone and tumour cell lines. Modified cells may be grafted into mouse hosts.

We propose to use the pCAGGS self-inactivating HIV-based lentiviral system obtained under licence from St Judes Childrens' Hospital, Memphis, Tennessee, USA (details below), although it may be necessary to employ other lentiviral systems, such as the commercially available HIV-based Virapower system from Invitrogen (see below) in order to achieve our research objectives. Any system used will incorporate the safety features outlined below.

**Recipient or parental organism**

Disabled auxotrophic non-mobilising Escherischia coli K12 strains, or B-derivatives such as BL-21 or DH5-alpha.
Human and rodent primary and established cell lines: 293T (human embryonal kidney) cells (virus packaging cell line), HeLa cells (biological titering) and other mammalian cell lines such as established models of human myeloma (eg NCIH 929, JNJ-3, RPMI 8226, OPM 2 and XG1) murine myeloma (eg 5T2MM and 5T33mm) AND PROSTATE CANCER (EG Incap, pc3), AS WELL AS OTHER BONE AND/OR STROMAL CELLS (EG saos2). It may be necessary to include other established mammalian cell lines in the study in order to achieve certain goals (eg to use TRAIL-sensitive cell lines such as Jurkat in order to investigate rescue of TRAIL-induced apoptosis by endogenous OPG).

**Host/vector system**

**Pcaggs LENTIVIRAL EXPRESSION SYSTEM:**

"Fourth generation" HIV-derived vectors, as follows:

- Gene transfer vector pCL10.1MSCV-IRES-GFP
- Viral packaging vectors: pCAGkGPIR or pCAGkGP3R (Gag/Pol)
- pCAG4-TR2 (Rev/Tat)
- pCAG-VSVG (Vesicular stomatitis virus-G envelope protein pseudotype) or pCAG4-10A1, pCAG4-Amph (both amphotropic envelope protein pseudotype).

Features that prevent generation of live virus, recombination with endogenous retroviruses and viable HIV

**A) pCL10.1 MSCV IRES GFP (gene transfer):**

The 5’ long terminal repeat (LTR) is chimera since the U3 region of the HIV-1 LTR is replaced with a CMV enhancer. A deletion of the U3 region of the 3’ LTR renders it self-inactivating.

A portion of the R region and the U5 region have been removed and replaced with the rabbit B-globin gene polyadenylation site to enhance safety and improve efficiency of vector production.

The Gag-Pol coding sequence has been "inserted" by filling in (and therefore eliminating) the Clal site (nt 830), thus creating a frameshift and termination codon.

**B) Pcaggs (VIRAL PACKAGING):**

This expression plasmid has been used to construct the cassettes expressing the HIV structural and regulatory proteins, as well as various envelope proteins. The accessory proteins tat and rev are expressed together on a separate plasmid from that expressing GAG/GAG-PRO-POL-precursor polyprotein.

The RRE element (included to enhance nuclear to cytoplasmic transfer of gag/pol encoding RNA molecules, and to modulate expression of rev and tat by fostering transport of unspliced transcripts) was incorporated in the rev/tat helper plasmid to ensure that homologous recombination will not generate a plasmid encoding both structural and functional accessory proteins.

**ViraPower lentiviral expression system:**

Features that prevent generation of the live virus, recombination with endogenous retroviruses and viable HIV

The pLenti expression vector contains a deletion in the 3’LTR that does not affect generation of the viral genome in the producer cell line, but results in 'self-inactivation' of the lentivirus after transduction of the target cell. This is a result of the natural duplication of 3’LTR into 5’ position that occurs during integration. Once integrated into the target cell, the lentiviral genome cannot produce packageable viral genome.

Only 3 HIV-1 genes are used, gag, pol, and rev. The absence of the env gene removes the gp160 precursor that is responsible for the lethal macrophage/T cell/neuro-tropism of HIV.

Production of the viruses from the producer cell line requires the transfection of 4 plasmids (three packaging, one the DNA to be packaged) in transient transfection. All four plasmids have been designed, through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging cell line produce retrovirus in any form during routine culture.

Expression of gag and pol has been rendered Rev-dependent, again minimising any possible opportunity for these genes to be transcribed except during the specific
packaging reaction when all the components are present together. The RSV promoter is used in the pLenti expression virus instead of Tat, again minimising HIV genes.

It should be noted that sequences that have caused concern in other systems, such as the Woodchuck Hepatitis virus sequence, are absent from both these systems.

Origin & function

CDBA to be expressed in this study will be cloned, using established reverse transcription - polymerase chain reaction, technology, from tumour, bone or bone-related (e.g. bone marrow stromal) human or rodent cell lines grown in the laboratory. It is intended that they be used to regulate aspects of normal or tumour-related bone turnover in vitro systems, as well as in mouse models of bone biology or disease. For example, OPG expressed by transduced cells is expected to modulate RANKL-induced osteoclastogenesis in an in vitro setting.

Evaluation of foreseeable effects

Environmental assessment:
These replication-incompetent viruses would be inactivated prior to disposal and, given their inability to replicate, they have no significant additional environmental hazard.

Worst case scenarios:
The above protocols should minimise any risk of exposure to personnel using, or in the vicinity of, work using this lentiviral transfection system. Virus particles, virally-transduced cells, and media and supernatants resulting from these systems will never be handled with glassware or hypodermic needles. Thus, the risks of accidental inoculation are remote. The worst scenario would be exposure to a main stock of virus, resulting from centrifuge failure or spillage. Risks of centrifuge failure-associated contamination (the only readily conceivable mechanism likely to generate a substantial aerosol of many infective particles) should be minimised by Good Laboratory Practice (GLP) and the steps outlined in section 12.

The major exposure routes would be cutaneous, mucocutaneous and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier and would be minimised by standards of GLP. The viruses may infect mucocutaneous surfaces and respiratory epithelia and microphages with which they come into contact. However, the particles are replication incompetent and have many safety features preventing generation of replication competent viral particles. None of the genes of interest are known oncogenes. Thus, although there is the possibility of limited tissue infection and damage, this would not result in sustained infection or risk of tumour generation or malignant transformation. It might be possible that exposure would generate an immune response to the VSVG or alternative envelope proteins but this would have a protective effect if so. The overall likelihood of serious or long-term harm resulting from experiments using these vectors is extremely small.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Anti-viral disinfectants (virusolve, virkon, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers easily to hand (e.g spraygun).
- All culture will be performed using a Category 2 hood, in a designated Category 2 molecular biology laboratory (DUI5/16 currently; the Committee would be notified before work commenced in any other laboratory). All cells exposed to virus will be handled in the Category 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench using good laboratory practice (GLP) but any cells taken out of the laboratory for analysis (e.g flow cytometry) will be fixed or rendered fully non-viable (e.g treated with formaldehyde solutions prior to flow cytometry).
- Where large volumes of supernatants containing, or potentially containing, viral particles require centrifugation, individually sealable buckets will be used in the relevant centrifuge. The bucket and contents will be inspected before opening (in the Category 2 hood). Buckets would be cleaned appropriately using virusolve, virkon or bleach.
after use. Supernatants from virally-transfected cells which had been cultured for more than one media change over several days would not be regarded as being likely to contain significant numbers of active virus, but would be handled according to GLP and neutralised prior to final disposal.

* Hoods will be carefully cleaned after each session in which culture with virus particles takes place and after each session, when cells that have been transfected by virus on a previous occasion are handled.
* Virus particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips.
* All supernatants, plastic ware and cells that have come into contact with virus particles or viral infected cells will be treated with virusolve, virkon or bleach, at concentrations recommended by the manufacturer, for 20-30 minutes prior to discard.
* Standards of GLP will be rigorously enforced (lab coats, gloves, etc).

The committee identified the point of greatest risk in the procedure as the preparation and handling of the stock virus. Aerosolisation of the virus stock was particularly discussed, and it was noted and found appropriate that Dr Buckle would be performing centrifugation inside sealed buckets at all times. Dr Buckle will put up notices to advise other lab users that non-transmissibkle lentiviral particles are being generated in certain labs, and will add notification when the viral stocks are being generated and handled.

The committee asked for assurance, which it received, that the lentiviral system would not be used to transduce oncogenes and it was stressed that the committee needed to give further consideration, perhaps preemptively, to the procedures that would be needed in handling oncogenes in similar systems.

neuronal cells using both in vitro and in vivo models of neurological disorders.

**Project Additional Information**

**Purposes of the contained use**

The purpose of this project is to assess gene therapy approaches to neuroprotection in experimental models of neurological disorders. Neuroprotection will be achieved by using lentiviral vectors expressing neurotrophic factors or anti-oxidant molecules. We also intend to express siRNA or miRNA to silence dominant genes and assess their effect in models of dominantly inherited disorders. Lentiviral vectors will also be used for gene replacement strategies in models of neurological disorders caused by deletion of genes. Lentiviral vectors will also be used for gene replacement strategies in models of neurological disorders caused by deletion of genes. Reporter genes such as green fluorescence proteins (GFP) or E.coli LacZ will be used as controls.

**Recipient or parental organism**

Various non-pathogenic disabled or non-colonisinf E.coli strains or B-derivatives such as BL-21 or DH5-alpha for propagation of plasmid constructs. Immortalized mammalian cell lines, such as HEK293T will be used for viral production. Hela cells and dog osteosarcoma D17 cells will be used for tittering. It may be necessary to include other established mammalian cell lines in the project in order to achieve certain goals. We also plan to use terminally differentiated mammalian cells including neurons (rodent) both in vitro and in vivo. Both in vitro and in vivo studies will be carried out at containment level 2.

**Host/vector system**

We intend to use both primate and non-primate derived replication defective lentiviral vectors. We will be testing two HIV-1-based vectors: (I) the self inactivating (SIN) HIV-based lentiviral system which will be provided by Dr.Nicole Deglon (France); (ii) commercially available HIV-based Virapower™ system from invitrogen. We also propose to use Equine infectious anaemia virus (EIAV)-based lentiviral vectors which will be provided by Oxford BioMedica Ltd (Oxford, UK).

HIV-derived lentiviral vectors:

We propose to use the self inactivating (SIN) HIV-based lentiviral system which will be provided by Dr. Nicole Deglon under MTA from Commissariat a L'Energie Atomique (CEA) CNRS URA2210, Service Hospitalier Frederic Joliot and ImagiGene Program, Orsay Cedex, France, although it may be necessary to employ other lentiviral systems such as the commercially available HIV-based Virapower™ system from Invitrogen in order to achieve our research objectives. Vectors-based on lentiviruses have been refined to a very high safety and efficiency levels. Any system used will incorporate the safety features outlined below.

1. SIN-lentiviral vector system (from Nicole Deglon)
Viral vectors will be generated with a four-plasmid system ("Fourth generation" HIV-based vectors (Zufferey et al. (1997) Nat Biotechnol 17:871-875; Hottinger et al. (2000) J Neurosci 20:5587-5593). The four plasmids are as follows:

- SIN-cPPT-PGK-W, gene transfer vector.
- pCMVΔR-8.92, packaging construct.
- pRSV-Rev, the accessory protein rev plasmid.
- pMD.G, Vesicular stomatitis virus-G envelope protein. It may be necessary to use other envelope proteins such as rabies-G glycoprotein to achieve specific tropism (see below for more details).

Features that prevent generation of live virus, recombination with endogenous retroviruses and viable HIV.

- Production of the viral vectors from the producer cell lines requires the transfection of 4 plasmids (SIN-cPPT-PGK-W, pCMVΔR-8.92, prsv-Rev, pMD.G) in a transient transfection. All four plasmids have been designed through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging
- Vector genomes SIN-cPPT-PGK-WPRE:A 400-bp fragment of the U3 region of the 3'LTR was deleted to obtain self-inactivating (SIN) transfer vector. The mouse phosphoglycerate kinase 1 (PGK) promoter was used as internal promoter. This plasmid was further modified by insertion of the posttranscriptional 1 cis-acting regulatory element WHV.
- pRSV-Rev is rev cDNA-expressing plasmid in which the joined second and third exons of HIV-1 rev are under the transcriptional control of the RSV U3 promoter.
- pCMVDR8.92 (packaging construct): The Vpu, Vpr, Nef and Rev coding sequences has been deleted. The accessory protein Rev is expressed on a separate plasmid. Expression of gag/pol is under the control of CMV promoter.

2. Virapower™ lentiviral expression system:

Features that prevent generation of live virus, recombination with endogenous retroviruses and viable HIV

- The plenti expression vector contains a deletion in the 3'LTR that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentiviral vectors after transduction of the target cell. This is a result of the natural duplication of the 3'LTR into 5' position that occurs during integration. Once integrated into the target cell, the lentiviral genome cannot produce packageable viral genome.
- Only 3 HIV-1 genes are used, gag, pol and rev. The absence of the env gene removes the gp 160 precursor that is responsible for the lethal macrophage/T cell/neurotropism of HIV.
- Production of the viral vectors from the producer cell line requires the transfection of 4 plasmids (three packaging, one the DNA to be packaged) in a transient transfection. All four plasmids have been designed, through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging cell line produce retrovirus in any form during routine culture.
- Expression of gag and pol has been rendered Rev-dependant. Again minimising any possible opportunity for these genes to be transcribed except during the specific packaging reaction when all the components are present together.
- The RSV promoter is used in the pLenti expression virus instead of Tat, again minimising HIV genes.
- Sequences that caused concerns in other systems, such as Woodchuck Hepatitis virus sequence are absent from Virapower™ lentiviral system.

EIAV-based lentiviral vector system (generated by Oxford BioMedica Ltd)

The EIAV minimal vector system

Equine infectious anaemia virus (EIAV) is a non-primate lentivirus that causes a self-limiting, lifelong but rarely fatal infection of all Equidae, and is a world-wide disease of...
horses, most prevalent in warmer climates. The aim when designing a EIAV-based lentiviral vector system is three-fold. The first is to minimise the amount of viral sequence in the transfer vector, thus increasing the capacity for transgenes and associated regulatory elements. The third is to express, in the production system, only those viral proteins required for efficient production of transduction competent vector. All three components, vector genome, Gag/Pol and envelope necessary to generate EIAV-base lentiviral system are being optimised by Oxford BioMedica Ltd and the current status is summarised below.

The safety profile of the EIAV vector system

EIAV vector system was modified with safety in mind making use of the strategies used in the MLV vector field to avoid the production of RCR. The most important features for safety are:

- The partition of the components of the vector system in three independent expression cassettes: vector genome, gag/pol and envelope plasmids.
- The minimal sequence homology between the vector, gag/pol and env components;
- The use of human cell lines with low of endogenous retoviral sequences as the basis for producer cell lines.

Some additional features that will reduce the potential for recombinant formation and the potential pathological consequences arising from the presence of such recombinants in the EIAV vector system are: These features provide a high safety margin.

- The use of a heterologous envelope component. Recombination events can not generate wild type EIAV;
- The use of vectors which have SIN or conditional SIN configurations and therefore are almost transcriptionally silent in transduced cells;
- The elimination of accessory proteins from the system. Tat, Rev and S2 can be eliminated from the system without affecting transduction efficiency, however, Rev is maintained in the producer system since it improves titre by increasing cytoplasmic levels of vector RNA. Expression of Rev is from an independent expression cassette, in which rev is ‘coden-optimised’ to minimise the chances of its involvement in recombination reactions.
- Transcription of the vector genome is driven by the human CMV enhancer/promoter fused to the R region of EIAV so that the first base of the transcript is the same as that formed as a result of transcription from the EIAV U3 region. This configuration allows high titres to be obtained in the absence of Tat protein.
- The coden-optimised gag/pol gene (pESYNPG) is now being utilised for construction of EIAV packaging and producer cell lines. The coden-optimisation process increases the safety of the system in two ways. First, gag/pol mRNA is unlikely to be packaged as efficiently as the wild type gag/pol RNA. Secondly, due to the lack of significant homology with the vector in the region of the packaging signal, it is unlikely to be involved in recombination reactions which might result in generation of replication competent retrovirus (RCR), even if it was incorporated into the vector particle. The optimisation process makes the expression of gag/pol Rev-independent, possibly as a result of removing RNA instability sequences.

Vector production methodology

Vector stocks will be generated by transient transfection of human kidney 293T cells plated on 10cm dishes with 3 plasmids (for EIAV vectors) or 4 plasmids (for HIV-based vectors). We will only grow virus producing cells in filter-capped flasks. After transfection for 24-48 h, supernatants will be filtered (0.45μm), aliquoted and stored at -70°C. Concentrated vector preparations will be made by initial low speed centrifugation at 6000 g and 4°C for 16 h followed by ultracentrifugation at 20,000-23,000rpm and 4°C for 90 min. The virus will be resuspended in PBS for 3-4 h, aliquoted and stored at 70°C.

Origin & function

cDNA to be expressed in these studies will be cloned, using established reverse transcription-polymerase chain reaction, technology. Some cDNA plasmids will be received from our collaborators (Oxford BioMedica Ltd, Oxford, UK; Dr. Nicole Deglon, Paris, France; Dr. Arthur Burghes, Ohio State University, USA). It is expected that neurotrophic factor genes (e.g. IGF-1, NT3, GDNF, VEGF) will be used to enhance survival of neuronal cells in vitro systems as well as in vivo models of neurodegenerative diseases. Some genetic material such as siRNA and miRNA expressed transduced cells is expected to suppress a toxic gain in function of genes with dominant mutations.

Evaluation of foreseeable effects

Environmental assessment:
The replication defective viruses would be inactivated prior to disposal and given their inability to replicate, they have no significant additional environmental hazard. The bacteria will also be inactivated (by disinfection) before they leave the laboratory.

Worst case scenarios:

The above protocols should minimise any risk of exposure to personnel using, or in the vicinity of, work using these lentiviral vector systems. The worst scenario would be exposure to a main stock of virus, resulting from the centrifuge failure or spillage. Risks of centrifuge failure-associated contamination (the only readily conceivable mechanism likely to generate a substantial aerosol of many infective particles) should be minimised by Good Laboratory Practice (GLP) and steps outlined in section 12. The major exposure routes would be cutaneous, mucocutaneous and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier and would be minimised by standards of GLP. The viruses may infect mucocutaneous surfaces and respiratory epithelia and macrophages with which they come into contact. Again this would be minimised by strict adherence by trained personnel to proper laboratory procedures e.g. use of microbiological safety cabinet class II, masks, eye protection and gloves will be observed. However the particles are replication defective and have many safety features preventing generation of replication competent viral particles. The vectors are replication defective hence spread from an initially infected cell is very unlikely. None of the genes of interest are known oncogenes. Some vectors to be used for this project may contain wild type or truncated forms of woodchuck post-transcriptional regulatory element (WPRE) sequences. Following the recommendation from HSE and the Scientific Advisory Committee on Genetic Modification (SACGM), measures will be taken to minimise the risks when using these sequences:

- Good microbiological practice by using safety cabinet class II
- Adopt procedures that reduce the likelihood of exposure, such as wearing gloves, mask and eye protection, etc
- Animal work which involves direct injection of the vector will be performed with caution and under good laboratory practice. Direct injection of the vector into the brain and spinal cord will be performed using Hamilton syringes fitted with blunt needles. Stereotaxic administrations will be performed using a 5µl Hamilton syringe with a 33-34 gauge blunt-tip needle. The vector solution will be slowly infused at the speed of 0.1-0.2µl/min using infusion pump. Thus, the risks of accidental self injection are remote. However, intramuscular (I.m.) administrations of the vector need to be done using type 2 needle (10°-12° Bevelled, non-coring needle; 33-34 gauge). During i.m. injections, operators will be asked to wear 2 pairs of gloves. We believe that, using 5µl Hamilton syringe, operators could not accidentally inject significant amount of vector if they mishandled the syringe. Based on our previous experience, it is almost impossible for an accident to happen because the 33-34 gauge needles are very thin and could be easily damaged in contact with the skin. Accidents would be minimised by strict adherence by well trained personnel to good laboratory practice. Intramuscular injections will be performed by scientists with extensive experience in the field. Professor Azzouz has successfully used this technique in the past (for more details see Azzouz et al., Nature 429: 413-417 (2004): Ralph et al., Nature Medicine, 11 (4):429-33 (2005)) and will provide training for staff in his team.

N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Anti-viral disinfectants (virusolve, virkon, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers, easily to hand (e.g. spraygun).
- All culture will be performed using a Class 2 hood, in a designed Class 2 laboratory. All cells exposed to the virus will be handled in the category 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench using good laboratory practice (GLP) but any cells taken out of the laboratory for analysis (e.g. flow cytometry) will be fixed or rendered fully non-viable (e.g. treated with formaldehyde solutions prior to flow cytometry). Where large volumes of supernatants containing, or potentially containing, viral particles require centrifugation, individually sealable buckets will be used in the relevant centrifuge. The buckets and contents will be inspected before opening (in the Class II hood). Buckets would be cleaned appropriately using virusolve, virkon or bleach.
after use. Supernatants from virtually-transfected cells which had been cultured for more than one media change over several days would not be regarded as being likely to contain significant numbers of active virus, but would be handled according to GLP and neutralised prior to final disposal.

- Hoods will be carefully cleaned after each session in which culture with virus particles takes place and after each session, when cells that have transfected by virus on a previous occasion are handled.
- Viral particles and supernatants from infected cells will be handled using filtered pipettes and pipetted tips.
- All supernatants, plastic ware and cells that have come into contact with virus particles or viral infected cells will be treated with virusolve, virkon or bleach, at concentrations recommended by the manufacturer, for 20-30 minutes prior to discard.
- Standards of GLP will be rigorously enforced (lab coats, eye protection, gloves, etc).
- Other lab personnel will be made aware of the use of lentiviral systems in the laboratory.

Please see annex for handling protocols and contamination management.

Contamination management
1. Where spills occur in contained environments such as Class 2 hoods, neat virusolve, bleach, or virkon will be added and left for 20-30 minutes to neutralise viral particles prior to wiping, cleaning and disposal.
2. If a small contained spill occurs outside of the Class 2 hoods, management will be as above. Any spill outside of Cat 2 hood will be reported to a principal investigator, and assessment made to determine whether avoidable features are present to prevent future accidents.
3. Where aerosolised contamination is suspected to have occurred outside of Class 2 hoods (e.g. as a result of centrifuge failure), the lab will be cleaned immediately to prevent aerosol inhalation. The air conditioning system will replace the air within the room within 10 min and will serve to desiccate and dilute the hazard. A single designated worker will return to the lab after 15 min and apply appropriate disinfectant to liquid traces.

02/03/2022  Page 4248 of 15326
The aim of the project is to investigate the role and regulation of genes involved in:

(i) stress sensing and survival (particularly extracytoplasmic function (ECF) sigma factors, their regulators and target genes)
(ii) secretion systems (including components of the secretion machine, their potential substrates and regulators)
(iii) iron acquisition, including regulatory genes
(iv) exopolysaccharide production, including regulatory genes

in the Burkholderia cepacia complex. Some of these genes are likely to play a role in virulence. In addition, we would like to overexpress potential secreted effector proteins from Bcc in E. coli for structure-function analysis.

Recipient or parental organism

Burkholderia cepacia complex (8cc).

The 8cc contains at least 10 closely related environmental saprophytic Gram-negative bacterial species (i.e. 8. cepacia, 8. cenocepacia, 8. multivorans etc), some strains of which can behave as a phytopathogens, while others have plant-protective effects. They can cause opportunistic infections in humans with cystic fibrosis (CF) and chronic granulomatous disease (CGD) Hazard Group 2 biological agent.

(iii) Escherichia coli strains K-I2 and B. Non-pathogenic, limited or no colonisation ability. Hazard Group 1.

Host/vector system

8. cenocepacia strains: 71 5j, J231 5, K58-2, Hill and representative strains from other members of the 8cc, i.e. ATOC 17760.
E. coli strains: MC1061, JM83, DH5cc (hosts for routine cloning).
CC118QLpir) (host for maintaining suicide plasmids).
S17-1, BW19851, 517-i (A.pir), SM1OQ.pir) (hosts for delivering plasmids by conjugation).
8L21 (DE3) (host for overexpression of 8cc proteins).
8cc plasmids: pBBR1MCS and derivatives carrying alternative antibiotic resistance markers (routine cloning vector).
pUCP22, pUCP2ST, pRK415 (routine cloning vectors)
PTZ10, pPR9TT derivatives, pME6O14, pME6O16 (for making iacZ reporter fusions).
pUT derivatives* (containing mini-Tn5 transposons for mutagenesis)
PSHAFT*, pGSStp* pJP56o3* pKNOCK* (for making chromosomal mutants).
F. coli plasmids: pHG165, pUC19, pBluesc np, pACYC184, pLG339, pWSK29 (routine cloning vectors)
pRW50 (for making iacZ reporter fusions)
pET4b, pTrc99A, pGEX-KG (for overproduction of 8cc proteins).
*suicide plasmids (these do not replicate in 8cc. Used as chromosomal integrative vectors or for allelic replacement or to deliver transposons to 8cc).
non-mobilisable broad host-range plasmid.
Further details of strains and plasmids are appended to the accompanying risk assessments.
Note: all plasmids used in 8cc must necessarily also be passaged through E. coli strains, since the cloning steps are carried out using transformable E. coli strains and delivery of the genetic material requires an E. coli donor strain.

Origin & function

(i) 8cc genes involved in sensing and responding to environmental stress (i.e. sigma factors and their regulators, as well as genes that are targets of sigma factors and response regulators that play a role in stress sensing and the stress response). The sigma factor genes are identifiable from the genome sequence, but the regulators and the genes that are targets of each sigma factor are currently unknown.
(ii) 8cc genes involved in protein secretion. Of particular interest is the type VI system, although it is possible that other secretion systems may also be investigated. Genes of interest include those encoding the components of the secretion system, their regulators and candidate substrate (i.e. secreted effector) genes. The genes encoding the different secretion systems are identifiable from the genomic sequence, but the genes encoding the substrates of these pathways (i.e. the secreted effectors) and the regulators are currently unknown.
(iii) 8cc genes involved in iron acquisition and its regulation.
(iv) 8cc genes involved in exopolysaccharide production and its regulation.

Activity 1: Transposon mutagenesis of 8cc. In this approach, a library of mini-Tn5 transposon mutants will be created, in which individual genes within the 8cc genome are insertionally inactivated. Mutants of interest are identified by their phenotype on agar plates (for example, loss of siderophore production, a secretion defect or stress sensitivity).

Activity 2: Subcloning transposon and flanking 8cc genomic DNA into E. coli K12*. Identification of transposon-inactivated genes generated in Activity 1 will be carried out by cloning the transposon and flanking genomic DNA into a plasmid (i.e. pHG165, pUC19 or related plasmids) in E. coli. follow by DNA sequencing.

Activity 3: Targeted inactivation of chromosomal 8cc genes. Genes of interest that are identified by genome sequence analysis will be inactivated to determine the role of the gene. This procedure will involve cloning the 8cc gene into a suicide vector in E. coli, inactivating the gene with an antibiotic or toxic metal resistance cassette, and then transferring the vector to 8cc by conjugation or electroporation. Selection will be imposed for recombinants that have undergone allelic replacement.

Activity 4: Cloning full-length Bcc gene(s) or operon into a broad host-range plasmid and introduction into corresponding mutant (complementation). This confirms that the phenotype of the mutant(s) of interest is due directly to the presence of the transposon (Activity 1) or antibiotic resistance cassette (Activity 3) in the gene of interest, rather than polar effects on downstream transcription. In cases where plasmid expression of a complementing gene turns out to be toxic to the bacterium, the re-introduced gene may be placed under control of a regulatable promoter.

Activity 5: Construction of reporter fusions in 8cc. To monitor the expression of 8cc genes, regulatory regions will be fused to iacZ (or another reporter gene such as gusA, gfp or lux) on a broad host-range, non-self-transmissible plasmid or an integrative (i.e. suicide) vector which will then be introduced into the appropriate host. Where applicable, the regulation of 8cc promoters may also be studied in E. coli K12, either using narrow or broad host-range plasmids.

Activity 6: Overexpression of secreted effector proteins in E. coli. To perform structure-function analysis of proteins secreted by the various secretion systems of 8cc, genes encoding such proteins will be expressed at a high level from a strong inducible promoter contained on an E. coli-specific plasmid. The gene may be fused to a sequence (i.e. hexahistidine or GST tags) that facilitates purification of the overproduced protein.

*As Activity 2 relies on use of GMM5 generated in Activity 1, the risk assessment for Activity 1 will cover this activity.
Evaluation of foreseeable effects

8cc are environmental saprophytic Gram-negative bacteria some of which can behave as phytopathogens, but many species also have plant-protective effects. They can cause opportunistic infections in (compromised) humans with cystic fibrosis or chronic granulomatous disease. They are unlikely to cause an infection in a healthy person. The antibiotics used for selecting plasmids and transposons in these organisms, are not generally used in the treatment of 8. cenocepacia infections. E. coli K-12 and E. coli B are potential colonisers of humans and other animals but are non-pathogenic. Most laboratory strains of C. coli K-12 are not able to colonise humans.

Thus, the acquisition of the antibiotic resistance markers to be used in these activities is very unlikely to constitute a hazard to human health or the environment. Any foreseeable additional properties of these organisms as a result of genetic modification are discussed below.

Activity 1: Transposon mutagenesis. This procedure results in gene inactivation, so it is unlikely that 8cc mutants will be more pathogenic or will be more able to survive in the environment as a result. Mutants will have gained resistance to an antibiotic or, where the iacZ reporter gene is present, gained the ability to hydrolyse lactose. These are not expected to increase the environmental fitness or virulence of the GMM. The plasmid used to deliver the transposon will be a mobilisable suicide vector which cannot be maintained in 8cc.

Activity 2: Subcloning transposon and flanking Dcc genomic DNA into 8. coli K-12. The foreseeable effects on 8cc are the same as described in Activity 1, since the mutants are derived from Activity 1. For the E. coli hosts, this activity will confer resistance to two antibiotics as specified by the plasmid vector and the marker in the cloned transposon. Individual E. coli clones may also express one or more 8cc genes either from a 8cc promoter present on the cloned insert or from a vector promoter present on the plasmid. This could lead to high level expression of 8cc genes in some cases. However, as the laboratory strains of E. coli K-12 employed are non-pathogenic, have a reduced fitness for survival, and do not possess mobilisation functions, there is a negligible risk of harm to humans or the environment.

Activity 3: Targeted inactivation of chromosomal 8cc genes. The initial step will involve the cloning of the 8cc gene of interest into a non-self-transmissible plasmid in E. coli and inactivating it with an antibiotic or metal resistance cassette. The inactivated gene will then be transferred to a suicide vector that is able to replicate only in an E. coli K-12 strain containing the pir gene. Thus, although it is mobilisable, the suicide plasmid will not replicate in any other host. The suicide plasmid containing the inactivated gene will then be transferred to an E. coli delivery strain, which is competent to mobilise the plasmid. In all these steps, there are no adverse foreseeable effects regarding human health or the environment associated with the E. COIL strains for reasons discussed in Activity 2 above. Individual 8cc genes would be extremely unlikely to render the E. coli laboratory strains fit to establish themselves in a human host or to harm a human or the environment.

The plasmid will then be introduced into 8cc, where it fails to replicate. Selection for the antibiotic resistance cassette inserted into the cloned gene allows for the isolation of rare recombinants where the plasmid has integrated into the genomic copy of the 8cc gene by single or double crossover homologous recombination. Double crossovers, resulting in aTlelic replacement and loss of plasmid sequences, will be identified and retained. The resultant strain, containing an insertionally inactivated gene, will be very unlikely to harm healthy individuals and will have acquired resistance to a single antibiotic or toxic metal. However, if a gene encoding a repressor of genes governing iron acquisition or a stress-response, or biosynthesis of a secretion pathway or exopolysaccharide, is inactivated, the GMM may express these genes at an inappropriate time or to a higher level. This is unlikely to make the GMM pathogenic to a healthy individual.

Activity 4: Introduction of individual Sec genes or operons on a broad host range vector into the corresponding mutant (complementation). Apart from the acquisition of the plasmid antibiotic resistance marker, it is unlikely that the phenotype of the recipient would be significantly different to the phenotype of the parent 8cc strain: either complementation will occur or it will not. Although no deliberate attempt is being made to overexpress the gene of interest, it is possible, given the multicopy nature of the system, that in some cases it will be expressed at higher levels than in the wild type strain. However, this is very unlikely to make the GMM more harmful to a healthy individual. Due to the fact that the BHR plasmids to be used are non-self-transmissible (i.e. pBBR1MCS series), they could be mobilised to another organism in the environment if the GM 8cc host naturally acquires a self- transmissible plasmid. However, in most cases, the cloned DNA would be very unlikely to confer a fitness advantage on another bacterium or render it harmful to humans or the environment. In some complementation experiments, the gene under investigation may encode a secreted effector. At present we do not know which genes encode the effectors secreted by the Type VI system or what their functions are (this is one aim of the programme of work to which this notification pertains). To be secreted by the recipient bacterium, the new host would have to express a compatible secretion system. There are unlikely to be any detrimental effects of cloning such genes in E. coli K-12, as the strains used are disabled and cannot colonise. Also, E. coli K-12 does not encode a Type VI secretion system.

Activity 5: Construction of reporter fusions in the 9cc. As only regulatory regions and gene segments, rather than complete gene sequences, are to be cloned into BHR plasmids or suicide plasmids and delivered into wild type or mutant 8cc, there is likely to be a negligible risk associated with this activity. The iac, gus, lux and gfp genes have been used extensively as reporter genes in bacterial systems without deleterious effects. Due to the fact that the BHR plasmids used are mobilisation-defective (i.e.
pPR9TT, pTZ11O), they could be mobilised to another organism in the environment if the GM Bcc host naturally acquires a plasmid containing mobilisation functions. However, the cloned regulatory DNA would be unlikely to confer a fitness advantage on another bacterium or render it a danger to humans or the environment. Integrative (suicide) reporter plasmids cannot be transferred from Bcc to another organism by conjugation as they have integrated into the bacterial genome and cannot replicate. In some cases it may be possible to investigate the regulation of a promoter in E. coli K-12 (for example in the presence of its regulator expressed in tiwis). As the E. coli host will be disabled there are no unforeseen deleterious effects of expressing a regulatory protein from a compatible plasmid.

Activity 6: Overexpression of putative Type VI secreted effector proteins from the Sec in 8. coli. For plasmids which depend upon the phage T7 41 promoter for high level expression of genes in E.coli, the E. coli B host BL21 (DE3) will be used. This strain can be viewed as being equivalent to E.coli K-12 in terms of its ability to behave as a pathogen. In some cases other strong inducible promoters may be used such as the tac promoter. Plasmids used will be derived from the narrow host-range plasmids pBR322 and pUC19 (i.e. pET series, pTrc99A or pGEX series) and will confer ampicillin or kanamycin resistance upon the host. Overproduction of an individual effector protein in BL21 (DL3) is unlikely to render it more pathogenic or increase its fitness for survival in the gut or in the environment, even though such proteins are likely to contribute to the virulence of their natural host. Such proteins require a cognate secretion system for their delivery out of the cell. E. coli K-12 does not encode a Type VI secretion system but it is not yet known whether E. coli BL21 (DE3) possesses a Type VI secretion system. As the identity and mechanism of action of the effectors is currently unknown, it would be prudent to designate the work as a class 2 activity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation not requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM waste will be inactivated prior to leaving the premises. Small volumes of liquid culture and small disposable items (i.e. plastic tubes, cuvettes and pipette tips) will be inactivated by immersion in disinfectant (5% Virusolve Plus) for a minimum of one hour. This has been validated for wild type B. cenocepacia by mixing 1.0 ml of Virusolve Plus with 1.0 ml of an overnight culture (12 x 1 o cfu/ml) (i.e. final concentration 2.5% Virusolve Plus), leaving foil hour at room temperature, and plating out 0.1 ml dilutions of the mixture on nutrient agar plates. No growth was observed on any of the plates (i.e. > 7.78 log reduction). In an assay run in parallel, Virusolve-treated samples were 'spiked' with untreated bacteria immediately prior to plating. This confirmed that the disinfectant was inactive on agar plates under these experimental conditions (thus validating the assay). In a separate assay, B. cenocepacia colonies were resuspended in broth at 1 5 x 1010 cfu/ml and treated with Virusolve Plus as described above This assay demonstrated complete killing of B. cenocepacia (i.e. > 8.9 log reduction for 8. cenocepacia).

Solid material inactivated by disinfectant will be autoclaved in the same building and then transferred to appropriate containers, whereupon it will be taken to another site by approved contractors for steam pressure treatment. All other items (larger cultures, agar plate cultures! contaminated glassware, larger items of contaminated plasticware) will be inactivated by autoclaving in the same building autoclaves are regularly serviced). This has also been validated by autoclaving an overnight culture of 8. cenocepacia (1.2 x 10 cfu/ml) and plating 0.1 ml of the undiluted culture on nutrient agar plates. This treatment was shown to be 100% effective. Disposable items that have been inactivated by this method will be placed in appropriate waste bags and removed from the site by approved contractors for steam pressure treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Recent studies have provided new insight into a way of reprogramming mature cells into a pluripotent embryonic stem cell stage. They show that the over-expression of four or recently even three or two transcription factors, can reprogram mature cells to a more immature cell type, seemingly with the same abilities as human embryonic stem cells (hESC). The ethical concerns connected to the derivation source of hESC could eventually be dismissed, as well as the potentiality of patient specific cells is promising. Compared to standard MLV-based retroviral vectors, which only transduce dividing cells, replication-defective lentiviral vectors (a subgroup of retroviral vectors)
provide an efficient method of gene transduction into both mitotic and post-mitotic primary cells. Additionally they have shown to be specifically effective in hESCs, where they are less silenced than their retroviral counterparts. To study hESCs and the pathways behind the re-programming, we intend to set up this lentiviral expression system in our facilities, able to transfer and appropriately express transcription factors to produce induced pluripotent stem (iPS) cells.

Recipient or parental organism

Bacterial host:
In all experiments the bacterial host strains used are non-pathogenic E. coli B and K12 derivatives: HB101, Stbl3, DG5-a, JM109, XL-1blue (genotypes listed in attached appendix). All are non-colonising and disabled and are therefore unlikely to survive either in the gut or in the environment. We consider assignment of ACDP hazard group1 appropriate.

Mammalian host:
Experimental procedures using virus to introduce novel genetic elements will be performed on human fibroblasts or other primary human cell types, hES cells, hEC cells and their derivatives. Virus particles will be manufactured in Human Kidney 293T cells transformed with SV40 large T antigen. As with all mammalian cells these cell lines are sensitive to culture conditions and have minimal survival potential outside of their normal tissue-culture environment.

Host/vector system

Lentiviral vector System - Overexpression of Transgenes
The majority of viral proteins have been removed from 3rd generation lentiviral transfer vectors; in particular the virulence genes vpr, vif, and nef are not present and are not required for transgene expression. The genes required to produce a packaged, transducible virus are distributed among at least 3 separate vectors. It is unlikely that a replication-enabled lentivirus could be produced, as it is unlikely that the three required recombinations would occur. As a precaution against the minimal risk, however, the work on human cells will be performed at Containment Level II.

In order to produce 3rd generation replication deficient lentiviral vectors, 4 plasmids must be co-transfected into 293 T cells.

We use similar vectors as published (Yu et al. 2007, Science)

1) Transfer vector containing the transgene
   (pSin-EF2-[transgene]-Pur; Transgenes: Lin 28, Nanog, Oct4, Sox2; all from Addgene),
2) Packaging plasmid 1 (gag_polMDLg/pRRE, Addgene),
3) Packaging plasmid 2 (pRSV-Rev, Addgene),
4) Plasmid (VSV-G amphotropic envelope, plasmid pMD2.G, Addgene)

Safety features of 3rd generation lentiviral vectors:

1. Vectors contains a deletion in the 3’LTR that does not affect generation of the viral genome in the producer cell line, but results in 'self-inactivation' of the lentivirus after transduction of the target cell. This is a result of the natural duplication of 3’LTR into 5’ position that occurs during integration. Once integrated into the target cell, the lentiviral genome cannot produce packageable viral genome.
2. Only three HIV-1 genes are used, gag, pol, and rev. the absence of the env gene removes the gp160 precursor that is responsible for the lethal macrophage/T cell/ neuro-tropism of HIV.
3. Production of the viruses from the producer cell line requires the transfection of 4 plasmids (three packaging, once the DNA to be packaged) in a transient transfection. All four plasmids have been designed, through lack of common sequences , to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging cell line produce retrovirus in any form during routine culture.
4. Internal promoters are used to eliminate the need of the HIV-promoter and reduce the risk of recombination events and trans-activation of surrounding genes.
The project requires the use of genes and/or gene fragments sourced either by cloning or from third parties to be overexpressed in human cells.

We want to induce transcription factors shown to induce reprogramming of cells to iPS cells. These transcription factors are Oct4, Nanog, Sox2 and Lin28 (Yu et al. 2007, Science), or Oct4, Sox2 alone with valproic acid (Huangfu et al. 2008, Nat biotech.), which need to be applied in combinations. These human genes are important for pluripotency but are not related to pathogenic phenotyped or known to be oncogenic.

However, one cannot exclude the possibility of tumo-inducing effects, as their function is not well defined. In order to reduce the possibility of accidental exposure of a worker to virus capable of introducing these genes, we propose to carry out the handling of live virus and transduction of EC/ES cells in our designated Class 2 facility.

The established 3rd generation lentiviral vector backbones may contain expression enhancing viral elements such as the WPRE element. These elements are inserted into the cells and may be oncogenic in some mouse models and it is therefore suggests to handle it in a class II environment.

The transfer vectors will possibly include but will not exclusively comprise selection markers such as PuromycinR, BlasticidinR, AmpicillinR or fluorescent proteins such as mCherry, GFP, Venus, Cerulean, mTomato. These proteins are considered non-hazardous owing to their non-mammalian origin. There is no evidence of any oncogenic potential for these proteins thus we consider it highly unlikely that exposure to these proteins would result in harmful effects. However we propose to carry out the handling of live virus and transduction of EC/ES cells in the designated Class 2 facility.

Origin & function

Environmental assessment:
These replication deficient viruses would be inactivated prior to disposal and, given their inability to replicate, they have no significant additional environmental hazard.

Worst case scenario

The above protocols should minimise any risk of exposure to the personnel using or in the vicinity of work using this lentiviral transfection system. Virus particles, virally-transduced cells, and media and supernatants resulting from these systems will never be handled with glassware or hypodermic needles. Thus, the risks of accidental inoculation are remote. The worst scenario would be exposure to a main stock of virus containing one transgene, perhaps resulting from spillage. The major exposure routes would be cutaneous, mucocutaneous and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier, and would be minimised by standards of Good Laboratory Practice. The viruses would infect mucocutaneous surfaces and respiratory epithelia and macrophages with which they came into contact. However, the particles are replication incompetent, and have many safety features preventing generation of replication competent viral particles. The genes of interest are not oncogenes. Thus although there might be limited tissue infection and damage, this would not result in sustained infection nor risks of tumour generation or malignant transformation. It might be possible that exposure would generate an immune response to the VSVG protein, but this would have a protective effect if so. The overall likelihood of serious or long-term harm resulting from experiments using these vectors seems extremely small.

Evaluation of foreseeable effects

Not applicable

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We propose to handle all material in Category 2 culture conditions.
1. Anti-viral disinfectants (virusolve, virkon, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers easily to hand (e.g. spray gun).
2. All culture will be performed using a Cat 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench using GLP.
3. Where small volumes of cells potentially containing viable viral particles require centrifugation, tubes will be sealed with parafilm prior to centrifugation.
4. Virus particles will be stored in the -80°C freezer in E229, in cryovials, held inside 50 ml falcon centrifuge tubes or equivalent, in clearly marked packaging.
5. Hoods will be carefully cleaned after each session in which culture with virus particles takes place, and after each session when cells that have been transfected by virus on a previous occasion are handled.
6. Only designated media will be used in cell culture.
7. Virus particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips.
8. No glassware or hypodermic needles will be used at any time with any culture producing or containing virus particles or any supernatant generated from any cell that has ever been exposed to virus particles.
9. All supernatants, plasticware, and cells that have come into contact with virus particles or viral infected cells will be treated with virusolve, virkon, or bleach at appropriate concentrations and for 20-30 minutes prior to discard.
10. Standards of GLP will be rigorously enforced (lab coats, gloves, etc).
11. All personnel using or producing virus will be appropriately registered through the University Health and Safety procedures, listed on the GMAG approval, and taught appropriate safe handling by the principal investigator.

Contamination management

1. Where spills occur in contained environments such as Cat 2 hoods, neat virusolve bleach, or virkon will be added and left for > 10 minutes to neutralise viral particles prior to wiping, cleaning and disposal.
2. If a small contained spill occurs outside of Cat 2 hoods, management will be as above. Any spill outside of the Cat 2 hood will be reported to a principal investigator, and assessment made to determine whether avoidable features are present to prevent future accidents.
3. Where aerosolised contamination is suspected to have occurred outside of Cat 2 hoods, the lab will be cleared immediately to prevent aerosol inhalation. The air conditioning system will replace the air within a room within 10 min and will serve to desiccate and dilute the hazard. A single designated worker will return to the lab after 20 min and apply appropriate disinfectant to liquid traces.

Internal GMO project number: GMO 2008_15 (Reviewed January 15, 2009)

Project Containment
The aim of the project is to prepare, isolate, store, and utilise recombinant, replication-deficient adenoviral particles to introduce wild-type or mutant forms of genes encoding either proteins involved in intracellular membrane trafficking or cell cycle checkpoint proteins into a variety of model mammalian cell lines to evaluate their cellular function.

(i) intracellular membrane trafficking involves the continuous sorting of membrane and soluble components between distinct membrane compartments within the cell and which often occurs by the packaging of material into small vesicles carrying specific cargo molecules. This work focuses on the internalisation and processing of clathrin-coated pits as a paradigm of membrane traffic control and seeks to identify components participating in and required for, coated vesicle formation, and progression through the endocytic pathway and to determine how dynamic interactions between these proteins are regulated both temporally and spatially.

Proteins involved in clathrin-mediated endocytosis include liganded receptors such as the transferrin receptor, TIR, coat and ancillary proteins such as clathrin, adaptins and dynamin, and regulators including the small GTPase rab5, GEFs RME-6 and Rabex-5, and the protein kinase AAK1.
(ii) cell-cycle checkpoint pathways in mammalian cells.

This work is concerned with understanding mechanisms of genomic integrity operating at the molecular and cellular level, and determining the consequences when they fail. Chromosomes in eukaryotes control their environment to ensure that genomic integrity is maximised. In normal cells, cell cycle checkpoints serve as a mechanism to monitor chromosomal integrity. In the progression towards tumorigenesis, checkpoint dysfunction is a commonly acquired molecular defect. Conventional cancer therapies, such as cytotoxic chemotherapy and ionising radiation, activate cell cycle checkpoints as part of their mechanism of action and seek to kill cancer cells on the basis of generating sufficient DNA damage to prevent cell replication and promote cell death.

Checkpoint pathways broadly consist of sensors (such as the 9-1-1 complex) which detect breaches in genomic integrity, proximal (such as the inherited breast cancer susceptibility gene, BRCA1, and ATR/ATRIP protein complex,) and distal transducers (such as Chk1 protein kinase, which signal this information through-out the cell, and effectors (such as cdc25 protein phosphatase) which enact cell cycle delay, initiate DNA repair pathways or promote apoptosis.

The broad aim of these projects is to gain a detailed understanding of the cellular mechanisms by utilising adenovirus vectors to constitutively express active or mutated forms of relevant components in cultured mammalian cells thereby manipulating the total cellular activity. Adenovirus vectors are used for protein expression in cells where the transfection efficiency is poor, or where high level or prolonged expression is required.

Recipient or parental organism

1. PER.C6 cells. These well-characterized and authenticated tissue culture cells are derived from human embryonic retinoblasts and have been transformed with the E1a gene of Adenovirus. They thus complement replication-defective adenovirus which lack this gene and are used for the propagation of the otherwise replication-defective virus.
2. A variety of mammalian cell lines such as human or simian lines HepG2, BeWo, HeLa, COS, U2OS, primary culitures (HUVECS) and rodent lines (3T3, L6, CHO). These cells have all been characterised with a history of safe use and are equivalent to ACDP hazard group 1.

Host/vector system

The AdEasy system (Stratagene, USA) includes a shuttle vector (pShuttle) for creating mammalian expression cassettes. Once constructed (through standard restriction enzyme digestion and ligation of the components) the shuttle vector, containing the relevant cDNA sourced from a mammalian expression plasmid background, is a linearized using Pme1 restriction enzyme. Linearised shuttle DNA is co-transformed into the bacterial line, BJ5183 along with the pAdEasy-1 plasmid (contains most of the human adenovirus serotype 5 (Ad5) genome, which is deleted for the genes E1 and E3). The removal of E1 and E3 renders the viruses defective for replication and incapable of producing infectious viral particles in target cells. In the BJ5183 line, the shuttle vector and pAdeasy-1 plasmid undergo homologous recombination. Transformants are selected with standard kanamycin resistance and successful recombination is determined through restriction digestion. Successful recombinants are amplified through transformation and culture in the XL-10 Gold bacterial strain. Purified recombinant adenoviral DNA is digested with Pac 1 (to generate appropriate inverted repeat sequences) and is then transfected into PER.C6 cells.

Recombinant adenovirus is harvested by freeze/thaw lysing of transfected cells. Viral particles are isolated and stored, in screw cap Eppendorf tubes at -80°C, for infection of selected host cells in order to express proteins in these cells.

Origin & function

Genes of human or rodent origin which are known or suspected to participate in mammalian cell cycle checkpoint or membrane trafficking pathways will be used to generate recombinant replication-deficient adenoviral particles capable of infecting a broad range of mammalian model cell lines. The intended function of the GMM is to act as a vehicle for the introduction of wild-type, tagged, dominant-negative or other mutants of genes of interest into cell lines to study their molecular function or to investigate the effects of restoring these genes in cells lines which currently lack them , to investigate their ability to rescue functional irregularities specific to each cell line.

Evaluation of foreseeable effects

The constructs to be used in these studies have not been reported to cause immortalisation or transformation in human cells and in many cases have been used for expression in adenoviral systems in other laboratories with no known harmful effects. Insertion of the constructs will not alter the tissue tropism, or increase the infectivity or pathogenicity of the recipient vector. Scope for recombination with wild type virus is limited and, due to the packaging limits of adenovirus, any such recombinants which might arise would be unviable. Additionally the recombinant adenovirus remains epichromosomal in a human cell, resulting in a minimal chance of insertional
activation/inactivation of host cellular genes. The expression procedure will involve the amplification of adenoviral particles carrying sequences coding for known or suspected checkpoint proteins or membrane trafficking proteins none of which have been shown, or are believed, to be oncogenic. The modified adenovirus proposed is replication-deficient, however in view of the capability of these vectors to infect human cells by aerosol or droplet route, and the high viral titres obtained, the level of containment is Level 2.

In the very unlikely event of a release from the Level 2 Containment facility, the virus might survive in the environment for a similar period of time to the wild-type virus. If the virus were to infect a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the virus cannot propagate in these circumstances, expression would be limited to the cells initially infected (i.e., once the cell divides, only one daughter cell will contain the adenovirus DNA. Eventually, this would result in loss of the DNA due to natural degradation of the episomal DNA. The effect that expression of the recombinant DNA would have on the cells is expected to be negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The local rules for working in the containment level 2 laboratories will be followed. These practices include the rules for work in a microbiological safety cabinet. Gloves and laboratory coats must be worn at all times. All cuts or abrasions will be covered with waterproof dressings. No sharps of any type (glass Pasteur pipettes, needles, razors) will be present in the vicinity of work when handling viral stocks. Waste will be bagged for autoclaving, and the bags sealed before removing from the designated rooms. Contaminated tips, pipettes etc will be treated with 3% Virkon for at least 60 minutes before draining and disposal into an autoclave bag. Bottles of media used for infection will be isolated from all others and immersed in 3% Virkon before being placed into standard glassware containers. Liquid waste will be treated with 3% Virkon for at least 60 minutes before disposal.

**INCUBATORS**

- Incubators reserved for transduced cultures will be used.

**SPILLAGE**

- Spills will be treated with 3% Virkon. If there is a spillage on the laboratory coat, it will be placed into a biohazard bag and autoclaved.

**AVOIDANCE OF AIRBOURNE TRANSMISSION**

- Procedures will be adopted to avoid the formation of aerosols. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS 5726).

**TREATMENT OF VIRUS BEFORE DISPOSAL**

- By autoclaving cultures and plasticware which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 mins.

**PROCESSING OF MATERIALS FOR USE IN LOCATIONS OUTSIDE OF THE VIRAL SUITE**

- In the viral suite, media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min. Cells will then be washed extensively (the wash again disinfected) in order to remove viral particles from the cultures. Since the virus used for transduction does not contain a viral genome, and is thus replication-deficient, there will be no viral particles produced by the transduced cells. Thus there is no harm connected to work with cultures previously transduced with these vectors, and these cultures can be handled safely. Containers holding the inactivated virus products will be wiped out 93% Virkon) before removal.

**Monitoring**

- Disinfection: The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's guidelines.
- Autoclaving: To ensure 100% efficacy, testing of the autoclave is carried out annually by the manufacturer to ensure that the correct temperature and pressure have been reached for the required time. Testing is arranged and test reports are kept by the Departmental Safety Officer.
- Inspectors: Safety Inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are maintained by the Departmental Safety Officer.
Microbiological Safety Cabinets: Serviced and tested on an annual basis. Certificates of conformity are displayed on each cabinet and copies kept by the Departmental Safety Officer.

Negative Pressure Suites: Tested annually by Estates and Buildings to ensure the suite is at negative pressure relative to the immediate surrounding. Testing is arranged and test reports are kept by Departmental Safety Officer.

**Project Additional Information**

**Purposes of the contained use**

To infect primary human or murine cells with an adenovirus encoding a therapeutic gene (such as thymidine kinase), under the control of the prostate specific membrane antigen (PSMA) promoter, a gene that is highly overexpressed in human prostate cancer cells. This is performed in conjunction with the co-transfection of a pCDNA3.1 plasmid encoding the Ad5, E1A region under the control of the HIF-α, hypoxia response element (HRE). This allows the adenovirus, encoding the therapeutic gene, under the control of the PSMA promoter, to undergo a single round of replication in the transduced and transfected primary human or murine cells, but only in areas of hypoxia. When these cells are injected into human prostate tumour bearing mice, these primary cells home to the hypoxic areas within these tumours where they replicate the adenovirus. Subsequent infection of the human tumour cells with the adenovirus initiates expression of the therapeutic gene, only within the tumour cells. Additionally, we would like to use a second adenovirus, where adenoviral E1A gene, from a stereotype Ad2 adenovirus is under the control of the TARP promoter (T-cell receptor, gamma chain alternate reading frame protein) together with the prostate specific antigen (PSA0 and PSMA enhancers (Ad(I/PPT-E1A), allows replication of the adenovirus only in human prostate cancer tissue. This adenovirus is initially transduced into primary human or murine cells, along with the co-transfection of the E1A gene under control of the HRE promoter on the pCDNA3.1 plasmid as described above. This permits delivery of the virus to hypoxic areas of prostate tumours in mice. Here the virus replicates in the primary cells under the control of the HRE and then infects and replicates, under the control of the TARP/PSA/PSMA promoter within the prostate cancer cells only, resulting in tumour cell death. An Ad5, E1/E3 deficient adenovirus encoding a dominant negative version of the 'Inhibitor of kB Kinase-β' (IKK-β DN), under the control of the CMV immediate-early promoter, will be obtained from a collaborator. This virus will be used to transduce primary human and murine cells to inhibit NF-κB defective cells will be studied in vitro or injected into human tumour bearing mice to investigate their affect on tumour biology and progression.

**Recipient or parental organism**

All adenoviruses are serotype Ad5 and carry deletions in the E1/E3 regions, rendering these viruses replication incompetent with the exception of the Ad(I/PPT-E1A) virus that has been reconstituted with the E1A gene from Serotype " human adenovirus under the control of the TARP/PSA/PSMA promoter enhancer regions. The TARP/PSA/PSMA adenovirus is replication competent only in human prostate tumour cells. All murine primary cells are obtained from mice maintained under pathogen free conditions within the animal facility at the University of Sheffield, therefore the risk of these cells harbouring adenoviral infections is minimal. Human primary cells will be obtained from the human blood transfusion service. Consequently, there is a possible risk that these cells might carry adenoviral infection from the general population. However, during the 3-5 day in vitro culture of these cells, the presence of an exogenous adenovirus would result in high levels of cell death, as the virus replicates, as such these cells would not be used for subsequent experimentation. Therefore, there is very low risk of transferring either, transgenic material to wild-type pathogenic strains, conveying replication competence to adenoviruses carrying transgenic material.

**Host/vector system**

HOSTS the pShuttle and pAdEasy vectors will be propagated in mon-pathogenic, disabled or non-colonising Ecoli strains. Per.C6/Adenovirus: There is a low level risk of producing replication competent virus (RCV) by recombination between the adenovirus encoding the therapeutic gene and the E1 viral gene within the packaging cell line. However, unlike HEK293T cells, Per C6 cells contain only the E1 region of the Ad5 genome and virtually no overlapping sequences with the pAdEasy vector. In the unlikely event of RCV, this would immediately infect and kill the primary cell in vitro. Macrophage: Primary human macrophages may also contain wild-type adenoviral sequences that could recombine with the adenoviral vector giving rise to RCV. However, the therapeutic gene would still be under the control of the tumour-specific producer and production of RCV's would rapidly kill the macrophages. In theory, a second recombination event could also lead to deregulation of the toxic gene. Again, however this would rapidly kill the macrophages before they would be used in any further experimentation. Mouse: Adenovirus produced by human macrophages in xenografted tumours might infect murine cells however, this would occur at low level due to the lowered infection rate of murine cells in comparison with human tissue. Therefore, the risk of viral transmission between infected mice is low.
Alphastatin (a-statin): An artificially produced 24 amino acid peptide fragment derived from the N-terminal 24 amino acids of human fibrinogen. This peptide has been shown to inhibit and endothelial cell migration and tubule formation in vitro and reduced tumour growth in vivo and intravascular thrombosis in vivo, in syngeneic murine tumour models. (Staton et al., 2004) a-statin's mechanism of action is not known at present. However, this peptide has not been shown to disrupt the quiescent vasculature.

VirR Thymidine Kinase (vTK): The human analogue of this gene is involved in the production of deoxynucleoside-5'-phosphate required for DNA replication. vTK can be expressed in tumour cells and specifically converts the inactive pro-drugs ganciclovir or acyclovir into their active forms, resulting in the death of infected tumour cells without altering normal cellular DNA replication or affecting uninfected cells. This is often used as a safety measure in gene therapy studies to ensure death of infected cells only. Additionally, the vTK can diffuse and render nearby cells sensitive to ganciclovir and acyclovir, resulting in localised cell death through 'bystander' effect. LIGHT: This is an immunotherapeutic gene and member of the TNF family (tumour necrosis factor superfamily, member 14). This protein functions as a co-stimulatory factor for lymphoid cells as well as triggering the proliferation of T-cells and can also induce the apoptosis of tumour cells. It triggers pro-inflammatory gene expression in endothelial cells and triggers Th1 responses in adaptive immune cells. Bacterial Hemolysin E (HylE): A novel octameric pore forming toxin (Hunt et al., 2008), originally identified in the E.coli-K12 strain and is a virulence determinant. This protein mediates cell death by making the cell membranes permeable to cellular contents. IKKßDN: IKKß is a member of the kinase complex required for the phosphorylation of inhibitor of NFkB (IkB). This phosphorylation step allows the activation of the transcription factor NFkB resulting in inflammatory gene expression in a variety of cell types including endothelial cells and myeloid cells. Sustained activation of NFkB signalling has been shown to mediate pro-tumour functions of macropores in tumours. Introduction of IKKßDN protein would inhibit this pro-tumour program in macropores allowing macropores to promote activation of the adaptive anti-tumour response and mediate cytotoxicity against the tumour cells directly.

Evaluation of foreseeable effects

Alphastatin (a-statin): The consequences of inappropriate expression are limited due to the tumour restricted vascular thrombosis observed in scientific studies. However, there is the possibility of a systemic inhibition to angiogenesis (possible inhibition to female luteal formation during the menstrual cycle) with unknown consequences for wound healing.

VirR Thymidine Kinase (vTK): The unrestricted expression of this gene in areas other than tumours would render these tissues or cells sensitive to acyclovir and ganciclovir treatment, this would be undesirable but on its own would have no detrimental affect without administration of the pro-drugs in vivo.

LIGHT: Unrestricted expression of this gene would have low impact given its role as a co-stimulatory factor for endothelial and T-cells.

Bacterial Hemolysin E (HylE): If the regulation governing the expression of this protein is lost it might result in cell death. However, the level of cell death would depend upon the concentration at which the protein accumulates either locally or systemically.

IKKßDN: The inappropriate expression of this gene would inhibit NFkB signalling in all infected cells, having unknown systemic effects at the organism level. Infected cells might also show a reduced ability to respond to cellular stresses such as hypoxia, ultimately resulting in cell death.

TARP/PSA/PSMA-E1A Adenovirus: In the unlikely event that recombination between this and wild-type virus should occur, a replication competent adenovirus would be
generated that would have the potential to infect human cells. However, as the Ad(1PPT-E1A) virus lacks additional transgenes this would be no more pathogenic than a wild-type Ad5 virus. Use of this virus in nude mice bearing human PC-446C prostate tumours demonstrates complete tumour selectivity (Cheng et al., 2004). Similarly, use of this type of virus in phase-1 human clinical trials has demonstrated a good safety profile and therapeutic effects (DeWesse et al., 2110). Should recombination take place between the Ad(1PPT-E1A) adenoviral replication in cells experiencing hypoxia.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In vitro culture will be performed in a laminar flow, class II biological safety cabinet. Waste plastics will be disposed of in viral waste bins for autoclaving. Liquid waste will be inactivated for 1hrs using fresh ‘Presept’ solution, with 2500ppm of available chlorine, according to manufacturer’s instructions, before being disposed of down the drain. Where the risk of aerosol production is highest ie during centrifugation, liquids will be contained in sealed buckets, opened only in laminar flow hoods. Human tumour bearing mice, that have been injected with primary murine or human cells, carrying adenovirus, will be maintained under classII animal containment within the animal facility on an isolated air supply, to prevent spread of viral particles to other animals within the facility, in the highly unlikely event that viral particles are generate by the murine hosts. Animal carcasses will be handled and incinerated within the animal facility.

The use of sharps will be kept to a minimum to avoid human contamination however, in order to deliver the primary human or murine cells, infected with adenovirus, the use of syringes is required and represents an unavoidable risk. The use of double gloves may offer limited protection against the risk of infection.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste will be autoclaved in a regularly validated autoclave and disposed of by the Hospital's clinical waste contractor. Liquid waste will be inactivated for at least 1hr using freshly prepared 'Presept' at 2500ppm of available chlorine or 'Virkon' solution at 1% final concentration to give > 5 log killing of bacteria and viruses and then disposed of down drains. Spillages will be treated with 'Virkon' powder, left for 3 minutes, then scraped up and disposed of via the clinical waste bins. Animal carcasses will be treated with 'Virkon' powder, left for 3 minutes, then scraped up and disposed of via the clinical waste bins. Animal carcasses will be handled internally by the animal house facility and incinerated resulting in total inactivation of all animal waste.

Identification and characterisation of potential virulence factors of oral pathogenic species: Tannerella forsythia, Porphyromonas gingivalis, Prevotella spp, Streptococcus sanguinis and Streptococcus gordonii

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to investigate the role and regulation of genes involved in:

1. Biofilm information - including regulatory pathways and extracellular polysaccharide encoding genes. And co-colonisation experiments with Gram-positive oral Streptococcal species.
2. Virulence factor regulation and production: including extracellular proteases, Hemolysin toxin, Bacteriocins
3. Epithelial cell invasion
4. Iron acquisition and its regulation

For Tannerella, Porphyromonas and Prevotella spp., we expect some of these to be essential for virulence.

In addition we aim to clone and overexpress in E. coli selected virulence proteins, from Porphyromonas, and Tannerella, and the bacteriocin nigrescin from Prevotella nigrescens and related Prevotellas spp. For biochemical and structure-function analysis. We also envisage using certain Streptococcal GMMs for co-colonisation biofilm experiments.
Tannerella forsythia is a Gram-negative anaerobic bacterium, which is frequently isolated from patients with periodontal disease. It was formerly known as Bacteroides forsythus and in some literature is named as T. forsythensis. It has extremely fastidious growth requirements and requires N-acetyl neuramic acid supplementation in media to enable growth. It falls into Hazard Group 2 with other Bacteroides spp.

Prevotella spp.: namely P. intermedia and P. nigrescens - Gram-negative, anaerobic black-pigmented bacteria both associated with periodontitis and as commensal organisms. Hazard Group 2.

E.coli K-12 and B strains, Non-pathogenic auxotrophic strains, limited or no-colonisation ability. Hazard Group 1.

Streptococcus sanguinis and Streptococcus gordonii - commensal Gram-positive cocci, primarily in the oral cavity, associated with infective endocarditis and dental infections (pulpitis and periapical disease). Hazard Group 2.

Host/vector system

Tannerella Forsythia ATCC 43037 - type strain, and clinical isolates from the Charles Clifford dental hospital

Porphyromonas gingivalis strains: NCTC 11834, W50 and 381
- ΔrgpA: Δrgpb: Δkgp (containing null mutations and lysine proteases - Prof M Curtis, QMUC London)

Prevotella: P. nigrescens: ATCC 25261
P. intermedia ATCC 25611

Streptococcus spp: S. sanguinis SK36 - ΔsrpA (containing null mutation in a platelet interactive protein)
- S. gordonii DL1 (Challi) - ΔscaA; ΔSspA:SspB: ΔCshA:CshB (containing null mutations in surface adhesins)

E.coli strains: TOP10 (host for routine cloning)
- CC118pir, MC4100pir (for maintaining suicide plasmids)
- BL21, C41, BL21 star (for protein expression)
- S17-1 x BW19851: SM70pir

E. coli plasmids: pBluescript2KS, pUC18, pACYC184, pBBR1MCS-1 (and 2-5) (broad host range, but does not replicate in anaerobic oral strains), pBR329 (routine cloning vectors)

Shuttle vectors: pCp23 (Tc), pCP11(Em), pCP29(Tc) (replicate in E.coli and Flavobacterium species, from Mark McBride University of Wisconsin-Milwaukee), pLYL01 (Tc), pE-COW(Em), pT-COW (tc) (From N. Shoemaker, Illinois) Ply05(Cefoxitin),

Suicide vectors: pVA198 (Em), pLYL03 (Em), pLY001 (tc), pGERM (Em) (From N. Shoemaker, Illinois)

Transposon delivery vectors: pEP4351-Tn4351 delivery plasmid-suicide vector
- phimarEm1 - Himar transposon delivery vector - Em resistance,

Reporter plasmids: lacZ-pGPS123, pRS-series (Simons RW et al., Gene 1987; 53; 85-96),
- lux reporter plasmids: pQF120,
and GFP: pBBR1MCS-GFP-E.coli reporter plasmids
pMJF2 and pMJF3-gus (uidA) reporter vectors (Jeffrey Smith)
pMTT-1,luxAB, reporter vectors
pBAD18, pGEX-4T3 and derivatives, pET15, pTrc99a- E.coli inducible expression plasmids

Origin & function

1. Biofilm formation and virulence factor regulation
It is our aim to characterise the genes up and down regulated during biofilm formation by the oral pathogens Tannerella forsythia and Porphyromonas gingivalis. The choice of genes to investigate has been informed by literature search microarray analysis and from an RT-PCR study of genes putative virulence genes identified from their respective genome sequences. We are also conducting a parallel proteomic study which will identify target proteins/genes involved in this phenomenon. We will generate null mutants of these genes encoding proteins up or down regulated in relation to the biofilm lifestyle. It is expected that this study may identify adhesins, stress proteins, regulators, exopolysaccharide genes and other unforeseen genes. We also intend to attempt to develop a reporter system to assess promoter regulation in vivo using either gfp, lux or gus based systems. It is also our intention to assess the possibility of constructing a transposon mutant library for Tannerella though this has not been attempted before, we have acquired the bacteroides transposon Tn 4351 and a Himar transposon that has been used in Flavobacterium species. We also intend to grow multi-species biofilms using Steptococcus gordonii and Streptococcus sanguinis.

2. Bacterium production
Our previous work identified a putative bacteriocin in Prevotella nigrescens. We intend now to clone and purify the individual genes within this operon to identify the active protein. Since the genome of Prevotella nigrescens has not been sequenced we also intend to use Inverse-PCR to clone flanking DNA from this operon to identify accessory genes for the bacteriocins production. We would then target gene for knockout mutagenesis and complementation studies. Genome searches of related Prevotella spp has identified putative homologous operons which we also intend to clone in to E. coli to assess biochemical activity.

3. Epithelial cell invasion
We have established an efficient means of infecting oral epithelial cells with Porphyromonas gingivalis and have noticed the existence of hyper-invasive strain. We are in the process of assessing the transcriptome of these strains to identify differentially regulated genes that would be targeted for knockdown mutagenesis.

4. Iron acquisition and its regulation
Using similar means to above we will investigate the iron acquisition mechanisms of Tannerella and its regulation.

Activity 1: Transposon mutagenesis: This has never been successfully achieved in T.forsythia but pEP4351 has been used to make Tn libraries in P. gingivalis. We will attempt to introduce the TN4351 or Himar transposons into T.forsythia and P. gingivalis. Mutants of interest will be identified by their phenotype in biofilm assays (microtitre well growth and assessment of adhered cells by crystal violet staining).

Activity 2: Subcloning of Tn flanking DNA If successful, identification of transposon inactivated genes generated in activity 1 will be carried out by cloning the Transposon and flanking genomic DNA into E. coli cloning plasmids such as pBluescriptIIKS in E. coli followed by DNA sequencing.

Activity 3: Cloning of nigrescin operon flanking DNA
This will involve cloning of DNA sequences of unknown sequence that flank the currently known nigABCD operon (see risk assessment). These DNA fragments will be cloned as PCR products into the TOPO-TA cloning kit vector pCR3.1-TOPO before DNA sequencing.

Activity 4: Targeted knockout mutagenesis of oral species AND attempted genetic complementation. This will be performed for selected genes from the genome that may have virulence functions, and of any genes identified from activity 1 and 2. The gene of interest will be an antibiotic resistance cassette that functions in these Bacteroides related species such as ermF or tetQ. We will also attempt to complement mutations by cloning genes of interest in trans into potential shuttle vectors (e.g.pCP23).

Activity 5: Cloning of reporter fusions – To monitor expression of virulence genes in oral species regulatory regions will be fused to lacZ/GFP/gus/lux as applicable on a...
broad-host range non-self-transmissible plasmid or suicide vector that will then be introduced into the appropriate host. Where applicable the regulation of oral bacterial promoters will be studied in E.coli K12 using either narrow or broad-host range plasmids.

**Activity 6:** Overexpression of nigrescin operon genes. The putative nigrescin bacteriocin genes will be cloned into E.coli expression vectors with either His-Tag (pET15b) or GST-tags (pGEX4T3) and overexpressed and purified to assess biochemical activity in vitro.

**Activity 7:** Co-colonisation biofilms- Streptococcus spp and Oral anaerobes. Certain wild-type and mutant Streptococcal spp will be grown in co-culture biofilms with oral anaerobes such as Porphyromonas. The strains used will have been created under risk assessments outlined in this proposal, so by following the considerations outlines therein the co-culture of these organisms will be managed safely.

### Evaluation of foreseeable effects

The oral bacteria T. forsythia, P. gingivalis, P. intermedia and P. nigrescens contribute to the oral disease of periodontitis. This disease has a multifactorial aetiology and acquisition of a single species is not thought to predispose to disease. These organisms are strict anaerobes with fastidious growth requirements – requiring culture on Blood agar or in the presence of Hemin, Menadione and cysteine. Therefore their ability to be transferred to the environment at large is extremely unlikely. While these organisms are associated with periodontal disease this is a multifactorial disease with contributions from the host immune system, risk factors (e.g. smoking, immune status) and from the oral bacterial community as a whole. It is not believed that any one organism is attributable to causing the condition, therefore transfer to humans is not likely to result in a periodontal infection unless other risk factors are present. In addition many of the antibiotic markers that will be transferred to the oral species listed above are unable to function aerobically or in enteric species for example, making their dissemination in the human microflora unlikely. The antibiotic markers will not affect the ability to treat infections since the drugs of choice is metronidazole.

S. sanguinis and S. gordonii are often recovered from cases of infective endocarditis and dental abscesses (periapical infections). Their involvement in infective endocarditis only occurs in at risk patients (i.e. requires the existence of previous damage to cardiac tissue) and for this they need to enter the blood circulation in fairly high numbers. Their involvement in dental abscesses is a part of a multispecies infection that gains access via open dentinal tubules or fractured tooth crowns. Consequently, it is very likely that these organisms would cause disease in healthy subjects.

E. coli K-12 and BL21 strains are potential colonisers of the human gut but are non-pathogenic. Activities 1 and 4 will result in gene inactivation, so it is unlikely that mutants will become more pathogenic or more able to survive in the environment as a result. Mutants will have gained resistance to an antibiotic or a reporter gene trait, but these are unlikely to increase the environmental fitness organisms given their fastidious strictly anaerobic growth requirements. Plasmids used to create these mutations will not replicate in these organisms, so do not pose any potential hazard.

Activities 2, 3, 5, and 6 involve the cloning of DNA from oral species into E. coli strains. Given the non-pathogenic nature of the E. coli strains and non-transmissible nature of the expression and narrow host-range of the cloning vectors used (e.g. pET15, pBAD18, PBBlueScript) the risk to health or of release is negligible. Some BHR plasmids (pBBR series) that are transmissible only when transfer functions are provided in trans by E. coli S-17 strains will be employed, but this inability to self-transmit will avoid their dissemination in the environment. The reporter systems proposed for use here (lux/gfp/lac/gus) have been used extensively elsewhere in bacterial systems without deleterious effects.

Activity 7: involves co-culture of organisms of low-risk to human health between which genetic transfer is very unlikely

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All GM waste will be inactivated before leaving the premises. 
Small volumes of liquid culture and small disposable items (i.e. plastic tubes, cuvettes, pipette tips) will be inactivated by immersion in disinfectant (1% Virkon solution) for a minimum of 24 hours before autoclaving. This procedure coupled with the fact that oral anaerobic bacteria cannot survive for more than an hour in an aerobic environment will ensure safe disposal of GM, material.
Solid material inactivated by immersion in disinfectant will be disposed of in appropriate containers. These are collected by approved contractors who then autoclave them before disposal.
All other items (larger cultures, agar culture plates, glasswares, larger plasticware) will be inactivated by autoclaving in the department of oral pathology (autoclaves are regularly serviced and validated).

Removal of the word “including” from the title of the project.
• On page 4 of the University of Sheffield Risk Assessment form under “Hazards associated with the vector”, also form cu2, page 2 and reference to pBBR1MCS-GFP on page 3 of form cu2- amend to indicate that pBBR1MCS-1 is not E. coli-specific and is a mobilisable BHR plasmid.
• On page 5 of form cu2 amend “5% Virkon solution” to “1%”. Validation for this concentration to be included.
• Clarification required on the Risk Assessment and cu2 forms with regards to the following: “…it is stated that these bacteria are “unlikely to cause infection in healthy individuals”.

The proposal was approved by quorum subject to the above – name removed to arrange a cheque made payable to the Health & Safety Executive and then forward on to name removed for the administration to be passed on to the HSE.

Project Additional Information

### Purposes of the contained use

The aim of the project is to identify the genes and proteins involved in the interaction of Candida species with human leukocytes, endothelial and epithelial cells.

### Recipient or parental organism

Candida species in particular C. albicans and C. glabrata are fungal organisms that are widely distributed and carried commensally in the oral cavity by at least 50% of the healthy population at any given time. These organisms have low pathogenic potential that rarely affect healthy individuals. However, Candida infections can become a potential medical problem when an individual's immune response is significantly impaired and Candida infections are relatively common only in immunocompromised patients. Because of their potential to cause disease in immunocompromised individuals the organisms fall into Hazard Group 2.

### Host/vector system

#### Host

All mutants are derived from Candida albicans and Candida glabrata parent strains. All strains used in the studies outlined below will be provided by our collaborators. See attached table for strains used and relevant references describing their manufacturer.

### Origin & function

1. Adhesion and transmigration of Candida to and through the endothelium

Our aim is to identify the Candida genes and gene products that are involved in the adhesion of Candida to the endothelial cells lining blood vessels. We also plan to
determine the Candida genes and gene products that facilitate the transmigration of Candida across the endothelium. We have access to a panel of Candida mutants that are deficient in adhesion molecules and cell wall molecules that may be potential adhesion molecules (see attached table). We also have the parent strains that these mutants have been developed from and all these are provided by our collaborators (Prof Pete Sudbery, University of Sheffield; Prof. Neil Gow, University of Aberdeen; Dr Lois Hoyer, University of Illinois; Prof. Ken Haynes, Imperial College London; Dr Aaron Mitchell, Carnegie Mellon University, Pittsburgh). We will use these Candida strains to assess their ability to adhere to and transmigrate through monolayers of endothelial cells in in vitro assays. We will use a flow adhesion assay (See fig 1) to measure adherence of Candida to endothelial cell monolayers as this allows adherence to be measured under conditions of flow and shear stress that mimic in vivo conditions. In these assays Candida are flowed across monolayers of endothelial cells grown on microscope slides using an enclosed tubing system and sealed chamber to avoid contamination or aerosol spread. In this system Candida can be re-circulated or removed directly into disinfectant (Vircon).

In addition, the importance of conversion from yeast to hyphal forms of Candida in adherence to the endothelium will be analysed using a C. albicans mutant (SSY50B, available via Dr Steven Saville, University of Texas) in which the conversion from yeast to hyphae is under the control of doxycycline.

2. Adhesion and penetration of Candida to the oral epithelium and leukocytes

We will use some of the wild-type and mutant Candida strains shown in table 1 to analyse the oral epithelial and leukocyte host response to these organisms. Candida will be used to infect monolayers of normal oral keratinocytes, keratinocytes form oral cell lines, leukocyte sub-populations or keratinocytes as part of an in vivo tissue engineered oral mucosal model and the host response analysed using several biological assays.

### Evaluation of foreseeable effects

Candida Sp. Are widely distributed (in the oral cavity, gastrointestinal tract and vagina) are carried commensally by at least 50% of the healthy population at any given time. However, under certain circumstances it is capable of becoming pathogenic leading to oral, vaginal, cutaneous or systemic candidiasis. These infections tend only to occur in immunocompromised individuals. It is a microorganism of low pathogenic potential that rarely affects healthy individuals.

The Candida strains to be used in our studies do not contain inserted genetic material derived from other organisms. These studies will use wild type laboratory strains that have been well characterised or mutated forms of these strains in which genes have been disrupted using short homology regions as previously described (Wilson RB et al. (1999) J. Bacteriology, 181:1868-1874). In all cases the mutated strains which have a 'loss of function' have been shown to be less virulent in their wild-type counterparts which are themselves unlikely to cause disease in healthy individuals. The exception is the SSY50-B strain obtained from Dr Stephen Saville in which yeast to hyphal transformation is under the direct control of doxycycline. The hyphal form (generally considered more pathogenic than the yeast form) can only develop in the presence of doxycycline and is therefore extremely unlikely to cause infection in any individual.

Pathogenicity in Candida is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, a reduction in any one of these parameters will attenuate Candida virulence. Furthermore, Candida strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals. It is important to note that although a large number of C. albicans mutants have been analysed, including virulence attributes, metabolic and cell wall genes, there is NO report of a mutation that increases the virulence of this yeast (e.g. Gow et al. (1994) PNAS 91, 6216; Leberer et al. (1996) PNAS 93.13217; Hube et al (1997) Infec. Immun. 65, 3529; Sanglard et al. (1997) Infect. Immun, 65 3539; Navarro-Garcia et al., (2001) FEMS Microbiol. Rev. 25: 245-268). This is unsurprising, since all evidence to date indicates that virulence in C. albicans is a multi-factorial process at the molecular level, with no single virulence factor of over-riding importance. While it is possible that inactivating a repressor might increase virulence this is NOT the case. For example, inactivation of TUP1 or NRG1 (both repressors of hyphal development) decreases virulence by attenuating growth in vivo (Murad et al. (2001) EMBO J. 20, 4742-4752). Therefore, mutations in wild isolates are expected to have a neutral or negative effect upon virulence. Some experiments will be done using C. glabrata. These Candida species are closely related to C. albicans; they generate similar types of infections in humans, but are considered to be less virulent than C. albicans as they do not naturally form hyphae.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

**Purposes of the contained use**

Bacteria are able to survive and thrive in a wide range of environments. This ability is rooted in altered patterns of gene expression. We propose to use Transposon Mediated Differential Hybridization’ (TMDH) to identify genes that are essential for Salmonella to survive within a particular environment. Briefly, this involves: (i) systemic introduction of large numbers of mutant Salmonella into a specific environments (e.g. aerobic and anaerobic conditions), (ii) isolation and labelling of DNA from Salmonella found in the aerobic and anaerobic cultures (iii) hybridisation of this DNA to a custom-made, genome-wide oligonucleotide array; and (iv) analysis of the differential hybridisation patterns to identify genes that are essential for growth and/or survival in the new condition. The Salmonella mutant library has been created in Cambridge and currently a PhD student in Sheffield is working with the library there. We would like to transfer the library to Sheffield to allow a series of experiments in which the input and output pools can be compared to identify genes that are involved in facilitating Salmonella survival in different environments. This proposal is to characterize the existing library and does not include the creation of new libraries. In follow up experiments we will create specific gene deletions using standard lambda red gene replacement (recombineering) technology to further characterize the phenotypes of mutants identified from screening the TMDH library, and we propose to use plasmid-based complementation experiments and promoter-lacZ fusions to monitor gene expression as part of these characterizations.

**Recipient or parental organism**

The transposon library is of Salmonella Typhimurium SL1344, a mouse-virulent strain. Hazard group 2. Plasmid propagation and molecular biology steps will be done using E. coli K-12 (MG1655, W3110, XL-10 Vblue, DH5alpha, MC1000), non-pathogenic strains with limited or no colonization potential. Hazard group 1.

**Host/vector system**

The plasmid pKD46 will be used in the creation of specific Salmonella Typhimurium mutants for phenotypic characterization following the results of the screening experiments. pKD46 has been widely used to create specific gene replacements in Salmonella. pKD46 has the following features: temperature sensitive replication (repA101ts encodes a protein required for replication that is inactivated at temperatures above 30°C); a conditional replicon (oriR101, requires Pir in trans for plasmid propagation).
replication); encodes lambda Red genes (exo, bet, gam); native terminator (tL3) after exo gene; arabinose-inducible promoter for expression (ParaB); encodes araC for repression of ParaB promoter; Ampicillin resistance. No significant hazards are associated with this vector. We will also use standard vectors (pBR322 and pUC) in complementation experiments. These are widely used commercially available vectors that are non-mobilisable.

For gene expression studies we will make promoter fusions to lacZ in the plasmid pRW50 (Lodge et al., 1992, FEMS Letters 95, 271-276. This is a widely used plasmid with no known hazards.

Origin & function

A library of transposon mutants in Salmonella SL1311 is available at the University of Cambridge. The library was constructed by transposon mutagenesis using a Tn5 transposome (Epicentre Biotechnology) that was modified to include outward facing T7 and SP6 promoters. These promoters allow the generation of RNA in vitro that corresponds to the regions of DNA flanking the site of transposon insertion. The presence of engineered rare restriction sites (Sce-I, Psp-1) can be used to specifically isolate transposon containing DNA fragments. The transposon is locked in because the transposase is not retained, severely limiting the possibility of transfer of antibiotic resistance to a related organism. Therefore, it is unlikely that sequences within the GMM will be transferred to related organisms which will increase the potential hazards associated with the latter.

For the complementation experiments the wild-type gene under the control of its own promoter will be amplified from Salmonella genomic DNA and ligated into pBR322 and/or pUC plasmids. The resulting expression plasmids will be transferred to the appropriate Salmonella mutants by electroporation to test whether the disrupted gene is responsible for the observed phenotype.

Evaluation of foreseeable effects

(a) Mutant library
Salmonella Typhimurium SL1344 is a mouse-virulent strain and can cause gastroenteritis in humans and is thus in Hazard Group 2. The Salmonella Typhimurium mutants in the library are most likely to be debilitated compared to the wild-type because of the gene disruptions created by the transposon. The transposomes that were used to create the library are based on a modified Tn5 that includes T7 and SP6 promoters, rare restriction sites (I-Sce-I and Psp-I) and a neomycin resistance cassette. The transposon is locked in because the transposase is not retained, severely limiting the possibility of transfer of antibiotic resistance to related organisms. Therefore, it is unlikely that sequences within the GMM will be transferred to related organisms in a way that will increase the potential hazards associated with the latter. As stated above it is most likely that the Salmonella Typhimurium mutants will be less harmful than the wild-type because of the associated gene disruptions. Depending on the location of the transposon the following possibilities can be considered: (i) interruption of an essential gene—the Salmonella will not be viable and therefore will not be present in the library; (ii) interruption of a non-essential gene will result in Salmonella that is either unaffected or less viable; (iii) it is highly unlikely that the fitness of Salmonella could be enhanced significantly by a transposon event.

(b) Recombineering and complementation
pKD46 has been widely used to create specific gene replacements in Salmonella. pKD46 has the following features: temperature sensitive replication (repA101ts encodes a protein required for replication that is inactivated at temperatures above 30°C); a condition replicon (oriR101, requires Pir in trans for plasmid replication); encodes Lambda Red genes (exo, bet, gam); native terminator (tL3) after exo gene; arabinose-inducible promoter for expression (ParaB); encodes araC for repression of ParaB promoter; Ampicillin resistance. No significant hazards are associated with this vector. We will also use standard vectors (pBR322 and pUC) in complementation experiments. These are widely used commercially available vectors that are non-mobilisable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The work outlined will be carried out in designated laboratories which meet containment level 2 standards. The work will generate contaminated plasticware (pipette tips, tubes) flasks, agar plates and spent media used in the growth of the bacteria. Bulk liquid waste will be decontaminated using 2% Virkon solution. Glassware will be decontaminated by autoclaving. Solid waste will be disposed of by incineration in line with University procedures which have been approved for disposal of class 1 and 2 GM waste. Hence, all contaminated solid waste (plastics etc.) will be treated with 2% Virkon for decontamination purposes (validated by manufacturer) before autoclaving in designated laboratories within the Department Molecular Biology & Biotechnology. The autoclaves are serviced and tested annually. These measures will ensure effective killing of bacteria and destruction of residual nucleic acids.

Project Additional Information

Purposes of the contained use

Measurements of specific binding forces associated with the secondary, lipophosphoglycan (LPG) independent binding mechanism used by Leishmania parasites when in the mid gut of their sand fly hosts. Comparison of results obtained for the wild type, lipophosphoglycan deficient (LPG1) and phosphoglycan deficient (LPG2) parasites will enable analysis of whether observed forces are due to LPG or a different surface molecule on the parasite. NB: flies are not involved in the project.

Recipient or parental organism

Leishmania major and Leishmania mexicana are ACDP Hazard Group 2 pathogens of both humans and other animals. They cause cutaneous Leishmaniasis, which manifests as self limiting ulcerous skin lesions and is naturally transmitted via an intermediate vector (female haematophagous phlebotomine sand flies). Lesions tend to be specific to the area surrounding the site of the bite although diffuse lesions can occur in some cases. They are similar to refractory ulcers and leave burn-like de pigmented atrophic scars once healed. Infections can be treated with agents such as sodium stibogluconate, paromomycin or pentamidine by tropical medicine specialists. These antimicrobials are available through the Department of Communicable Disease, where they have experience of treating these infections.

An infective dose can be anything between hundreds to multiple thousands of metacyclics in typical sand fly bite situations. Infections used for murine trials are typically much larger and established by intra-dermal injection. Although all parasite loads can cause an infection, the severity of the induced pathology is increased with larger doses. In murine models, both a high number and low number challenge caused lesions of different severity but were cleared over a period of several weeks to a couple of months. [N.Kimblin et al., PNAS, 105 29 pp. 10125-10130 (2008)]

Approximately 1 x 10^7 parasites will be in single pellet, and in some cases they will be in metacyclic form. This would therefore be enough to establish a reasonably severe clinical infection should there be an entry point on the skin for any significant proportion of the sample.

Handling of the wild type organisms must be undertaken with due care as direct inoculation could lead to a skin infection (occupational infection). The natural insect vector for the parasites is not present in the UK and so there is no likelihood of ongoing infection and therefore negligible risk to the environment upon accidental release.

Host/vector system

The mutants in this project have been modified by targeted gene replacement or deletion. They are well characterised organisms which have been used for several years to study variations in adhesion properties between wild type parasites and those lacking in certain prolific surface molecules. Details on these modifications are given in the next box.

Origin & function

LPG1 and LPG2 genes were subcloned into BamHI-HindIII-cut pQE30 (Qiagen). Positive clones were subcloned into pBSK+ or pGEM-5Z (Promega). LPG1 and LPG2
vectors had phleomycin and hygromycin resistance genes incorporated in them for positive selection of transfectants. This does not infer any increased virulence to these organisms because (i) they have reduced capacity for survival in both mammals and sand fly vectors (also, no sand flies in UK) and (ii) Phleomycin and hygromycin may act on fly-stages in culture, but are unable to treat leishmaniasis in animals.

Specific mutant information:
Leishmania mexicana LPG1: Homology cloning using a fragment amplified by polymerase chain reaction (PCR) with primers derived from the known sequence of Leishmania donovani was used to isolate the Imexlpg gene. Two rounds of targeted gene replacement were performed by PCR amplification of the 5'-untranslated region (UTR) of Imexlpg1 and amplications of the 3'-UTR of Imexlpg1. This resulted in parasites deficient in LPG but with an up-regulation in proteophosphoglycan surface molecules. Hygromycin phosphotransferase and phleomycin-binding protein containing gene replacement cassettes were transfected into L. mexicana promastigotes. Selection of mutants in culture was achieved by adding hygromycin B and phleomycin to the culture medium. Resistance to other antimicrobials is unaffected. Infection of BALB/c and C57/BL6 mice show that the mutants are at least as virulent as the wild-type strain. [T. Ilg, EMBOJ., 19.9 pp. 1953-1962 (2000)]

Leishmania mexicana LPG2: A spontaneous mutant isolated from an infected mouse and an Imexlpg2 gene deletion mutant. The generated mutant lacks a Golgi guanosine diphosphate-mannose (GDP-Man) transporter; it is deficient in phosphoglycan repeat synthesis and shows downgraded mannoooligosaccharide phosphate cap expression. It was produced through double targeted gene replacement by PCR amplification of the 5'-UTR regions and 3'-UTR regions of Imexpg2. The spontaneous mutant lacks PG repeats but does not show reduced cap production. Hygromycin phosphotransferase and phleomycin-binding protein containing gene replacement cassettes were transfected into the L. mexicana promastigotes. Mutants were selected by adding hygromycin B and phleomycin to the culture medium. Resistance to other antimicrobials is unaffected. The two mutants are indistinguishable from wild type parasites with respect to colonisation of and multiplication inside host cells. They did not show any reduced virulence in BALB/c mice. [T. Ilg, J. Bio. Chem, 276 7, pp. 4988-4997 (2001)]

Leishmania major LPG1: Parasites lacking the LPG1 encoding gene are made through two rounds of targeted gene disruption using a 7-kb HindIII-Smal LPG1::HYG fragment followed by the 6.7-kb BamHI fragment LPG1::PAC. Hygromycin B and puromycin were used to select for mutants but resistance to other anti-infectives is unaltered. The mutant contained normal levels of related glycoconjugates and GPI-anchored proteins but lacked LPG. It still caused infection of BALB/c mice but some reduction in virulence was observed. [G. Späthe, PNAS, 97 16, pp. 9258-9263 (2000)]

Leishmania major LPG2: Parasites lacking both lpg5A and lpg5B genes and which have no LPG or protein-linked PGs due to deletion of the parasite Golgi GDP-Man transporter LPG2. They showed attenuation in early mammalian macrophage infection but, once established, amastigote virulence was maintained in BALB/c mice. They should not have any reduced susceptibility to anti-infectives. [A. Capul, Infection and Immunity, 75 9, pp. 4629-4637 (2007)]

Evaluation of foreseeable effects

Since Balb/c mouse trials have shown that several mutants retain virulence in mammalian hosts (although they do not display enhanced pathogenicity) and there is no reduction in susceptibility to antibiotics used for treatment, the parasites are likely to pose a hazard similar to that of the wild type organisms. The user is at risk when handling the parasites as infection can occur through direct inoculation. There is negligible risk to the environment as the natural insect vector is not present in the U.K. so ongoing disease spread is very unlikely.

All handling will be conducted in a Class II microbiological safety cabinet in a category 2 laboratory and gloves and a lab coat will be worn at all times when handling the pathogens. Good microbiological practice will be followed. The different species and mutants will be handled separately to minimise the risk of cross-contamination. There should not be any additional pathology associated with the mutant strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Laboratory manipulations, passaging and sample preparation will be carried out in a standard containment level 2 facility and good microbiological practice will be employed. When transferring small live parasite samples to the Department of Physics and Astronomy, the sealed sample holder will be placed within a secondary sealed unbreakable container to prevent accidental spillage in case of dropping or collision with an object. Usage in the AFM suite will be restricted to the AFM with a protective box covering it, and experiments will not be left unattended. The cantilever which has been in contact with the parasites will be disposed of in a contaminated sharps bin after disinfection. The cantilever holder which has been in contact with the imaging media will be disinfected and cleaned after use. All waste will be treated using 70% hypochlorite solution or freshly made up 10% Virusolve solution (the standard killing procedure used by Dr M R's group in the London School of Hygiene and Tropical Medicine) and will be collected, transported back to the Medical School using a yellow bag in a box, and autoclaved. In the event of accidental spillage of live organisms in the Department of Physics and Astronomy, the Medical School spillage procedure will be followed.

As sharps present the main route to infection, they will not be used in the project.

Killing tests mimicking a spill type environment have been carried out for wild type Leishmania mexicana (Sept 2011). The results showed that all spills should be sprayed with 10% Virusolve solution and covered with paper towels. They should be left for at least 5 minutes before being cleared and discarded. This was shown to cause an immediate loss of organism motility (observed using a 20 x magnification optical microscope) and no manipulation after a 72 hour period (i.e. 100% kill). A similar treatment with 70% methylated spirit was only sufficient to cause partial inactivation and reduced multiplication. It is likely that similar kill levels will be observed in tests for the Leishmania major and Leishmania mexicana mutants. Confirmation tests can be conducted once the mutant parasites have been received.

Validated autoclaves in the Medical School will be used to inactivate any remaining material with a 100% kill rate.

Soak contaminated materials overnight in 70% hypochlorite and use 10% Virusolve solution to disinfect surfaces e.g. MSC after use.

Please enter comments on the GM safety committee on the risk assessment

The committee made several suggestions following an initial review of the application. These have since been addressed and approved.

The requests included clarification of the methods used to obtain the mutants, including information about any selective resistance markers, more information about the infective dose and subsequent disease progression, and clarification that sharps and sand flies are not used in the project as they present the main risk of infection and disease spread, respectively. The laboratory numbers in the Department of Physics and Astronomy where the parasites will be imaged using the AFM have also been added to the risk assessment.

02/03/2022
The purpose of the work is to elucidate mechanisms by which host cells respond to respiratory consequences and the consequences of these responses. The aim is to improve understanding of the mechanisms of pulmonary infection with the goal of identifying new therapies and preventive measures.

Recipient or parental organism

Streptococcus pneumoniae, Neisseria meningitidis, Haemophilus influenzae, Klebsiella pneumonia, Staphylococcus aureus and Pseudomonas aeruginosa are all human pathogens and all hazard group 2 organisms. Each organism can cause pulmonary infection or invasive disease, including meningitis in the case of S. pneumoniae and N. meningitidis after colonisation of the respiratory tract. P. aeruginosa can also cause opportunistic infections of wounds, including keratitis. Staphylococcus aureus can also cause soft tissue infections. Although vaccination is available for the first three named organisms, it is not effective against group B meningococci the type worked with in the lab and pneumococcal vaccination with polysaccharide is of only moderate efficacy and does not appear to prevent pneumonia. Neither of these vaccines will be routinely offered but future development of more effective vaccines will be monitored and this policy may be modified accordingly. Hib vaccination will be considered for anyone working with Haemophilus influenzae type b on a sustained basis.

All these organisms cause clinical symptoms of fever, respiratory tract illness or invasive disease (including for meningococcal and pneumococcal meningitis). All workers...
will be counselled re potential symptoms and to seek urgent medical advice if they show any symptoms of ill health. All infections are effectively treated with prompt administration of antimicrobials as outlined above. All workers will be advised to contact their GP and to ask for referral to the regional Infectious Disease unit if indicated.

Host/vector system

Inactivated chromosomal genes may or may not contain antibiotic resistance cassettes (e.g. Janus cassettes) but where these are used they will involve antibiotics such as streptomycin, kanamycin, chloramphenicol, lincomycin, macrodiles or tetracyclines which are not the antimicrobials used as the primary treatment of these organisms, which are primarily treated with penicillins, cephalosporins, carbapenams, or where beta-lactam resistant, glycopeptides, lipopeptides or fluoroquinolones. Mutants will be of reduced virulence or will have no alteration of virulence compared to parental strains.

Origin & function

The mutants will have been created by external collaborators using techniques such as insertional mutagenesis or in frame deletions and inactivated chromosomal genes may have been complemented by reinsertion of a copy of the deleted gene, which may have been achieved by use of a plasmid maintained by an antibiotic resistance marker. Confirmation of the genetic mutation and initial analysis of function will have been carried out in the collaborators laboratories. Any potential further manipulation of parental or genetically modified strains will be under the direct guidance of the primary laboratory who have created the strains.

Further details of the genetic modification used to generate the externally acquired GM strains is not included since it is expected these will be covered by the collaborators approvals and the specifics of the modifications will vary with each mutant. We include an appendix of several mutants we anticipate we would like to investigate as part of this study and will update this appendix as further mutants are investigated. This outlines strains, the genes mutated and any antibiotics resistance markers used for the mutant.

Evaluation of foreseeable effects

The GM organisms to be studied will be selected because of their capacity of the wild-type genes to interact with the host innate immune system. As such the consequences of the deletions or of complementation are predictable and will produce strains that are less pathogenic or of comparable pathogenicity to the wild-type strains and will not have altered routes of transmission or host range. The most likely consequence of inadvertent exposure would be colonisation of the skin (for S. aureus) or the respiratory tract for other organisms. Respiratory tract colonisation only occurs for those with underlying lung disease and the same is largely true for H. influenzae, K. pneumoniae and S. aureus. Transient colonisation of S. pneumoniae occurs in 10-70% of the normal population and for N. meningitis in 10-30% of adults so if this were to occur it would replicate a situation that commonly occurs in normal life. If colonisation were to occur there is a small chance of invasive disease. We cannot predict the exact magnitude of this risk but since invasive disease occurs at a frequency of <10/100,000 in adults in the UK that means the risk of invasive disease is <1 in a thousand if it were to occur. As invasive meningococcal disease occurs at a rate of 2-6/100,000 then we can estimate that colonisation is likely to result in invasive disease also in less than 1 case per thousand.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Small volumes (<30ml) of mutants will be propagated and harvested by centrifugation (centrifuge has buckets with lids). All strains will be grown in a sealed incubator shaker. In all cases, spillage's will be safely contained and treated with freshly prepared 1:10 solution of Virusolve Plus and by autoclaving.

Laboratory manipulations with the risk of aerosol generation should be carried out in a microbiological safety cabinet (MSC), for other manipulations a standard containment level 2 facility and the use of good microbiological practice will limit contact with humans and the environment. There is unlikely to be any increased potential hazards arising from the GM bacteria described above as these are likely to be no more fit than the wild-type.
All cultures are inactivated by mixing in fresh 1:10 solutions of Virusolve Plus or solid material is inactivated by autoclaving. Records of bacterial killing in virusolve and maintenance records of autoclave will be used to validate procedures.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Please note this application is to allow investigators work with mutants created by collaborators with appropriate approvals. It will potentially allow the investigators work with a range of mutants of the indicated species but these will all be of less or equivalent virulence to the parental strains.

Approved at the Biosafety Committee 01/10/2012

Project Additional Information

Purposes of the contained use

The aim of the project is to identify and characterise genes (and their products) required for cell growth, division and pathogenesis in Gram-positive bacteria. This work will deal with biological processes (such as cell division or cell surface biogenesis) and pathogenesis mechanisms conserved amongst Gram-positive bacteria. For comparison purposes, the project will therefore involve several model organism that will be genetically modified. The work will involve making a large number of genetic constructs to analyse gene function. These will include the use of insertional mutagenesis systems, transposon mutagenesis and replicative plasmids and will involve a wide range of clinical isolates. The model organisms Escherichia coli and Lactococcus lactis will also be used for routine cloning and expression of individual gene products for biochemical and structural characterisation.

The ultimate translational aim is to identify new drug targets and develop new therapeutic strategies to eradicate these pathogens.

Recipient or parental organism

Escherichia coli will be used as a host for routine gene cloning and for the production of recombinant proteins for biochemical and structural characterisation. All E. coli strains used will be derivatives of the K-12 (routinely used for molecular biology applications) and B lineages (routinely used for protein expression). The E. coli strains to be used are considered non-pathogenic (Chart, H et al. Jour. Appl. Microbiol.2000, 89, 1048-1058) and are generally regarded as safe.

Lactococcus lactis will also be used to express recombinant proteins. The strains used are NZ9000 isogenic derivatives (Kuipers OP, de Ruyter PGG, Kleerebezem M, de Vos WM (1998) J Biotechnol, 64: 15-21.) L. lactis is used in the dairy industry and has the GRAS status (Generally Recognised As Safe); it is used as a probiotic.

Some of the Gram positive bacteria used in the context of this application are normally commensals and can be readily isolated from the human normal flora (E. faecalis, E. faecium and all Clostridia spp.) or found in the environment (L. monocytogenes and B. cereus). All the above-mentioned organisms are considered as opportunistic pathogens as they can cause a wide range of infection in exceptional circumstances (e.g. in an immunocompromised host, following antibiotics treatment or during pregnancy for L. monocytogenes) if ingested or in contact with a wound.

S. pneumoniae and D. pyogenes are primary human pathogens, whereas S. suis is a pig pathogen.

The species considered in this application, with the exception of S. pneumoniae, are not readily transmissible via aerosol and the risk of infection to the worker is therefore minimal. The GLP and control measures described below (and in the attached document) will further minimise the risk. In the case of S. pneumoniae, the live organism will be handled exclusively within an appropriate microbiological safety cabinet to minimise the risk of exposure to bacterial aerosols.

The risks associated with each species are detailed below.

E. faecalis and E. faecium are commensal bacteria commonly found in the gastrointestinal and vaginal tracts, and in the oral cavity of Humans and other mammals. They
can cause a wide range of infections in humans including urinary tract infection, peritonitis, bacteraemia and endocarditis, usually associated with perturbation of the gut flora following antibiotic or immunosuppressive therapies. Most *E. faecalis* and *E. faecium* infections can be treated with antibiotics (ampicillin or amoxicillin, eventually in association with gentamycin).

*S. pneumoniae* is a bacterium which can cause several diseases that range in severity from sinusitis and acute otitis media to meningitis, septicaemia, and pneumonia. Rates of carriage are highest in infants and the elderly and much lower in other adults. *S. pneumoniae* are sensitive to several antibiotics (beta-lactams, sulfamides and macrolides). Since *S. pneumoniae* can lead to infections in healthy adults, workers manipulating this particular bacterium will be informed about associated risks and advised to seek early medical attention in the event of a suspected exposure to consider appropriate antibiotic treatment if required.

*S. pyogenes* (Group A Streptococci) are usually found in the respiratory tract, without signs of disease. They can cause a wide variety of clinical manifestations including pharyngitis, scarlet fever (rash), skin (impetigo or cellulitis). Invasive toxigenic infections can result in necrotizing of soft tissues, myositis (inflammation of muscles) and toxic shock syndrome. In most cases, systemic or oral anti-biotherapy (penicillin or clindamycin) efficiently cures *S. pyogenes* infection. However, because *S. pyogenes* can lead to serious infections in healthy adults, workers manipulating this particular bacterium will be informed about associated risks and advised to seek early medical attention in the event of a suspected exposure to consider appropriate antibiotic treatment if required.

*L. monocytogenes* primarily affects older adults, pregnant women, newborns, and adults with weakened immune systems. The manifestations of listeriosis include septicemia, meningitis (or meningoencephalitis), encephalitis, and intrauterine or cervical infections in pregnant women, which may result in spontaneous abortion or still birth. The onset of the aforementioned disorders is usually preceded by influenza-like symptoms including persistent fever. Gastrointestinal symptoms such as nausea, vomiting, and diarrhea may occur. Once diagnosed, treatment of listeriosis is not an issue, as the bacterium is sensitive to several class of antibiotics; ampicillin alone or in combination with gentamycin is a treatment of choice.

*S. suis* is an important pathogen of pigs that can occasionally cause zoontic infections in humans. Meningitis is the common manifestation, followed by septicaemia and endocarditis. Most *S. suis* strains respond to treatment with ampicillin and amoxicillin. All *S. suis* derivatives used in the laboratory will be acapsulated derivatives, severely attenuated.

*B. cereus* is a soil bacterium that can cause wound infections, bacteraemia, septicaemia, meningitis, pneumonia, central nervous system infections, endocarditis, pericarditis, respiratory or infections. Some form of infections involving toxigenic strains are associated with nausea, vomiting, and malaise, occasionally with diarrhea. Most strains (if not all) are sensitive to fluoroquinolones and aminosides such as gentamycin.

*C. difficile* can cause antibiotic-associated diarrhoea in humans, which, in a minority of cases, can lead to severe colitis. Advancing age, in combination with underlying health problems and antibiotic therapy, is the greatest risk factor for *C. difficile* infection. There are several effective treatments available, including vancomycin, metronidazole and the *C. difficile*-specific antibiotic fidaxomicin.

*C. perfingens* can cause enteritis in humans and, rarely, gas gangrene following deep wound infections. It causes a variety of veterinary diseases including wound infections and necrotic enteritis. *C. perfingens* enteritis is usually mild and requires no treatment however the organism is susceptible to penicillins, cephalosporins, clindamycin, metrinidazole, and tetracyclines.

*C. sordeillii* causes bloodstream and necrotising soft-tissue infections in animals. In humans, infections (toxic shock syndrome) have been reported in both postpartum and post abortive women and tissue infections have been reported in intravenous drug users. Antibiotic susceptibilities are the same as for *C. perfingens*.

*C. tetani* can cause tetanus in man and in some animals. Infections result from contamination of a deep wound with spores. A highly effective vaccine is available.
C. chauvoei can cause necrotic muscle infections in animals; not known in humans.

C. septicum is an important pathogen of turkeys, in which it causes gangrenous dermatitis. In humans the organism can cause myonecrosis as a consequence of bowel carcinoma and other malignancies. Antibiotic susceptibilities are the same as for C. perfingens.

C. novyi causes a range of gangrenous infections in animals. In humans infection is rare but has been reported in intravenous drug users. The organism is currently being used in clinical trials for the treatment of hypoxic refractory solid tumours.

C. glycolicum causes ulcerative colitis in domestic fowl and can occasionally cause infections in humans (bacteraemia, septic shock, wound infections).

C. histolyticum can cause gas gangrene in humans, but this is now extremely rare.

C. colinum is the causative agent of ulcerative enteritis, a serious disease of the bobwhite quail.

C. sporogenes is an umbrella name given C. botulinum strains which lack the genes encoding the botulinum neurotoxins and is generally regarded as non-pathogenic.

### Host/vector system

We will use broad host-range, non self-transmissible plasmids carrying resistance markers (kanamycin, spectinomycin, neomycin, tetracycline, minocycline, chloramphenicol, streptomycin or erythromycin).

For cloning experiments in E. coli, plasmids carrying various origins of replication will be used, including derivatives of pMB1 p322 and pUC[1,2]), pSC101 (3), p15A (pACYC [4]), colE1 (5) and M13 (6).

L. lactis vectors are pNZ8048 derivatives (7).

For E. faecalis, E. faecium, S. pneumoniae, S. pyogenes, S. suis, L. monocutogenes and B. cereus, derivatives of pWV01 (8) and pam-beta1 (9) replicons will be used.

For clostridia spp. native clostridial replicons will be used, including pBP1, pCB102, pCD6 and pM13 (10).

None of the vectors used will encode resistance to antibiotics used in the treatment of infections caused by these organisms (which are, in any case, rare). None of the vectors used are hazardous and they are very likely to confer any advantage to the host bacterium.

Additional plasmid vectors will also be constructed using standard components such as those described above.

1. We will construct gene "knock-outs" using available genetic tools, e.g. targeted insertional disruption, gene deletion, transposon mutagenesis, etc. These procedures will not introduce foreign DNA into the recipient, other than an antibiotic resistance cassette and non-coding transposon components. The antibiotic resistance markers used will not confer resistance to antimicrobials used in the clinic for outline treatment of infections caused by these microorganisms.

2. We will introduce homologous DNA (same as the host) into wild type and mutant strains, for example, mutant complementation, multi-copy suppression and protein tagging. We will also introduce heterologous DNA (from another related strain or species), for example, trans-complementation with orthologous genes from another species. Introduced genes of interest will include genes encoding cell wall proteins, proteins involved in cell division/wall metabolism, cell surface structure synthesis and envelope biogenesis. None of the inserts will encode proteins constituting a hazard.

3. Wild type and mutant strains will also be modified by the introduction of genes encoding commonly used reporters, e.g. green fluorescent protein (and derivatives), fluorescent flavin mononucleotide-based proteins, luciferase, β-galactosidase, β-glucuronidase etc.

4. At no point will toxin encoding genes, or genes encoding known harmful proteins, be cloned or introduced into any bacterial species.

**Evaluation of foreseeable effects**

**Hazards to the worker:**

The work described will generally involve generating loss-of-function mutants, and complementing such mutants. It is expected that most mutants will have an unaltered or decreased pathogenic potential compared to parental strains. Therefore, there is no foreseeable significant change in the risk associated with the genetic modifications carried out.

No genetic material will be introduced that could be predicted to increase virulence, e.g. bacterial toxins, characterised virulence factors from other species.

It is possible that increasing gene dosage by the introduction of a gene on a plasmid could alter the virulence of a strain. However, maintenance of such a plasmid would be dependent on continued antibiotic selection and the plasmid would be rapidly lost outside of the laboratory.

The risk of transfer of plasmids between species will be negligible. Plasmids used for complementation experiments are able to replicate in a broad range of Gram positive species but are not transferrable in the absence of a helper plasmid carrying mobilisation functions.

Marker genes which confer resistance to antimicrobials currently used against these organisms will not be used.

It is very unlikely that, in the event of exposure, the GMOs generated will harm human health. All of the organisms considered here are capable of causing disease in humans but standard laboratory practice (outlined in the attached document) and the specific control measures outlined in this risk assessment will minimise the risk to the worker. In the event of accidental exposure the worker will be advised to seek immediate medical advice and will be provided with information on strain characterisation, including antibiotic susceptibility. In addition, the GMO's generated are predicted to have an unaltered or a decreased pathogenic potential and will not increase the infection risk.

Some of the organisms described here pose a greater risk to certain individuals or individuals with underlying health conditions. For example, L. monocytogenes is a serious risk to the unborn child. Each worker will undergo a pre-assessment by Occupational Health and will be advised to seek advice should their circumstances change. Where an individual worker is deemed to be at greater risk a specific risk assessment will be prepared in consultation with Occupational Health, the Health and Safety Dept. and the BioSafety committee.

**Hazards to the environment:**

All bacteria to be manipulated are ubiquitous in the environment. Although hazard likelihood is low for all the organisms, the GLP and control measures outlined in the attached risk assessment will further reduce risk. The work will be carried out in designated areas and all waste will be decontaminated prior to disposal.

Standard processes will be designed to avoid/minimise emission, release and spread of HG2 organisms. These include restricting the number of people exposed to the
organisms during routine work and using the minimum practical volumes at a given time. Equipment capable of generating a significant aerosol (e.g. centrifuges) will be operated with appropriate controls.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated solid waste (agar plates, disposable plasticware, etc) will be placed in yellow bins, autoclaved and disposed via the designated waste contractor.

Liquid cultures will be chemically-inactivated (Virkon 1% or PeraSafe 0.16% for 30 min) or autoclaved prior to disposal down the sink.

All contaminated glassware and reusable plasticware will be decontaminated as above.

Virkon and Perasafe are disinfectants with proven efficacy against Gram positive spp. and are commonly used in both research laboratories and hospital environments. Sporocidal activity has been validated by the manufacturer (see manufacturer's website) and in several articles in the published literature.

The designated waste-disposal autoclaves are serviced and 12-point validated by Consolidated Medical Industries (CMI) twice a year.

Is an emergency plan required according to regulation 20? **N**

If yes, tick to confirm that it is attached to this form **N**

Tick to confirm that you have attached a risk assessment to this form **Y**

Tick if you are claiming exemption from disclosure for section of the risk assessment **N**

Please enter comments on the GM safety committee on the risk assessment

This project was approved by the BioSafety Committee on the 10/05/2013

CU2 Project Title Quantifying the extent of colonization of plants by beneficial or pathogenic microbes using isolates that express fluorescent proteins or bioluminescent proteins

Date Project Ceased

Class 2

CultureVol Class 2 < 1 Litre

Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To prevent environmental spreading of plant-associated GM microbes

Recipient or parental organism

Phytophthora infestans, Pseudomonas putida KT2440, Pseudomonas syringae pv. tomato DC3000

Host/vector system

The transgenes encoding for fluorescent protein (GFP; Phytophthora infestans and Pseudomonas putida) or bioluminescent protein (Luciferase; Pseudomonas syringae pv. Tomato) are stably inserted into the genome of the organisms.

Origin & function

The GFP-expressing Phytophthora infestans is a pathogenic line that is derived from an isolate that is distributed worldwide, including major Solanum (tomato and potato) growing regions in Europe, North America, and South America. The LuxCDABE-expressing P. syringae pv. Tomato strain is a pathogenic line (DC3000) derived from a North American isolate, but P. syringae pathovars with similar virulence and host range exist worldwide, including Europe and American isolate, but P. syringae pathovars
with similar virulence and host range exist worldwide, including Europe and the UK thus it is already present in the environment. The GFP-expressing P. putida strain is derived from a beneficial plant growth promoting European strain (KT2440). This strain is a non-pathogenic, root-colonising isolate with a relatively wide host range of predominantly cereal plant species. The strain is widely distributed across the world. All three GM strains will be used to assess compatibility with host plants (Arabidopsis, tomato, wheat, or maize) by means of in planta colonization.

All of the above GM organisms have previously been constructed elsewhere, and are described in the following publications:

The GM organisms will be obtained from the following donors:

- GFP-expressing **P. infestans** will be obtained from Dr W, the James Hutton Institute (Dundee, UK).

- GFP-expressing **P. putida** KT2440 will be obtained from Dr N Rothamsted Research (Harpenden, UK).

- Luciferase-expressing **P. syringae pv. Tomato DC3000**, will be obtained from Dr F, John Innes Institute (Norwich, UK).

### Evaluation of foreseeable effects

All experiments will be carried out by trained personnel in the laboratory. Personnel will be required to wear disposable gloves and coloured lab coats, which will be kept within the plant growth facility. The scale of work will vary from a few plants (e.g. 10-20) to one hundred, depending on the nature of the experiment. As for the microscopy analysis of in planta colonization by the microbes, collected material (either leaves of roots) will be sampled to fit within the borders of the microscopy slide, in order to make sure that all colonized material is covered by the fixative (25% glycerol). The fixative immobilises the microbial dispersal and will therefore reduce infectivity of the microbes. As plant material has been detached from the plant both the leaf and associated microbe will die within a day.

#### I. Phytophthora infestans:

As mentioned above, the GFP-expressing line is derived from an isolate that is distributed worldwide, including major Solanum growing regions in Europe, North America, and South America. The host range of this P. infestans strain is primary potato (Solanum tuberosum) and tomato (Solanum lycopersicum). The requested strain expresses the GFP protein from a stable (genomic) GFP gene insertion, which does not alter its virulence, host range or survival. The strain will not be used in greenhouse or field trials.

During the course of all P. infestans experiments, the Oomycete will be kept in its asexual cycle. Asexual spores (chlamydospores) of this microbe germinate to form sporania, which in turn produce infectious zoospores when they come in contact with plant tissues. The pathogen will be cultured from a frozen spore suspension (stored in a locked minus 80 freezer in the C51 lab; Alfred Denny Building). With the exception of quantification of in planta colonization (see below), all experimental procedures will be carried out within the Sir David Read plant growth facility (G-19, Central Annex-Department of Animal and Plant Science). The plant pathogen will be cultured inside an incubator in the G19 growth facility. Agar plugs and/or zoospore suspensions will be prepared in G19. Inoculation will be carried out inside the Conviron growth chambers by applying agar plugs with hyphal material or droplets containing a suspension of zoospores onto leaves, thereby preventing formation of aerosols.

Samples of inoculated leaves will be collected between 1 and 5 days after inoculation and placed onto glass microscopy slides into fixative (25% glycerol), and sealed with...
a cover slip using transparent nail polish and transferred clean into secondary containers. The microscopy slides will be transported from the Central Annex laboratory to the C43 lab in the Alfred Denny Building inside plastic sealed leak-proof secondary boxes containers, where they will be examined further for GFP fluorescence, using an epi-fluorescence microscope.

Escape of *P. infestans* from the growth facility is very low. Escape can only occur via three routes: (a) zoospores (b) chlamydospores (c) infected plant material/colonised agar:

(a) zoospores of *P. infestans*. *P. infestans* zoospores have two flagellae, which allow the zoospore to travel in water on the surface of leaves and in the soil, but will survive outside a watery environment. Plants will be inoculated by placing drops of zoospores onto the leaves. Plants will be watered from below (in a propagator tray) to avoid splashes. The requirements for a suitable host and short viability of germinated zoospores spores make the risk of escape via drainage system low. In addition, when transgenic microorganisms are used in the Conviron chambers, waste water from the cabinet is collected in a special chamber inserted into the drain. The chamber contains an autoclavable filter which will trap any spores. This filter is autoclaved and replaced daily. The water in the chamber is treated with 3% Virkon before disposal.

(b) chlamydospores. Chlamydospores are able to detach and travel in the air. The plant growth chamber is maintained at a negative pressure with respect to the external environment which minimizes the chlamydospore escape. The growth facilities also contain filters on the outlet vents to prevent spores from escaping via this route.

(c) infected plant material/colonized agar.

Plants infected with *P. infestans* can produce chlamydospores to infect other tissues of the same plant or nearby plants. Infected plant material and colonized agar will be contained within the Central Annex of growth facility. Disease symptom scoring will be performed within Conviron growth cabinet. For in planta visualization of *P. infestans*, infected, non-sporulating leaf samples will be collected and fixed onto sealed microscopy slides to prevent escape, as detailed above. Microscopy slides will be transported clean from the Central Annex laboratory to the C43 lab in the Alfred Denny building in plastic leak-proof secondary containers (but slides are sealed anyway). All contaminated (plant) material will be autoclaved and disposed in the Alfred Denny building as detailed under waste disposal.

II. *P. syringae* pv. *Tomato* DC3000.

The requested strain is derived from a North American isolate, but *P. syringae* pathovars with similar virulence and host range exist worldwide, including Europe and the UK thus it is already present in the environment. The luxCDABE operon present in the requested transgenic strain is stably inserted into the bacterial chromosome and does not alter its virulence or host range. This bacterial strain does not produce long-lasting survival structures. The strain will not be used in greenhouse or field trials.

The pathogen will be cultured from a frozen spore suspension (stored in a locked minus 80 freezer in the C51 lab; Alfred Denny Building). With the exception of quantification of in planta colonization, all experimental procedures will be carried out within the Central Annex of Sir David Read plant growth facility (G19). The plant pathogen will be cultured in liquid growth medium inside an orbital shaker that is present in the Central Annex of the growth facility. The O/N culture will be adjusted to the appropriate cell density in the Central Annex laboratory. Inoculation of tomato and/or Arabidopsis will be carried out inside the plant growth chambers of plant growth facility. Inoculations will be carried out by pressure infiltrating of leaves, or dipping the leaves into a bacterial suspension, thereby preventing formation of aerosols. Samples of inoculated leaves will be collected between 1 and 5 days after inoculation and placed into glass microscopy slides into fixative (25% glycerol) and sealed with a cover slide, using transparent nail polish. Microscopy slides will then be transported inside airtight plastic leak-proof secondary container boxes to the C43 lab in the Alfred Denny building, where they will be examined further for bioluminescence, using a CCD camera.

Opportunities for escape of *P. syringae* pv. *Tomato* from the lab or growth facility are very low. Escape can only occur via bacterial cell suspensions or colonized plant material. In vitro cultivation of the pathogen and preparation of the inoculum, will be carried out in the Central Annex laboratory of the growth facility. Colonized plant material will be contained within the growth cabinet during cultivation of inoculated plants. For in planta visualization of *P. syringae* pv. *Tomato*, leaf samples will be collected in the growth chamber, and fixed onto microscopy slides in the Central Annex laboratory, as detailed above. Slides will be transported clean in sealed plastic leak-proof secondary containers from the growth facility to the C43 lab in the Alfred Denny Building. All contaminated (plant) material and agar plates, will be autoclaved as
detailed under waste disposal.

III. P. putida KT2440

As mentioned above, the GFP-expressing strain of this beneficial plant growth promoting bacterium is derived from a non-pathogenic, root-colonising isolate with a relatively wide host range of predominantly cereal plant species. The strain is widely distributed across the world. The GFP transgene does not affect the plant-beneficial traits of the strain, nor does it change its host range. P. putida KT2440 does not produce long-lasting survival structures. The strain will not be used in greenhouse or field trials.

With the exception of quantification of on planta root colonization, all experimental procedures will be carried out in the Central Annex of the Sir David Read plant growth facility. The soil microbe will be cultured in liquid growth medium inside an orbital shaker that is present in the Central Annex laboratory. The O/N culture will be adjusted to the appropriate cell density in the Central Annex laboratory. Soil matrix (sand/peat or sand/vermiculite) will be inoculated with a bacterial suspension prior to planting of seedlings, which will be carried out inside the growth chambers. Root systems will be diluted and plated onto agar plates in the Central Annex laboratory, and kept inside the incubator. After 48h of growth, plates will be analysed for numbers of GFP-fluorescent colonies using a blue-light box that is present in the Central Annex laboratory. Alternatively, root tissues will be collected, placed onto glass microscopy slides into fixative (25% glycerol) and sealed with a cover slip, using transparent nail polish. Slides will be transported clean inside airtight plastic boxes leak-proof secondary containers to the C43 lab in the Alfred Denny building, where they will be examined further for root colonization using an epi-fluorescence microscope.

Opportunities for escape of P. putida KT2440 from the lab or growth facility are very low. Escape can occur via bacterial cell suspension or colonized agar medium/roots/soil. Cell suspensions and agar plates will all be prepared in the Central Annex laboratory of the growth facility. Colonized plant material and contaminated soil will be contained within the growth cabinet during the cultivation of infected plants. Dilution plating of rhizosphere extracts will be carried out in the growth facility. For on planta visualization of P. putida KT2440, root/rhizosphere samples will be collected in the Central Annex laboratory in growth facility, and fixed onto microscopy slides as detailed above. Slides will be transported from the Central Annex to the C43 lab in the Alfred Denny building inside airtight plastic leak-proof secondary containers. All contaminated (plant) material and agar plates will be autoclaved as detailed under waste disposal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested or needed for the planned work

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All pots, spoil, plant material will be placed in biohazard bags, sealed and autoclaved before disposal (see next section for more details). Microscopy slides will be placed inside shock bottles prior to autoclaving and subsequently disposed with normal glass waste.

Material contaminated with GMOs is autoclaved at 134°C for 20 minutes. This cycle kills all plant materials and (soil) microorganisms, and has been validated by Bmm Western (the autoclave manufacturer). In all autoclave runs, the temperature is monitored and recorded by a probe placed in the centre of one of the bags being autoclaved. The autoclave is checked and tested by BMM Western every 3 months. Autoclave conditions are automatically recorded and checked and achieved for 3 years. The autoclave is regularly serviced and maintained.

In the unlikely case of a broken/leaking microscopy slide in lab C43, the cohesion of the fixative will prevent spreading of plant-associated microbes in the plant samples. The leak itself will then be treated with 3% virkon, which is insufficient to kill all microbes. Broken slides will be collected in shock bottles and autoclaved as detailed above. Emergency spillage procedure:
In the case of spillage during the in vitro cultivation of the bacterial microbes within the orbital shaker the spillage will be wiped up and the contaminated cleaning materials will be autoclaved. The incubator will be cleaned thoroughly cleaned with 3% virkon.

N

Project notified under transitional arrangements  
N
**Purposes of the contained use**

In this research, supported by the Leverhume Trust we will (i) test the hypothesis that judicious application of CO and/or CO-RMs, in combination with other antimicrobial agents, especially antibiotics, may be used to combat bacterial pathogens, (ii) understand the interactions between the CO and antimicrobial agents, and (iii) obtain new information on the fundamental mechanisms that underlie the antibacterial activity of CO-RMs. Our working model (the Trojan Horse hypothesis) is that a CO-RM may release CO extracellularly but more likely is transported into a bacterial cell via currently unknown pathways (possible via a membrane importer). In the cell, the CO dissociated from the CO-RM (with formation of iCO-RM, the inactive form). This is followed by reaction of CO with biological targets, notably the haem centres of membrane oxidases. Other targets include membrane transporters, metal homeostasis, intermediary metabolism and transcription factors that regulate gene expression. The fate of CO-RM or iCO-RM in the cell is unknown but the compounds may be re-exported. This work should make a valuable contribution to our understanding of bacterial resistance to CORMs and their potential for acting as adjuvants to antibiotics.

**Recipient or parental organism**

Uropathogenic strains of E. coli (UPECs) are clonally disseminated and cause urinary tract infections (UTI). This project will use strain ST131, a cause of UTI and bloodstream infections in the community, hospitals and long-term care facilities. It belongs to the international O2: H4-ST131 clone. There has been a worldwide increase in UPECs that produce Extended Spectrum Beta Lactamases (ESBLs), which mediate resistance to cephalosporins and monobactams but not cephamycins. This strain is virulent but is widely studied in laboratories worldwide to understand pathogenicity and antibiotic resistance traits.

**Host/vector system**

The genome ST131 and similar bacteria encodes virulence genes commonly associated with UPECs. Some of these factors are encoded by plasmids. The plasmids contain up to 10 antibiotic resistance genes, including genes that mediate resistance to beta-lactams, chloramphenicol, erythromycin and tetracycline. These plasmids will not be manipulated in any way. Lambda-red methods will be used to introduce mutations in the chromosome only in due course (Datensko and Wanner, 2000, PNAS 87, 6640-6645) The only deviation is the use of a gentamycin -resistance cassette not Tn10 or Tn5.

**Origin & function**

The hazards associated with the host organisms are described above. The only alterations proposed would be in genes not thought to affect virulence or antibiotic resistance, but rather in genes whose products are thought to be targets for CORMs, such as transporters and haem proteins. Genes to be targeted will probably decrease fitness of the organism not increase it. Examples are genes involved in solute uptake and efflux, respiratory enzymes, metal homeostasis and intermediary metabolism, especially thiol metabolism. Genes will not be introduced that encode pathogenicity or virulence determinants, that alter susceptibility to the immune system, affect host range or alter the sensitivity of the organisms to prophylactic treatment.

**Evaluation of foreseeable effects**

The risks and potential effects are the same as those of the unmodified strain. Strain ST131 is a cause of UTI and bloodstream infections in the community, hospitals and long-term care facilities.

The work to be carried out or the alterations proposed will not affect transfer to other organism or give rise to harm if transferred to another organism. It is not envisaged that modification will affect the organism's ability to acquire other sequences.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The organism will be contained in the specified areas and its use and storage will be clearly marked. Good Laboratory practice will ensure that the organism is not released. The risk of hazards is low. Laboratory scale cultures (agar plates and liquid cultures up to 1000 ml) will be used. The work outlined will be carried out in the designated laboratory (F13), which has been inspected and meets containment level 2 standards. Workers will wear appropriate coats and gloves. The work will generate contaminated plastic ware (tips, pipettes, small containers), flasks, agar plates and spent media used in the growth of bacteria. Bulk liquid waste will be decontaminated using 2% solutions of Virkon. Glassware will be sterilised by autoclaving. Solid waste will be disposed of in line with the University's procedures which have been approved for disposal of Class 1 and 2 GM waste. All contaminated solid waste (plastic etc) will be treated using 2% solutions of Virkon as recommended by the manufacturer before autoclaving (two are available) in the designated laboratory (F13). Autoclaves are serviced and checked annually. These measures will ensure effective killing and removal of bacteria and any residual nucleic acid material. "Contamination " of workers in this context would be due to inadequate hand washing or poor personal hygiene. The main threat is in causing UTI's via the normal routes. The strain is not an enteric pathogen and will not pose any additional threat over and above normal 'lab' strains in this regard. Showering or drenching a contaminated worker is unlikely to be effective. Workers with UTI-related problems would be expected to consult a doctor whatever the source of infection. To minimise spillage affecting others not using the organism, all materials used for the strain will be labelled, small cultures will be grown in incubators used only for this strain and accidental spills will be treated with Virkon or similar. There is a complete Drizit laboratory spills kit in the corridor a few metres away. Two researchers only will use this strain and they will work in the same bay of the laboratory.

Project Ref 168/14.2
**Project Additional Information**

**Purposes of the contained use**

To use recombinant vaccinia, an oncolytic virus, to selectively infect mammalian cells in vitro and/or in vivo to assess oncolytic potency in tumour and normal cells and to analyse levels of viral replication, selectivity of infection, oncolytic potency, viral cell viability and mechanisms of tumour cell lysis.

**Recipient or parental organism**

Recombinant oncolytic VACV will be used to infect tumour and normal cells. VACV is a replication competent oncolytic virus that can efficiently infect a wide range of target cells, however viral engineering has rendered some of the rVACV variants tumour selective. The experimental work proposed here involves the addition of VACV particles encoding therapeutic gene sequences to mammalian cell lines (Hazard Group 1 and 2 and Activity Class 1 and 2 cells) in vitro and the direct administration in vivo. Following the transduction of the mammalian cell lines with rVACV, RNA and protein will be extracted from the cells to determine expression levels of viral RNA, target gene RNA or gene product and functional assays will be performed. Following the direct administration of rVACV in vivo, animals will undergo monitoring and tumour measurements (as detailed in the project licence) and/or tissues/cells will be harvested and used in downstream functional assays.

**Host/vector system**

Hosts: The host organism would be normal and cancer cell lines of human and mouse origin. These would include Hazard Group 1 and 2 cell lines and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.

Vectors: Recombinant attenuated Western Reserve (WR) or Lister strains of Vaccinia are the backbone vectors for carrying the genes and are covered by appropriate risk assessments. Attenuation mechanisms are outlined briefly below and fall under the categories of Disabled and attenuated vectors and Conditionally replicative vectors (outlined
Various permutations of VACV have been created and attenuated for virulence by the deletion of the following genes, alone or in combination:

- **Thymidine Kinase (TK):** TK deletion from VACV engenders enhanced specificity for tumour cells. TK-deleted VACV is highly attenuated in non-dividing cells but is able to replicate robustly in transformed cells.
- **Vaccinia Growth Factor (VGF):** VGF is a viral ortholog of EGF that encourages increased metabolic activity in cells and promotes viral replication and spread. Deletion of VGF from vaccinia virus severely attenuated viral replication in vivo, and increases the LD50 of the virus by over 2 logs. VACV that are deleted for both VGF and TK appear to replicate specifically in tumour cells.
- **B18R:** B18R is a Type I IFN decoy receptor encoded by VACV. Deletion of the B18R gene enables infected cells to generate a stronger type I IFN response in response to VACV infection and protects surrounding nontransformed cells from viral-mediated cell killing by eliciting the antiviral state. Tumour cells often have defects in the type I IFN response, rendering them still susceptible to oncolysis by B18R deleted VACV.

Specific Open reading frames, cDNAs and gene sequences encoding therapeutic gene sequences or therapeutic proteins (e.g. cytokines and antibodies) and/or si/shRNAs or miRNAs (designed to knockdown the expression of cancer causing genes) and reporter genes can be inserted into rVACV. An example of a transgene insert includes (but is not limited to) immune modulating cytokines such as human or mouse granulocyte-macrophage colony-stimulation factor (GM-CSF), a cytokine for stimulating proliferation of haematopoietic stem cells which would augment the anti-tumour and anti-viral immune response.

Guidance on inserts that may have a greater risk of adverse effects on human health can be found in SACGM compendium of guidance, Part 2-2, p37-46. Inserts will generally have a therapeutic effect.

**Origin & function**

Specific Open reading frames, cDNAs and gene sequences encoding therapeutic gene sequences or therapeutic proteins (e.g. cytokines and antibodies) and/or si/shRNAs or miRNAs (designed to knockdown the expression of cancer causing genes) and reporter genes can be inserted into rVACV. An example of a transgene insert includes (but is not limited to) immune modulating cytokines such as human or mouse granulocyte-macrophage colony-stimulation factor (GM-CSF), a cytokine for stimulating proliferation of haematopoietic stem cells which would augment the anti-tumour and anti-viral immune response.

Guidance on inserts that may have a greater risk of adverse effects on human health can be found in SACGM compendium of guidance, Part 2-2, p37-46. Inserts will generally have a therapeutic effect.

**Evaluation of foreseeable effects**

**Potential hazards associated with the recipient host:**

These will vary depending on the cell type used and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens: hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

Note: Hazard Group 2 cells and Activity Class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

**Potential hazards arising from the gene product:**

The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. The work outlined in this assessment covers therapeutic transgenes and gene sequences expressed by rVACV. By their very nature these will have a therapeutic effect. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines and expression of a therapeutic transgene will often result in cancer cell death or arrest and render the cells more immunogenic in vivo which would result in greater clearance.

**Potential hazards arising from the combination of gene and host:**

The knockdown of, or increased expression of, the majority of genes is predicted to generally have little or no adverse effect. Gene products will only ever be expressed in cells that are able to support viral replication (tumour cells) and the greater the expression levels, the more likely the cell is permissive to viral replication and will ultimately die due to this property. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines, many of which harbour mutations within these genes or expressing these genes through other delivery vectors (adeno- or lentiviral transduction). Enhanced tumour cell killing is a beneficial additional effect of combination
of host and gene.

Potential for transfer of gene to other hosts:

Vaccinia can infect many cells, although the majority of variants used here are disabled/attenuated and conditionally replicative vectors, i.e. replicate selectively in tumour cells. Normal cells will not support viral replication and the virus will be inactivated. In cancer cells where replication is permissible the virus will be propagated and will result in cell lysis and death and release of virus which will go on to infect other surrounding cells. By their very nature, the replication component virus cells that support viral replication will ultimately die due to viral replication and the level of viral replication will drive the level of the therapeutic transgene which will also enhance immune clearance in vivo or cell killing. Vaccinia replication takes place in the cytosol so there is no chance of stable integration or recombination with the host genome. Additionally many of the variants that will be used are disabled and attenuated vectors.

Poxviruses have a large number of genes, many of which are dispensable for growth in vitro and cause attenuation when disrupted.

Potential for harm to human health in the event of exposure:

Typical characteristics of the poxvirus family include a large dsDNA viral genome (varying from 130 to 300kb in size) which is enclosed in a multi-membrane virion, making them some of the largest known viruses. Replication takes place within the cytoplasm of permissive cells and all the enzymes required to initiate viral gene transcription are carried within the virion. Other general features include the induction of virus containing pustular, epidermal lesions, although the severity of the disease is dependent on the host organism and poxvirus species. (Ref: SACGM, Table 2.10. Host range of poxviruses and the typical symptomatic consequences of infection. *Less common adverse reactions to Vaccinia virus inoculation in humans, p104).

VACV normally has no serious health effects in humans, although it can cause disease of the skin when used as a vaccine vector. Vaccinia virus is usually injected in the dermis where a localised lesion appears (a "take") and then scabs over and heals in about 10-14 days. The vaccination is accompanied by fever, rash, lymphadenopathy, fatigue, myalgia and headaches in some patients. Accidental infection with the virus can occur through contact between the vaccination lesion and broken skin (inadvertent inoculation). Serious complications such as ocular vaccinia, myopericarditis, eczema vaccinatum (a papular, vesicular and pustular rash that is very infectious, 38 cases per million doses), progressive vaccinia (progressive necrosis at the vaccination site, 3 cases per million doses), postvaccinal CNS disease (headache, lethargy, seizures and coma, 12 cases per million doses), foetal malformations and abortion (very rare) sometimes occur after vaccination. Complications are more serious in immunosuppressed individuals and the smallpox vaccine usually causes one death for every million doses.

Contraindications to vaccine are their use in immunocompromised individuals, individuals with certain skin (e.g. eczema) and cardiac diseases and pregnant women. However it must be noted that VACV is a poxvirus that has an extensive safety record and has been used widely as a vaccine vector in vaccination campaign for the eradication of smallpox and is therefore considered to pose minimal risk to human health.

Vaccinia virus may cause disease in situations whereby immunity may be reduced, i.e. during pregnancy, in people with active skin disorders such as eczema or psoriasis, or in immuno-compromised individuals such as those infected with HIV, those individuals who have undergone splenectomy or are on high dose steroid treatment or immune suppressive chemotherapy. It is well documented that vaccinia can be passed to close contacts of vaccine recipients generally with little adverse consequence. Therefore, although an individual with a laboratory-acquired infection is unlikely to receive the virus dose given for vaccination purposes, close contacts, particularly those with contraindications for vaccination, may also be at risk.

The viruses that will be used in this assessment do not cause full blown Vaccinia infection but tend to cause more localised infections such as a pustule or blister (with or without necrosis and scarring) particularly on the hands, mouth or around the eyes. It is possible for one infected area to contaminate and infect another (e.g. finger to eye). A wide
range of photographs of Vaccinia virus infections are available at: www.bt.cdc.gov/training/smallpoxvaccine/reactions/default.htm and by searching for "smallpox vaccine" or Vaccinia virus on the internet. SHE should maintain a list of people who work with Vaccinia and all people that work with Vaccinia will be given a letter for their family doctor to be kept with their general practice notes, to prompt their general practitioner to consider Vaccinia if they develop such a blister or sore.

Potential to disseminate and harm the environment in the event of accidental release:

Poxviruses are highly stable and resistant to dehydration; infectious virus can be stored in dried powder form. Transmission is usually via aerosol or direct contact and infectious virus can survive for protracted periods in dried scab material shed from epidermal lesions. In the event of any release into the environment, genetically modified poxviruses might persist and could be transmitted to other humans or animal species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All in vivo work will be carried out under Containment Level 2 conditions using rodents. All handling of rVACV agents will be in Class II safety cabinets and all treated animals will be kept in separate red-line isolation cages, which are completely sealed with separate negative pressure air supply and HEPA filters on the inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals.

Only Home Office-approved operatives, trained in safe handling, will be used to undertake in vivo work, to minimise the risk of infection from potentially infectious adventitious agents from the host cell lines.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

It is well known that Vaccinia and other poxviruses have the capacity to survive for considerable periods in dried material such as detached vaccination scabs, but it is less well appreciated that survival in aqueous solutions can be for several weeks. Live virus can also be isolated from solid surfaces and fabric for as long as two weeks after contamination. For laboratory workers, ingestion, inoculation via needles or sharps, and droplet or aerosol exposure of mucous membranes or broken skin are possible routes of infection. Laboratories working with Vaccinia and other poxviruses should have suitable local rules to control these potential sources of infection, including suitable procedures for decontamination of equipment and surfaces.

It is imperative that strict hygiene is adhered to, including hand-washing after work and the use of an alcohol gel to limit transfer. All door handles and equipment must be wiped down with 20% Trigene Advance as a precautionary measure.

Laboratory coats should be disposable or will require to be washed at a high temperature (at least 60°C) or autoclaved frequently as VV is relatively heat resistant, can survive for long periods on fabrics, and has been shown to transfer from fabrics to other objects by direct contact.

Other information

SUSCEPTIBILITY TO DISINFECTANTS: Susceptible to 0.02% sodium hypochlorite, 30% isopropanol, 40% ethanol, 0.02% glutaraldehyde, 0.01% benzalkonium chloride, 0.0075% iodine, 30% Sanytex and 0.12% ortho phenylphenol. The virus is resistant to solvent/detergent combinations (TNBP/Triton X-100 and TNBP/ Tween 80) and longer incubation periods (between 10 minutes and 24h depending on the solvent/detergent used) are necessary to
inactivate the virus.

PHYSICAL INACTIVATION: The virus is inactivated by dry heat at 95 ºC for 2 hours. The heat-sensitive fraction of the virus is inactivated by moist heat at 60 ºC while the heat-resistant fraction may take higher temperatures to fully inactivate it. The virus in its aerosol form is also sensitive to UV light (254 nm).

SURVIVAL OUTSIDE HOST: The dried virus can survive up to 39 weeks at 6.7% moisture and 4 ºC.

The Biosafety Committee asked the author to expand on the goals, give an explanation as to why they were doing this work, is it oncolytic, and is it being used for tumour cell lines. The Committee agreed this would be AC2 and therefore require an HSE notification.

Non-GMM Consent Granted Yes

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Investigate the role, function and regulation of *N. meningitidis* (also known as the meningococcus, abbreviated Me) genes involved in:

(i) bacterial physiology, particularly the stringent response, anaerobic metabolism, amongst others

(ii) carbon metabolism, utilisation of lactate, glyceraldehyde, pyruvate, glucose and leucine responsive regulatory protein

(iii) secreted proteins (IgA protease, Gly-1)

(iv) pathogenesis.

In addition we would like to overexpress several of the above classes of proteins from *N. meningitidis* (MC) in *E. coli* for role, structure function studies.

**Recipient or parental organism**

*Neisseria meningitidis* strain MCS8, or strain H44176 both are wild-type serogroup 8 strains. *N. meningitidis* (MC) can be a commensal or serious pathogen of humans with the ability to cause meningitis and septicaemia.

(ii) *Escherichia coli* strains K12 and B. Non-pathogenic or limited colonisation ability. Hazard group 1.

**Host/vector system**

*Neisseria meningitidis* MCS8 or H44176 both are wild-type serogroup B strains. *N. meningitidis* plasmids: pGEMlacZermC neisserial transcriptional fusion vector, pYHS24 an MC ectopic chromosomal integration vector for mutant complementation, both are non-self transmissible and are chromosomal integration vectors in MC.

*E. coli* strains: DH5 alpha, XL-1 blue, JM83 (hosts for routine cloning) BL21 (OE3) or BL21 derivatives for the overproduction of *N. meningitidis* proteins

*E. coli* plasmids: pGEMTeasy, pUC19, pBluescript (routine cloning vectors) pET -derivatives, pGEX-derivatives, pMAL-derivatives (overproduction of *N. meningitidis* proteins)

All plasmids used in MC must be passaged though *E. coli* strains, since cloning steps are carried out using transformable *E. coli* strains. All the MC plasmids have their beta-lactam resistance genes deleted.

**Origin & function**

(i) Me genes involved in bacterial cellular physiology and anaerobic metabolism that help the bacterium respond to environmental stress. The majority of these have been identified from the MeSS genome sequence. Of particular interest are the genes relA and spoT involved in the bacterial stringent response and the genes involved in the response to oxidative and nitrosative stress, anIA, norB, and the genes encoding the regulatory genes narP, narO.
nsR and fnr amongst others.

(ii) Me genes involved in carbon metabolism. Of particular interest are the genes involved in the utilisation, uptake and regulation of pyruvate, lactate, glucose, gluconate and other sugar metabolism. Although amino acid metabolism and regulation may also be investigated (e.g. leucine responsive regulatory protein Lrp).

(iii) Me genes encoding the secreted proteins IgA protease and the potential haemin binding protein GIIY-1 and genes encoding associated proteins.

(iv) Me genes involved in pathogenesis, especially those involved in the interaction of the bacterium or its products with the innate immune system, these will be mainly associated with LPS biosynthesis. capsule. biosynthesis, porin biosynthesis and adhesion such as pili and opacity proteins.

Activity 1. Targeted inactivation of chromosomal MC genes. Genes of interest that have been identified by genome sequence analysis will be inactivated to determine the role of the gene. This procedure will involve spliced overlap extension (SOE) PCR, in which the neisserial gene of interest will be insertionally inactivated by an antibiotic resistance cassette (erythromycin or kanamycin), then the mutated allele on the PCR fragment will be transferred into Me by natural transformation. Selection will be imposed for recombinants that have under-gone allelic replacement. Separately the SOE-PCR fragment will also be cloned into E. coli plasmids and propagated in E. coli to facilitate sequencing to check the correct construction of the SOE PCR fragment. In addition mutant strains in a N. meningitidis MeS8 background that have been created in other national and EU labs using similar techniques will be used, these will be transported to Sheffield, as category A pathogens (UN2814) following packaging instructions P1620.

Activity 2. Cloning of the fun length MC genes into an ectopic chromosomal insertion vector and introduction into the corresponding MC mutant (complementation), where the plasmid can not replicate but rather recombines into the neisserial chromosome. This procedure is employed in order to confirm the phenotype of the mutants of interest generated by activity 1 is due to the insertion of the antibiotic resistance cassette and not down to polar effects on downstream genes.

Activity 3. Construction of reporter fusions in MC. To monitor the expression of the MC genes, regulatory regions will be fused to lacZ in a chromosomal integrative vector that will then be introduced into the appropriate MC host. Where applicable the regulation of MC promoters may also be studied in E. coli K-12 using narrow host range plasmids.

Activity 4. Overexpression of MC proteins in E. coli. To perform, role, structure-function analysis of various Me proteins. Such proteins will be expressed at high level from a strong inducible promoter contained in an E. coli specific plasmid. The genes will be fused to a sequence (i.e. hexahistidine, GST, MBP tags) that facilitates the purification of the overexpressed protein.

Evaluation of foreseeable effects

Neisseria meningitidis aka the meningococcus (MC) is a Gram negative bacterium and is the aetiological agent of meningitis and sepsis syndrome it is a serious pathogen of humans. The antibiotic resistance cassettes used to select the mutants and plasmids in these strains are not generally used to treat N. meningitidis infections (erythromycin and kanamycin). Because beta-lactam antibiotics are used for neisserial treatment any of the vectors used with N. meningitidis will have had their beta-lactam resistance genes deleted, even though the current drug of choice for meningococcal disease is a modern cephalosporin such as ceftazidime, and this antibiotic is known to be resistant to these plasmid encoded beta-lactamases.

E. coli K-12 and E. coli B are potential colonisers of humans and other animals but are non-pathogenic. Most laboratory strains of E. coli K-12 are unable to colonise humans.

Thus the acquisition of the antibiotic resistance markers to be used in these activities are very unlikely to constitute a hazard to human health or the environment.

Any foreseeable additional properties of these organisms as a result of genetic modification are outlined below.

Activity 1. Targeted inactivation of chromosomal MC genes. The initial step will include the amplification of the MC gene of interest and inactivating it through the insertion of an antibiotic resistance cassette using spliced overlap extension.
extension (SOE) PCR. This will generate a non-self-replicating non-mobilisable fragment of DNA that there are no foreseeable effects regarding human health or the environment.

The linear SOE PCR DNA fragment will be introduced into MC by natural transformation where it will be unable to replicate. Selection of the antibiotic resistance cassette inserted into the gene will allow for the isolation of rare recombinants in which homologous recombination has occurred and the mutated allele has replaced the wild-type allele on the MC chromosome. The resultant strain containing the insertionally inactivated gene will be very unlikely to have gained fitness and be more pathogenic than the wild-type strain. The MC mutant strain will have gained resistance to a single antibiotic. These features will be the same for MC strains imported from other national or EU laboratories, these will be transported as category A pathogens (UN2814) following packaging instructions P1620.

Cloning of the inactivated MC gene into a non-self transmissable plasmid in E. coli to facilitate sequence analysis of the construct is not likely to create a foreseeable effect that is hazardous to human health or the environment. The E. coli K-12 are laboratory strains and are non-pathogenic and the Me gene of interest will have been inactivated.

Activity 2. Introduction of individual MC genes in a non-mobilisable chromosomal integration vector. Apart from the acquisition of the plasmid resistance marker, it is unlikely that the phenotype of the recipient would be significantly different from the parental MC strain. Complementation will take place or not. The complementation vector pYHS24 inserts the gene of interest in single copy on the MC chromosome between the genes NMB0103 and NMB0102 on the MC chromosome. There are therefore unlikely to be overexpression issues due to multi-copy or transmission issues to other bacteria. However, the gene of interest will be under the control of the opa promoter which may lead to elevated expression levels compared with the natural gene, but this is unlikely to make the GM strain more pathogenic than the MC wild-type strain. There are unlikely to be any detrimental effects of cloning such genes in E. coli K-12, as these strains are disabled and unable to colonise.

Activity 3. Construction of reporter fusions in MC. Only the regulatory regions and gene segments, rather than the complete structural gene will be cloned into the chromosomal integrative vector and delivered into the wild-type and mutant Me strains. There is likely to be a negligible risk associated with this activity. The lacZ gene has been extensively used as a reporter in bacterial systems. The plasmid pGEMlacZermC' is non-mobilisable and narrow host range and is non-self-transmissable. The cloned DNA would be very unlikely to confer a fitness advantage on Me or other bacteria or result in effects harmful to humans or the environment. In some cases it may be possible to investigate the regulation of a MC promoter in E. coli K-12 (for example in the presence of its regulator in trans). As the E. coli host will be disabled there are no foreseen deleterious effects of expressing a regulatory protein from a compatible plasmid.

Activity 4. Overexpression of MC proteins in E. coli. Plasmids harbouring the phage T7 promoter will be used these depend on the T7 RNA polymerase for high level expression of genes in E. coli, the host E. coli B BL21 (DE3) or similar will be used. The activated expression system is lethal to the host strain. This strain can be viewed as being similar to E. coli K-12 in terms of its ability to behave as a pathogen. In some cases plasmids harbouring other strong promoters may be used such as the lac promoter. Plasmids used will be derived from the narrow host range plasmids (pBR322 and pUC19 (pET series, pGEX, pMAL), and will confer ampicillin or kanamycin resistance upon the E. coli host. Overproduction of an individual Me protein in E. coli BL21 (DE3) is unlikely to render it more pathogenic or increase its survival fitness in the human gut or environment. As the mechanism of action of some of the Me proteins to be expressed is unknown.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NIA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation not requested

02/03/2022
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM waste will be inactivated prior to leaving the premises.
Small volumes of liquid culture and small disposable items (plastic tubes, cuvettes, pipette tips) will be inactivated by immersion in disinfectant (5% Virusolve Plus) for a minimum of one hour, this has been validated to kill MC.
Solid material inactivated by disinfectant will be autoclaved in the same laboratory and then transferred to the appropriate containers whereupon it will be taken to another site by approved contractors for final disposal.
All other items, (larger cultures, agar plate cultures, contaminated glassware) will be inactivated by autoclaving in the same laboratory (autoclaves are regularly serviced and validated). Items that have been inactivated by this method will be placed in the appropriate waste bags and removed from the site by approved contractors for final disposal.
Only the material specified below will be removed from the containment 3 facility.
Certain material will be brought out of the containment 3 laboratory including ethanol precipitated DNA and RNA extracted and purified from lysed MC cells. These will be brought out in tubes whose exterior surfaces have been wiped in 70% ethanol.
MC protein samples for 50S-PAGE from lysed cells will have been boiled in Laemmli buffer and again transported in tubes wiped with 70% ethanol.
Host and Me cells that have been fixed in 4% paraformaldehyde will be used for microscopy.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

This proposal have been approved by the University of Sheffield Biosafety committee on the 24th November 2014.

Project Ref 168/15.1
Use of Lentiviral CRISPR or shRNA technology to knockout target genes and assess function

The lentiviral vectors are 3rd generation HIV-based lentiviral vectors, from which the majority of viral proteins have been removed and contain a 3' deletion which results in self-inactivation following transduction. Furthermore, the genes required to produce a packaged, transducible virus are distributed among 3 separate vectors: pMD2.G, pRSV-Rev and pMDLg/pRRE. Therefore it is unlikely that a replication-enabled lentivirus could be produced, given the rare possibility that the required recombination would occur. As a precaution against this minimal risk, however, the work on human cells will be performed at Containment Level II.

In mammalian cell lines, a potential hazard may arise from the introduction of genes into the cells which may enhance the ability of the cell proliferate, or evade host immune surveillance. However, some cell lines already possess proliferative ability due to their cancerous origin, but cannot survive any significant period of time outside of their normal tissue culture environment. Therefore daily precautions will be taken as with any mammalian cell culture work.

The lentiviral vectors are 3rd generation HIV-based lentiviral vector and packaged among 3 separate vectors: pMD2.G, pRSV-Rev and pMDLg/pRRE. As a precaution against the minimal risk of the production of a replication-enabled lentivirus, the work will be performed at Containment Level II. Nucleotide sequences will be used to knockout genes including tumour suppressor genes, proto-oncogenes and genes of unknown function. The potential hazard arising from knockout of such genes could be oncogenic. It is also likely that the target sequence will also target other places in the genome and therefore pose additional hazards of gene editing elsewhere in the genome. We therefore propose to carry out the handling of live virus and transduction of cells in the designated Class 2 facility.
The project requires the use of genes and/or gene fragments sourced either by cloning or obtained from third parties to be overexpressed in human cell lines. The transfer vectors may incorporate one or more genes encoding selection markers, or fluorescence reporter proteins. Examples of these include PuromycinR, BlasticidinR, AmpicillinR or fluorescent proteins such as mCherry, GFP, Venus, Cerulean, mTomato. These proteins are considered non-hazardous owing to their non-mammalian origin. There is no evidence of any oncogenic potential for these proteins thus we consider it highly unlikely that exposure to these proteins would result in harmful effects.

Evaluation of foreseeable effects

A worst-case scenario would be a worker being exposed through a respiratory or dermal route to live lentivirus during titre production such as centrifuge rotor failure. To minimise the risk of exposure all work is to be carried out in a dedicated viral tissue culture room in a class II microbiological safety cabinet. Viral supernatant produced from the 293T cells will not be concentrated and cells transduced with lentivirus will only be removed from class II containment following 4 passages and all cells and viral supernatant for disposal will be treated in a final concentration of 1 % virkon.

Another potential hazardous scenario would be a transduced cell being introduced into a worker through a needlestick injury. However, the human cell lines we intend to use are already proliferative in nature, which are handled routinely in class II containment. Therefore we feel that no special precautions are necessary when handling transduced cells above and beyond the pre-existing requirement for good laboratory practice. Human megakaryocytes and endothelial cells express class I MHC antigens and would most likely illicit rapid immune rejection if accidentally injected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Viral titre will not be concentrated thereby removing the risk of respiratory exposure due to potential centrifuge rotor failure that could occur during ultracentrifugation. Lentiviral supernatant will be inactivated by incubation with Virkon to a final concentration of 1 %, following manufacturers’ instructions (incubation for >30min before disposal). Virkon effectively destroys any virus. Virkon is safe, non-toxic and biodegradable. All other waste, which was in contact with lentiviral supernatant will be disinfected with Virkon to a final concentration of 1 % prior to disposal. This waste is placed in sealed medical waste bins and incinerated. All work will be carried out at containment level II.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Lentiviral supernatants and lentivirally-transduced cells will be inactivated by incubation with Virkon to a final concentration of 1 %, following manufacturers’ instructions (incubation for >30min before disposal). Virkon effectively destroys any virus. Virkon is safe, non-toxic and biodegradable. All other waste, which was in contact with lentiviral supernatant will be disinfected with Virkon to a final concentration of 1% prior to disposal. ### Project Additional Information

#### Purposes of the contained use

Constitutive secretion is a conserved process required for the delivery of newly synthesised proteins and lipids to plasma membrane as well as the exocytosis of extracellular factors such as cytokines, lipoproteins and antibodies. My lab is interested in identifying and characterising the pathways and cellular machinery involved in constitutive secretion. We aim to identify this machinery using a combination of proteomics and functional genomics. The majority of the proteins identified in these screen are likely to be house keeping genes such as (coat proteins, rabs, tethers and SNAREs) so not biologically hazardous or oncogenic. We will use lentivirus to: a) Express cDNAs encoding wild type and mutant proteins required for constitutive secretion in mammalian cells. b) Knock down proteins required for constitutive secretion in mammalian cells using shRNA. c) Knock out proteins required for constitutive secretion in mammalian cells using CRISPR/CAS9.

#### Recipient or parental organism

**Bacterial host**

In all experiments the bacterial host strains used are non-pathogenic E.Coli K12 derivatives: OH5.a, JM109, XI-1blue, HB101 (genotypes listed in attached appendix). All are non-colonising and disabled and are therefore unlikely to survive either in the gut or in the environment. We consider assignment of ACDP hazard group 1 appropriate.

**Mammalian host**

Experimental procedures using virus to introduce novel genetic elements will be performed on primary murine cells and well established cell lines such as HeLa, Caco2 and I.29. Virus particles will be manufactured in Human Kidney 293T cells transformed with SV40 large T antigen. As with all mammalian cells these cell lines are sensitive to culture conditions and have no survival potential outside of their normal tissue-culture environment.

#### Host/vector system

**Lentiviral vector system**

Replication deficient self-inactivating lentivirus particles will be produced by transfection of at least 3 different plasmids. We intend to use 2nd and 3rd generation lentiviral transfer vectors. The majority of viral proteins have been removed; in particular the virulence genes vpr, vif, vpu and nef are not present and are not required for transgene expression.

The vector system consists of: (1) self-inactivating transfer vector containing the expressed DNA sequence (2) Packaging and structural proteins (3) Envelope protein. The genes required to produce a packaged, transducible virus are distributed among at least 3 separate vectors. Thus it is unlikely that a replication-enabled lentivirus could be produced, as it is unlikely that the three required recombinations would occur. However we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.

**Transfer vectors**

a) vectors designed to give constitutive gene expression utilising a promoter such as CMV (plenti-Puro, Addgene).

b) vectors designed to constitutively express shRNA utilising promoters such as U6 or H1 (pLKO-Puro, Addgene).

b) vectors designed to constitutively express CRISPR/Cas9 utilising a promoter such as CMV and guide RNA using a RNA pol IIII promoter (lentiCRISPR V2, Addgene).
Packaging plasmids
a) Packaging plasmid 3rd generation (gag_pol_pMDLg/pRRE, Addgene).
   b) Packaging plasmid 3rd generation (pRSV-Rev, Addgene).
   c) Packaging plasmid 2nd generation (psPAX2, Addgene).

Envelope plasmid
a) Amphotropic plasmid, VSV-G (pMD2.G, Addgene).
   b) Ecotropic plasmid, MLV, (pCAG-Eco, Addgene)

Safety features of 2nd and 3rd generation lentiviral vectors
1. Vectors contain a deletion in the 3'LTR that does not affect generation of the viral genome in the producer cell line, but results in 'self-inactivation' of the lentivirus after transduction of the target cell. This is a result of the natural duplication of 3'LTR into 5' position that occurs during integration. Once integrated into the target cell, the lentiviral genome cannot produce packageable viral genome.
2. Virulence HIV genes like vpr, vit, vpu, and nef are not present and are not required for transgene expression. The absence of the env gene removes the gp160 precursor that is responsible for the lethal macrophage/T cell/neurotropism of HIV.
3. Production of the viruses from the producer cell line requires the transfection of at least 3 plasmids (two packaging, one the DNA to be packaged) in a transient transfection. All three plasmids have been designed, through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging cell line produce retrovirus in any form during routine culture.
4. Internal promoters are used to eliminate the need of the HIV-promoter and reduce the risk of recombination events and trans-activation of surrounding genes.
5. We will not concentrate the viral particles.
6. Where possible ecotropic pseudotyped viral particles will be used which are unable to infect humans.

Origin & function
We plan to express cDNAs of wild type and mutant proteins required for constitutive secretion such as coat proteins, rabs, tethers and SNAREs. These proteins are house keeping genes so are not likely to be oncogenic or biologically hazardous. We plan to express shRNA or CRISPR/Cas9 constructs targeting genes involved constitutive secretion such as coat proteins, rabs, tethers and SNAREs. Loss of these proteins is unlikely to confer any known selective advantage to the host. However, we cannot exclude the possibility of tumor-inducing effects, as their functions are not well defined. In order to reduce the possibility of accidental exposure of a worker to virus we propose to carry out the handling of live virus and transduction of cells in our designated Class 2 laboratory.

The 2nd and 3rd generation lentiviral vector backbones may contain expression enhancing viral elements such as the WPRE element which in its wild type form can express the so-called x-protein which may have oncogenic properties. Thus we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.
The transfer vectors may also incorporate one or more genes encoding selection markers and fluorescence reporter proteins. Examples of these include 1) PuromycinR, BlasticidinR, AmpicillinR, 2) fluorescent proteins such as mCherry, GFP, Venus, Cerulean, mTomato. These proteins are considered non-hazardous owing to their nonmammalian origin. There is no evidence of any oncogenic potential for these proteins thus we consider it highly unlikely that exposure to these proteins would result in harmful effects. However, we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.

**Evaluation of foreseeable effects**

**Environmental assessment**

These replication-incompetent viruses would be inactivated prior to disposal, and given their inability to replicate they have no significant additional environmental hazard.

**Worst-case scenarios**

The above protocols should minimise any risk of exposure to the personnel using or in the vicinity of work using this lentiviral transfection system. Virus particles, virally-transduced cells, and media and supernatants resulting from these systems will never be handled with glassware or hypodermic needles. Thus, the risks of accidental inoculation are remote. The worst scenario would be exposure to a main stock of virus containing one transgene, perhaps resulting from spillage. The major exposure routes would be cutaneous, mucocutaneous, and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier, and would be minimised by standards of Good Laboratory Practice. The viruses would infect mucocutaneous surfaces and respiratory epithelia and macrophages with which they came into contact. However, the particles are replication incompetent, and have many safety features preventing generation of replication competent viral particles. The genes of interest are not oncogenes. Thus although there might be limited tissue infection and damage, this would not result in sustained infection or risks of tumour generation or malignant transformation. It might be possible that exposure would generate an immune response to the VSVG protein, but this would have a protective effect if so. The overall likelihood of serious or long-term harm resulting from experiments using these vectors seems extremely small.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We propose to handle all material in Category 2 culture conditions.

1. Anti-viral disinfectants (Virkon, Trigene, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers easily to hand (e.g. spray gun).
2. All culture will be perfumed within a Class 2 hood, in a designated Class 2 molecular biology lab. All cells exposed to virus will be handled in the Class 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench.
3. Where small volumes of cells potentially containing viable viral particles require centrifugation, tubes will be
sealed with parafilm prior to centrifugation.
4. Virus particles will be stored in the -80°C freezer, in cryovials, held inside 50 ml falcon centrifuge tubes or equivalent, in clearly marked packaging.
5. Hoods will be carefully cleaned with 10% solution of Trigene after each session in which culture which virus particles takes place, and after each session when cells that have been transfected by virus on a previous occasion are handled.
6. Only designated media will be used in cell culture.
7. Virus particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips.
8. No glassware or hypodermic needles will be used at any time with any culture producing or containing virus particles, or any supernatant generated from any cell that has ever been exposed to virus particles.
9. All supernatants, plasticware, and cells that have come into contact with virus particles or viral infected cells will be treated with Trigene, Virkon, or bleach at appropriate concentrations and for 20-30 minutes prior to discard.
10. Standards of GLP will be rigorously enforced (lab coats, gloves, etc).
11. All personnel using or producing virus will be appropriately registered through the University Health and Safety procedures, listed on the GMAG approval, and taught appropriate safe handling by the principal investigator.
12. Other lab personnel will be made aware of the use of lentiviral systems in the laboratory.

Contamination management
1. Where spills occur in contained environments such as Class 2 hoods, neat Trigene, bleach, or Virkon will be added and left for >10 minutes to neutralise viral particles prior to wiping, cleaning and disposal.
2. If a small contained spill occurs outside of Class 2 hoods, management will be as above. Any spill outside of the Class 2 hood will be reported to a principal investigator, and assessment made to determine whether avoidable features are present to prevent future accidents.
3. Where aerosolised contamination is suspected to have occurred outside of Class 2 hoods, the lab will be cleared immediately to prevent aerosol inhalation. The air conditioning system will replace the air within a room within 10 min and will serve to desiccate and dilute the hazard. A single designated worker will return to the lab after 20 min and apply appropriate disinfectant to liquid traces.

This project proposal was reviewed and approved by the University of Sheffield Biosafety Committee on the 24th February 2016, with only minor administrative recommendations made to the Proposer.

Project Containment
Project Ref: 168/17.1

Date Ackn'd: 22/02/2017

Investigation of the mammalian host cell biology manipulated by bacterial pathogens Salmonella enterica, enteropathogenic Escherichia coli (EPEC), enterohaemorrhagic E.coli (EHEC) and Shigella species during infection.

Recipient or parental organism:
- Laboratory derivatives of:
  - Wild-type Salmonella Typhimurium (e.g. SL 1344)
  - Auxotrophic for histidine, reducing fitness, and has been used safely in research labs since 1977. Possibly able to cause localised gastroenteritis in humans that resolves itself with 3-7 days or can be managed with antibiotics, though laboratory passage means SL 1344 likely more attenuated.

Project Additional Information:

- Investigate the mammalian host cell biology manipulated by hazard group 2 (HG2) bacterial pathogens Salmonella enterica, enteropathogenic Escherichia coli (EPEC), enterohaemorrhagic E.coli (EHEC) and Shigella species during infection. Recombinant vaccinia virus will also be used to compare the mechanisms by which pathogen exploit host cell biology to establish infections. In particular, the study addresses how bacterial virulence effectors injected and secreted toxins hijack intracellular host cell functions.
- Attenuated Salmonella Typhi (e.g. BR0948/CVO 908-htrA).
The vaccine candidate strain S.Typhi BR0948/CV0908-htrA has been recognised as disabled by the HSE since 1993
and the organism is derogated from CL3 to CL2. The strain carries non-reverting attenuating mutations making it
stably attenuated and fails to colonise the human host and has an excellent safety record with no evidence of human
infection both in the UK and abroad. S.Typhi secretes a cytolethal distending toxin (COT). There is no direct evidence
that the COT of Salmonella Typhi enhances virulence. Rather than inducing overt cytotoxicity and lethality like other
toxins, COT 'cyclomodulins' drive more subtle alterations in cultured mammalian cells by arresting cell cycle
progression. Given the safety record of the BRD948 strain the risk is extremely low.
- Escherichia coli 0157:H7 (henceforth EHEC) EDL933 or TUV93-0 which are both toxin negative for the stx genes
(stx 1 and/or stx 2) encoding Shiga-like STX or Verocytotoxin VT.
The toxin-deleted strains are nevertheless potentially capable of causing gastrointestinal illness, though rarely life
threatening to those in normal health, self limiting, lasting up to 7 days, or readily treatable with antibiotics.
- enteropathogenic Escherichia coli E2348/69 0127:H6 (Levine et al 1978), henceforth EPEC.
EPEC may cause a self-limiting gastrointestinal illness in humans if ingested. At suitable doses (above 1 x 10^6), can
cause self-limiting diarrhoea in a susceptible host, e.g. children, immunocompromised, that is treatable with antibiotics.
- wild-type Shigella flexneri (e.g. serotype 5a strain M90T)
- Shigella species, e.g. Shigella Flexneri M90T, Shigella Sonnei 53G, cause a localised gastroenteritis (Shigellosis)
that resolves itself after several days and is treatable with antibiotics. The pathogens have a low infective dose (10-
100 colony forming units) though the strain M90T is likely attenuated due to lab passage. The risk is very low as it is
managed through the containment and protocols.
- Vaccinia virus (VACV) strain Western Reserve
Commercially available laboratory strain that has been passed in mice and used to already generate vEGPA5L
where the endogenous Vaccinia A5L gene has been replaced with the A5L gene fused to GFP for use as a visual
reporter. VACV can infect humans and was used in hundreds of millions of people as the live vaccine that eradicated
smallpox. A hazard of working with VACV is infection if the skin is pierced, e.g. via a needle or abrasion. The risk of
accidental infection is low and the resulting infection is typically mild, but may cause a rash or fever that is self-limiting
and healed within 2-3 weeks. Infections can be more serious during immunosuppression, pregnancy, or with
eczema/psoriasis sufferers who are precluded from working with VACV.
All the bacterial pathogens in the study use a Type 3 Secretion Sytem (T3SS) to inject virulence effectors into the host
cell (-30-60) that work collectively to establish infections. Thus, no single effector can confer a disease phenotype
when expressed recombinantly from a plasmid, and effectors are considered non-toxic and non-hazardous.
The risks for all pathogens in this form are considered very low and are managed through the containment and protocols.

Host/vector system

<table>

<tr>
<th>Source of genetic material</th>
<th>pACYC184 (NEB), and pUC series (e.g. NEB), pBR322 series (e.g. NEB) vectors, and pKD3, pKD4, pKD46, pCP20 plasmid vectors.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Origin &amp; function</td>
<td>For bacteria, well characterised vector systems with a history of safe use will be used, for example, commercially available non-mobilisable/mobilisation defective plasmids, pUC series, pACYC184, pBR322 series vectors, and pKD3, pKD4, pKD46, pCP20 plasmid vectors. For Vaccinia, the vector pSJH7 or equivalent derivatives of the commercially available vector pUC13 (Hughes et al 1991).</td>
</tr>
</tbody>
</table>

Intended function

High-copy pUC vectors will be used to express GFP or RFP that will act as a reporter to allow direct visualisation of the pathogen during cell infection.

Low-copy pBR322/pACYC184 vectors encoding virulence effectors (e.g. injected via T3SSs) or toxin components (i.e. CDT encoded by S.Typhi) will be used to complement parental null mutant strains and investigate virulence factors inside the target host cell (e.g. manipulation of cell membrane trafficking).

The lambda red gene disruption method will be used to generate specific deletions in virulence genes to generate null mutants. Briefly, antibiotic resistant cassettes will be amplified from pKD3 or pKD4 (maintained in E. coli XL 1 Blue) with primers to allow homologous recombination into the chromosome of the parental target pathogen strain (expressing the lambda Red recombinase from pKD46) and subsequent gene disruption. Antibiotic resistance cassettes will be removed using the FLP-recombinase encoded by pCP20. Mutations will be complemented using expression of the gene on pBR322/pACYC184.

For Vaccinia, the vector pSJH7 or equivalent derivatives of the commercially available vector pUC13 (Hughes et al 1991) that contain the vaccinia late 4b promoter for dominant transient selection of recombinant VACV. pSJH7 is cotransfected into mammalian cell lines along with a second vector containing an attenuated version of the wild type VACV genome (e.g. LIA5L VACV), such that viral replication can only occur following recombination of the two plasmids.

Evaluation of foreseeable effects

In the first bacterial modification high-copy pUC vectors will be used to express GFP or RFP that will act as a visual reporter for bacterial pathogens during cell infection, The modifications are expected to have no effect on the virulence or fitness of any of the recipient pathogens.

The expression of T3SS virulence effectors or the CDT (in the case of S.Typhi BRD948) to complement null mutations in the parental strains involves somewhat higher level expression (~2.5-fold more, Cain et al 2004) that in theory can increase virulence potential, although actual risk is extremely small given that disease relies upon optimal expression levels, and the containment procedures, The likelihood of harm to human health in the event of exposure would be no greater than that with the parental organism and can be considered extremely low, The chance of transfer of the vectors to other organisms in the environment can be considered low given the containment, the use of nonmobilisable vectors, and the use of certain nutritional auxotrophs such as Salmonella strains SL 1344 and BRD948, It is difficult to envisage how any of the genetic manipulations proposed could mediate a harmful phenotype or competitive advantage to the host strains in the environment. The environmental hazards associated with the project are therefore considered no greater than those associated with handling the parental strains, The project involves small scale work for research purposes and all contaminated material will be completely inactivated by autoclaving or proprietary disinfectants prior to disposal, In the highly unlikely event of release into the environment, no risks are envisaged,

The third bacterial modification will involve mutagenesis work via the method of Datsenko and Warner (PNAS 97, 6640-6645, 2000), which will generate attenuated mutant strains that are expected to be less virulent. The excision of antibiotic resistance cassettes will leave an unmarked lesion in a strain of wild type antibiotic susceptibility, Regarding Vaccinia virus, the study plans to use the recombinant vEGFPAS5L strain carrying an A51-GFP gene in place of an endogenous A5L copy for use as a visual reporter. A5L is a core structural virion protein required for VACV morphogenesis and is non-toxic and non-hazardous, The results of the genetic modification reduce the pathogenicity of the parental organism, i.e. evidence indicates vEGFPAS5L is less pathogenic than wild-type VACV (Doceul et al 2010). No advantage in terms of fitness or virulence to the recombinant VACV is expected, or if the A5L-GFP sequence was transferred to a related organism. The risk of accidental infection with vEGFPAS5L is low given the containment and the resulting infection would be expected to typically mild, like the parental host, but may cause a rash or fever that is self-limiting and healed within 2-3 weeks. VACV can infect animals including mice, rabbits and
cattle, and can be transmitted to broken skin, abrasions. Human-to-animal transmission can occur. The risk is extremely low given no animals are to be used in the study, and the containment procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The vaccine candidate strain Salmonella Typhl BRD948/CVD908-htrA has been recognised as disabled by the Health and Safety Executive since 1993 and the organism is derogated from HG3 to HG2. The S.Typhi BRD948 strain carries non-reverting attenuating mutations making it stably attenuated (Tacket et al 1997). The strain fails to colonise the human host and has an excellent safety record with no evidence of human infection both in the UK and abroad and has been proven to be highly attenuated in many scores of human volunteers in phase 2 clinical trials infected with up to 5x1 0 exp 9 colony forming units (Tacket et al1997, Lowe et al 1999, Tacket et al 2000, Tacket & Levine 2007). Genetically attenuated variants of EHEC strains where the Shiga-like (Vero) toxin genes have been deleted will be used in some experiments, but Wild-type EHEC or other verotoxigenic strains will not be used. Non-toxigenic E. coli 0157 lacking the Shiga toxin genes and are designated HG2 pathogens.

For laboratory operations the use of standard Containment Level 2 facilities and good microbiological practice will be sufficient to limit contact with humans and the environment.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Containment protocols that minimise aerosols and spillages during bacteria culture via use of airtight sealed tubes, i.e. falcon tubes, in as small a volume as possible, typically 1 ml.
  - Autoclaving of waste material at 121°C for 60 minutes provides 100% inactivation. The autoclave used for waste is located in the building; all waste to be transported is double bagged in autoclave bags and then sealed in a plastic container. Annual validation of the autoclave by independent means will be performed.
  - For spillages, ethanol is an effective surface disinfectant in an aqueous solution of 70% (v/v) , and ready-to-use proprietary disinfectant, such as Distel spray (formely known as Trigene) which is proven to kill bacteria. Virkon powder can be used directly for larger spillages.
  - Liquid waste will be aspirated into liquid vessels containing proprietary Distel or Virkon proven to disable bacteria/viruses, incubated for at least 30 minutes before disposal of the deactivated waste down the sink.

This project was approved by the University of Sheffield Biosafety Committee on 15th July 2016, with minor amendments. The committee have also advised that additional health surveillance be provided, if appropriate, for any workers with pre-existing conditions that may increase their risk from infection with vaccinia virus.
We need to increase expression of IL-1B and/or IL-1R1 in cancer cells or remove these molecules from cancer cells using lentiviral transfection methods in order to answer the following research questions:

1. How does IL-1B/IL-1R1 from breast cancer cells affect the spontaneous spread of cancer cells to bone.
2. Establish the importance of direct interactions between IL-1B/IL-1R1 and cancer cells in the spread of early stage disease.
3. Identify how IL-1B produced by cancer cells and IL-1B/IL-1R1 produced by bone each alter the environment in the skeleton that cancer cells live and grow in.
This project uses replication defective lentiviral vectors for the transfer of cDNA sequences of genes of interest into mammalian cells (mouse and human). Lentiviruses are pathogenic to humans, targeting both dividing and non-dividing cells, and can deliver significant amounts of genetic information to the DNA of the host cell. The native envelope of lentiviruses determines its host range. In order to broaden the range of cells that can be infected by laboratory engineered virus the native envelope is substituted for an amphotropic one. These will not be used routinely, but will be used to infect cells that are difficult to infect by other techniques where high levels of transfection efficacy are required.

Recipient/Host(s): Will be standard (disabled) competent E.coli K12, TOPII or B strains for DNA production. We will use standard viral packaging cell lines such as HEK293T for lentivirus production. The packaging cell lines produce replication-incompetent virus and, for increased safety, express the genes needed for virus assembly at two separate sites in the host genome.

Host/vector system

Vector(s): We will use second and third generation lentiviral systems such as the ViraPower system or the pLKO system. These lentiviral systems are based on HIV-1 and will be used to produce infectious viral parcels by co-transfection of 3-plasmids separately expressing the lentiviral vectors, the viral structural components (packaging helper plasmids: pCMV-gag/pol, pSPAX) and envelope protein (pMD2.G, pCMV-VSV-G and others). All viral constructs are replication incompetent, self-inactivating and do not contain Woodchuck Posttranscriptional Regulatory Element).

Normal/expected biological actions of the inserted DNA or transcribed/translated gene product: Evidence from multiple cancer types suggest that knocking out or overexpressing IL1-B and/or IL-1R1 will alter the behaviour of the host cells. Specifically overexpression of IL-1B in non-metastatic prostate cancer cells has been shown to promote bone metastasis whereas knockdown of IL-1B in metastatic cells impaired bone progression (Liu, et al. Cancer Res. 73(11):3297-305). Experimental models of Lewis lung carcinoma and pulmonary adenocarcinoma have shown that local production of IL-1B stimulates tumour growth and metastasis, either through direct proliferative effects or by promoting inflammatory and angiogenic pathways (Saiko, et al. J Immunol. 169(1):469-75; Gemma, et al. Eur J Cancer. 37(12):1554-61). Furthermore, work from our team and others have shown that, blocking IL1-R1 with a receptor antagonist decreased tumour growth, angiogenesis and metastasis from melanoma and breast cancer (Holen, et al. Oncotarget 2016). We are intending to use cell lines transfected to over-express or not express IL-1B/IL-1R1 to establish the function of these molecules in the processes of breast cancer development and bone metastasis.

Technique used to insert vector into host: The vectors will be transfected into mammalian packaging cells using standard, non-viral, transfection techniques including calcium phosphate, electroporation and liposome based methods. The resulting virus containing supernatant will be used to infect the recipient cell lines without further steps involving concentration of the virus containing supernatant.

Origin & function

Once lentiviral vectors have been used to transfer cDNA sequences of genes of interest to mouse and/or human cancer cells these stable cell lines will be used in the laboratory to assess the effects of IL-1B and/or IL-1R1 expression on factors associated with tumourigenicity and metastasis. For all experiments the genetic material will be inserted into immortalised cell lines that have been made from mouse models of human cancer or patient derived xenografts. Cell lines containing transduced to express genes of interest or to not express these genes will be injected into mice to analyse effects of gene expression on metastasis. This work will be carried out with Home Office approval under project licence 70/8964

Evaluation of foreseeable effects

Genetically modified organisms produced are not predicted to pose any risk to human health. The E. Coli used are a non-pathogenic strain and cell lines containing gene inserts pose minimal risk of harm as the DNA is non-transferable once this has become integrated. Although insert of IL-1B is predicted to promote metastasis in cancer and also induces inflammation, these properties will be retained within the cancer cells that have been transduced and these cells pose no additional risk to other metastatic cancer cell lines.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We have no intention of making GM animals or plants in this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Use of viral infected cell lines will be at containment level 1 following demonstration that no active virus is present as these cells pose no additional threat above that of parental cells (see hazards arising from alterations in existing pathogenic traits; risk assessment). Presence of active virus will be assessed following exposure of parental cells to conditioned media taken from virally transfected cells. Potential infection of parental cells from active virus in conditioned media will be determined by monitoring reporter gene expression.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All culture will be performed within a Class 2 hood. Antiviral disinfectants (Virkon, virusolve, bleach) will always be available prior to starting work involving handling of viral particles, in identifiable containers easily to hand. Replication incompetent viruses will be inactivated prior to disposal by placing in antiviral agents (described above) for a minimum of >30 minutes before washing down the drains with copious amounts of water.

Hoods will be carefully cleaned with Virkon following handing of bacteria or cells that have been transfected with virus. Virus particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips to prevent contamination of equipment.

All supernatants, plastics and cells that have come into contact with bacteria virus particles or viral transfected cells will be treated with Virkon, virusolve or bleach at appropriate concentrations (as recommended by the manufacturer) for >30 minutes prior to being discarded for incineration.

Where appropriate, autoclaving of potentially contaminated equipment will be performed prior to sending off site for incineration.

Successful autoclaving to ensure deactivation of GMs will be assessed using autoclave indicator tape.

Experimental evolution of bacterial pathogens and their mobile genetic elements

In vitro experimental evolution is an experimental tool for studying the evolutionary dynamics of microbes, such as bacteria. Replicate experimental population of microbes are propagated under controlled laboratory conditions for several 100s or 1000s of generations and the evolution of their phenotypes observed over time. We are interested in how bacterial populations adapt to their abiotic and biotic environment. Genome sequencing is used to determine the mutations targeted by natural selection that underpin the observed evolutionary adaptation. These mutations are then introduced into the ancestral genotype to test their phenotypic effects. Labelled strains of the ancestral genotype allow for these to be distinguished in mixed cultures, allowing for changes in Darwinian fitness to be measured by direct competition. We will use these approaches to understand how opportunistic bacterial pathogens, Escherichia coli and Pseudomonas aeruginosa, adapt to their biotic and abiotic environment. Specifically, we will test how bacterial pathogens adapt following acquisition of mobile genetic elements (e.g. plasmids), and how bacterial pathogens adapt to different microenvironments known to be present within hosts or natural environments.

Recipient or parental organism

Pseudomonas aeruginosa
Escherichia coli

Host/vector system

During this project we will generate the following GMMs:
1) Variants of bacterial strains carrying selectable markers. This allows us to:
   a) select for transconjugants (i.e. bacteria which are carrying the plasmid).
   b) identify differently marked strains when in co-culture, for example, during competition experiments.
2) Variants of bacterial strains in which we have deleted genes that were the target of natural selection during the experimental evolution.
3) Variants of plasmids labelled with derivatives of green fluorescent protein (GFP), enabling their identification using fluorescence.
4) Variants of bacterial strains carrying vectors allowing complementation, e.g. by reintroducing different alleles of a gene into a strain in which that gene has been deleted.
5) Generating these strains will also require us to use standard laboratory E. coli cloning strains such as DH5-alpha and constructs such as pUC18.

Inserted genes:
- aacC1 (encodes gentamicin acetyltransferase-3-1), confers resistance to the antibiotic gentamicin
- strpAB (encodes aminoglycoside 3-phosphotransferase), confers resistance to the antibiotic streptomycin
- aphA1 (encodes aminoglycoside 3-phosphotransferase II), confers resistance to the antibiotic kanamycin
- aadA (encodes aminoglycoside 3-adenylyltransferase), confers resistance to the antibiotic spectinomycin
- gfp and derivatives (encodes green fluorescent protein)
- telAB (and similar), confers tellurite resistance
- lacZ (encodes beta-galactosidase), results in production of blue pigment when grown on X-gal

These inserts encode enzymes that modify antibiotics rendering them non-functional (aacC1, strpAB, aphA1, aadA), that detoxify tellurite (telAB), or that produce fluorescent or chromogenic markers (gfp, lacZ). None of them are likely to pose any direct risk to humans, animals, or plants. The insertion cassettes are designed to encode the gfp variants under the control of the lactose-inducible PA1/04/03 promoter followed by the resistance gene under its own native level promoter. Total expression of inserted proteins is unknown, however as the inserts are generally of low copy number, total amount of protein produced should be similarly low and unlikely to pose any additional risk.

Evaluation of foreseeable effects

P. aeruginosa and E. coli are designated as Class II organisms by ATCC and as Hazard Group 2 by the Advisory Committee on Dangerous Pathogens (ACDP).

E. coli is a commensal bacterium and part of a healthy mammalian gut flora but may also cause opportunistic infections. The project uses environmental and clinical isolates of E. coli. Healthy individuals are not typically at a high risk of infection. Infection may occur where the user is immuno-compromised (e.g. undergoing treatment for cancer or HIV) or via infection of existing wounds or burns. Certain strains of E. coli can cause diarrhoea, while others cause urinary tract infections, respiratory illness and pneumonia, and other illnesses (CDC). Infections of healthy people are readily treatable with antibiotics and most patients recover within 10 days.

P. aeruginosa is an environmental bacterium inhabiting freshwater and soil environments, but also causes opportunistic infections. Healthy individuals are not typically at risk of infection. Infection may occur where the user is immuno-compromised (e.g. undergoing treatment for cancer or HIV, cystic fibrosis patients) or has exposed burns. Infections of healthy people are readily treatable with antibiotics and most patients recover within 10 days.

The addition of resistance markers may increase the risk that infections are harder to treat with antibiotics. However, such risks will be mitigated by selecting resistance gene markers against antibacterials that are not used clinically (e.g. streptomycin, gentamycin).

The inserted genes will be introduced using a mini-Tn7 transposon system or homologous recombination system, both of which introduce the marker into a known location in the genome (confirmed using PCR). Labelling the bacterial chromosome poses little risk of horizontal gene transfer as the delivery vectors are unable to replicate and therefore are rapidly lost. The E. coli cloning strains are highly compromised laboratory strains and are uncompetitive outside of the lab environment.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection using Virkon or Distel: company testing shows effectively 100% killing of related strains of P. aeruginosa and E. coli.

Autoclaving using standard cycles effects 100% killing. Material contaminated with GMOs is autoclaved at 134 degrees C for 20 minutes. This cycle kills all plant materials and (soil) microorganisms, and has been validated by BMM Western (the autoclave manufacturer). In all autoclave runs, the temperature is monitored and recorded by a probe placed in the centre of one of the bags being autoclaved. The autoclave is checked and tested by BMM Western every 3 months. Autoclave conditions are automatically recorded and checked and archived for 3 years. The autoclave is regularly serviced and maintained.

02/03/2022
Mycobacteria are a group of pathogens, of which several are important causes of human disease (including M. tuberculosis: the causative agent of TB, M. abscessus: causing deadly infections in cystic fibrosis patients and M. Leprae: the causative agent of leprosy). Immune cells play an important part in both the host’s ability to resist disease, and in the ability of the mycobacteria to avoid the host immune system. Model systems for the study of this disease include the zebrafish larvae, and several important advances in understanding mycobacterial disease have now come from this model (Adams 2011, Clay 2007, Davis 2009, Tobin 2010, Volkman 2010). Mycobacterium marinum (Mm) is a non-tuberculous mycobacterium, and as a human pathogen is an opportunistic pathogen, with no evidence of person to person spread, which occurs commonly in the environment. It is, however, a natural pathogen of fish, causing a wasting illness with disseminated mycobacteria and characterised by the presence of granulomas (Tobin and Ramakrishnan, 2008).

The aim of this research project is to understand how the interaction of mycobacteria with the immune system results in disease, with the aim of developing novel treatment avenues, importantly ones that might circumvent the growing problem of multi-drug resistant infections. To achieve this aim, transgenic fluorescent Mycobacterium marinum will be used to investigate via fluorescent microscopy their interactions with immune cells. These strains will have fluorescent proteins, such as GFP, dsRed and their derivatives inserted using selectable plasmids (with antibiotic resistance genes, such as hygromycin resistance and kanamycin resistance). We will also use genetically modified Mycobacterium marinum with gene knockout. These will be attenuated strains, eg the esx1 mutation which has no type 7 secretion system and will not be more virulent than the wildtype. These mycobacterial strains will be analysed in vitro, and introduced into cell and animal models of infection. In the first instance these will be zebrafish infection models. To demonstrate conservation of cellular mechanisms in mammals, findings from zebrafish will be followed up in vitro, using human/mouse immune cells (primary cells and immortalised cell lines) by infection with Mm in cell culture. Mycobacterium results may be compared to other zebrafish infection models (Hazard Group I and II pathogens only) currently in-use in Sheffield which are covered by existing risk assessments.

Zebrafish infection will be established by injection at early stages (Carvalho et al, 2011), into wildtype or transgenic zebrafish embryos labelling neutrophil, macrophage and other immune markers. At 0-5 days postfertilisation, the larvae will be mounted and imaged on a confocal microscope to acquire qualitative and quantitative information on immune interaction during Mm infection.

Recipient or parental organism

Mycobacterium marinum is an ACDP category II bacterial pathogen. Mycobacterium marinum is a non-tuberculous mycobacterium, and in humans is an opportunistic pathogen, with no evidence of person to person spread, which occurs commonly in the environment. It is, however, a natural pathogen of fish, causing a wasting illness with disseminated mycobacteria and characterised by the presence of granulomas (Tobin and Ramakrishnan, 2008). Mycobacterium marinum M-Strain (aka M-USA), a clinical isolate. Including variants expressing crimson, mCherry and GFP fluorescent reporters. As noted below Mycobacterium marinum does have the potential to cause disease in humans. The GMM would be less likely to cause disease given the burden of carrying the insert without any gain to pathogenicity.

Host/vector system

The vectors carried by the bacteria have no associated hazards. The inserts drive the expression of fluorescent proteins and anti-bacterial resistance. The anti-bacterial resistance inserts are against hygromycin or kanamycin, commonly used laboratory antibiotics which would not be used as a treatment and so no hazard arises from this.

Origin & function

We do not plan to alter any existing pathogenic of Mycobacterium marinum traits ourselves. Attenuated mutant strains would not be made in Sheffield but would be obtained from collaborators in the UK or The Netherlands (or from elsewhere in the EU).

Evaluation of foreseeable effects

Mm has the potential to infect humans, to cause normally superficial infections due to its low tolerance of the high temperatures of mammals. Mm have been described to cause tenosynovitis in the hand and wrist, associated with penetrating injuries in the presence of contaminated water, occasionally progressing to osteomyelitis. More commonly, they cause skin and soft tissue infection following trauma in the presence of contaminated water, most commonly from fish fins, bites or unrelated trauma accompanied by exposure to contaminated water. In temperate climates, infection is commonly related to fishing, fish tank cleaning or in aquarium workers. Due to the lower temperature to which Mm is adapted, infection is usually confined to the skin and extremities. Infection begins as one or more nodules at the site of trauma. Spread to deeper tissues can occur. Treatment is with multiple antibiotics, as with other nontuberculous mycobacteria (Piersimoni, 2008). Infections can be more severe and disseminated in the immunosuppressed, including anti-TNF therapies (Ramos 2010).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For laboratory manipulations, a standard containment level 2 facility and the use of good microbiological practice will
be employed. A Class I or Class II MSC should be used for all manipulations that may generate an aerosol (pipetting, mixing, sonication etc) and sealed rotors or buckets must be used during centrifugation. All contaminated waste will be autoclaved via validated autoclaves or treated with disinfectant (Virusolve Plus, 1:20) before removal from the building. Spillages can be safely contained within the lab and treated with disinfectant (Virusolve Plus, 1:10). 1 part Virusolve Plus per 20 parts water (i.e. 5%) is the recommended concentration. This has been validated in our laboratory for Mycobacterium marinum by mixing 1 ml of 5% Virusolve Plus with an equal volume of an appropriate culture, leaving for up to one hour, then plating serial dilutions of the mixture on suitable plates. Mycobactericidal effect was confirmed by an EN 14348 compatible test, with 4 log10 reduction in growth after 5 minutes.

This project was reviewed and approved by the University of Sheffield Biosafety Committee on 05 June 2019, with only minor recommendations made.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Pseudotyped lentiviruses are required for the safe assay and characterisation of anti-SARS-CoV2 neutralising antibodies in patient serum, without recourse to culturing SARS-CoV2 itself. Mutations of the Spike are included in this application as they will allow us to study the effect of mutation on the neutralising antigenicity of Spike mutants, as they are discovered. Pseudotyping with VSV-G will be required as a positive control for the transduced retroviral construct and as a negative control for neutralisation.

We will use a second-generation HIV-derived system in which some HIV viral components are included on two plasmids, a packaging plasmid and a transfer vector plasmid. A third plasmid will be an expression vector for a heterologous envelope protein, namely either Spike or VSV-G. The significant parental organism is therefore a distant derivative of HIV. Defective virus particles will contain only protein products of the Gag-Pol and Tat genes of HIV and one active LTR RNA sequence. The woodchuck hepatitis virus post-transcriptional response element (WPRE) will be included in the transfer plasmid, to stabilise the transfer plasmid mRNA in the packaging cell line. Expression of the packaging plasmid is driven by a cytomegalovirus (CMV) promoter-enhancer and encodes Gag-Pol, Rev and Tat genes from HIV. The Env gene of HIV, which determines HIV's tropism, is entirely absent from the system. Instead, transduction of lentivirus-like RNA into recipient cells is mediated by Spike or the VSV-G (as a positive control) that is exposed on the external surface of the defective virus particles. The pseudovirus will transduce an RNA segment, derived from the transfer plasmid, for reverse transcription and genomic insertion into the recipient cells. The integrated sequence will include a reporter gene such as a Photinus luciferase or a fluorescent protein gene, under control of a Friend murine leukaemia virus promoter. RNA packaging into defective virus in the helper cell line requires the presence of the packaging signal within the 5' HIV LTR. For a second round of viral replication to occur, the 3' LTR would need to be functional as well because it would be copied into the position of the 5' LTR during replication. The 3' LTR is truncated in the vectors that we will use, which removes the packaging signal sequence and the enhancer sequence. Consequently the incorporated cDNA is self-inactivating for virus replication after integration into the target cell. Virus-like particles will be generated after transient co-transfection of the three plasmids into the packaging cell line, 293T cells. Co-expression of VSV-G or Spike from a co-transfected plasmid will lead to pseudotyping of the defective virus particles. Expression of these exogenous envelope proteins will be driven by CMV promoters. The transfer plasmid and hence the transduced template RNA will encode one or a combination of selectable markers, fluorescent proteins or enzymatic reporter genes, particularly a luciferase. No lentiviral protein-encoding gene will be included in the transfer vector. To yield useful virus-like titres in assays for neutralisation of the defective viral particles by patients' sera, particle production will need to be as high as possible since pseudotyping with coronavirus S-glycoproteins has resulted in less efficient transduction than for particles pseudotyped with VSV-G. For this reason, we intend to use a three plasmid second generation system including pCMVΔR8.91 (Zufferey et al., 1997. Nature Biotech. 15, 871-875) in preference to the available four-plasmid lentiviral systems, which typically produce an order of magnitude fewer transducing particles. An additional potentially hazardous feature ids the WPRE in the transfer plasmid; again, it is incorporated to increase the yield of defective virus particles.
BACTERIA
Plasmids will not contain functional promoters for expression of the mammalian genes in bacteria. Plasmids will be created and manipulated as necessary and will be expanded in the auxotrophic laboratory K12 strain of Escherichia coli, DH5-alpha, which requires only level 1 containment. The bacteria do not survive in the gut or the environment and therefore can represent no significant environmental risk.

PSEUDOTYPED LENTIVIRUS
Level 2 containment will be required for the generation of virus-like particles in immortalised 293T human embryonic kidney (HEK)-derived cells that are stably transformed with large T antigen of Simian Virus 40 (SV40). The vector plasmids contain the SV40 origin of replication and are therefore transiently amplified as episomes after transfection in the presence of the endogenous large T-antigen of 293T cells.

The packaging expression plasmid will be pCMVΔ8.91 or derivatives of it (Zufferey et al.1997, Nature Biotechnology 15, 871-875). Here viral long terminal repeats and the viral genes Env, Vif, Vpr, Vpu and Nef, have been eliminated by deletion. Tat and Rev remain in this plasmid. The packaging sequence (psi) is also deleted from the 5'-end of Gag, so that the packaging RNA itself cannot be packaged. The HIV-LTR promoter has been replaced by the strong, constitutive cytomegalovirus (CMV) promoter-enhancer.

Pseudotyping vectors provide a coat for the defective virus-like particles. Experimentally, we will test whether patient serum can neutralise the entry of virus-like particles into cells as a result of reaction with the pseudotype protein. The second vector is therefore a CMV promoter-enhancer driven expression vector for a humanised coding sequence of the trimeric Spike. A similar vector will be used in control transduction experiments to transduce the VSV-G protein. Neither of these open reading frames can be incorporated into the transduced reporter vector because vectors and ORFs lack packaging sequences.

The transfer vector plasmid will contain the transduced packaged sequence, which will be limited to the following--
An ORF encoding an enzyme based reporter gene such as luciferase, a fluorescent marker protein or a cytotoxic drug-resistance marker. The defective virus particles, produced from the transfected packaging cell line, will transduce the reporter gene's coding sequence into target cells. The transfer sequence is flanked by LTRs and contains the psi and is therefore packaged. HIV Pol protein (reverse transcriptase/RNaseH/integrase) is expressed from the packaging plasmid and associates with viral RNA to allow synthesis of the defective virion cDNA and its incorporation into the target genome.

The transduced construct also contains Woodchuck Hepatitis Virus post-transcriptional regulatory sequence (WPRE) which stabilises the transfer RNA in the packaging cell line and increases particle yield. The WPRE in these vectors encodes a truncation of the small protein (X) which has been identified as oncogenic in mouse liver. The product virus-like particles will be replication incompetent and therefore of no environmental significance, should the virus-like particles escape from containment. The particles are also destroyed by dessication in the environment.

Host/vector system

The recombinant plasmids are either pre-existing constructs or will be derived from the same. All plasmids contain standard antibiotic resistance markers for selection, to allow for plasmid cultivation in E. coli.
Cytomegalovirus promoters are used to drive expression of HIV Gag-Pol, Rev and Tat and (separately) the VSV-G or Spike.
HIV LTR drives expression of the reporter gene and the woodchuck hepatitis virus post-transcriptional response element.
The left HIV LTR contains an HIV-Tat-activated enhancer and the packaging signal (psi) for the transfer plasmid RNA.
Gag is required to form the pseudoviral envelope; Pol is required for the production and integration of the transduced reporter gene. Rev and Tat are required for the expression, in the packaging line, of the LTR-driven RNA sequences that become packaged.
The WPRE element is required to stabilise the transfer plasmid RNA within the packaging cell line, increasing the yield of enveloped reporter gene.
The pseudo-typing Spike glycoprotein is central to the purpose of the process, which is a study of the activity of neutralising, anti-Spike antibodies in convalescent patients' serum. The alternative pseudo-typing envelope gene VSV-G is required as a positive control to assess the production of infectious virus-like particles from the 293T packaging line and as a negative control for the effect of antisera.
Also fundamental to the process, a reporter gene (such as luciferase, a fluorescent protein or a mammalian selectable marker) is required for the quantification of single-round infected cells, allowing the assessment of virus neutralisation.

Evaluation of foreseeable effects

[1] High titre lentiviral transduction of the WPRE has been found to cause tumours in mice. Accidental transduction of the WPRE element into the cells of workers must therefore be considered a potential hazard.
The possibility exists that a series of recombinational events between the transfer vector, the packaging plasmid and an endogenous lentivirus could re-create an infectious lentivirus. However, an endogenous lentivirus would need to provide the Env gene, which determines the tropism of HIV. Gag, Pol, Rev and Tat from the packaging plasmid would need to be incorporated between the LTRs in the transfer plasmid. The defective 3'-LTR would need to be replaced with a functional copy, and Vif, Vpu, Vpr and Nef would need to be introduced from an endogenous lentivirus.

All retroviral vectors present the very small risk, per cell infected of oncogenic gene activation, as a result of the possibility of insertional mutagenesis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

HIV may only be cultured under level 3 containment but second generation systems, derived from it, such as we are proposing here do not produce detectable virus and are generally created and used under level 2 containment.

We expect to store batches of pseudotyped lentivirus in medium indefinitely at -80°C in screw capped crovials.

To mitigate the potential risk of re-creating replication-competent HIV-like virus, the first batches of defective viruses will be tested as follows and then new batches will be tested at six-monthly intervals and results will be recorded.

Samples of medium will be taken from recipient cells that have been washed approximately 48 hours after infection with the highest multiplicity of virus-like particles. The presence of Pol gene activity will be tested by a standard quantitative method. Positive detection will indicate that cells are producing potentially infectious particles.

If Pol activity is detected, cultures and affected defective virus stocks will be destroyed.

To mitigate the risk of accidental WPRE transduction or oncogenic insertional mutagenesis to the worker, all open handling of transfected helper-cell supernatants, including defective-virus stocks, will be confined entirely to a Class II MSC. All centrifugation of samples containing defective-virus particles will be in screw-capped sealed tubes in a sealed rotor. In the event of suspected breakage, the rotor will be opened after 30 min and after evacuating the laboratory and decontaminated with copious 70% industrial methylated spirit or ethanol. In such an emergency, the operator will wear disposable respirator masks while the rotor is opened and decontaminated.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cell supernatants that contain or might contain defective virus particles will be pooled and inactivated within a Class II MSC by a concentration of at least 5% Virusolve for at least 30 minutes, which has been shown to be effective and is routinely used to destroy HIV. Further validation should not be required. Inactivated liquid waste will be released to the drains.

Plastic waste will be treated with 5% Virusolve for at least 30 minutes before disposal to the contaminated waste stream, which is incinerated.

Bacterial waste from plasmid generation is categorised as Class 1 GM material. Liquid waste will be treated with 1% Virkon or 5% Virusolve. Solid waste, including bacterial plates will be autoclaved in a validated Departmental waste autoclave. Solid autoclave residue is disposed of to the contaminated waste stream and liquid waste to the drains.

This project proposal was reviewed and approved by the University of Sheffield Biosafety Committee on 11/08/2020 with no recommendations.
Constitutive secretion is a conserved process required for the delivery of newly synthesised proteins and lipids to plasma membrane as well as the exocytosis of extracellular factors such as cytokines, lipoproteins and antibodies. My lab is interested in identifying and characterising the pathways and cellular machinery involved in constitutive secretion. We aim to identify this machinery using a combination of proteomics and functional genomics. The majority of the proteins identified in these screens are likely to be housekeeping genes such as coat proteins, rabs, tethers and SNAREs so not biologically hazardous or oncogenic.

We will use lentivirus to:

a) Express cDNAs encoding wild type and mutant proteins required for constitutive secretion in mammalian cells.

b) Knock down proteins required for constitutive secretion in mammalian cells using shRNA.

c) Knock out proteins required for constitutive secretion in mammalian cells using CRISPR/CAS9.
Bacterial host
In all experiments the bacterial host strains used are non-pathogenic E.Coli K12 derivatives: DH5-a, JM109, XL-1blue, HB101 (genotypes listed in attached appendix). All are non-colonising and disabled and are therefore unlikely to survive either in the gut or in the environment. We consider assignment of ACDP hazard group1 appropriate.

Mammalian host
Experimental procedures using virus to introduce novel genetic elements will be performed on primary murine cells and well established cell lines such as HeLa, Caco2 and I.29. Virus particles will be manufactured in Human Kidney 293T cells transformed with SV40 large T antigen. As with all mammalian cells these cell lines are sensitive to culture conditions and have no survival potential outside of their normal tissue-culture environment.

Host/vector system

Lentiviral vector system
Replication deficient self-inactivating lentivirus particles will be produced by transfection of at least 3 different plasmids. We intend to use 2nd and 3rd generation lentiviral transfer vectors. The majority of viral proteins have been removed; in particular the virulence genes vpr, vif, vpu and nef are not present and are not required for transgene expression.

The vector system consists of: (1) self-inactivating transfer vector containing the expressed DNA sequence (2) Packaging and structural proteins (3) Envelope protein. The genes required to produce a packaged, transducible virus are distributed among at least 3 separate vectors. Thus it is unlikely that a replication-enabled lentivirus could be produced, as it is unlikely that the three required recombinations would occur. However we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.

Transfer vectors
a) vectors designed to give constitutive gene expression utilising a promoter such as CMV (pLenti-Puro, Addgene).

b) vectors designed to constitutively express shRNA utilising promoters such as U6 or H1 (pLKO-Puro, Addgene).

c) vectors designed to constitutively express CRISPR/Cas9 utilising a promoter such as CMV and guide RNA using a RNA pol III promoter (lentiCRISPR V2, Addgene).

Packaging plasmids
a) packaging plasmid 3rd generation (gag_pol_pMDLg/pRRE, Addgene).

b) packaging plasmid 3rd generation (pRSV-Rev, Addgene).

c) packaging plasmid 2nd generation (psPAX2, Addgene).

Envelope plasmid
a) Amphotropic plasmid, VSV-G (pMD2.G, Addgene).
b) Ecotropic plasmid, MLV, (pCAG-Eco, Addgene)

Safety features of 2nd and 3rd generation lentiviral vectors
1. Vectors contains a deletion in the 3'LTR that does not affect generation of the viral genome in the producer cell line, but results in 'self-inactivation' of the lentivirus after transduction of the target cell. This is a result of the natural duplication of 3'LTR into 5' position that occurs during integration. Once integrated into the target cell, the lentiviral genome cannot produce packageable viral genome.

2. Virulence HIV genes like vpr, vif, vpu and nef are not present and are not required for tranogene expression. The absence of the env gene removes the gp160 precursor that is responsible for the lethal macrophage/T cell/neuro-tropism of HIV.

3. Production of the viruses from the producer cell line requires the transfection of at least 3 plasmids (two packaging, one the DNA to be packaged) in a transient transfection. All three plasmids have been designed, through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus,
replication-competent viruses cannot be produced, nor can the packaging cell line produce retrovirus in any form during routine culture.

4. Internal promoters are used to eliminate the need of the HIV-promoter and reduce the risk of recombination events and trans-activation of surrounding genes.

5. We will not concentrate the viral particles.

6. Where possible ecotropic pseudotyped viral particles will be used which are unable to infect humans.

**Origin & function**

We plan to express cDNAs of wild type and mutant proteins required for constitutive secretion such as coat proteins, rabs, tethers and SNAREs. These proteins are housekeeping genes so are not likely to be oncogenic or biologically hazardous.

We plan to express shRNA or CRIPSR/Cas9 constructs targeting genes involved constitutive secretion such as coat proteins, rabs, tethers and SNAREs. Loss of these proteins is unlikely to confer any known selective advantage to the host. However, we cannot exclude the possibility of tumor-inducing effects, as their functions are not well defined. In order to reduce the possibility of accidental exposure of a worker to virus we propose to carry out the handling of live virus and transduction of cells in our designated Class 2 laboratory.

The 2nd and 3rd generation lentiviral vector backbones may contain expression enhancing viral elements such as the WPRE element which in its wild type form can express the so called x-protein which may have oncogenic properties. Thus we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.

The transfer vectors may also incorporate one or more genes encoding selection markers and fluorescence reporter proteins. Examples of these include 1) PuromycinR, BlasticidinR, AmpicillinR, 2) fluorescent proteins such as mCherry, GFP, Venus, Cerulean, mTomato. These proteins are considered non-hazardous owing to their non-mammalian origin. There is no evidence of any oncogenic potential for these proteins thus we consider to highly unlikely that exposure to these proteins would result in harmful effects. However we propose to carry out the handling of live virus and transduction of cells in the designated Class 2 laboratory.

**Evaluation of foreseeable effects**

Environmental assessment
These replication-incompetent viruses would be inactivated prior to disposal, and given their inability to replicate they have no significant additional environmental hazard.

Worst-case scenarios
The above protocols should minimise any risk of exposure to the personnel using or in the vicinity of work using this lentiviral transfection system. Virus particles, virally-transduced cells, and media and supernatants resulting from these systems will never be handled with glassware or hypodermic needles. Thus, the risks of accidental inoculation are remote. The worst scenario would be exposure to a main stock of virus containing one transgene, perhaps resulting from spillage. The major exposure routes would be cutaneous, mucocutaneous, and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier, and would be minimised by standards of Good Laboratory Practice. The viruses would infect mucocutaneous surfaces and respiratory epithelia and macrophages with which they came into contact. However, the particles are replication incompetent, and have many safety features preventing generation of replication competent viral particles. The genes of interest are not oncogenes. Thus although there might be limited tissue infection and damage, this would not result in sustained infection nor risks of tumour generation or malignant transformation. It might be possible that exposure would generate an immune response to the VSVG protein, but this would have a protective effect if so. The overall likelihood of serious or long-term harm resulting from experiments using these vectors seems extremely small.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
We propose to handle all material in Category 2 culture conditions.

1. Anti-viral disinfectants (Virkon, Trigene, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers easily to hand (e.g. spray gun).
2. All culture will be performed within a Class 2 hood, in a designated Class 2 molecular biology lab. All cells exposed to virus will be handled in the Class 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench.
3. Where small volumes of cells potentially containing viable viral particles require centrifugation, tubes will be sealed with parafilm prior to centrifugation.
4. Virus particles will be stored in the –80°C freezer, in cryovials, held inside 50 ml falcon centrifuge tubes or equivalent, in clearly marked packaging.
5. Hoods will be carefully cleaned with 10% solution of Trigene after each session in which culture with virus particles takes place, and after each session when cells that have been transfected by virus on a previous occasion are handled.
6. Only designated media will be used in cell culture.
7. Virus particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips.
8. No glassware or hypodermic needles will be used at any time with any culture producing or containing virus particles, or any supernatant generated from any cell that has ever been exposed to virus particles.
9. All supernatants, plasticware, and cells that have come into contact with virus particles or viral infected cells will be treated with Trigene, Virkon, or bleach at appropriate concentrations and for 20-30 minutes prior to discard.
10. Standards of GLP will be rigorously enforced (lab coats, gloves, etc).
11. All personnel using or producing virus will be appropriately registered through the University Health and Safety procedures, listed on the GMAG approval, and taught appropriate safe handling by the principal investigator (Peter Andrews).
12. Other lab personnel will be made aware of the use of lentiviral systems in the laboratory.

Contamination management
1. Where spills occur in contained environments such as Class 2 hoods, neat Trigene, bleach, or Virkon will be added and left for >10 minutes to neutralise viral particles prior to wiping, cleaning and disposal.
2. If a small contained spill occurs outside of Class 2 hoods, management will be as above. Any spill outside of the Class 2 hood will be reported to a principal investigator, and assessment made to determine whether avoidable features are present to prevent future accidents.
3. Where aerosolised contamination is suspected to have occurred outside of Class 2 hoods, the lab will be cleared immediately to prevent aerosol inhalation. The air conditioning system will replace the air within a room within 10 min and will serve to desiccate and dilute the hazard. A single designated worker will return to the lab after 20 min and apply appropriate disinfectant to liquid traces.

The maximum volume of liquid to be disposed of from a single work session is 2 litres. This is pre-treated with 2% Clearsol (Phenolic) Disinfectant. The pre-treated liquid waste and any bacterial plates are then autoclaved at 126°C for 50 minutes daily as required. The autoclave cycle is verified by a chart recording and a monthly independent check is carried out to ensure the correct functioning of the autoclave.

Lentiviral expression of mutant and wild-type candidate obesity and insulin resistance genes in cell culture. Lentiviral expression of short hairpin RNAs (shRNA) to mediate RNA interference (RNAi) for knock-down genes involved in the development of obesity and insulin resistance.

Class 2

< 1 Litre

Consent Granted Not Applicable

Project notified under transitional arrangements N
The objective of this proposal is to study candidate genes for obesity and insulin resistance by using lentiviral gene transfer technology to express those genes (or mutated genes) in cell lines and primary cell cultures which would otherwise be difficult to transfect. Furthermore, genes involved in the development of obesity and insulin resistance may be knocked-down by RNAi using shRNA expression cassettes integrated into lentiviral vectors. All of the genes we will be studying are involved in energy homeostasis, differentiation, signal transduction or gene expression.

We plan to use lentivirus-based vectors to express genes of interest in both cell lines and primary culture. Likewise, we plan to introduce shRNA expression cassettes with lentivirus vectors into those cells to downregulate the expression of specific genes by RNAi. Rodent cell lines will include CHO (Chinese ovary hamster) cells, FAO hepatocytes, L6 and C2C12 myotubes, and 3T3-L1 pre- and adipocytes. So far, no rodent lentivirus has been identified. Furthermore, these cells are not HIV infected and therefore the replication-deficient lentivirus used are not not able to replicate and no recombination to WT virus can occur. We also plan to express genes of interest or shRNAs in primary cultures of murine, rat or human preadipocytes, differentiated adipocytes, myotubes, hepatocytes or neurons. Primary rodent cells should be of no risk to harbour or produce lentiviruses and therefore recombination and virus production can be excluded after lentiviral gene transfer. Donors of human material will be checked for HIV-infection to reduce the risk and production of infectious virus. In addition, modification of these strategies we may also infect cells with lentiviruses encoding Cre recombinase (LV-Cre). This enzyme mediates recombination of DNA at specific loxP sites. If a DNA fragment is flanked by these loxP sites, it will be excised by Cre-mediated recombination. In this strategy, stable cell lines are established using retrovirally gene transfer using Moloney murine leukemia virus (MMLV) based vectors or lentiviral vectors which contain the GNA encoding the gene of interest, or mutant version of it, downstream of a promoter region with a blocking sequence inter.posing the two. The blocking sequence prevents expression of the gene of interest but is flanked by loxP sites. Once the cells have been cultured, and in most cases differentiated into mature adipocytes or myotubes, infection of the cells with lentiviruses encoding Cre recombinase causes excision of the loxP flanked blocking sequence and consequent induction of expression of the gene of interest. In the absence of target loxP sites the Cre recombinase would be expected to have no effect on cells. The initial retroviral (lentiviral) infection step will be entirely carried out physically separated from the LV-Cre infection. The latter would also be temporally distanced from the former by several cell passages and, typically, a period of culture to terminally de-differentiate the cell type undergoing study. Moreover, the MMLV-based retroviruses used in this case are ecotropic and capable only of infecting rodent cells. The used retroviral and lentiviral vectors are both lacking most of the viral genes and show only limited sequence homology. Therefore no recombination and production of infectious virus is possible in dually infected cells.
lentiviral parts the generation of replication competent virus via homologous recombination can be excluded. Furthermore all of HIV accessory protein genes (vif, vpr, vpu, nef) have been deleted (from all four plasmids) which are associated with possible pathogenesis. Likewise all regulatory genes (tat, rev) are deleted from the transfer vector. Virions containing the vector genome are produced by co-transfecting HEK 293T cells with transfer vector (expressing the gene of interest of the shRNA) together with three helper plasmids expressing the gag/pol genes, the rev gene or a gene encoding a heterologous viral glycoprotein (VSV-G) respectively. The resulting lentiviruses are replication deficient as they lack nearly all viral genes (only minor parts of the gag gene remain which are essential for genome packaging into virions). Furthermore they are mostly self inactivating as they harbour U3 deletions in the 3'-LTR region. Therefore only the gene of interest or the shRNA are expressed from the integrated lentiviral genome. The gene of interest is expressed from the CMV, murine PGK1 promoter or from tissue specific promotors while shRNAs are expressed from either the U6 or the H1 pol III promoter. The transgene expression cassette will be introduced downstream of the rev responsive element (RRE) or into the deleted U3 region in the 3'-LTR. In some cases the post-transcriptional regulatory element from woodchuck hepatitis B virus is introduced downstream of the transgene to enhance its expression. It may be useful to produce bicistronic vectors which express a mammalian gene of interest and a reporter gene (e.g. EGFP) or a gene mediating antibiotic resistance (e.g. puromycin resistance gene) to allow selection of successfully transduced cells. Furthermore it may be necessary to incorporate an inducible expression cassette into the viral genome. For this reason loxP sites may be introduced into the viral genome to take advantage of the Cre/loxP recombination system. Another option may be the use of tetracycline regulated promotors.

Origin & function

1. Wild-type and mutant mammalian genomic DNAs and cDNAs encoding a variety of candidate obesity and insulin resistance genes. These will be cloned either from mammalian mRNA or genomic DNA from mammalian tissue or mammalian-derived cell cultures. Mutations may be introduced into those genes.
2. The reporters GST, EGFP, FLAG, His, Myc, Renilla Luciferase and Firefly Luciferase may be used. These will allow verification of infection rates and quantification of transgene expression levels in cell types used.
3. Short hairpins directed against specific mammalian ORFs will be expressed from the Pol III promoters U6 or H1 and will mediate the specific degradation of the targeted RNA. These loss of function experiments will be carried out to further define gene function.
4. Cre recombinase is derived from bacteriophage P1 and expressed to excise DNA flanked by loxP sites.

Evaluation of foreseeable effects

Expression: Expression of the gene of interest is either driven by the strong PGK-1 or the CMV promotor. Both are active in host cell types. After integration of the reverse transcribed lentiviral genome into the host cell only of the gene of interest will be stably expressed. As genes are most likely involved in metabolism, differentiation, signal transduction or gene expression the probability of toxic or mitogenic effects are very low. But some of the genes or mutants may not be sufficiently characterised and therefore handling will need some caution. The expression of shRNAs is either driven by the U6 or H1 promotor. These Pol III promotors are active in most cell types. By stably expressing those shRNAs the respective target gene will be specifically expressed.

Damage: Replication-defective and self-inactivating lentiviruses are considered unlikely to cause disease for the purposes of Class II classification, although the nature of the inserted gene and of the used glycoprotein for pseudotyping should be considered when assessing potential damage from infection by engineered viruses. As all viral genes are deleted the generated virus is unable to replicate inside any cell. Also cytotoxic or cytopathogenic effects mediated by viral gene products are therefore circumvented.

As mainly self-inactivating (SIN) viruses are used and deleted U3 regions within the 3'-LTR (contains the viral promotor) no downstream gene should transcriptionally activated after integration into the host genome. During the integration process the U3 region is usually copied to the 5'-LTR and drives the transcription of the viral genome. If large parts of the U3 region are deleted the viral promotor is inactive and no transcription is initiated from the 5'-LTR of the provirus. Therefore using SIN vectors the production of infectious virus is further disabled. Only the random integration of the provirus into the host genome of the cell may alter extremely rarely the expression of genes situated near the integration site in individual cells infected.

Viruses pseudotyped with glycoprotein or vesclar stomatitis virus (VSV-G) shop a different host cell tropism and higher stability and may therefore be transmitted not only directly by injection but also by ingestion or via aerosols. However it has been shown that lentiviruses pseudotyped with VSV-G are rapidly inactivated in human serum. Taken the safety measures into further account the risk for humans is very low.

Furthermore these lentiviruses are unable to infect plants and are incapable of replicating in mammalian cells and therefore cannot be transmitted to any animal or human population.

As HIV-1 does not belong to the onco-retroviruses and the genes we are interested in are not recognised oncogenes, work with our virus is not expected to pose a cancer risk. However, the biological activity of mutany genes remain to be characterised. These are likely to differ from the wild-type counterpart. Therefore some degree of caution is required.
will be exercised when handling lentiviruses expressing these.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. All liquid waste will be disinfected/inactivated by treatment with Virkon and autoclaved prior to disposal to drains.
2. All solid waste will be soaked in Virkon, securely contained and afterwards incinerated.
3. Autoclave cycles are calibrated for type and amount of waste. Assumed 100% kill.
4. Disinfection with 70% EtOH will be used to decontaminate exposed work areas (+30 min UV).

CU2 Project Title Study of regulatory networks involving SECIS binding protein 2 (SBP2) and

Class 2

CultureVolClass2 1-50 Litres

CultureVolumeClass3-4

02/03/2022
Selenium (Se) is an essential trace element which is fundamental to human health. Its biological role is mediated principally by cotranslational incorporation of selenocysteine (Sec) into selenium-containing proteins (25 known human selenoproteins). Selenoproteins represent a diverse group, with functions ranging from metabolism of thyroid hormones (deiodinases, DIOs), removal of cellular reactive oxygen species (ROS) (glutathione peroxidase (GPx) types 1, 2, 3, 4 & 6, thioredoxin reductase (TrxR) types 1, 2, 3), reduction of oxidised methionine (selenoprotein X/MSRB1), transport and delivery of selenium to peripheral tissues (seIP), protein folding and ER stress (Sep-15, SELM), to proteins (SELO, SELV, SEPW, SELK, SELH) whose precise function is unknown. A molecular mechanism that is highly conserved from archaeabacteria to higher eukaryotes mediates the translational incorporation of Sec during selenoprotein synthesis. Interaction of a stem-loop RNA structure (Sec insertion sequence (SECIS) element), usually located in the 3'-UTR of selenoprotein mRNAs, with a multiprotein complex which includes SECIS binding protein 2 (SBP2), leads to Sec incorporation mediated by a specific selenocysteyl-transfer RNA (tRNA[Ser]Sec) at UGA codons. Failure of this mechanism can result in miscoding of the UGA as a stop codon and, depending on its location in the mRNA, the transcript may undergo nonsense mediated decay (NMD). The architecture of SECISBP2 is highly complex, with alternative splicing of the gene to generate multiple transcripts and internal methionine residues capable of directing synthesis of shorter protein isoforms.

Our laboratory (unpublished) and others (Dumitrescu Nature Genetics 2005, Cosmo JCEM 2009) have characterised mutant SBP2 in different patients resulting in a knock down of SBP2 expression. We describe several features in our affected subjects (elevated circulating thyroxine (T4) with low selenium and selenoprotein (SEPP, GPx3) levels, infertility, skeletal myopathy, skin photosensitivity, abnormal immune cell function, enhanced fat mass with preserved insulin sensitivity) that can be attributed to loss of selenoprotein function in specific tissues and have also documented cellular deficiencies of additional members of the selenoproteome whose function is unknown. Non of the patients have been presented with cancer. Our observations define a multisystem disorder, involving the defective biosynthesis of many selenoproteins, which can elucidate their role in human biological processes. The effects of SBP2 inactivation are poorly understood, cell line and animal studies using knockout mouse models has been hindered by lethal phenotype.

With the use of an inducible lentiviral system for introducing shRNA we want to generate stable expressing cells to assess the effect of SBP2 knock down, and/or its splice variants, or knockdown of individual selenoproteins (see appendix) on various physiological processes in different cell types.
themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs).

Host/vector system

The pGIPZ and pTRIPZ lentiviral package systems will be used were described by Kappes et al. 2001; Kappes et al. 2003; Wu et al. 2000; Wu et al. 2001. and developed by Open Biosystems (see appendix). This new generation of lentiviral systems includes a significant number of safety features designed to enhance its biosafety and to minimize its relation to the wild type, human HIV-1 virus. More significantly the reverse transcriptase (RT) and integrase (IN) proteins are split from the native Gag-pol polyprotein and are provided in trans from a separate plasmid producing a novel class of HIV-based vectors. The lentivirus is produced by co-transfecting the packaging plasmid mix (four plasmids for gag, pro, RT, IN, VSV-G, rev and tat expression) and the transfer vector into the TLA-HEK293T cell line (10 cm dish). Particles will be harvested at 48 and 72 hours after transfection and stored at -80°C, spun down in a ultracentrifuge to concentrate or immediately used for transduction of recipient cells (tissue culture with primary human cells and immortalised human and murine cell lines and infection of those cells (6-well dish)).

Origin & function

With the use of an inducible lentiviral system for introducing shRNA we want to generate stable expressing cells to assess the effect of SBP2 knock down, and/or its splice variants, or knockdown of individual selenoproteins (see appendix) on various physiological processes in different cell types.

Our laboratory and others have characterised mutant SBP2 in different patients resulting in a knock down of SBP2 expression. We describe several features in our affected subjects (elevated circulating thyroxine (T4) with low selenium and selenoprotein (SEPP, GPx3) levels, infertility, skeletal myopathy, skin photosensitivity, abnormal immune cell function, enhanced fat mass with preserved insulin sensitivity) that can be attributed to loss of selenoprotein function in specific tissues and have also documented cellular deficiencies of additional members of the selenoproteome whose function is unknown. Our observations define a multisystem disorder, involving the defective biosynthesis of many selenoproteins, which can elucidate their role in human biological processes.

Evaluation of foreseeable effects

The expressed shRNA products will reduce SBP2 or selenoprotein expression and may be expected to affect cellular processes such as growth, differentiation, self-renewal and apoptosis but are not considered to be oncogenic. Defective retroviral/lentiviral in which the helper genes are located on separate blocks of DNA. Such vectors may infect human cells and integrate into the cellular DNA, but when unmodified are considered hazard group 1.

The cells may be transformed/oncogenic; however they are still relatively fastidious and would be incapable of colonising/causing disease; cells could present a genuine risk to corresponding donor, but there will be no opportunity of donors to be so exposed.

The Trans-Lentiviral™ GIPZ Packaging System includes the following key safety features:

- The expression vectors contain a deletion in the 3′ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell.
- The number of genes from HIV-1 that are used in the system has been reduced (i.e. gag, pol, rev, tat and vpr).
- The VSV-G gene from Vesicular Stomatitis Virus is used to pseudotype the vector particles. The HIV-1 envelope has been completely removed from the vector.
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
- Although the packaging plasmids allow expression in trans of genes required to produce viral progeny (e.g. gag, pol, rev, tat, env) in the TLA-HEK293T™ producer cell line, none of them contain LTRs or the ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus has been shown to be produced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Class 2 1-50 Litres

Non-GMM Consent Granted

Non-GMM Consent Granted
Purposes of the contained use

Protein misfolding in cells contributes to important diseases ranging from neurodegenerative disorders, such as Parkinson's Disease, to metabolic diseases such as type II diabetes mellitus. A common theme of these conditions is the accumulation, or the threat of accumulation, of misfolded and unfolded proteins that contribute to attrition of key cellular functions. Cells have an elaborate apparatus for recognizing and responding to the threat of protein misfolding, known as the Unfolded Protein Response (UPR). This apparatus has numerous components that promote fitness in the face of the aforementioned threat. Surprisingly, however, the machinery of the unfolded protein response also has components whose activity, in certain contexts appear to enhance the deleterious effects of misfolding [Ron, 2007 #3066].

Rational therapeutic interventions aimed at the pathophysiology of protein misfolding requires the establishment of experimental systems in which the threat of protein misfolding is imposed and the activity of various components of the response to misfolded proteins (the Unfolded Protein Response) are either inactivated or enhanced. Because the clinically-relevant burden of protein misfolding is experienced disproportionately by terminally-differentiated, non-dividing cells, the tools for constructing the aforementioned experimental system must be geared to manipulating gene expression in non-dividing cells. HIV1-based lentiviruses, modified for safety and gene delivery have emerged as powerful tools for effecting changes in gene expression in terminally-differentiated cultured cells. Therefore, authorization is sought to use such vectors to enforce expression of genes encoding known misfolding-prone proteins in cultured mammalian cells and at the same time alter the cellular response to the misfolded proteins by introducing activated alleles, dominant loss-of-function alleles or shRNA inactivating alleles of genes encoding components of the unfolded protein response. By comparing the response of cells with diverse perturbations in the unfolded protein response to comparable burdens of protein misfolding we can begin to identify components of the unfolded protein response whose activation or inactivation (by pharmacological means) may be of therapeutic benefit in combating diseases of protein misfolding.

Recipient or parental organism

The lentivirus is produced by co-transfecting the packaging plasmid mix and the transfer vector into human HEK293T cells.
The recipient cells will be various murine and human cells in culture.
Both the recipient cells and the producing cells are fastidious and non harmful. They cannot colonise the environment nor cause disease by colonizing human or animal hosts and thus are classified as Hazard Group 1. Cells from human volunteers, which may be used in this project are uncharacterised and although themselves present...
no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs).

**Host/vector system**

The pGIPZ and pTRIPZ lentiviral package systems and derivatives thereof like the pLenti6_V5 of invitrogen or the delivery vehicle for Sigma mission shRNA (pLKO.1–Puro) to be used were described by Kappes et al. 2001; Kappes et al. 2003; Wu et al. 2000; Wu et al. 2001 and developed by Open Biosystems. This new generation of lentiviral systems has been used extensively throughout the world and includes important features designed to enhance its biosafety:

The reverse transcriptase (RT) and integrase (IN) genes were split from the Gag-pol polyprotein-encoding gene and are provided in trans from two separate plasmid. The ENV function, provided by the VSV glycoprotein, is introduced in trans by a third plasmid and the only packaging signal is on the transfer plasmid that lacks important HIV genes. Thus, the probability of a series of recombination events that produce a replication-competent virus that can spread in and between hosts is vanishingly small. In the context of this project, the main risk is the consequence of primary infection of humans by high titre viral stocks (see below).

The lentivirus is produced by co-transfecting the packaging plasmid mix (four plasmids for gag, pro, RT, IN, VSV-G, rev and tat expression) and the transfer vector into the HEK293T cells. Particles are harvested over a period of 48 to 72 hours after transfection and are stored at -80°C. If titres are low, the virus can be concentrated by ultracentrifugation. Transduction of recipient cells follows. These will be tissue cultures of primary human or other mammalian cell lines.

**Origin & function**

The shRNA sequences to inactivate genes in the host are derived from the host cell genome. They will be directed to genes that function in protein folding in the endoplasmic reticulum and the response to protein misfolding (examples include: chaperone-encoding genes like Erdj3, enzymes involved in oxidative protein folding like Ero1l and Ero1lb, components of the unfolded protein response like Ern1 or Eif2aK3). These genes are neither oncogenes nor tumor suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an “empty” virus.

To activate components of the unfolded protein response we will use cloned cDNA that will be over-expressed. As the genes in question are neither oncogenes nor tumour suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an “empty” virus.

To promote misfolded protein stress we will express known misfolding-prone mutants versions of secreted proteins, for example, Ins2 with a mutation that prevents proper disulfide bond formation. As the secreted proteins are not oncogenic and in fact harbour mutations that promote endoplasmic reticulum retention the are either inert or enfeeble the targeted cell, the risk of oncogenic transformation by a virus harbouring a misfolding prone protein are diminished compared to the empty virus. A theoretical exception to this principle is a retrovirus encoding a prion-forming protein, which could in an extremely fanciful scenario set up a prion infection in the host. Therefore, proteins with a potential to undergo prionization (e.g. mutant PrPsc) will not be used.
Following is a table of the specific genes:

<table>
<thead>
<tr>
<th>List of mutant genes encoding proteins that misfold in the endoplasmic reticulum and that will be expressed from lentiviral vectors:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Mouse Ins2C96Y Encodes insulin, a hormone normally present in serum</td>
</tr>
<tr>
<td>b) Human PLAPC121S. Encodes placental alkaline phosphatase, an enzyme normally present in tissue</td>
</tr>
<tr>
<td>c) Human SERPINA1PIZ. Encodes a misfold serum protease inhibitor</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>List of genes encoding proteins that function in the processing of protein folding in endoplasmic reticulum or in the response to the stress of protein misfolding in the endoplasmic reticulum. The expression of these genes will be inhibited by shRNA-containing lentiviral vectors or the genes will be over-expressed by lentiviral vectors:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Mouse or human Hspa5, Hsp90b1, ERDJ (1-6). Encode chaperones that folds proteins in the ER</td>
</tr>
<tr>
<td>b) Mouse or human PDI1, Erp44, Erp57, Erp72. Encode disulfide isomerases/transfereases than function in oxidative protein folding in the secretory pathway</td>
</tr>
<tr>
<td>c) Mouse or Human Ero1l, Ero1lb, Qsox1, Qsox2. Encode protein disulfide oxidases involved in protein folding</td>
</tr>
<tr>
<td>d) Mouse or human EIF2AK3, ERN1, ATF6. Encode detectors of unfolded protein stress in the endoplasmic reticulum</td>
</tr>
</tbody>
</table>

**Evaluation of foreseeable effects**

RNAi inactivation of most genes involved in protein handling in the endoplasmic reticulum or in the response to misfolded proteins, will enfeeble cells and render them more sensitive to misfolded protein load. Even those genes that encode proteins that are known to reduce the fitness of cells experiencing high levels of misfolded protein stress are not known oncogenes (example CHOP/Ddit3) Thus the risk associated with viruses encoding such genetic elements is predicted to be less than that of empty lentiviruses.

Gain-of-function of unfolded protein response components, which may have a benefit in the special circumstances of severe protein misfolding is unlikely to translate to a survival benefit for accidentally-transduced cells, let alone serve as an oncogenic event. Thus the risk posed by gain-of-function vectors is likewise less than that of empty viruses. Lastly, as noted above, the expression of a misfolding-prone protein is severely enfeebling to cells and part from the theoretical establishment of a new strain of prions the risk posed by such vectors is less than that of the empty ones.

**Circadian (circa- approximately, -diem day) rhythms are a fundamental property of the life of a cell. When held in temporal isolation, organisms from unicells to humans exhibit behavioural and physiological rhythms that persist with a period of approximately 24 hours. These rhythms are driven by cell-autonomous molecular circadian clocks. They confer selective advantages to organisms by facilitating anticipation, and thereby adaptation to, the alternating day/night cycle. The competitive value of circadian clocks has been demonstrated in prokaryotes and higher plants, whilst disturbance of circadian timing in humans, as seen in rotational shift workers for example, carries significant long-term health costs.**

We have developed novel tools, based on variants of fluorescent proteins and the luciferase enzyme, that allow us to probe the inner workings of the clockwork in more detail than previously possible. Since we now want to study the clockwork in neuronal systems and in primary cells, lentiviral systems are necessary to introduce relevant transgenes into the host cell genome for stable expression, especially in intact organotypic tissue slice cultures. Moreover, we also wish to perturb the clockwork by knocking down the expression of various ‘clock genes’ (and their modifiers such as peroxiredoxin proteins), and lentiviral systems allow this in neuronal and ‘difficult-to-transfect’ cell lines, including primary cells.

HIV1-based lentiviruses, modified for safety, have emerged as powerful tools for effecting changes in gene expression in terminally-differentiated cultured cells such as neurons and organotypic tissue slices. Therefore, we seek authorization to use such vectors to attain our goals in relation to clock research.

**Recipient or parental organism**

The lentivirus is produced by co-transfecting the packaging plasmid mix and the transfer vector into human HEK293FT cells. The recipient cells will be various murine and human cells in culture, including primary cells. Both the recipient cells and the producing cells require specific cell culture conditions to grow and are not harmful. They cannot colonise the environment nor cause disease by colonizing human or animal hosts and thus are classified as ACDP Group 1. Cells from human volunteers, which may be used in this project are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at Containment Level 2 within the host laboratory.
The ViraPower™ Lentiviral Expression System (Invitrogen), facilitates highly efficient, in vitro or in vivo delivery of a target gene to dividing and non-dividing mammalian cells using a replication-incompetent lentivirus. Similar systems have been developed by multiple companies and use very similar (if not identical) components, e.g. Sigma Mission shRNA pLKO based system. This new generation of lentiviral systems has been used extensively throughout the World and includes important features designed to enhance its biosafety:

- The pLenti expression vector contains a deletion in the 3′ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes from pLP1 has been rendered Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
- A constitutive promoter (RSV promoter) has been placed upstream of the 5′ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

References

Yu, S. F., Ruden, T. v., Kantoff, P. W., Garber, C., Seiberg, M., Ruther, U., Anderson, W. F., Wagner, E. F., and
activate components of the circadian clock we will use cloned cDNA that will be over-expressed. The genes in question are neither oncogenes nor tumour suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an empty virus. We will also express bioluminescent and fluorescent proteins as 'reporters' of the clock within cells, which are derived from firefly and jelly fish sequences respectively. These have a long history of safe use in various non-replicative lentiviral systems.

A theoretical exception to this principle is a retrovirus encoding a prion-forming protein, which could theoretically set up a prion infection in the host. Therefore, proteins with a potential to undergo prion formation (e.g. mutant PrPSc) will not be used.

The short hairpin RNA (shRNA) sequences used to inactivate genes in the host are derived from the host cell genome and tested in conventional (non-lentiviral) vectors before use to test their function in cell lines. They will be directed to genes that function in the circadian clockwork, usually as transcription factors that switch oscillating genes on/off over the 24 hour day. These genes are neither oncogenes nor tumor suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an empty virus.

List of genes / fusions encoding 'reporter' proteins that will be expressed from lentiviral vectors:

- Basic fluorescent proteins: GFP, RFP, dsRED, CFP, YFP
- Redox-sensitive fluorescent proteins: roGFP1/2, roGFP1/2-Grx1, roGFP1/2-Trx, roGFP1/2-Prx1, roGFP1/2-Prx2, roGFP1/2-GAPDH
- NAD/NADH-sensitive fluorescent proteins: SuperFres
- H2O2-sensitive fluorescent proteins: Hyper, Hyper-2, Hyper2-Grx1, Hyper2-Trx, Hyper2-Prx1, Hyper2-Prx2, Hyper2-GAPDH
- Bioluminescent proteins: Luciferase (Luc2), OxyLUC
- Light-sensitive ion channels: Channelrhodopsin, Halorhodopsin (and variants)
- Light-sensitive expression systems: Lite-On
- Voltage/Calcium sensing fluorescent proteins: Cameleon, Case12, GCAMPS, Arch3, PROPS, VFSP3
- pH-sensitive fluorescent proteins: pHluorin, synapto-pHluorin, pHred

List of genes encoding proteins that function in the circadian clockwork. The expression of these genes will be inhibited by shRNA-containing lentiviral vectors, or the genes will be over-expressed by lentiviral vectors:

- Mouse or human Clock, Bmal1/2. Encode clock-relevant transcription factors.
- Mouse or human peroxiredoxins (Prx1, 2, 3, 4, 5, 6). Encode clock-relevant antioxidant response proteins.
- Mouse or human catalase. Encode clock-relevant antioxidant response proteins.
- Mouse or human superoxide dismutase. Encode clock-relevant antioxidant response proteins.
- Mouse or human thioredoxins (Trx1, 2). Encode clock-relevant antioxidant response proteins.
- Mouse or human glutaredoxin (Grx). Encode clock-relevant antioxidant response proteins.
- Mouse or human glutathione reductases. Encode clock-relevant antioxidant response proteins.

Evaluation of foreseeable effects

Inactivation of most genes involved in circadian clock function by RNA interference (RNAi) will have no significant effect on the cell, and if anything, make them more susceptible to undergo apoptosis. The genes that will be disabled
are not known oncogenes. Thus, the risk associated with viruses encoding such genetic elements is predicted to be
less than that or empty lentiviruses.
Gain-of-function of clock components by overexpression is unlikely to translate to a survival benefit for accidentally-transduced
cells, let alone serve as an oncogenic event. The same is true for bioluminescent and fluorescent reporter
proteins; these have no other recognised function than to produce light. Thus, the risk posed by gain-of-function
vectors is likewise less than that of empty viruses.

02/03/2022
Herpesviruses are ubiquitous pathogens of man and all vertebrates. In humans, herpes simplex virus (HSV) causes oral and genital lesions and occasionally more serious diseases such as keratitis and encephalitis. Following primary infection latent virus resides in sensory neurones and can reactivate from these cells to facilitate recurrent disease/transmission. Murine gammaherpesvirus 68 is a gamma-2 herpesvirus, originally isolated from small free-living rodents in Slovakia. It behaves as a natural pathogen in conventional laboratory mice and has been used extensively as a model for the study of gammaherpesvirus pathogenesis. MHV-68 causes an infectious mononucleosis-like illness but is otherwise avirulent in adult, immunocompromised mice. Spread between mice is rare, even when housed in the same cage; intimate contact is probably required for virus transmission. Infection of humans has not been documented. In mice the virus productively infects epithelial cells and establishes a latent infection in B lymphocytes. The object of this research is to identify metabolic processes that influence the kinetics of virus replication in vitro and viral dissemination in vivo using reporter gene expressing HSV and MHV-68. This will be achieved by infecting mammalian cell lines and both wild type and genetically altered mice. The contribution of individual virus encoded
gene products to such interactions will be assessed using viral mutants with specific gene truncations or deletions. In addition, viral gene products cloned into replication defective retroviral and/or Adenovirus vectors to facilitate the transduction of mammalian cells will be used to probe such interactions further.

### Recipient or parental organism

Parental viruses: HSV 1/2 (HG2 pathogens), MHV68 (HG1 pathogen)
The biological functions of HSV-1, HSV-2 and MHV-68 genes are largely undefined however HSV and MHV-68 do not encode known toxins or proven oncogenes. In common with other well studied and genetically related herpesviruses it is expected that both HSV and MHV-68 will encode gene products including miRNAs that affect multiple cellular pathways/processes.

HSV encodes some 80 different gene products and at least 15 miRNAs involved in various aspects of virus replication, cell modification and immune evasion. The detailed mode of action of these virus encoded products is in many cases poorly understood. A number of gene products are known to be toxic in the expressing cell, for example the HSV-1 UL41 gene shuts off host protein synthesis and overexpression of a number of immediate early gene products prevent cell division (e.g. ICP0).

MHV-68 encodes some 70 different gene products and at least 8 miRNAs involved in various aspects of virus replication, cell modification and immune evasion. The detailed mode of action of these virus encoded products is in many cases poorly understood. A number of gene products are know to be toxic in the expressing cell, for example MHV-68 shuts off host protein synthesis and the virus can induce cell division and proliferation of B cells. In addition, specific gene products are involved in immune evasion, such as the K3 gene product that specifically degrades mouse (but not human) MHC class I, and M3, which is a pan chemokine binding protein.

Standard mammalian cell lines such as NIH 3T3, HEK (human embryonic kidney) 293, MEF (murine embryonic fibroblasts), HeLa and BHK (baby hamster kidney) cells. All mammalian cell lines used have a history of safe use and it is unlikely that they will carry adventitious pathogens.

### Host/vector system

Bacterial artificial chromosomes (BAC): The use of full-length infectious herpesvirus genomes cloned as BAC has significantly improved the process of genetic manipulation of the genomes and is an approach widely used throughout the herpesvirus research community. The risks posed by working with either naked viral DNA or genomes cloned as BACs are low since the specific infectivity of DNA is many orders of magnitude lower than that of fully formed virus particles. Herpesvirus genomic DNA is however capable of infecting human cell lines in culture if introduced in certain ways (e.g. by transfection procedures) and therefore there is a potential risk of infection when working with or handling virus genomes cloned as BACs. The risk is very low because a route of direct delivery of the BAC DNA into cells is necessary for infection and would be highly unlikely during normal laboratory handling. Non mobilizable bacterial genomic vectors to be used: pUC series, HSV cloned as bacterial artificial chromosome in a derivative of pBAC108L (disabled F plasmid), MHV-68 cloned as bacterial artificial chromosome in a derivative of pBAC108L. Bacterial hosts will be multiply disabled E.coli K12 derivatives eg DH5 alpha, DH10B, JC8679 for all bacterial cloning. These derivatives (HG1 pathogens) are disabled and do not compete with normal gut flora.

Adenovirus vectors: The parent vector is an Ad-5 recombinant in which the E1 region is replaced by a lacZ coding cassette. This virus grows only in helper cells (eg 293 cells) that provide the E1 gene product in trans, and is an ACDP hazard group 1 organism. All insertions will be in the E1 region, replacing the lacZ cassette. This effectively eliminates the possibility of generating a replication competent virus carrying the foreign insert by recombination with a wild type virus. Adenoviruses are spread via the respiratory aerosol route and this route represents the major risk of infection.

Retrovirus vectors: Third generation lentivirus vectors lack pol, tat, env, rev and gag genes and can only be packaged...
following complementation with helper plasmids expressing RT, IN, tat, rev together with the VSV G protein. These are expressed from different plasmids so reconstitution of wild type virus is not possible. In addition, the vector genome has a self inactivation LTR to reduce the risk associated with insertional mutagenesis. Host range and virus stability is expanded by incorporation of the VSV G protein.

Herpesvirus vectors: Herpes simplex virus deleted for the gH gene is replication defective and cannot complete a full round of replication. Such vectors can be propagated on gH expressing complementing cell lines that do not result in the generation of detectable levels of replication competent virus since there is no homology between the virus and the gH expression cassette in the CR1 cell line. Following infection of noncomplementing cell lines the virus can only go through a single round of replication and produces non infectious virus progeny. This vector is classified as a class I GMO by the HSE.

Technique used to introduce insert or vector into host:
Infection of mammalian cell lines and mice with recombinant HSV or recombinant MHV-68 containing gene disruptions and/or expressing reporter genes.
Cloned genomic fragments of HSV or MHV-68 will be cloned directly into pUC-based vectors and transformed into E.coli K12 derivatives. HSV or MHV-68 cloned as a bacterial artificial chromosome will be transformed into E.coli K12 derivatives and purified plasmid DNA used to reconstitute virus following transfection of mammalian cell lines. Retroviral and Adenovirus vector mediated transduction of mammalian cell lines with HSV or MHV-68 encoded gene products.

Investigation into the interaction between viral replication and cellular metabolic processes may involve:
1. Genomic cloning of HSV1/2 or MHV68 sequences into plasmid and replication defective viral vectors.
2. Inactivation/modification of virus encoded genes and non-coding RNAs, including alteration of their regulation of expression, using full-length infectious herpesvirus genomes cloned as bacterial artificial chromosomes (BAC).
3. Cloning of reporter genes (e.g. GFP, betagalactosidase, Cre recombinase, luciferase) under latent or lytic cycle promoter control. Each of these proteins has no known biological effects in eukaryotes.
4. The expression of virus and/or cellular gene products in a glycoprotein H (gH) deleted HSV-1 (Class I GMO as agreed with Dr Mark Bale at the HSE) vector. This gH deleted vector is severely disabled and can only be propagated in a gH complementing cell line. The severely disabled nature of such a gH deleted vector makes it very unlikely that it will pose a risk greater that wild type HSV-1 since any cell entering a productive replication cycle will be killed and no infectious progeny will be produced.

Evaluation of foreseeable effects

HSV-1/2 (HG2): Recombinant viruses containing mutations of individual gene products or encoding reporter gene cassettes are most likely to be less virulent than wild type parental virus.
MHV-68 (HG1): recombinant viruses containing mutations of individual gene products or encoding reporter gene cassettes are most likely to be less virulent than wild type parental virus.
Retrovirus vectors: There is a low risk of aerosol transmission and efficient transduction would require breach of mucosal membrane or the skin surface. This would result in transduction of a small number of cells as the virus is defective and cannot spread.
Adenovirus vectors: Deliberate attempts to deliver foreign genes in vivo using adenovirus vectors (in gene therapy experiments) establish that this is an inefficient process. In the event of accidental infection:
1. A small number of cells would express the foreign gene. This might result in death of those particular cells if the gene product was cytotoxic.
2. There is a very small risk that a pre-existing adenovirus infection might result in complementation of a recombinant
vector by wild type virus. Transient growth of the recombinant might then occur. Infected cells would be killed by virus growth or by immune response to infection. There is no expectation that a herpesvirus gene product would exacerbate an adenovirus infection or modify tissue tropism (note the receptor binding proteins of herpesviruses are integral membrane proteins which cannot assemble into and adenovirus virion). Given these factors, the proposed recombinants are of no greater risk than the parental adenovirus vector but given the uncertainty about the functions of herpesvirus gene products, category 2 containment is appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture materials and labware will be autoclaved and incinerated which eliminates 100% of the infectious material. All solid waste will be collected in double autoclave bags, sealed with autoclave tape, labelled with the users name and the room number and will be autoclaved and incinerated. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) and disposed to drains. Alternatively, disinfected liquid waste will be gelled with Vernagel in sealed containers labelled with autoclave tape, and taken to the autoclave room for transfer to the incinerator. Spills will be sprinkled with Virkon powder/Trigene and Vernagel reagent to solidify. Recyclable labware will be soaked in 1% Virkon for 16 hours (which eliminates 100% of infectious material). Bench/cabinet surfaces will be wiped down with 10% Trigene and 70% ethanol (which eliminates 100% of infectious material).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project has been reviewed by the Institute of Metabolic Science's biological and genetic modification safety committee, and we are satisfied that the risk assessment is accurate and that the work will be carried out under the appropriate conditions.

02/03/2022 Page 4366 of 15326
Insulin resistance (IR) refers to reduced ability of insulin to lower blood glucose. In its common form, it is closely associated with obesity, and is causally linked to major pandemic diseases including type 2 diabetes, liver disease, subfertilitf and atherisckerisus. Nevertheless the underlying cellular and molecular basis is poorly un derstood, and this is a major rate limiting step in the development of novel therapies. A highly productive strategy in study of IR has been to focus on patients with rare and extreme disorders of insulin action, whether severe IR, or insulin supersensitivity. The Semple Lab has a large prgramme of genetic study of such affected patients, and using next generation sequencing in collaboration with the Sanger Institute has discovered many single gene variants plausibly linked to the diseases being studied. To verify that these variants do alter gene function it is critical to undertake downstream cellular studies either in model cell lines, or in primary human cells where available.

For the following reaons, the use of the HIV1-based lentiviral vectors described below is highly desirable for these studies:

1. The acute metabolic actions of insulin are exerted on terminally differentiated, non-dividing cells, and so the tools for constructing experimental cellular systems to model in vivo cellular pathology must be geared to manipulatin gene expression in non-dividing cells.

2. The ability to express or knock down genes conditionally is extremely valuable in study of human primary cells, helping to circumvent problems arising from high inter-cell
line variability in some assays. Conditional expression or knockdown or expression in terminal differentiation of primary cells and cell lines before induction, avoiding
problems which are commonly experienced due to adverse effects of overexpression or knockdown on differentiation itself. The pSLIK system described offers the
opportunity to achieve conditional gene expression or knockdown with only one viral infection, which is a major advantage with when working in fragile primary cells with a
finite replicative capacity.

HIV1-based lentiviruses, modified for safety and gene delivery have emerged as powerful tools for effecting changes in gene expression in terminally-differentiated cultured
cells. We propose to use one such vector to allow conditional knockdown or expression of putative pathogenic alleles of genes implicated by human genetic studies in
severe clinical disorders of insulin action, while at the same time, and where necessary, altering known insulin signalling pathways by introducing activated alleles, dominant
loss-of-function alleles or shRNA inactivating alleles of genes known to be involved in insulin signal transduction. By comparing the response of cells with and without
naturally occurring mutation or loss of gene function we can provide evidence that the mutations identified in human genetic studies are indeed disease causing, and can
elucidate their precise role in perturbing insulin action, which will be essential for the development of targeted therapeutic strategies for affected patients.

The lentiviral particles will be used solely in cultured cells. No experiments with lentivirus will be undertaken in animals.

Specifically, the types of studies to be undertaken are as follows:

1. Heterologous expression of naturally occurring mutants known to cause a monogenic disorder of insulin action. In primary cells or cell lines, to create disease models for
screening of pharmacological treatments.
2. Knockdown of expression of genes in which naturally occurring loss-of-function mutation have been identified in association with a disorder of insulin action to provide
evidence for pathogenicity.
3. Overexpression or knockdown of genes functionally involved in insulin action, fat cell differentiation, or other cellular functions being studied, to assess links between
these and the mutations being studied.

The most highly used downstream assays after these manipulations will assess:
1. Effects of insulin on such endpoints as glucose uptake, lipogenesis, lipolysis, gluconeogenesis, apoptosis and cell division.
2. Cell growth at baseline and in response to growth factors
3. Tolerance of DNA damage

Recipient or parental organism

Standard disabled laboratory chemically-competent E. coli derived bacterial strains (DH5alpha, XL-1blue, STBL3) for plasmid propagation. Non-pathogenic to humans and
animals. Cannot survive or establish in the environment.

The lentivirus will be produced by co-transfecting the packaging (pMDLg/pRRE and pRSV-Rev), the pseudotyping (pVSV-G), and the lentiviral transfer plasmids into a
variant of human embryonic kidney 293 cells stably and constitutively expressing the SV40 Large T-antigen (HEK 293T). This is a cell line that has been extensively used in
human or animal host and thus are classified as Hazard Group 1. HEK293T were obtained from ATCC. The packaging pMDLg/pRRE (contains the genes gag, pol, and
RRE) and pRSV-Rev (contains rev), and the pseudotyping pVSV-G plasmids offer maximal biosafety as described in Dull et al. (1) and Klages et al. (2) and were obtained
from the non-profit repository Addgene (www.addgene.com).

The recipient cells will be the following murine/rodent and human cells in culture:

Primary human dermal fibroblasts
Human dermal fibroblasts immortalised using hTERT
Induced pluripotent stem cells and derived cell lines
EBV-transformed human lymphoblastoid cells
Immortalised cell lines:
Human HEK293, HepG2, SGBS
Rodent: 3T3-L1 (preadipocytes and quiescent mature adipocytes), CHO

Both the producer and recipient cells are fastidious and non-harmful. They cannot colonise the environment nor cause disease by colonising human or animal hosts and thus are classified as Hazard Group 1. Only the primary cells from human volunteers and derived cells are uncharacterised, and although they themselves present no greater risk, they may contain adventitious infectious agents, and therefore all work will be undertaken within a Class II microbiological safety cabinet in a Containment Level 2 laboratory (risk assessment under COSHH Regulations). Other cells are well characterised tissue culture cell lines that have been/will be acquired from commercial or non-profit repositories.

The pSLIK Single Lentivector for Knockdown) lentiviral platform system to be used in this project is a HIV-1-based third-generation lentivirus system developed by The Alliance for Cell Signalling (AfCS), Berkeley, CA. The platform was described by Shin et al. (3) and is based in the four-plasmid packaging system originally described by Dull et al. in 1998. We will use the pSLIK system to conditionally express heterologous genes or shRNA sequences for targeted inactivation of host genes in various mammalian and primary human cell lines in culture.

The pSLIK platform is a third-generation lentiviral packaging system. This new generation of packaging system has been extensively used throughout the world and is likely to provide a greater margin of safety than earlier systems(2, 3). Importantly, it includes the following key features engineered for maximal biosafety:
- It uses only a fractional set of HIV genes. All of the four accessory genes (vif, vpr, vpu and nef) which are not crucial for viral growth in vitro but are critical for in vivo replication and pathogenesis have been deleted. Importantly, the two regulatory genes essential for viral replication (tat and rev) have also been deleted from the lentiviral transfer vector.
- The remaining of the virus genome, including rev, has been split onto three separate plasmids.
- The vector's self-inactivating design (SIN) deletes the viral transcriptional promoter and enhancer elements thus further minimising the risk for generating a replication-competent virus (4)
- The HIV-derived constructs, any any recombinant between them, are contingent on trans-complementation and upstream regulatory elements and thus are non-functional outside of the producer cells.
- The virus are pseudotyped with the heterologous fusogenic envelope glycoprotein of the vesicular stomatitis virus (VSV-G, also supplied in a separate plasmid) in place of the native HIV-1 native protein promoter and coding sequence truncated. Furthermore, both the start and stop codons in the naturally occurring x-protein sequence have been deleted.

The VSV G envelope expands the host range and tropism of the vector and confers enhanced virion physical stability compared to lentivirus particles; the modes of transmission are likely to be extended beyond the percutaneous routes of parental lentiviruses to include contact and aerosol routes.

This split-genome, conditional packaging system acts as a built-in biosafety device as it prevents the generation of replication-competent recombinants. The system conserves only three of nine genes of HIV-1 and relies on four separate transcriptional units for the production of transducing viral particles. As the vector particle packages only the genetic information contained in the transfer vector, infection is limited to a single round without spreading. The probability of a series of recombination events that would produce a replication-incompetent in mammalian cells and unable to infect plant cells the risk of transmission to animal populations is effectively null.

In the context of this project, the main risks are those of insertional mutagenesis by the primary vector particles and long term expression of transgenes after vector delivery.

(1) A third generation lentivirus vector with a conditional packaging system" (1998) J. Virol. 72, 8463-8471
(2) A stable cell line for the high-titer production of third generation lentiviral vectors". Mol. Ther. (2000)2, 170-6
The Gene sequences used to for overexpression and knock down studies will be derived from the human or mouse genome. Mutations to be introduced will either have been identified in human genetic studies, or will represent previously studied and well established molecular tools to be used to dissect insulin signalling. Genes to be studied will be those that human studies have implicated in human disorders of insulin action, whether severe insulin resistance or insulin supersensitivity. No oncogenic mutations will be studied, and no tumor suppressor genes are included in the list, thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an “empty” virus.

Following is a list of the specific genes to be studied:

Insulin/Phosphatidylinositol-3 kinase/AKT/mTOR signalling pathway

We additionally propose to study further genes, yet to be identified, in which likely pathogenic mutations causing severe disorders of insulin action are identified in ongoing genetic studies.

* Genes in which mutations are known to cause monogenic disorders of insulin action
# Genes recently discovered to harbour mutations plausibly linked to monogenic disorders of insulin action, but so far unpublished.

**Evaluation of foreseeable effects**

**Insulin Signalling Genes**
Given the anti-apoptotic action of insulin on cells, and its critical role in the assimilation of nutrients, expression of loss-of-function alleles or RNAi directed against most genes involved in insulin signalling with enfeebled cells and render them more sensitive to apoptosis. Thus the risk associated with viruses encoding such genetic elements is predicted to be less than that of empty lentiviruses.

Some of the syndromes to be studied are accounted for by gain-of-function alleles in insulin signalling molecules, such as the AKT2 p.Glu17Lys variant that we have reported in patients with severe hypoglucaemia and asymmetric mild overgrowth. Although some insulin signalling molecules are shared by other growth factor signalling pathways, and have been found in cancer, critically, we shall only be studying novel variants that we have discovered occurring naturally in patients with severe metabolic disorders but with no or minimal excess cancer risk across a lifetime.

**DNA damage repair and centrosomal proteins**
A subset of the genes to be studied have role in DNA damage repair or centrosomal function. In all cases modelling of human disease results in cells that show reduced growth and increases sensitivity to apoptosis, rendering them at a selective disadvantage to wild type cells.

**Genes involved in adipocyte differentiation**
Adipocytes are terminally differentiated, non-dividing cells. Several genes involved in programming the differentiation process will be studied. In each case, the consequence of human mutations is known, and is limited to severe metabolic disease due to failed adipose development. There is no reason to suppose that introduction of human lipodystrophy-associated mutations, or knockdown of these genes, will confer any selective advantage on infected cells.

**Genes in which plausible pathogenic mutations have recently been discovered in extreme disorders of insulin action.**
Intensive genetic studies of patients with severe metabolic problems due to impaired or enhanced insulin action continue to be studied. A key aim of future experiments will be to assess whether naturally-occurring mutations identified are likely to cause altered insulin action, and use of the pSLIK lentiviral system to express the mutated genes in primary cells and cell lines will be of enormous value. Although not all the genes and mutations to be identified in these studies are yet known, it is critical to emphasise that 1. Mutations to be studied will have first been identified in patients with metabolic disease, giving no reason to suspect that introduction of these mutations will confer any selective advantage to expressing cells. 2. There is no reason to suppose that any gene products releases from living or dying cells have the potential to exert harmful remote effects on other tissues.

*Please enter comments on the GM safety committee on the risk assessment*

*The project has been reviewed by the Institute of Metabolic Science biological and genetic modification Safety Committee, and we are satisfied that the risk assessment is accurate and that the work will be carried out under the appropriate conditions.*
The project aims to understand how metabolic signals (nutrients, hormones) influence the central mechanisms implicated in the regulation of energy homeostasis. More specifically, this research will characterize neuronal metabolic-sensing circuits implicated in the regulation of energy and glucose homeostasis.

The central nervous system is emerging as a unique point of neuroanatomical convergence of multiple signals conveying information about the body’s acute and chronic metabolic status (circulating nutrients and hormones, nutrient-activated afferents, incretins etc...). Specialized neurons have the ability to detect and integrate these signals through poorly characterized intracellular signalling pathways, and engage downstream neurocircuits producing commands to autonomic motor circuits coordinating multiple effectors of energy balance to ensure the maintenance of fuel homeostasis. In addition, recent evidence indicate that metabolic signals may also alter adult neurogenesis in discrete brain areas, which may contribute to the mechanisms through which the metabolic environment regulates central pathways implicated in the control of metabolism.

In this work, we will characterize neuronal metabolic-sensing pathways implicated in the regulation of energy and glucose homeostasis, and decipher the neuronal circuits activated downstream from metabolic sensing neurons to regulate metabolic functions. To do so, we are planning to use tools to 1) alter the expression of candidate metabolic-sensing proteins in discrete neuronal populations in adult mice (including potential adult-born neurons) 2) label neuronal circuits upstream or downstream from nutrient-sensing neurons.

To investigate the role of known or candidate metabolic-sensing pathways in adult neurons and adult-born neurons, we will use lentivectors to express relevant transgenes or shRNA in a cre-dependent manner, and bidirectionally alter the cellular activity of these candidates (overexpression or knockdown) in neurochemically discrete neuronal subpopulations. This will enable us to directly test the role of these pathways in metabolic functions in vivo and gain considerable understanding of the metabolic mechanisms underlying neuronal metabolic sensing.

Lentivectors present several advantages compared to alternative gene delivery strategies. They can infect nondividing cells, and DNA is integrated into the host genome, which enables lineage studies. The immune response in target cells is low. Last, lentiviral backbones enable the insertion of large DNA fragments. The metabolic-sensing pathways of interest include the mTORC1 signalling pathway; proteins whose expression may be up- or downregulated include: TSC1, TSC2, mTORC1, raptor, rictor, Rheb1, p70 S6kinase 1. Following cell-specific modification of the activity of these candidate metabolic-sensing proteins, we will characterize the metabolic consequences using measurements that will include food intake, body weight, adiposity, energy expenditure, glucose tolerance and insulin sensitivity.

To map the network of neuronal connections implicated in metabolic sensing, we will use cre-activable polysynaptic retrograde (PRV Bartha strain) and anterograde (HSV-1 H129) viral tracers that express green or red fluorescent markers in infected neurons. These tools are unique in their ability to travel in a specific direction within the neuronal circuits, which makes them reliable tools to perform neuronal mapping studies. We will use these tracers in transgenic mice expressing CRE in relevant neurochemical subpopulations of the brain and expose these neurons to various metabolic inputs. This will enable us to gain considerable understanding of the organization of the brain circuits implicated in metabolic sensing and the regulation of glucose and energy balance.
amplification. Non-pathogenic to humans and animals. Cannot survive or establish in the environment. Classified as hazard Group 1.

The recipient cells for studies with lentivectors will be the following immortalised cell lines in culture:

- Embryonic Mouse Hypothalamic Cell Lines N41 and N46
- Adult Mouse hypothalamus Cell Line (mHypoA-NPY/GFP)
- Adult Rat hypothalamic GnRH neuronal Cell Line (GT1-7)

Non-pathogenic to humans and animals. Cannot survive or establish in the environment. Classified as hazard Group 1.

The following cell lines will be used for production and titering of high titer tracing viruses HSV1 H129 (initially provided by DR Anderson, California Institute of Technology) and PRV Bartha (initially provided by Dr. Ekstrand, Rockefeller University):

- Adult Cercopithecus aethiops kidney Cell Line (Vero)
- Adult Sus scrofa kidney Cell Line (PK15)

Non-pathogenic to humans and animals. Cannot survive or establish in the environment. Classified as hazard group 1.

Packaging, production and titering of high titer lentiviral particles will be done by a third party (System Bioscience). See "Host/vector system" section below for details on vectors.

Transgenic reporter mice expressing the cre recombinase gene in specific neuronal subpopulations. Mice are transgenic and carry the cre recombinase gene. Not harmful to humans or the environment.

Host/vector system

LENTIVECTORS: Lentiviral based on third-generation packaging replication-incompetent HIV-1: pCDH platform for conditional transgene expression and pSIH1 for conditional shRNA expression

3rd generation lentivectors have been designed with a series of biosafety features that make them replication - incompetent in mammalian cells, and they do not infect plant cells, thus they are very safe to use. Lentivectors have the following biosafety features that make the risk for human health or environmental hazard very low:

1. Self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells through the deletion of the viral transcriptional promoter and enhancer elements, which minimises the risk for generating a replication-competent virus.

2. Efficient Tat-independent production of viral RNA, reducing the number of genes from HIV-1 (less than 30% that are used in this system). Importantly, all of the four accessory genes (vif, vpr, vpu, and nef) which are critical for in vivo replication and pathogenesis have been deleted.

3. The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev).

4. The corresponding proteins (gag, pol, rev) are expressed from different plasmids that lack packaging signals. The packaging plasmids share no significant homology to any of the expression lentivectors, the pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus.

5. None of the HIV-1 genes (gag, pol, rev) are present in the packaged viral genome,as they are expressed from separate plasmids lacking packaging signal. Therefore, the lentiviral particles generated are replication-incompetent.

6. Produced pseudoviral particles will carry only a copy of the expression construct.

7. The virus are pseudotyped with the heterologous fusogenic envelope glycoprotein of the vesicular stomatitis virus (VSV-G, also supplied in a separate plasmid) in place of the native HIV-1 native protein. It was found that lentivirus pseudotyped with VSV-G are rapidly inactivated in human hosts by the human serum complement

However, these vectors integrate the host's genome and therefore could result in insertional mutagenesis through a
series of recombination events (very low risk). The VSV G envelope expands the host range and tropism of the vector and confers enhanced virion physical stability compared to lentivirus particles; the modes or transmission are likely to be extended beyond the percutaneous routes of parental lentiviruses to include contact and aerosol routes. These vectors include the WPRE motif, which increases transduction. For all these reasons, these lentivectors belong to GM class 2.

PRV Bartha strain:

IMPORTANT NOTE: A SAPO LICENSE WILL BE APPLIED FOR AND OBTAINED BEFORE THE START OF THE WORK WITH PRV

PRV is an animal pathogen, lethal in non-native hosts and transmitted via direct mucosal contact. The natural host for PRV is swine, but PRV has also been reported to infect a wide range of vertebrates, which include the cattle, sheep, dogs, cats, goats, chickens, raccoons, possums, rodents, rabbits and guinea pigs. Transmission only occurs when these species are kept in close contact with acutely infected swine. PRV does not infect Humans and is no a health threat to Humans.

The PRV strain we will use (Bartha strain) is a mutated strain with reduced virulence and increased survival times. There is no wild-type PRV present at any stage of preparation.

PRV Bartha causes death after 9 days (220 hours) in an inoculated mouse. PRV Bartha strain is highly neurotropic and the infected hosts suffer from neurological abnormalities. However, the severe pruritus and relatively shorter time to death by infection with wild-type strains of PRV, coupled with the barely detectable infection of the central nervous system, suggests that the fatal outcome of virulent infection is more a result of the host immune system response, or peripheral nervous system injury, rather than the result of fatal viral encephalitis.

There are three known independent mutations contributing to the reduced virulence of our PRV vector (Bartha strain):

Point mutations within UL21, a signal sequence mutation in the UL44 (gC) gene and a 3-kb deletion encompassing US8 (gE), US9 and a large portion of US7 (gI) and US2. Deletion of US8, US7 and US2 also make PRV Bartha completely defective for anterograde transneuronal spread and therefore a highly specific tool for retrograde tracing.

In addition, the PRV Bartha that we will use has been made conditional replication-deficient: an artificial exon has been inserted inside the coding sequence of the thymidine kinase gene, and is flanked with loxP and lox2272 sites (expression controlled with the double-floxed inverted open reading frame system). Therefore, the PRV Bartha strain that we are using replicates only in cells expressing Cre or in cells expressing thymidine kinase (like PK15). These attenuated features enabled PRV-Bartha suitable for tracing studies because they penetrate further into neuronal circuits due to increased host survival time. Classified as class 2 GM and group 2 SAPO pathogen.

HSV-1 H129 strain:

HSV-1 is a human virus, common in the general population. The classic presentation of primary HSV-1 is herpes gingivostomatitis, usually mild (10% of cases can be severe). Reactivation of latent infection results in fever blisters or cold sores, usually on the face and lips which crust and heal within a few days. In rare cases, HSV-1 can lead to meningoencephalitis with high mortality rate if left untreated.

In the context of this work, we are using a modified version of the HSV-1 H129 strain, in which Herpes Thymidine Kinase (HTK), required for replication, has been inactivated and its coding sequence has been replaced with a Cre-dependent loxP-STOP-loxP-tdTomato-2A-TK cassette via homologous recombination using a codon-modified form of HTK to prevent recombination within the coding sequence. Therefore the HSV-1 H129 virus we are using replicates only in cells expressing cre or in cells expressing thymidine kinase (such as Vero cells that will be used to grow more virus). Classified as GM class 2.

Origin & function

We will use lentivectors to express recombinant proteins or shRNA under the control of cre recombinase. The wild type or mutant sequences used for overexpression and knockdown studies will be derived from the rat or mouse.
genome and obtained through a non-profit plasmid depository (addgene) or through collaborators. Genes to be studied include, but are not limited to: TSC1, TSC2, mTORC1, p70 S6kinase 1. These proteins are implicated in cell growth, differentiation and are expected to have little effects on adult neurons. In the tracing studies, the genetic material involved will enable the expression of TK (PRV Bartha) or HTK (HSV-1 H129) replication genes upon cre recombination, as well as reporter proteins (HA), red (Sea anemone) or green fluorescent (jelly fish) proteins in infected neurons that will be used as tracers.

Evaluation of foreseeable effects

All the genetic material to be inserted through the use of lentivectors regulate the activity of signalling pathways associated with cellular metabolic sensing, and is non pathogenic and non hazardous. In addition, expression is limited to cre positive cells and will always be restricted to small neuronal subpopulations within discrete brain areas. Animals infected with our lentivectors will not create risks above those presented by the properties of the starting viral lentivectors. In the case of tracing vectors, non pathogenic and non-infectious reporter proteins (Ha, green or red fluorescent markers) will be expressed, as well as replication genes. None of these genetic modifications are expected to be biotoxic, oncogenic, or increase the risk level of the viral vectors. None of the inserted genetic material is harmful or would express gene products that would be secreted or released upon cell death and cause harm to humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All studies will only be performed by supervised, trained and informed personnel with daily access to SOP and risk assessments. All in vivo viral injections will be performed in line with Level 2 Containment requirements. Viruses will only be handled in a microbiological safety cabinet. Brain viral injections will be performed in a Class I or Class II microbiological safety cabinet. Sharps will not be used with the virus at any point during the surgery and viral vectors will be delivered via cannula after preparatory surgery. Tubes containing unused reagent will be discarded at the end of the experiment as below. Specific disinfection and inactivation methods and waste procedures will be performed as described below. 3rd generation lentivectors do not replicate, stay in the group of cells initially infected (in our experiments, subgroup of neurons expressing Cre in a discrete brain area) and are not excreted. HSV1 is not airborne and is not shed (information obtained through personal communication with the Dr Lynn Enquist, world expert on alpha herpes viruses). Therefore, both of these viruses are contained within infected animals and the risk of contamination through the air, the cage, bedding, saliva or faeces/urine is effectively zero (see below). Therefore we will house these animals in ventilated rooms that are not HEPA-filtered and not a negative pressure, and treat bedding and cages as non contaminated. Infected animals will be maintained in individually ventilated cages, in a locked animal facility with restricted access and isolated from other activities. Suitable protective clothing will be worn (including mask, gloves and overshoes) and animals will always be handled in a class I microbiological safety cabinet. Animals will be sacrificed by fixative perfusion that inactivates the viruses and carcasses will be incinerated. In the event that animals are not fixed, carcasses will be autoclaved on site and incinerated. PRV Bartha studies:

In addition to the containment measures described above, the following specific containment measures will be taken for PRV bartha studies, in accordance with Defra regulations. All in vivo work will be performed in the SAPO designated site under a DEFRA licence with DEFRA CL2 containment measures. All in vivo viral injections of lentivectors will be performed in a class 1 Microbiological Safety Cabinet within a Level 2
Containment Facility. Only trained personnel will have access to infected cages and animals. All staff working with this specific virus will be trained, have daily access to all SOPs related to these reagents, and properly supervised, and not have contact with swine and ruminants for at least 48 hours after working with the PRVBartha virus. In addition, all work will be performed with application of the principles of good microbiological practice and GOSH.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All culture fluids will be treated with 1% Virkon for 30 minutes to 1 hour, autoclaved and disposed to drains. Safety cabinet, bench surfaces and tools will be cleaned with a 10% Virosol solution and 70% ethanol. Spills will be sprinkled with Virkon powder and Vernagel to solidify. All in vitro and surgical solid waste will be collected in double autoclave plastic bags or adequate containers, sealed with autoclave tape, labelled with the user's name and the room number and autoclaved on site before incineration. Surgical tools will be sprayed with virosol and soaked in 70% Ethanol, dedicated the 1 type of virus and not used for other purposes. Carcasses of perfused fixed animals will be double bagged and disposed of by incineration. Carcasses of nonperfused animals will be double bagged, autoclaved and incinerated. Because HSV1 and lentivectors are not shed, all solid animal waste (bedding, faeces etc…) will be treated as non contaminated. For animal experiments with PRV Bartha, cage waste (bedding, faeces etc..) will be autoclaved before disposal by incineration. Carcasses will be fixed and incinirated. IVC cages and water bottles will be autoclaved before re-use and dedicated to PRV experiments.

## Project Additional Information

**Purposes of the contained use**

Glucose homeostasis. Specifically, this work will characterize neuronal metabolic-sensing pathways implicated in the regulation of energy and glucose homeostasis, and decipher the neuronal circuits activated downstream from metabolic sensing neurons to regulate metabolic functions. We will use lentivectors to alter the activity of metabolic sensing pathways in discrete areas of the central nervous system, and neuronal tracing vectors to map the networks implicated in metabolic sensing.

**LENTIVECTORS**

To investigate the role of known or candidate metabolic-sensing pathways, we will use lentivectors to express relevant transgenes, shRNA and sgRNA/Cas9 to bidirectionally alter the cellular activity of these candidates (overexpression or knockdown) in anatomically and/or neurochemically discrete neuronal populations in vivo or in cell cultures. This will enable us to directly test the role of these pathways in metabolic functions in vivo and gain considerable understanding of the metabolic mechanisms underlying neuronal metabolic sensing. Lentivectors present several advantages compared to alternative gene delivery strategies. They can infect non-dividing cells, and DNA is integrated into the host genome, which enables lineage studies. The immune response in target cells is low, and specific strategies are available to increase tropism. Last, lentiviral backbones enable the insertion of large DNA fragments. The metabolic-sensing pathways of interest include the mTORC1 signalling pathway; proteins whose expression may be up- or down regulated include, for example: TSC1, TSC2, mTORC1, p70 S6 kinase 1, Raptor,
Rheb1, rictor. Following cell-specific modification of the activity of these candidate metabolic-sensing proteins, we will characterize the metabolic consequences using measurements that will include food intake, body weight, adiposity, energy expenditure, glucose tolerance and insulin sensitivity. This work has already been notified to the HSE (19-06-2014, ref GM 170). Here we are introducing new host systems (new immortalized cell lines and primary cultures) and new lentiviral expression platforms, and we propose to perform part of the lentiviral packaging in house.

TRACING VECTORS

To map the network of neuronal connections implicated in metabolic sensing, we will use a cre-activable monosynaptic retrograde viral tracer (RVdG) that expresses fluorescent proteins in infected neurons. This tool is unique in its ability to travel in a specific direction within the neuronal circuits and stop after 1 synapse, which makes them reliable tools to perform neuronal mapping studies. We will use this tracer in transgenic mice expressing CRE in relevant neurochemical subpopulations of the brain and expose these neurons to various metabolic inputs. This will enable us to gain considerable understanding of the organization of the brain circuits implicated in metabolic sensing and the regulation of glucose and energy balance.

The tracing system described here relies on the use of 3 vectors:

1- AAV-FLEX-H2B-GFP-2A-oG, expressing green fluorescent protein (GFP) and the modified rabies Glycoprotein oG in a cre-dependant manner (FLEX cassette).

2- AAV-FLEX-EGFP-TVA, expressing enhanced GFP (eGFP) and the cellular receptor for subgroup A avian leukemia viruses (TVA) in a cre-dependant manner.

3- EnvA pseudotyped Glycoprotein (G)-deleted rabies virus (EnvA+RVdG-dsRed), a modified rabies virus. In EnvA+RVdG-dsRed, the rabies glycoprotein G is deleted, which makes this virus unable to propagate from infected cells. In addition, EnvA pseudotyping makes the virus unable to infect cells unless they express the TVA receptor, not expressed in mammals.

These vectors will be used to characterize neurocircuits implicated in metabolic sensing and label monosynaptic inputs going to a neurochemically-defined subgroup of neurons.

In WT animals, all constructs administered alone or in combination will have no biological effect, as cre recombinase is required for the expression of the inserted genetic material in the AAVs, and EnvA+RVdG-dsRed can not infect mammalian cells and is propagation incompetent.

In transgenic animals expressing cre recombinase, the genetic material inserted in each construct is not expected to have any biological action if vectors are administered separately.

Co-administration of AAV-FLEX-H2B-GFP-2A-G and AAV-FLEX-EGFP-TVA in Cre-expressing animals will induce the expression of TVA receptor and a modified rabies glycoprotein, oG, but is not expected to have any biological effect in the absence of rabies virion.

Biological action will occur only in the presence of the 3 viruses: cre-expressing cells expressing TVA will be infected by the RVdG virus, and if they co-express oG (cells will have to be coinfected with the 2 AAVs), RVdG will spread to cells projecting to the first infected cells in the retrograde manner. In the second-order cells, oG will not be present, and therefore RVdG will not spread further.

We will use the combination of the 3 vectors in animals expressing cre recombinase in small neuronal population of the mouse brain (3000 to 10000 cells will express Cre) and therefore, the number of infected cells will be extremely limited.

Plasmids will be propagated using standard laboratory chemically competent E. coli strains (DH5alpha, STBL3) in rich-medium liquid shaking cultures (200 mL) containing appropriate antibiotics. Plasmid extraction and purification will be achieved using commercial DNA purification mini- and maxi-prep kits (Qiagen).

Packaging and production of lentiviral vector particles: The procedures will be done either in-house or by a third party
Using the established 3rd generation system, the in-house packaging will be done by coexpressing the packaging plasmids pMDLg/pRRE, pRSVREV, and pVSV-G together with the transgene vectors in HEK293T cells. Centrifugations will be performed using sealed buckets. Production and titration of AAVS and EnvA-RGdG virus high titer will be done by a third party (Cal Tech Viral Core, USA).

Transgenic reporter mice expressing the cre recombinase gene in discrete neuronal subpopulations will receive nanoinjections into restricted areas of the brain. Mice are transgenic and carry the cre recombinase gene. Not harmful to humans or the environment.

Host/vector system

LENTIVECTORS:
The lentiviral vectors used are 'pseudotyped' with VSV-G envelope protein meaning they are capable of infecting a wide range of quiescent and non-quiescent cells by an extended range of routes of transmission. They will integrate into the genomes of infected cells leading to long term gene expression and possible insertional mutagenesis. In addition, the vectors utilise the WPRE motif which current advice indicates could be oncogenic and requires handling at CL2.

However, these lentivectors are third generation and have the following biosafety features that make the risk for human health hazard very low:
- self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.
- efficient Tat-independent production of viral RNA, reducing the number of genes from HIV-1 (less than 30% of that are used in this system).
- The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev).
- The corresponding proteins are expressed from different plasmids that lack packaging signals. The packaging plasmids share no significant homology to any of the expression lentivectors, the pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus.

Health and Safety

Executive
- None of the HIV-1 genes (gag, pol, rev) are present in the packaged viral genome, as they are expressed from separate plasmids lacking packaging signals. Therefore, the lentiviral particles generated are replication-incompetent.
- Produced pseudoviral particles will carry only a copy of the expression construct.

RABIES

Two vectors will be used in this system: AAV and rabies virus. AAVs are not harmful to humans. Wild type rabies virus is a human pathogen. Here we will use the EnvA-RGdG virus, which we will obtain from the CalTech viral core in the USA. They screen routinely their cultures to ensure the absence of WT rabies virus. EnvA-RGdG has been designed to be unable to infect mammalian cells and is propagation deficient. Due to EnvA pseudotyping, infection requires the presence of TVA receptors, which are absent in mammals. Even in the presence of TVA expressing cells, EnvA-RGdG will not propagate as it will not express the rabies G protein, necessary for propagation.

Origin & function

LENTIVIRUS:
Constructs to be inserted through the use of lentivectors are expected to regulate the activity of signalling pathways associated with cellular metabolic sensing upon expression; products are non-toxic, non-oncogenic and require
production in discrete loci to exert effects on metabolism. Expressed gene might disrupt cellular energy sensing and fluxes, and in some cases lead to impairment of cellular activity, neurotransmitter release and in some cases the death of the infected cell.

The Cas9 in the lentiCRISPR vectors upon expression is non-toxic, non-oncogenic and has negligible non-specific nuclease bioactivity unless co-expressed with targeting sgRNA.

**RABIES**

The inserted genetic material will allow, upon cre recombination, the expression of:

1. TVA, the cellular receptor for subgroup A avian leukosis viruses,
2. oG, a modified rabies glycoprotein, and
3. fluorescent proteins.

These constructs will not cause harm to humans as their expression is conditioned to the presence of cre recombinase. In the event of cre leakage, no pathogenicity is expected to arise from the TVA and oG proteins alone.

**Evaluation of foreseeable effects**

**LENTIVECTORS:**

Health and Safety

Executive

None of the genetic modifications under study are expected to release biotoxic products, or increase the risk level (pathogenicity, oncogenic potential) of the starting viral vectors. The risks for human health are not above the ones associated with the starting vectors. No expressed gene products will be secreted or released upon cell death that would cause harm to humans.

**RABIES**

Animals expressing Cre-recombinase and infected with the 3 vectors will express, in discrete cell subpopulations, the TVA receptor and oG and be exposed to RgdG. Therefore rabies infection and spread will occur. However, because we will use cre-reporter mouse models where only small populations of cells express cre, the second-order infected cells will most likely not express G and therefore virus spread will stop.

In the event of cre leakage, TVA and oG may be expressed in a larger cell population, and in the presence of RgdG, rabies will infect a larger cell population and spread to their first-degree synaptic input. However, only small brain nuclei will be exposed to the viruses as we will perform nano-injections in the discrete regions of the brain parenchyma, and therefore spread of the virus will remain contained within this small brain area and their first-order synaptic input.

Potential generation of propagation competent rabies virus could occur in the event of recombination between the viral RNA and oG RNA produced from the oG AAV virus. However, recombination in (-)RNA viruses has not been documented previously, and experts consulted about this question consider it is impossible. Therefore, the likelihood of propagation competent virus being recovered is virtually nonexistent.

However, to maintain control over the RgdG vector, CL2 control measures including restricted access and safe storage will be put in place.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All studies will only be performed by supervised, trained and informed personnel with daily access to SOP and risk assessments.

LENTIVECTORS.

All in vivo viral injections will be performed in line with Level 2 Containment requirements. Viruses will only be handled in a microbiological safety cabinet. Brain viral injections will be performed in a Class I or Class II microbiological safety cabinet.
cabinet. Sharps will not be used with the virus at any point during the surgery and viral vectors will be delivered via cannula after preparatory surgery. Tubes containing unused reagent will be discarded at the end of the experiment as below. Specific disinfection and inactivation methods and waste procedures will be performed as described below. 3rd generation lentivectors do not replicate, stay in the group of cells initially infected (in our experiments, subgroup of neurons expressing Cre in a discrete brain area) and are not excreted. HSV1 is not airborne and is not shed (information obtained through personal communication with the Dr Lynn Enquist, world expert on alpha herpes viruses). Therefore, both of these viruses are contained within infected animals and the risk of contamination through the air, the cage, bedding, saliva or faeces/urine is effectively zero (see below). Therefore we will house these animals in ventilated rooms that are not HEPA-filtered and not a negative pressure, and treat bedding and cages as non contaminated.

Infected animals will be maintained in individually ventilated cages, in a locked animal facility with restricted access and isolated from other activities. Suitable protective clothing will be worn (including mask, gloves and overshoes) and animals will always be handled in a class I microbiological safety cabinet. Animals will be sacrificed by fixative perfusion that inactivates the viruses and carcasses will be incinerated. In the event that animals are not fixed, carcasses will be autoclaved on site and incinerated.

### Project Additional Information

#### Purposes of the contained use

The aim of this work is to:

i) optimise a protocol to knock-down the gene encoding Steroid Receptor Coactivator (SRC)-1 in cells using an shRNA delivered by an adenoviral vector. This experiment will test the optimal multiplicity of infection (MOI), and the number of treatments required to maintain gene knock-down for the duration of the experiment proposed in part ii) (11 days).

ii) we propose to use this protocol to knockdown SRC-1 in 3D co-cultures of primary human hepatocytes, stellate cells and Kupffer cells (this work will be conducted at the premises of a Cambridge-based biotechnology company (CN Bio Innovations Ltd)). In the company’s prior experience, these cells are prone to toxicity when lipid-based transfection reagents such as lipofectamine are used. In their experience, the adenoviral vector serotype 5 has been well tolerated in these cells. We therefore propose to use the same vector backbone for our work.

#### Recipient or parental organism

**Human Hepatic Cell Lines: HepG2, LX-2, THP-1 Cells**

We plan to introduce shRNA expression cassettes with adenoviral vectors into these well characterised (ACDP Hazard Group 1) cells lines to downregulate expression of SRC-1.

#### Host/vector system

Recombinant human adenovirus subtype 5, genetically modified by deletions which remove the E1 and E3 expression cassettes, thereby rendering it non-replicative and reducing the risk of harm to human health.

#### Origin & function

Replication defective viral vectors will be purchased from Vector Biolabs (Pennsylvania, USA), and will contain the following genes:

**SRC-1 shRNA**: Small inhibitory RNA sequence used to inhibit the SRC-1 gene. We will test whether knock-down of SRC-1 can induce accelerated fibrosis in a multicellular liver model.

**eGFP**: This is a constitutively fluorescent protein with an excitation / emission spectrum of 488 / 509 nm. Detection of eGFP in cell types will be indicative of successful viral transduction, and will serve as a control.

#### Evaluation of foreseeable effects

Adenoviral transmission is via the aerosol route - all work will be undertaken in class II biological safety cabinets, thus minimising the risk of aerosol-mediated infection. Further, this vector contains a deletion of the E1 gene, rendering it replication defective in humans, plants and animals, and hence of low risk to human health and environmentally safe.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Once an experiment has been completed, all disposable culture and lab ware will be disposed of in double autoclave plastic bags, which should be duly sealed with autoclave tape, labelled with the user's name and tissue culture room number, autoclaved and subsequently incinerated. All liquid waste will be treated with 10% Chemgene before autoclaving and incineration as above. All surfaces, tube racks and pipettors will be wiped with solution of 10% Chemgene and 70% ethanol.
All solid waste will be autoclaved in the laboratory building and then incinerated in the Addenbrooke's Hospital incinerators. Autoclave cycles will be adjusted to type and amount of waste and a systematic record of cycles will be kept on site. Methods give effectively 100% kill. Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project has been reviewed by the Institute of Metabolic Science's biological and genetic modification safety committee, and we are satisfied that the risk assessment is accurate and that the work will be carried out under the appropriate conditions.

Project Additional Information

Purposes of the contained use

There is evidence that neurodegenerative disease and obesity are epidemiologically linked suggesting shared mechanisms, but the cell types and molecular pathways underlying these connections remain poorly understood. Several of the disease-relevant cell types can be produced in vitro from human pluripotent stem cells (hPSC), but the chemical (e.g. directed) differentiation of these cells frequently produces mixed populations that may contain only a small fraction of the intended cell types. The forced expression of candidate genes, often transcription factors but also including RNA binding proteins, microRNAs (miRNA), and other genetic elements may "forward program" hPSCs and other somatic cell types into the cell type(s) of interest with greater speed, efficacy, purity, and maturity, facilitating downstream studies of cellular function in health and disease by functional and molecular characterisation. These benefits are particularly acute when target cell types are rare, which is true of the extreme diversity of cell types present in the brain. Other cell types of relevance to metabolic and neurodegenerative disease modelling include non-neural cell types that are difficult to produce and study in any other way, and that have no suitable counterpart in animal models. Once produced, the gene expression of target cell populations can be manipulated using gene overexpression, RNA-mediated knockdown techniques, or gene editing techniques such as the CRISPR/Cas9 system, zinc fingers (ZFNs) or transcription activator-like effector nucleases (TALENs). The CRISPR/Cas system consists of two main components: the guide RNA (gRNA) and a Cas protein. Most often, this consists of Cas9 protein from Streptococcus Pyogenes. The gRNA consists of a scaffold domain that associates with Cas9 protein, as well as a unique short oligonucleotide sequence that facilitates binding of the Cas9-gRNA complex to a complementary DNA sequence. The unique RNA sequence and constant scaffold domain can be synthetically fused into a single guide RNA (sgRNA) that can be synthesised in vitro, or expressed off of DNA constructs. If a native Cas9 derivative is used and the targeted DNA sequence contains a protospacer adjacent motif (PAM, which is NGG for Streptococcus Pyogenes Cas9), it will induce a DNA double strand break that can lead to gene knockout (CRISPR KO), which can also be achieved with the use of dual Cas9 nickase enzymes. If an enzymatically dead Cas9 (dCas9) derivative is used and fused to either transcriptionally activating or inhibiting domains, then transcriptional up-regulation (CRISPRa) down-regulation (CRISPRi or CRISPRoff), base editing, epigenetic regulation may occur without introducing DNA double-strand breaks. Gene expression can also be manipulated with small RNA molecules that reduce functional gene expression by either targeting mRNA for degradation or reduce translation, including the RNA interference (RNAi) mediators small interfering RNA (siRNA) or short hairpin RNA (shRNA), and miRNA. The CRISPR/Cas system requires both the sgRNA and Cas9 or dCas9 derivative to be expressed to be functional. These can be expressed from a single DNA or viral vector, or the Cas9 complex can be engineered into a cell line and the sgRNA delivered by transient transfection or a viral vector for greater safety and efficacy. Both approaches will be utilised throughout the project depending on experimental needs, and cell lines stably expressing Cas9 or Cas9 derivatives will be utilised wherever possible. The use of viral vectors throughout these experiments provides several advantages, such as the ability to screen large pools of candidates rapidly and the potential to create stable lines in safe harbour loci. Candidate genes targeted for knockout or knockdown studies in disease relevant cell types will be shortlisted based on the current literature and genetic studies suggesting a role for these genes in the onset and progression of diseases such as obesity and neurodegeneration. For example, genes associated with cilia formation and function (e.g. BBSome proteins, IFT88, Kif3a), cell signalling (KSR2, LEPR, NTRK2, PCKS1, PCKS2), metabolic pathways (HMGCR, HACD2), transcription factors (SREBF2, TBX3) and others have been implicated in obesity phenotypes and will be shortlisted for gene misexpression to study their role in disease. In this project, we aim to 1) produce relevant cell types, test for gain-of-function phenotypes, and generate reporter cell lines using integrating and non-integrating viral vectors and 2) use gene manipulation techniques to elucidate the cellular mechanisms underlying metabolic and/or neurodegenerative disease in relevant cell populations.

Recipient or parental organism

Standard disabled laboratory chemically-competent E. coli-derived bacterial strains (DH5alpha, STBL3, or similar) for plasmid propagation. Non-pathogenic to humans and animals (Hazard Group 1). The lentivirus will be produced by co-transfecting the packaging plasmids (third generation: pMDLg/pRRE and pRSV-rev or second generation: psPAX2), the pseudotyping plasmid (pMD2.G) and the lentiviral expression plasmid into a variant of human embryonic kidney 293 cells stably expressing the SV40 large T antigen (HEK 293FT). This is a cell line that has been extensively used for the optimum generation of lentivirus particles and cannot survive outside of culture or colonies nor cause disease in humans or animal hosts and are therefore considered to be especially disabled (Hazard Group 1). The lentivirus packaging and envelope plasmids
offer maximal biosafety features as described by Dull et al and Kappes et al (1, 2, 3). Sendai virus production will be outsourced to licensed companies such as Charles River Laboratories or equivalent. The recipient cells will be the following murine/rodent cells and human cells in culture: Human induced pluripotent stem cells (hiPSCs) and derived cell lines
•Human embryonic stem cells (hESCs) and derived cell lines
•Primary cell lines (including fibroblasts, astrocytes, and blood-derived cells and others)
•Immortalised cell lines (including HEK293T and others)
Rodent:
•Embryonic fibroblasts (MEF)
•Primary cell lines (including fibroblasts and others)
The various human and/or rodent cell lines used in this project will be only handled within a Class 2 microbiological safety cabinet in a Containment Level 2 laboratory (risk assessment under COSHH regulations for adventitious agents). Immunologically non-self cells cannot survive or establish in humans with normal functional immune systems. Especially disabled (Hazard Group 1).
Other cells are well characterised cell lines that have been/will be acquired from commercial or non-profit repositories.

Host/vector system

Lentivirus System.
The pMD2.G envelope plasmid is used for both 2nd- and 3rd-generation packaging systems and is gift from Didier Trono (Addgene plasmid # 12259 ; http://n2t.net/addgene:12259 ; RRID:Addgene_12259). The psPAX2 2nd generation packaging plasmid is gift from Didier Trono (Addgene plasmid # 12260 ; http://n2t.net/addgene:12260 ; RRID:Addgene_12260). The 3rd generation lentiviral packaging plasmids pRSV-rev (Addgene plasmid # 12253 ; http://n2t.net/addgene:12253 ; RRID:Addgene_12253) and pMDLg/pRRE (Addgene plasmid # 12251 ; http://n2t.net/addgene:12251 ; RRID:Addgene_12251) are both gifts from Didier Trono(1). The pLIX_403 lentiviral platform system is a human immunodeficiency virus type 1 (HIV-1)-based lentivirus system compatible with both second- and third-generation packaging systems and is a gift from David Root (Addgene plasmid # 41395 ; http://n2t.net/addgene:41395 ; RRID:Addgene_41395). The all-in-one lentiCRISPR v2 lentiviral platform is compatible with the same packaging systems and is a gift from Feng Zhang (Addgene plasmid # 52961 ; http://n2t.net/addgene:52961 ; RRID:Addgene_52961) (2). The pKLV-U6gRNA lentiviral platform and related derivatives modified to accommodate two gRNAs is compatible with the same packaging systems and is a gift from Kosuke Yusa (Addgene plasmid # 50946 ; http://n2t.net/addgene:50946 ; RRID:Addgene_50946)(3). These platforms have since been used in multiple studies by different academic laboratories in the UK and other countries. Importantly, it includes the following key features engineered for maximal biosafety (4,5):
-It uses only a fractional set of HIV genes. All of the four accessory genes (vif, vpr, vpu, and nef) which are not crucial for viral growth in vitro but are critical for in vivo replication and pathogenesis have been deleted.Importantly, the two regulatory genes essential for viral replication (tat and rev) have also been deleted from the lentiviral transfer vector.
- The-vector's self-inactivating design (SIN) deletes the viral transcriptional promoter and enhancer elements thus further minimising the risk for generating a replication-competent virus and may reduce the risk of tumorigenesis via promoter insertion (6).
- The HIV-derived constructs, and any recombinant between them, are contingent on trans complementation and upstream regulatory elements and thus are non-functional outside of the producer cells.
- The virus particles are pseudotyped with the heterologous fusigenic envelope glycoprotein of the vesicular stomatitis virus (VSV-G, also supplied in a separate plasmid) in place of the native HIV-1 protein. While this extends the tropism and transmission routes of the vector, it was found that lentivirus pseudotyped with VSV-G are rapidly neutralised by the immune responses triggered by the complement system in humans (7).
- The enhancer of transgene expression derived from the woodchuck post-transcriptional regulatory element (WPRE) and located at the 3' untranslated region of lentivectors has been truncated and does not contain an open-reading frame for the WHV X-protein (in addition to containing only a portion of the X coding sequence, both the naturally-occurring start and termination codons have been mutated). This safety feature is not present in the pKLV-U6gRNA vector, as this vector lacks a WPRE and does not produce a poly-adenylated transcript.
Both second and third generation packaging systems will be used in this project. These systems differ principally in their division of the gag, pol, and rev genes. In...
third-generation systems, rev is on one plasmid while gag and pol are on another. While this nearly eliminates the risk of producing a replication-competent virus, it also reduces the titre and efficiency of the packaging process. In second generation systems, all 3 genes are on a single plasmid, allowing them to be expressed at a near-optimal ratio. This greatly increases the titre and efficiency of packaging, allowing for less virus to be used during transduction. Third generation packaging systems will be used in the first instance; however in cases where using the third generation system negatively impacts the nature of the research due to low efficiencies and low virus titres, the second generation packaging system will be used. While the second-generation system could lead to an increased risk of producing a replication-competent virus, this risk remains very small. This split-genome, conditional packaging system acts as a built-in biosafety device as it prevents the generation of replication-competent recombinants (RCR). The system conserves only three of nine genes of HIV-1 and relies on three or four separate transcriptional units (see above) for the production of transducing viral particles. As the vector particle packages only the genetic information contained in the transfer vector, infection is limited to a single round without spreading. The probability of a series of recombination events that would produce a replication-competent virus that can spread between hosts is negligible. Furthermore, given that these lentiviruses are replication-incompetent in mammalian cells and unable to infect plant cells the risk of spreading is effectively null.

The deltaF-TS Sendai virus system.

These recombinant viruses derive from the Sendai virus which belongs to the Paramyxoviridae family. Sendai virus are enveloped viruses with a nonsegmented negative-strand RNA genome which are not capable of integration in the host genome. DeltaF/TS Sendai viral vectors to be used have had the F gene deleted and encompass specific mutations in the HN and M genes. DeltaF/TS Sendai virus is capable of intracytoplasmic self-replication, leading to the formation of non-transmissible viral-like particles (NTVLP), but is incapable of infecting neighboring cells since progeny lack the F protein, which is one of the endogenous envelope proteins necessary for transmission. The F protein is incorporated in trans during the production of the vector viruses. Importantly, Sendai virus vectors are not likely to generate wild-type virus in a packaging cell line, since homologous recombination between RNA genomes has not been observed in nonsegmented, negative-strand RNA viruses. In addition, the temperature sensitive (TS) HN and M proteins strongly inhibit the production of NTVLP in transduced cells at 37°C. Consequently, DeltaF/TS Sendai can be maintained during several passages in transduced cells without being infectious. Notably, the DeltaF/DS Sendai virus tends to disappear from proliferative cells after several passages since its capacity of replication is limited (1); moreover, previously infected cells that no longer contain the DeltaF/TS Sendai viral genome can be purified using antibody-mediated depletion as described in (1) and the absence of Sendai virus can be validated using PCR to detect the Sendai viral genome or transgene expression. Importantly, this system has been used extensively to generate iPSCs free of genetic modifications and free of viruses (1,2).

DeltaF/TS Sendai virus will be used in the context of reprogramming cell fate and gene overexpression studies. Indeed, such vectors have been proved to be a robust and efficient strategy for reprogramming cells to pluripotency in the literature. The DeltaF/TS Sendai virus vectors will encompass all the coding sequences for the selected transgenes or small RNA molecules used for reprogramming.

### Origin & function

The expression of genetic elements from viruses will be used to 1) alter cell state in order to test for phenotypes related to disease, 2) generate stable reporters, and/or 3) alter cell identity. To ensure the safety of these studies, we will not over-express oncogenes or knock out tumour suppressor genes whose loss is known to cause cancer.

1. To better understand the function of candidate genes in metabolic disease or neurodegenerative disease, we will over-express, knock down, or knock out their function. These genes to be tested have been identified in genomewide association studies (GWAS), or genetic sequencing studies, and/or transcriptional studies of relevant celltypes

02/03/2022

Page 4388 of 15326
and tissues.
2. To generate stable cell lines, genetic elements such as fluorescent reporters will be introduced via lentiviruses into the genomes of hSPCs and other mammalian cell types.
3. To program cell identity, we will use genetic elements that have either been used in the literature, or have been identified to be differentially expressed and/or differentially active in those cell types to ensure cell-type specific differentiation.

**Evaluation of foreseeable effects**

1. Inactivation or over-expression of target genes:
   We expect some selected genes to produce phenotypes relevant to disease, ranging from cell death to minor changes in morphology and/or gene expression, to no detectable effect in control experiment. We do not expect to observe uncontrolled cell growth as we will avoid oncogene overexpression. Therefore, the cells undergoing these genetic perturbations will have a selective disadvantage over wild-type cells.

2. Generation of stable cell lines:
   We do not anticipate biological actions beyond expression of the reporter gene that would render the cells dangerous in any way to human health.

3. Programmed cell identities:
   Typically, cells will be programmed into a post-mitotic state (e.g. neurons) that are incapable of further division. In this case, we would expect to see the loss of mitotic activity and acquisition of neuron-like morphological and transcriptional properties. We will also seek to generate other cell types capable of mitosis such as astrocytes and tanycytes, but as stated above we will avoid working with oncogenes and tumour suppressor genes. These cell types may continue to divide, but will also acquire morphological and transcriptional properties relevant to the target cell population. Reprogramming cells to a pluripotent state will only be performed using non-integrating viruses. Reprogramming is not expected to confer any selective advantage to reprogrammed cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All disposable culture/lab ware will be collected in double autoclave plastic bags, sealed with autoclave tape, labelled with the user's name and the tissue culture room number and will be autoclaved before incineration. 100% kill. All culture fluids will be treated with a solution of 5% Chemgene for 30 minutes, autoclaved and disposed to drains. All surfaces (bench/cabinet), tube racks, and pipettors will be wiped with a solution of 5% Chemgene and 70% ethanol. Spills will be cleaned with 5% Chemgene and 70% ethanol. All solid waste will be autoclaved in the Institute and then incinerated in the Addenbrooke's Hospital incinerators. Autoclave cycles will be adjusted for liquid or solid waste and a systemic record of cycles will be kept on site. Methods give efficiently 100% kill.

N

**If yes, tick to confirm that it is attached to this form**

N

**Tick to confirm that you have attached a risk assessment to this form**

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N

The project will be reviewed by the Institute of Metabolic Science biological and genetic modification Safety Committee, and work will not commence until they are satisfied that the risk assessment is accurate and appropriate.
The nuclear hormone receptor PPARg (peroxisome proliferator-activated receptor gamma) is a ligand inducible transcription factor involved in a number of biological processes, including fat cell differentiation, glucose homeostasis and atherogenesis. A number of PPAR-specific agonists, including naturally occurring fatty acids and prostaglandin J2 and synthetic anti-diabetic thiazolidinediones have been identified and shown to be useful tools for investigating the effects of PPARg stimulation in vivo. For example, thiazolidinediones accelerate differentiation of cultured preadipocytes into adipocytes, activate monocytes and increase leptin secretion from cultured trophoblasts. The effects of PPARg inactivation are poorly understood however. Animal studies using PPARg knockout mouse has been hindered by lethal phenotype and no antagonist ligand have been described. Patients harbouring loss-of-function PPARg mutations exhibit varying degrees of lipodystrophy and insulin resistance. In order to study the function of such mutant PPARg, they will be expressed in mammalian cells using a lentiviral expression system. A major advantage of the lentiviral system is
the possibility to infect most cells from different species.

Recipient or parental organism

A 293 producer cell line will be used to generate the virus particles. Initially, we will analyse the effect of the mutants on the differentiation of murine 3T3-L1 preadipocytes in response to PPARg ligands. Subsequent experiments will address the effects on human preadipocyte and other relevant cells.

Host/vector system

A 293 producer cell line will be transfected with the gene of interest constructs and three plasmids each containing different and necessary proteins for virus formation will result in the generation of the viral particles. These three different plasmids used are CMV 8.9 (gag, pol and tat); pRSVrev (rev); pCMV-VSV-G (VSV-G). Only the pHR'CMV-GFP vector containing the gene of interest contains packaging signals and this will result in lentiviral particles which are replication incompetent and only carry the gene of interest. All cloning and lentiviral vectors lack sequences for prokaryotic expression.

Expression of PPARg and GFP are driven by the CMV promoter which is active in most mammalian cell types. The lentiviral particles are replication incompetent and only carry the gene of interest and GFP.

Origin & function

The human nuclear hormone receptor PPARg is a ligand inducible transcription factor involved in a number of biological processes, including fat cell differentiation, glucose homeostasis and atherogenesis which can be analysed in the appropriate cell lines.

Evaluation of foreseeable effects

Neither GFP nor wild type or mutant PPARg are recognised oncogenes, so work with these lentiviral constructs is not expected to pose a cancer risk.

Expression of PPARg and mutants will lead to differences in gene expression in mammalian cells. This will be evaluated by analysing differences in predipocyte differentiation and gene expression patterns.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated for 24 hrs with 2% Virkon or Presept tablets before disposal into the laboratory drainage system. Alternatively disinfected waste will be gelled with Vernagel in sealed containers and removed for incineration. Solid waste such as plastics will be double bagged before transfer to a waste autoclave within the building, and then disposed of by incineration on site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The project has been reviewed by the CIMR Biological and Genetic Modification Safety Committee, and we are satisfied that the risk assessment is accurate and that the work will be carried out under the appropriate conditions.

Adenoviral and/or Lentiviral over-expression and siRNA knock-down of reporter constructs and genes to investigate stimulus secretion coupling in enteroendocrine cells in tissue culture

**Class** Class 2

**Culture Volume** Class 2 ≤ 1 Litre

**Consent** Non-GMM Consent Granted

**Project notified under transitional arrangements** N

**Historical Significant Changes**

Transferred from GM678 on 28/07/2014

**Project Additional Information**

Purposes of the contained use

Hormones such as glucagon-like peptide 1 (GLP-1), and glucose-dependent insulino tropic polypeptide (GIP) play key roles in postprandial nutrient homeostasis, but little is...
known of the molecular mechanisms underlying and regulating their release from enteroendocrine cells. Enteroendocrine cells lie scattered throughout the gut epithelium and at least 16 different types, classified by the secreted hormones, have been defined, amounting together to about 1% of the gut epithelium. While they are not readily distinguishable from the surrounding enterocytes (nor from each other) by live cell microscopy, we have recently successfully labeled enteroendocrine cells by expressing fluorescent protein markers under the control of the relevant hormone promoter either delivered as a stable transgene in mice or after adenoviral transfection of mixed gut epithelial cells in primary culture.

We now wish to further investigate the stimulus secretion coupling in these cells using:

(a) fluorescent sensor probes allowing live monitoring of intracellular concentrations of a range of different cell components. Initially we will focus on 2nd messengers such as cAMP and nutrients such as glucose, for which probes based on fusion proteins with fluorescent proteins have been described in recent literature. To achieve the necessary high delivery efficiency for the targeting of a minor cell component in our mixed epithelial cultures, we will initially use adenoviral transfection, which we have used successfully before. Should the lentiviral work (see below) prove more efficient, we will swap the vector system.

(b) Knock-down and/or overexpression of candidate genes. Selection of candidate genes will be guided by expression analysis; having labeled hormone specific subpopulations of enteroendocrine cells with fluorescent marker proteins has enabled us to isolate relatively pure populations of these cells by fluorescent assisted cell sorting. So far we have performed Affymetrix gene expression analysis on glucagon gene expressing L- and pancreatic α-cells, GIP expressing K-cells, and corresponding unlabeled cells from the surrounding tissues (including insulin-expressing pancreatic β-cells), allowing us to identify for example K-cell or L-cell enriched genes. To address their role in enteroendocrine cell physiology, we wish to overexpress and knock-down these genes. As many commercially available shRNA are provided in a lentiviral vector system, we will first investigate if this is suitable to target enteroendocrine cells in culture, using fluorescent marker proteins. As lentiviral vectors have been successfully used to target related endocrine cells, such as pancreatic β-cells, there is a high likelihood for this to succeed. We will then target other genes guided by the expression data from the Affymetrix array results.

(c) While the transgenic approach was successful to identify L- and K-cells in mixed epithelial cultures, we wish to investigate if stimulus secretion mechanisms identified in the murine cultures are preserved in human enteroendocrine cells. To be able to identify the enteroendocrine cells in human cultures we want to express fluorescent proteins under the control of the relevant hormone promoters. To achieve the necessary high delivery efficiency for the targeting of a minor cell component in our mixed epithelial cultures, we will initially use adenoviral transfection, which we have used successfully before in the rodent cultures. Should the lentiviral work (see above) prove more efficient, we will swap the vector system. Once we have demonstrated that we can target human enteroendocrine cells, we will also use constructs developed under (a) and (b) in the human culture system.

Recipient or parental organism

Recipients:

a) E.coli: Strains of bacteria used for initial construction and plasmid amplification are derived from E.coli K12 and are therefore disabled and non-colonising.

b) Mammalian cells: Recipients will be various mammalian cells in culture. Most are moderately well characterised (e.g. HEK293 cell, GLUTag cells) and considered fastidious and non harmful, cannot colonise/cause disease, (ACDP hazard group 1). Primary epithelial cultures established from unscreened human intestinal tissue could harbour infectious agents and should therefore be handled at containment level 2.

Host/vector system

(1) Replication disabled adenovirus vector, based on Ad5. This virus is deleted for essential replication functions (E1A region) and can only replicate in cells complementing this function (HEK 293 cell line). Naturally the virus is transmitted by aerosol to respiratory tissues from where it may infect adenoid tissue. There are no reports of other infections such as enteric/kidney. However as the vector is incapable of completing a single round of replication, no progeny virus can be produced and infection would be (self) limited to any initial cells exposed. The number if cells affected would be related to the amount of virus encountered but effects would not progress to any extent approaching natural disease. The vector is considered HG 1.

(2) Replication disabled lentivirus. Although the starting viruses like HIV themselves are hazard group 3 pathogens, vectors considered for his proposal are all second or third generation (distinguished in the UK by deletion of the tat-gene and replacement of the tat-responsive promoter in the 5’LTR by heterologous alternatives). The theoretical potential for re-emergence of replication competent virus through recombination has been significantly reduced in these vectors, by splitting the replicative, packaging and envelope functions and the desired transgene over ≥ three independent plasmids, therefore requiring multiple recombination events to generate replication competent virus. The emergence of replication competent virus is therefore unlikely and such viruses would be expected to have lost the transgene. In addition, many accessory functions/pathogenicity determinants such as vif have been deleted and they are all self-inactivating, carrying the SIN-deletion in the 3’LTR, including re-activation after integration into the host genome and as the U3 promoter is thereby compromised reducing the risk of transactivation of genes near the integration site.
But, as the constructs all carry other (usually constitutively active (eg CMV)) promoters to drive expression of the transgene this can not be excluded, nor can the inactivation of nearby genes due to integration within these genes be excluded. However, as problems arising from the insertion site have only been reported in studies involving administration of very high viral titers, the likelihood of similar problems in this study is considered low, taking into account the comparatively low viral titers likely to be administered accidentally and the defective replication and self-inactivation of the virus. As some of the commercially available vectors contain the WPRE (woodchuck hepatitis B virus post-transcriptional regulatory element) to boost viral titres and gene expression, and as this element can express an oncogene (part of the X-protein), which has resulted in increased tumor frequencies in mice, these viruses should be considered class 2. The lentiviral particles in this project will be 'pseudotyped' with vesicular stomatitis virus envelope protein G (VSVG); this increases host cell range/tropism and such vectors may represent an aerosol means of transmission in addition to the expected percutaneous risk from lentiviruses. Such viruses are more stable and can be purified to high titre. However, they are rendered sensitive to complement.

Origin & function

The expressed proteins range from fluorescent markers, such as GFP, which are unlikely to be harmful, and fusion proteins of fluorescent proteins with activity retaining protein kinase A catalytic subunit (overexpression of which might alter cell physiology, although the probe has successfully been used to investigate cAMP responses in pancreatic beta-cells, without altering their normal Ca²⁺-homeostasis or stimulant-secretion coupling) to other proteins involved in enteroendocrine physiology. Similarly the knock down targets are genes involved in enteroendocrine physiology, including, but nor restricted to, glucokinase, SGLT-1 and Kir6.2. As overexpression or knock-down of such genes is unlikely to transform infected cells and is not expected to be toxic, the risk to human health or the environment from accidental infection is considered low.

Evaluation of foreseeable effects

As constitutively active promotors are used, virtually every transfected cell will be expected to express the inserted cDNA or shRNA. The expressed proteins range from fluorescent proteins with activity retaining protein kinase A catalytic subunit (overexpression of which might alter cell physiology although the probe has successfully been used to investigate cAMP responses in pancreatic beta-cells, without altering their normal Ca²⁺-homeostasis or stimulant-secretion coupling) to other proteins involved in enteroendocrine physiology. Similarly the knock down infected cells is not expected to be toxic in context of the transfected cells nor after release of proteins from lysed cells the risk to the environment due to accidental infection is considered low. Cells will remain especially disabled and unable to survive outside of laboratory culture.

1) Adenovirus: Adenoviruses are generally species specific; Ad5 infects humans and does not naturally infect other animals (but can experimentally infect cotton tail rats, which are not endogenous in the UK). Therefore there is no risk to other organisms. The virus is replication incompetent therefore could not spread to the wider human population from any infected individual.

2) Lentivirus: VSVG enables these vectors to infect a wide variety of animal cell types including those of different mammalian species. There may be enhanced environmental stability. However the viruses are replication disabled; they cannot produce progeny virus and so cannot spread to the wider human population or other animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable tissue culture plastics will be autoclaved and incinerated. Culture medium will be treated 2% Virkon for 16 h and solidified prior to incineration. Liquid spills will be treated with 2% Virkon (non metallic surfaces) or 10% Trigene (metallic surfaces). Absorbed with paper towels, which will then be autoclaved/incinerated. Benches are cleaned with 10% Trigene.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This project has been reviewed by the Institute's Biological Genetic Safety. The Committee is satisfied that the risks have been properly addressed and the work will be carried out under the appropriate controls and conditions.

**Historical Significant Changes**

GM171/03.1 has transferred to GM470 on 18/02/2005

**Project Additional Information**
### Purposes of the contained use

This aim is to express cell signalling molecules in hormone-secreting cell lines, to examine their functional roles in hormone secretion in these cells. The tet-on inducible expression allows for control levels of expression, with activated transcription in the presence of tetracycline (Tc) or analogues.

### Recipient or parental organism

The cell lines used for packaging of the replication deficient retroviral vectors and for the expression of signalling-molecule cDNAs have a history of safe use. Alterations in the properties of the cells used in this work as a result of expression of these cDNAs will be negligible if any. The genetically modified cells are very unlikely to pose more of a hazard than the parental cell lines.

### Host/vector system

Genes of interest will be inserted into the expression vector (pRev-TRE, Clontech). Both this and the pRev-TET-on (Clontech) vector are considered as non-mobilisable. Both these vectors will be propagated in a suitable E. coli strain (e.g. DH5alpha, XL-1 Blue), which are recognised as non-colonising and disabled. The pRevTRE vector and the pRevTET-on plasmid will be independently transfected into the packaging cell line (RetropackTM PT67, Clontech), which produces viral proteins from stably integrated genes. Viral lysates will be used to infect cultured mammalian cell (PC-12, alphaTC, RINm5F, INS-1E), which do not have the ability to infect or transfer the inserted DNA to other cells.

### Origin & function

cDNAs for a number of cell signalling protein molecules, including GTP binding proteins, have been cloned. These will be inserted into the pRev-TRE expression vector (Clontech), into a site not specifically situated to facilitate expression in E. coli. It is highly improbable that the proteins will be expressed within the bacterial cells. The E. coli strains used for propagation are not considered pathogenic to humans or animals and they are expected to have a low probability of survival outside of the laboratory culture environment - they always have auxotrophic requirements which are unlikely to be satisfied outside the laboratory.

The pRevTRE vector and the pRevTET-on plasmid will be independently transfected into the packaging cell line PT67, which allows for the safe, efficient production of high titer, infectious replication-incompetent retrovirus.

Phage produced by the pRevTet-on vector will be used to establish stable Tet-On cell lines expressing the "reverse" tet repressor (rTetR). Once established, the cell line (hormone-secreting) will be infected with the pRevTRE phage containing the inserted gene sequence. Transcription of the gene will only begin upon integration into a stable (r)tTA expressing line and in the presence of Tc or the Tc derivative doxycycline (Dox).

### Evaluation of foreseeable effects

The RetroPack PT67 packaging cell line provides the genes necessary for recombinant virus particle formation: gag (core structural proteins), pol (reverse transcriptase, integrase), and env (coat glycoproteins). The recombinant virus produced by this cell line contain the products of these genes but lack the genes themselves, thus these retroviral particles can infect target cells and transmit the gene of interest but cannot replicate (replication-ioncompetence) within these cells. Retroviral production from subsequently infected cell lines is prevented. All retroviral packaging cells from Clontech have been safety-tested for replication incompetence, and a product analysis certificate accompanies the RetroPack PT67 cells.

Retrovirus such as Moloney murine leukaemia virus (MoMuLV) do not naturally infect human cells, however recombinant virus packaged from the MoMuLV-based vector described here maybe capable of infecting human cells and therefore could have deleterious effect if they were to infect a laboratory worker. The viral supernatants produced could, depending on the gene insert, contain potentially hazardous recombinant virus. Users are advised not to create retroviruses capable of expressing known or potential oncogenes.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and manipulations of cells will be performed in a Class II biological safety cabinet (identifiable to other users), preventing release of aerosols. Protective clothing, double gloves to be worn at all times.

Because of viral nature of the work, no glassware or sharps will be used, only disposable plasticware. All potential infectious waste (solutions and microbiological plates) will be de-contaminated and autoclaved prior to disposal. Due to the labile lipid-derived nature of membranes of cells etc, the use of alcohol, detergents or bleach will be sufficient for decontamination. In the event of spillage, the area will be effectively disinfected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee considered that the molecules being expressed using the retroviral vectors pose no significant risk to the people carrying out the procedures or to the environment. However because the ACDP guidelines indicate that the minimum level of containment for the use of retroviral vectors is at level 2 this work has to be carried out at this level.

Project Ref 171/04.1

Date Ackn’d 27/07/2004

CU2 Project Title Using short hairpin RNA (shRNA) genes and shRNA gene libraries to investigate

Class Culture Vol Class 2 Culture Volume Class 3-4

Class 2 ≤ 1 Litre
The aim of this work is to knock down expression of genes by introducing synthetic "genes" (random DNA sequences less than 100bp), encoding shRNA, these are processed by the cell to generate silencing RNAs (siRNAs). The siRNA leads to the degradation of the targeted mRNA and hence knockdown expression of that gene.

shRNA libraries will be used to carry out a genetic screens (when coupled with an intracellular fluorescent reporter system) in tissue cultured cell lines. The shRNA is delivered to the cells by transfection with eukaryotic expression vectors or infection with replication defective adenoviral or lentiviral vectors. This work is directed at identifying components of signal transduction pathways.

Recipient or parental organism

The shRNA library will be constructed in E. coli. The E. coli strains used for propagation are not considered pathogenic to humans or animals and they are expected to have a low probability of survival outside of the laboratory culture environment - they always have auxotrophic requirements which are unlikely to be satisfied outside the laboratory. They are considered to be ACDP group 1. shRNA libraries will also be constructed in commercially-available, replication-deficient adenoviral vectors and replication-defective lentiviral vectors.

The cell lines used for packaging of the replication-deficient retroviral vectors and for the expression of signalling-molecule cDNAs have a history of safe use. Alterations in the properties of the cells used in this work as a result of expression of these cDNAs will be negligible, if any. The genetically modified cells are very unlikely to pose more of a hazard than the parental cell lines.

Host/vector system

The shRNA library will be constructed in E. coli (ACDP group 1 strains). Commercially available eukaryotic expression plasmids with optimal antibiotic selection will be used eg pSilencer (Ambion), pSiren (BD Biosciences), pSiEx(Novagen), psiStrike (Promega). These vectors are mobilisation defective.

Plasmid or virus will be used to infect transfect the cell line of interest (eg HeLa, HEK293, nB2A, IN157, MCF-7, PC12, ES cells, and primary cells such as human macrophage and fibroblasts) (ACDP group 2).
The shRNA genes are small oligonucleotides synthesised in vitro. The shRNA genes (small, random DNA sequences) are cloned downstream of a eukaryotic RNA polymerase III promoter consequently they cannot be expressed in E. coli and not affect their pathogenicity. DNA from the shRNA libraries generated will be used to transfect/infect eukaryotic cells to carry out genetic screens. Using a promoter-specific intracellular fluorescent reporter system in eukaryotic cells, changes in the level of expression from that promoter (detected by a change in fluorescence) will indicate that a component of the signal transduction pathway has been affected by the particular siRNA expressed in that cell.

**Evaluation of foreseeable effects**

The recombinant virus particles are capable of infecting human cells and could have a deleterious effect if delivered to a target tissue. However, as the virus is unable to replicate, only the initially infected cells would be affected, making serious effects very unlikely unless the infection was massive. The packaging cell lines to be used are supplied along with the commercially available vectors and contain the genes necessary for recombinant virus particle formation. Recombinant virus produced in the packaging cell lines contain the gene products provided in trans by the packaging cells, but they lack the genes themselves. The viral particles produced by the packaging cells can infect target cells and transmit the gene of interest but cannot replicate within these cells. Virus production from cells infected subsequently is therefore prevented. (The packaging cell lines provided by commercial suppliers are safety tested for replication incompetence, and a product analysis certificate is provided).

Primary human macrophage and fibroblast cells will be used in some experiments. These will be obtained from donors outside the school and grown to only low passage numbers to avoid any risk of transformation and accidental introduction into the original donor.

The Modified E. coli and viral vectors are not hazardous to the environment and in the event of accidental release from containment are unlikely to survive and propagate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and manipulations of cells will be performed in a Class II biological safety cabinet (identifiable to other users), preventing release of aerosols. Protective clothing, double gloves to be worn at all times. Because of viral nature of the work, no glassware or sharps will be used, only disposable plastic-ware. All potential infectious waste (solutions and microbiological plates) will be either disinfected [using 2% Virkon] or autoclaved, prior to disposal via drains or incineration as appropriate. Due to the labile lipid-derived nature of membranes of cells etc, the use of alcohol, detergents or bleach will be sufficient for decontamination.

In event of spillage, the spill will be absorbed onto paper towel, the area will be effectively disinfected with Trigene (1:100 dilution) or Virkon (1:100 dilution). Towels to autoclaved prior to disposal.

Disinfectants are effective against the organisms in question. Data on the appropriateness and effective degree of kill for these detergents are provided by Brindle Microbiological Consultants (Trigene) and Antek International; a subsidiary of Du Pont International (Virkon).

The autoclave is subject to calibration and vvalidation by a service company twice yearly.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N

**Tick to confirm that you have attached a risk assessment to this form**

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
The genetic modification safety committee considered that the molecules being expressed and the vectors described post no significant risk to the people carrying out the procedures or to the environment. However because the ACDP guidelines indicate that the minimum level of containment for the use of the viral vectors to be used is at level 2, this work has to be carried out at this level. The GMSC has approved the assessment as CL 2 in respect of the work involving lentiviral vectors, though the genetic modification is unlikely to result in the production of a more harmful GMM than the parental strain.

### Project Additional Information

**Purposes of the contained use**

Investigation of expression of proteins of medical/veterinary importance in plant viruses such as Tobacco Mosaic Virus (TMV) and Potato Virus X (PVX). TMV will replicate in edible host plants such as spinach, thereby allowing assessment of the chimeric virus particles as edible vaccines.

**Recipient or parental organism**

Tobacco Mosaic Virus (TMV) and Potato Virus X (PVX). See risk assessment for specific details.

**Host/vector system**

Laboratory animals, mice and rats. See risk assessment for specific details.

**Origin & function**

In the first instance, polypeptides of 18 and 41 amino acids from the major outer membrane (MOMP) of Chalmydophila abortus expressed as a fusion with the coat protein of the plant viruses will be tested. Epitopes (peptides) from other pathogens of medical or veterinary importance may also be investigated. See risk assessment for details.

**Evaluation of foreseeable effects**

Wild-type TMV and PVX have inherently high replication error rates. Both TMV and PVX form stable rod-shaped particles in infected tissues and have wide experimental host ranges, including many members of the family Solanceae, predominantly from the genus Nicotiana. Both viruses are mechanically transmissible, with transmission by arthropods, nematodes or fungi not having been reported. PVX is neither seed nor pollen transmitted whereas wild-type TMV can occasionally be transmitted in seeds. TMV and PVX are indigenous to the United Kingdom and are not subject to legislative control; both are Class 1 organisms. Both TMV and PVX are plant viruses that are not harmful to humans or animals and are only pathogenic on their natural plant hosts.

It is not thought that the pathogen derived sequence inserted into the coat protein of the virus will increase the pathogenicity of the recombinant virus in comparison to wild-type. The modified viruses have a lower specific infectivity, replicate to lower levels, move cell-to-cell more slowly and are severely impaired or completely disabled in long distance movement.

See risk assessment for specific details.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

TMV is a member of the Tobamovirus genus. These plant viruses can be killed by 2% solution of Virkon within 1-2 hours. PVX belongs to a different genus (Potexvirus) but is of a similar structure such that virkon affects it in the same way. Recombinant virus will be handled in a Class 2 Safety Cabinet, which will be sprayed with 2% virkon solution after use and left 1-2 hours before re-use. All waste plastics and gloves will be put in double bags, the outside surfaces of which will be sprayed with 2% virkon and left for 1-2 hours prior to removal for autoclaving. All plastics used for immunisation of laboratory animals will be autoclaved as above and needles will be disinfected with 2% virkon before being disposed of into "Sharps" box for incineration. All animal waste and bedding will be disposed of in double bags and sprayed with 2% virkon 1-2 hours prior to incineration. Animals will be killed by terminal anaesthesia and carcasses disposed of in double bags and sprayed with virkon prior to incineration, as before. All surfaces will be sprayed with 2% virkon and any instruments used will be disinfected with 2% virkon 1-2 hours prior to washing and re-sterilisation.
This proposal presents a program of work aimed at testing the feasibility of producing antibodies against proteins of medical/veterinary importance by expressing epitopes from said proteins in an edible form. The proposal indicates that the parental viruses are both considered to be class 1 plant pathogens and the committee considered that the modifications made to each were unlikely to significantly increase the risk of harm either to the environment or to human health. Neither virus is considered to be a human or animal pathogen. However a question was raised over the persistence of the virus (parental or recombinant) in the environment and more details were sought about decontamination procedures. The committee also noted that the Scottish Crop Research Institute (SCRI) who are partners in the project and who produce the recombinant virus handle both recombinant viruses at level 2 containment. The committee agreed that the proposal should be forwarded to the HSE as a "level 2" project.

**Project Additional Information**

**Purposes of the contained use**

The purpose is to model particular aspects of the pathogenesis of JSRV in sheep;  
To determine which cells in the lung express the receptor which allows entry mediated by JSRV Env.  
To determine the effect of expression of JSRV Env alone on infected cells in vivo.

**Recipient or parental organism**

The pseudotyped virus consists of a JSRV envelope and murine leukaemia virus (MLV) gag and pol products encapsidating an RNA pseudo-genome, which encodes an alkaline phosphatase (AP) reporter gene and JSRV env.  This chimaeric virus contains all the components to infect a cell with the appropriate receptor, to integrate and express AP and env under the control of their respective promoters.  However, as no gag, pro or pol genes are present in the packaged RNA this virus is non-replicative and can only act in a single round of infection.  Therefore, so spread to new cells beyond those receiving the "first hit" or between animals is possible.  

The control virus, LAPSN, has a JSRV envelope, MLV gag and pol proteins and encodes expression of AP but lacks the JSRV env gene.  

It is predicted that the JSRV Env will be able to mediate infection of many cell types in the sheep.  
Expression of JSRVEnv can have transforming activity in cells in vitro.  It is not known if this will occur in vivo.

**Host/vector system**

Sheep and lambs.

**Origin & function**

MuLV Gag and pol genes are expressed in the cell line 293-GP (Clontech).  The proteins produced package the pseudo-retroviral genome and provide the enzymes to facilitate infection and integration of the genome.  

The envelope gene expressing the envelope of the pseudotyped virus will determine which cell types express a functional receptor for the virus of origin.  It is provided by an expression plasmid which is transfected into 293-GP cells.  Concomitantly the RNA pseudogenome is provided by co-transfection with plasmid pLAPN-JSLE.  This includes MuLV LTRs, Alakaline phosphatase and JSRV env genes and the appropriate packaging signal.  Detection of AP activity can be used to determine which cells have been infected by this pseudotype virus.  Expression of env will determine whether expression of env has transforming properties in vivo in the specific cells targeted by JSRV.

In the first instance JSRV Env of the same sequence as JSRV21 (Genbank Accession: AF105220) will be used as envelope for the pseudotyped virus and will be expressed from the replication incompetent genome.  Depending on the outcome of these experiments, mutations may be made to define regions important for receptor recognition and or transforming activity.  With this system the two functions of Env can be assessed independently.
### Evaluation of foreseeable effects

The GM virus will consist of RNA packaged by MLV virion and JSRV envelope, which will introduce the genome into the host cell. However, the RNA will encode only Env and alkaline phosphatase and therefore will not be able to replicate. Infection will be a "one hit event" and no further spread within the host or between hosts will be possible.

Cell attachment and entry of the GM virus will be mediated by JSRV Env. Any cell expressing the receptor Hyal-2, including human cells, could therefore potentially be infected. There are likely to be other, post-entry, blocks to JSRV infection of human cells, but this has not been studied. JSRV env will be under the control of the JSRV LTR, as it is in wild type JSRV. This will restrict expression to those cells where the LTR is active, namely type 2 pneumocytes and Clara cells.

This replication defective recombinant retrovirus is therefore likely to be less hazardous than JSRV, and certainly not more hazardous. Wild type JSRV is not considered infectious for humans and no evident occupational risk of working with JSRV infected animals has ever been noted.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

(b) 01/08 infection with replication-defective JSRV-based vectors expressing the envelope protein.

Although the parental virus is handled in conventional housing (level 1) this proposal aimed to carry out infection with the chimeric JSRV at containment level 2 in order to minimise the risk, however small, to the animal handlers. Once infected it was proposed to remove animals to containment level 1 after a period of two weeks. Concerns were raised by the committee as to whether or not the chimeric virus although non-replicative could persist in the lungs of infected lambs for any length of time. This would impinge on the proposal to remove the lambs from containment 2 weeks after infection. CC pointed out that the chimeric virus would not be expected to pose any greater risk, and probably a much lesser risk, to human or animal health than the parental JSRV. Nevertheless it was suggested that if possible a pilot experiment should be performed first in order to assess whether or not there was any persistence of the virus. The Committee were happy to allow the proposal to proceed as requiring level 2/level 1 containment, but it was pointed out that clear justification for removal of the lambs to conventional housing would be required.

### Project Additional Information

#### Purposes of the contained use
- To improve on existing control products

#### Recipient or parental organism
- Pasteurella multocida

#### Host/vector system
- Deletion mutant of Pasteurella multocida

#### Origin & function
- Origin is from naturally occurring outbreak of haemorrhagic septicaemia in Sri Lanka with intention of producing an attenuated strain

#### Evaluation of foreseeable effects
- The strain will be highly attenuated and not expected to have any deleterious effects

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| The containment level to which the animal facility will operate is CL2. All animal rooms to be used will be at negative pressure and conform in all respects to the requirements stated in Table 1c, Schedule 8 for containment at level 2. |

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
- N/A

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| All waste generated during these studies will be rendered non-infectious by chemical disinfection, autoclaving or formaldehyde gas sterilisation and disposed of by on-site incineration or via a licenced clinical waste contractor according to the procedures documented and held at the Institute. Chemical disinfection methods will be monitored to ensure that the correct solution strengths are used. Formaldehyde gas generating chemicals and equipment will be calibrated to ensure that the correct concentration of gas is liberated and decontamination chambers and gas cycles will be timed to ensure that surfaces are exposed for the correct period of time. Internal temperature and pressure readings will be taken during sterilisation cycles from all autoclave equipment that alarm in the event of a cycle failure. All non-plastic containing waste will be disposed of by on-site incineration, all plastic waste will be autoclaved on-site prior to disposal via a licenced clinical waste contractor. All waste including infected carcasses, animal excrement and bedding generated during these studies will be placed in plastic bags that, after surface sterilisation with Trigene 1% v/v (Medichem Intl Ltd) in the unit, will be transferred either to the autoclave or to the adjacent incinerator house for burning, as appropriate. All wasted disposal procedures will be recorded using logbooks. Drains in the floor of the animal rooms will be blocked off, liquid waste will be absorbed by sawdust bedding and removed as necessary for incineration. At the end of the experiment after the removal of all solid waste the rooms will be fumigated using formaldehyde prior to washing with high pressure hoses. |

This proposal was deemed to be fairly straightforward. Clarification was sought on the curing of all "non-native" plasmid sequences from the attenuated strain after which approval was given for the proposal to be forwarded to the HSE as requiring Level 2 containment.

Purposes of the contained use

Corynebacterium pseudotuberculosis is the causative agent of caseous lymphadenitis (CLA) in sheep and goats, resulting in significant economic losses to sheep and goat industries worldwide. The pathogenesis of C. pseudotuberculosis disease is poorly understood; however, as with all bacterial pathogens, certain proteins produced during infection allow bacteria to evade/combat host immune responses, and persist within the infected host. Proposed is a connected program of work, which will attempt to identify novel C. pseudotuberculosis proteins, and determine their role (if any) as potential virulence factors. A description of the proposed work follows:

Genetic cloning of DNA sequences from C. pseudotuberculosis derived from various sources, including:

i. Polymerase Chain Reactions (PCR)
ii. Libraries of random restriction fragments
iii. DNA flanking the sites of targeted or randomly integrated plasmids

Once cloned, novel DNA sequences will be determined. As novel sequence data becomes available, specific genes (or gene fragments) will be cloned into bacterial expression vectors, for the purpose of obtaining recombinant protein. This will facilitate the study of the proteins’ physical/biochemical characteristics, as well as providing pure antigen in sufficient amounts for ELISA’s, immunisation of rabbits for polyclonal antibody production, and to allow immunisation of sheep prior to subsequent bacterial challenge in vaccine development studies.

A procedure for transforming C. pseudotuberculosis with plasmid DNA will be developed. Temperature-sensitive suicide plasmids, encoding antibiotic resistance markers, will be used to transform cells by electroporation. Transformants will be identified by virtue of their antibiotic resistance at 30°C.

Allele-replacement mutagenesis of C. pseudotuberculosis genes will be performed. Mutant derivatives of putative virulence genes will be constructed in plasmid suicide vectors. Genetic mutations may take the form of deletions, point mutations, or disruptions using antibiotic resistance markers. A non-mobilisable random-insertion suicide plasmid will also be used to create random-insertion mutants of C. pseudotuberculosis. Ultimately, the intention is to create well-defined mutant strains, deficient in particular gene(s) of interest. Subsequent comparison of the mutants with their wild type parent strains will allow the role of the mutant gene(s) in virulence to be studied, both in vitro and in vivo.

Identification of secreted C. pseudotuberculosis proteins, using plasmid-encoded nuclease gene. Random restriction fragments will be cloned as fusions to the nuclease gene. Fragments containing secretional signal sequences will be used to guide the export of the nuclease out of the cell, allowing subsequent detection on selective agar plates. Sequences containing signal sequences will be sequenced.

Identification of inducible promoters of C. pseudotuberculosis. Random restriction fragments will be cloned into plasmids containing promoterless antibiotic resistance genes. Recombinant plasmids containing promoter sequences will be isolated by virtue of conferring antibiotic resistance to the host cell. Replica plating of resistant clones on different media (e.g. high/low pH) will allow identification of promoters induced by specific environmental conditions.

Experimental infection of sheep and/or mice with the C. pseudotuberculosis allele-replacement mutants and their wild type parent strains will be performed.

Recipient or parental organism

Plasmid-containing GMO’s will contain plasmid-encoded antibiotic resistance markers. The majority of cloned sequences will not be expressed in the host strain (E. coli or C. pseudotuberculosis), due absence of complete coding sequences or promoters. Random pGh9:ISS1 insertion mutants will contain chromosomally integrated plasmid (and associated antibiotic resistance). Sequences cloned for protein expression will be propagated in E. coli host strains, where expression is dependent on defined chemical media. It is not anticipated that cloning of any C. pseudotuberculosis sequences in E. coli will result in an increase in virulence (given that all strains are non-pathogenic and auxotrophic). Furthermore, GM C. pseudotuberculosis will likely be less virulent, or of equal virulence, to the naturally occurring, wild type parent strain.

Host/vector system

Host strains for cloning/expression purposes will primarily be non-pathogenic, auxotrophic laboratory E.coli. In some instances proteins expressed from cloned sequences may only be active in the original host, in which case C. pseudotuberculosis will be used as a host strain.

General DNA-cloning/expression vectors (plasmids) will include standard, commercially available, laboratory plasmids, including pPCR-Script and pET-15b, which contain ampicillin resistance determinants. Such plasmids will only be propagated in an E. coli host strain; where expression is dependent on defined chemical media. It is not anticipated that cloning of any C. pseudotuberculosis sequences in E. coli will result in an increase in virulence (given that all strains are non-pathogenic and auxotrophic). Furthermore, GM C. pseudotuberculosis will likely be less virulent, or of equal virulence, to the naturally occurring, wild type parent strain.

To allow mutagenesis of wild type corynebacterial genes, the plasmids pG+host 9 and pGh9:ISS1 will be used. Both plasmids derive from a naturally occurring Lactococcus lactis plasmid, and are unable to replicate at 37°C (in the host cytoplasm). Both can replicate in E.coli and a range of Gram-positive bacteria, and contain the...
Plasmid-containing GMO's will express plasmid-encoded antibiotic resistance markers (ampicillin in E. coli; erythromycin, spectinomycin, and kanamycin in C. pseudotuberculosis). All genes cloned in this work will derive from naturally occurring C. pseudotuberculosis strains, and as such pose no threat in terms of environmental contamination. Genetic material will mainly derive from naturally occurring C. pseudotuberculosis strains. It is the intention to identify virulence factors (genes involved in the ability of the organism to cause disease), and eventually construct defined mutant C. pseudotuberculosis strains, to derive a greater understanding of the mechanisms by which bacterium causes infection. The majority of the work will be performed in vitro, under class 2 containment conditions (such as gene cloning, protein expression, and use of the pFUN, and pMM223 and pMM225 plasmids, construction of mutant strains, and initial characterisation of mutants v's wild type parent strains). In addition to using the pFUN, and pMM plasmids to identify potentially interesting genes, the pGh9:ISS1 plasmid will be used to create random-insertion mutant libraries of C. pseudotuberculosis. This involves integration of the plasmid into the bacterial chromosome, which, in turn results in disruption of gene sequences at the site of insertion. These mutant libraries will be erythromycin resistant at 37°C, due to the chromosomally located resistance gene. Mutants, lacking phenotypically observable traits (such as phospholipase D, secreted nuclease(s), protease(s), etc.) will be identified, and further characterised in vitro. Chromosomal sequences flanking the sites of pGh9:ISS1 insertion will be cloned, sequenced, and used to construct defined mutations. Mutant derivatives of these genes will be created in pG+ host 9, and used to construct stable, mutant strains through a two-step procedure; primarily, the plasmid will be integrated into the C. pseudotuberculosis chromosome homologous recombination. This will result in an intermediate mutant strain, containing a chromosomal copy of the plasmid-borne erythromycin resistance gene (resulting in resistance at 37°C). By selection of a secondary recombination event, stable mutant strains will be obtained as a result of the plasmid exercising from the chromosome, leaving the mutant genes resident in place of the wild type. Such mutants will have lost the erythromycin resistance determinant during excision of the plasmid, and hence pose no threat to the environment. Sequences cloned for protein expression will be propagated in auxotrophic, non-pathogenic E. coli strains. Expressed proteins will be purified to provide antigen for ELISA’s, vaccine formulations, etc.

Evaluation of foreseeable effects

All genes cloned in this work will derive from naturally occurring C. pseudotuberculosis strains, and as such pose no threat in terms of environmental contamination. Genetic material will mainly derive from naturally occurring C. pseudotuberculosis strains. It is the intention to identify virulence factors (genes involved in the ability of the organism to cause disease), and eventually construct defined mutant C. pseudotuberculosis strains, to derive a greater understanding of the mechanisms by which bacterium causes infection. The majority of the work will be performed in vitro, under class 2 containment conditions (such as gene cloning, protein expression, and use of the pFUN, and pMM223 and pMM225 plasmids, construction of mutant strains, and initial characterisation of mutants v's wild type parent strains). In addition to using the pFUN, and pMM plasmids to identify potentially interesting genes, the pGh9:ISS1 plasmid will be used to create random-insertion mutant libraries of C. pseudotuberculosis. This involves integration of the plasmid into the bacterial chromosome, which, in turn results in disruption of gene sequences at the site of insertion. These mutant libraries will be erythromycin resistant at 37°C, due to the chromosomally located resistance gene. Mutants, lacking phenotypically observable traits (such as phospholipase D, secreted nuclease(s), protease(s), etc.) will be identified, and further characterised in vitro. Chromosomal sequences flanking the sites of pGh9:ISS1 insertion will be cloned, sequenced, and used to construct defined mutations. Mutant derivatives of these genes will be created in pG+ host 9, and used to construct stable, mutant strains through a two-step procedure; primarily, the plasmid will be integrated into the C. pseudotuberculosis chromosome homologous recombination. This will result in an intermediate mutant strain, containing a chromosomal copy of the plasmid-borne erythromycin resistance gene (resulting in resistance at 37°C). By selection of a secondary recombination event, stable mutant strains will be obtained as a result of the plasmid exercising from the chromosome, leaving the mutant genes resident in place of the wild type. Such mutants will have lost the erythromycin resistance determinant during excision of the plasmid, and hence pose no threat to the environment. Sequences cloned for protein expression will be propagated in auxotrophic, non-pathogenic E. coli strains. Expressed proteins will be purified to provide antigen for ELISA’s, vaccine formulations, etc.

Origin & function

Pseudomonas aeruginosa will be used as host strains for pFUN constructs. The pMM223 and pMM225 plasmids will be used to identify environmentally inducible promoters of C. pseudotuberculosis. Gene libraries will be constructed, by cloning small fragments directly upstream of a promoterless antibiotic resistance gene (either spectinomycin or kanamycin depending on which vector is used). Subsequently, clones identified as resistant to antibiotic selection under the imposed environmental conditions (e.g. temperature, pH, osmolarity, etc.) will contain inducible promoter sequences, and can be sequenced to allow further characterisation. Both E. coli and C. pseudotuberculosis will be used as host strains for pMM-based recombinant plasmids.

All of the above plasmids proposed for use in this work are non-mobilisable.
proposed containment restrictions, the risk of environmental hazard is considered to be low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All microbiologically contaminated waste generated in this study will be autoclaved prior to disposal (121°C for 15 min), which should result in complete sterilisation. Internal temperature and pressure readings will be taken during sterilisation cycles from all autoclave equipment that alarm in the event of cycle failure. Any animal bedding or carcasses and other non-plastic waste from the clinical studies will be disposed of by on-site incineration, all plastic waste will be autoclaved on-site prior to disposal via a licenced clinical waste contractor.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

The committee were satisfied that the risk assessment was appropriate in the most part. However in the parts of the program where unknowns were being expressed it was suggested that unless there was specific evidence to suggest that the expressed product was unlikely to be harmful to humans or the environment then it should be handled at level 2 containment. Specifically in Part 4b if the protein is being expressed is unknown or if it is unlikely to be a virulence determinant then it should be handled at class 2. Also in parts 4e and f there is a chance, albeit small, that a "harmful" protein could be expressed during the initial screening stage and so the committee felt that the screening should be performed at level 2 containment and any candidate clones kept there until it is shown eg. by sequencing, that there are no harmful sequences downstream of the promoter regions or attached to the signal sequences.

TO DETERMINE WHETHER THE MOTIFS/REGIONS OF THE ENVELOPE PROTEIN (ENV) OF JAAGSIEKTE SHEEP RETROVIRUS (JSRV) SHOWN TO BE NECESSARY FOR IN VITRO TRANSFORMATION ARE ALSO IMPORTANT IN VIVO.

Production of virus will take place at the University of California, Irvine, and at University of Athens, Georgia. It will be transported as 1ml aliquots of concentrated tissue culture supernatant in sealed plastic vials in approved packaging for containment of biological hazardous materials. A license has been granted for importation of this material. The work to be carried out at the Moredun Research Institute is the experimental infection of neo-natal lambs with the recombinant JSRV described below.

Expression of JSRV Env has been shown to transform a number of different cell lines. The YXXM motif (amino acids 590-594) in the intracytoplasmic domain of the JSRV Envelope protein has been implicated in transformation by this protein. Substitution of the Y with a D abrogates the transforming activity of this virus in vitro whilst receptor usage and growth kinetics remain similar to wild type JSRV. The purpose is to determine whether this substitution allows in vivo replication without transformation. The result has implications for the use of JSRV Env in vaccination and in retroviral constructs to deliver human gene therapy.

Wild type JSRV (JSRV21) causes lung tumours in infected sheep. JSRV Env (envelope protein) has been shown to have transforming activity in vitro in several cell lines when overexpressed in the context of a Maloney murine leukemia virus vector (Rai et al., 2001, Maeda et al., 2001). This transforming activity was mapped to a Y-X-X-M motif in the intracytoplasmic tail of the Env TM subunit (Palmarini et al., 2001).

A derivative of JSRV21 has been generated called JSRV21 TM-Y590D. In this virus the amino acid tyrosine at 590 of the envelope protein has been changed to aspartic acid by a single nucleotide substitution. It is likely from the in vitro data showing that this Y to D substitution abrogated transformation by Env, JSRV21 TM-Y590D will have reduced or absent transforming activity in vivo compared to JSRV21.
Sheep

**Origin & function**

JSRV virions can be produced in vitro by transient transfection of 293T cells with the plasmid pCMV2JS21 (Palmarini et al., 1999, J.Virol, 73, 6964-6972). These virions have been shown to reproduce ovine pulmonary adenocarcinoma (OPA). In experimentally infected lambs. The plasmid pJSRV21 TM has a single base change which encodes aspartic acid instead of tyrosine at amino acid 590 of Env. Virions will be produced by transient transfection exactly as is done for JSRV21. The only difference between JSRV21 TM and JSRV21 (wild type virus) will be the Y590D substitution. The virus will be produced in the US and shipped to the UK in an appropriate form.

**Evaluation of foreseeable effects**

If the hypothesis is correct infection with JSRV21 TM should produce no symptoms in infected animals, if incorrect then a disease similar to that induced by wild type JSRV is likely. (Note that the mutations are in the intracytoplasmic region of env TM and therefore will not affect the receptor usage/host cell specificity.) This recombinant retrovirus is therefore likely to be less hazardous than JSRV. JSRV is not considered infectious for humans and no occupational risk of working with JSRV infected animals has ever been noted.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from full cat2 facilities for the animal experiments; The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator or autoclave as appropriate. We also request derogation from incineration of waste bedding. This is because we believe that the virus, being a retrovirus, is inherently labile and would not be expected to survive for an extended period in the environment. This together with the fact that the virus is not known to be shed either in urine or in faeces would suggest that there is an extremely low likelihood of the straw bedding being significantly contaminated with viable GMOs. Instead we request permission to transfer the straw bedding to a compost heap on a monthly basis. The bedding would then be composted for a minimum of six months. Please note that all other waste generated during the experiment would be inactivated by autoclaving or incineration as appropriate. JSRV21 is a pathogen of sheep, being capable of causing OPA. Experimental data has shown that this in vitro produced virus demonstrates the same phenotype as virus harvested from lung fluid naturally OPA-affected sheep, but is much less efficient at reproducing OPA. In OPA-affected sheep the main risk of transmission comes from those that produce lung fluid as it is well described that this fluid contains large amounts of infectious virus. This fluid is produced when there is significant amount of tumour in these animals. It is very rarely produced in animals experimentally infected with JSRV derived from lung fluid and has not been seen in any of the animals infected with tissue culture derived JSRV. Indeed the animals which have been infected with in vitro derived JSRV mostly had minimal tumour, not visible by gross pathology but detectable histopathologically. Therefore, when OPA is reproduced experimentally but without allowing late stage disease and production of fluid to occur, the risk of transmission of the virus is significantly reduced.

It is assumed that JSRV is transmitted by aerosol. However it is thought that close contact between animals is necessary for transmission to occur. It has been our experience from about 20 years working with the disease that sheep housed in the next stable (ie the other side of a solid wall) do not succumb to OPA. We regularly have field cases of OPA being brought to the institute as a source of lung fluid and tissues for our research. These are housed in similar buildings to the one we propose to use here. Despite the fact that the clinical cases are producing virus, the veterinarians regard as low, the risk of transfer to the other sheep here including those involved in long term experiments.

For the above reasons, we believe that negative air pressure with respect to the outside environment and filtration of air is not necessary for containment of this GMM.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

02/03/2022
Recombinant virus will be handled in a class 2 safety cabinet which will be sprayed with a 2% Virkon solution and left at least 1h before re-use. [Retroviruses can be inactivated (> a 4 log reduction in titre) with 0.5% Virkon within 30 minutes (Manufacturer's handbook)]. All waste plastics and gloves will be put in double bags the outside surface of which will be sprayed with Virkon and left for 1-2 hours prior to removal for autoclaving. All plastics used for immunisation of animals will be autoclaved as above. [JSRV-Env pseudotype viruses retroviruses can be inactivated by more than 99.7% by 50% ethanol solution in as little as 10 seconds (Coil et al., 2001, J. Virol. 75, 8864-7)].

After post-mortem, carcasses will be incinerated. Tissue and blood samples will be handled under cat 2 containment for DNA extraction. Sample remaining at the end of the experiment will be destroyed by incineration.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The GM safety committee discussed the proposal to infect sheep with the mutated form of the retrovirus JSRV. It was noted that JSRV is not known to be a human pathogen. Many years of experience have shown that there is no known risk to humans of occupational exposure to this virus. There was general agreement that there was good in vitro evidence that the recombinant virus was likely to be potentially less harmful to the environment than the parental or wild type virus, but that since it was a pathogen of sheep then it would need to be handled at containment level 2.

There then followed a debate as to whether or not the containment level 2 room would be required to be kept at negative air pressure with respect to the outside environment or whether or not the air leaving the containment room would have to be HEPA filtered. It was agreed that the virus was likely to be transmitted by aerosol, but that fairly close contact between sheep was required for transmission of the virus. Clinicians and the biological safety officer were content that sheep infected naturally with the wild type virus (and therefore the risk posed by these sheep to other experimental animals we keep on site) could be successfully isolated by housing them in a designated sheep pen known as the "red range". These sheep pens have concrete floors and walls with access doors at two sides, one for experimental workers coming from an anti-room, the other to allow access to the pen for preparing it for animals and for removal of waste and carcasses at the end of the experimental period. On one side of the room the upper part of the wall has "Yorkshire boarding" which essentially has a one inch gap between six inch boards. The opposite wall has louvered panels and windows. Thus the room has a constant air flow through it to comply with Home office regulations. The nearest animals to be experimental group would either be on the other side of solid concrete wall separating the pen from the adjoining one or in a similar pen on the other side of a courtyard. Previous experience has suggested that unaffected animals in adjoining pens or across the courtyard have not succumbed to the disease. It was also pointed out that it was expected that the greatest risk of transmission is likely to be when affected animals have tumour development in the lungs and therefore are producing large quantities of lung fluid which contains the greatest concentration of virus particles. It was noted that animals in the proposed experiment would be monitored for respiratory distress and were likely to be euthanased before there was significant tumour development and therefore fluid production. Experience in the past with experimental infections with wild type virus have generally been halted before tumour could be detected macroscopically and only one experimental animal has ever produced significant quantities of lung fluid. It was also noted that retroviruses are generally labile in the environment and are not suspected to survive for long periods of time outside the animal. Thus separation of animals by relatively small distances was considered generally efficient to separate unaffected animals from the risk. The final consideration taken into account was that it was known that disease caused by JSRV is endemic in the local environment. Taking all the evidence together the committee felt that the risk assessment was such that it did not indicate that the room would be required to be kept at negative pressure or that the extract air required to be HEPA filtered given the balance of probabilities that the virus being used was likely to be less harmful than the wild type virus. However it was pointed out that should the red range pens be used derogation from the HSE would have to be sought for the requirement to have an autoclave in the building housing the pens.

A request for a further derogation was also considered. It was pointed out that due to the labile nature of the virus and the assertion that the virus is not secreted either in the faeces or urine the committee were asked to consider whether or not the straw bedding on the floor of the pens would have to be incinerated or could be composted. The composting procedure would entail removing bedding on a monthly basis and transferring to a compost heap. Composting would be allowed to proceed for a minimum of 6 months. The committee felt that this was a reasonable request and agreed that it could be passed on to the HSE, although it was pointed out that all other waste should be inactivated by normal means.

It was agreed that the project should be notified to the HSE as requiring class 2 containment, without the requirement on air pressure or filtering, but applying for the derogations not to have an autoclave in the building and for the straw bedding to be composted.

E. coli 0157:H7 strains that can express verotoxins/shiga-like toxins pose a serious threat to human health and are responsible for about 1000 cases of food-poisoning in the UK each year. As a result of the activity of the phage-encoded toxins gastroenteritis can develop into bloody diarrhoea and may also lead to more systemic effects, particularly damage to blood vessels in the kidney and brain by toxic effects on endothelial cells expressing GB3 (CD77). Ruminants are considered to be the primary carriers of enterohaemorrhagic E. coli (EHEC) 0157:H7 strains and the organism does not cause disease in sheep or cattle. Our work has recently established that EHEC 0157 has a unique tropism for the bovine terminal rectum (final 3-5 cm) and that this is the principle colonisation site in this host. We are now trying to define the bacterial and host factors that drive this specific tropism. Several lines of evidence indicate that one of a number of fimbrial gene clusters, including LPF1/2, may play an important role.

Recipient or parental organism

The parental strain is an E. coli 0157:H7 strain (ZAP198) that was isolated from a human patient and has been cured naturally of the shiga-toxin carrying phage. This has been demonstrated using PCR and toxin test kits. Without the toxin the strain is ACDP 2 rather than ACDP 3. This strain colonises cattle in an identical way to the toxin-positive strains but can be used in level-2 containment facilities.
The parental strain has been genetically modified to delete genes in both the lpf1 and lpf2 operons. These deletions prevent the expression of the ahesins. The deletions were made under the HSE GM Centre number GM215 notification "Analysis of virulence determinant regulation and importance to colonisation and persistance of E. coli 0157 in ruminants and humans" (GM215/01.1; Medical Microbiology, University of Edinburgh). The deleted genes have extensive homology to established chaperone/ usher class fimbrial adhesins in E. coli such as the type 1 fimbriae. The deletion process used several allelic exchange steps in order to delete defined regions of the lpf genes without insertion of any foreign DNA. The genetically modified strains will be used to infect calves to assess effect on colonisation. The same process will also be applied to delete other homologous fimbrial operons in the parental strain which may also be tested in cattle at a later date. These additional chaperone/ usher class adhesins have been called HCP1, 2 and 3. Only the cattle infection experiments will be performed at the Moredun Research Institute.

**Evaluation of foreseeable effects**

There is no reason to suggest that the mutant strains to be used will be any more virulent or competitive in the environment than the parent strain.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Animals will be kept in secure accommodation, which meets the requirements for class 2 containment. All animal handlers will be fully trained. All personnel will wear appropriate personal protection equipment such as rubber boots, gloves and over-suits asx appropriate. All protective clothing will be removed before leaving the animal accommodation and will be disposed of as set out below. Rubber boots will be cleaned with 1% Trigene.

Each experiment is scheduled to last for 4 weeks after which the animals will be euthanased. The carcasses of the animals will be placed in a double layer of strong plastic clinical waste bags, the outside surfaces of which will be decontaminated using 1% Trigene. The carcasses will then be lifted on to a pallet and transferred, by forklift, to the incinerator for immediate incineration. All animal waste, and waste bedding, generated throughout the experiment will be placed in a double layer of plastic clinical waste bags and transferred to the incinerator on a regular basis for incineration. The outside surfaces of the bags will be decontaminated using 1% Trigene before transfer. All sharps generated during the experiment will be placed in a rigid plastic cin-bin, the outside surfaces of which will be decontaminated with 1% Trigene before transfer to the autoclave. After autoclaving the cin-bin will be removed from the PSP site by our licensed clinical waste contractor for incineration. All non-organic waste, ie plastics, rubber gloves etc., will be handled similarly.

All clinical samples generated during the course of the experiment will be placed in appropriate containers for transfer to laboratory areas for further analysis.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
The GMSC agreed that the mutant strains described were unlikely to be any more virulent than the parental strain and agreed that the cattle experiments described could go ahead in level 2 containment. There was some debate as to whether or not all the requirements of level 2 containment had to be applied. The committee unanimously decided that the risk assessment did not require the animal accommodation to be held at negative pressure relative to the pressure of the immediate surroundings, but that all other measures outlined in the tables in Part 3E Annex 1 of the GMO Regulations 2000 Compendium of Guidance should be adhered to.

**Purposes of the contained use**

To develop a vaccine against bovine pneumonic pasteurellosis caused by the bacterium Pasteurella multocida

**Recipient or parental organism**

02/03/2022

Page 4467 of 15326
**Host/vector system**

Derivative of a naturally occurring P. multocida plasmid engineered to contain a multiple cloning site within a Beta-gal gene, an E. coli origin of replication and an AmpR gene.

**Origin & function**

A naturally occurring gene from Pasteurella multocida

**Evaluation of foreseeable effects**

It is not expected that the gene inserted into the plasmid will be expressed when grown in E. coli, as no regulatory elements will be knowingly cloned into the plasmid although there is the possibility of leaky expression from the Beta-gal promotor. This is not thought to present a problem as E. coli naturally contains an orthologous gene. The intention is to produce a "knockout" strain of Pasteurella multocida lacking the gene in question. This is likely to result in attenuation since removal of the equivalent gene in other Gram-negative bacteria results in attenuation. All plasmid sequences will be cured from the final process organism by withdrawing Amp selection. Therefore the resultant organism should carry no foreign DNA. It is expected that the resultant organism will be less virulent than the parental scale.

Y
This proposal involves the removal from a strain of Pasteurella multocida. Although the committee agreed that the proposal was likely to require a level 2 containment, they asked for clarification on several points prior to the submission of the proposal to the HSE. Specifically, clarification is sought as to the specific strain being used for producing the mutan. All relevant information about the strain, in terms of how it was isolated, its associated pathology etc., should be given. Also more information about the suicide shuttle vector should be given as well as a more detailed description of the steps involved in producing the knockout strain. In addition the committee wanted to know if there will be intermediate strains generated with multiple antibiotic resistance genes which are subsequently cured from the final strain. If so what procedures are in place to ensure that the antibiotic resistance genes have been successfully removed from the mutant strain? The committee agreed that the cloning of the Pasteurella multocida gene into pGem-T-Easy could proceed at level 1.

### Project Additional Information

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**
### Purposes of the contained use

The intention is that a modified vaccine would be tested in Moredun's experimental pasteurellosis (M. haemolytica) challenge model. The modified vaccine will be shipped to Moredun as a ready to use test material. Calves would be vaccinated with the modified vaccine at 8 weeks of age and challenged at 11 weeks of age. Efficacy will be determined by comparison of clinical findings and lung lesion scores between vaccinated and non-vaccinated calves.

Any modified vaccine remaining at the end of the study will be incinerated or returned to the sponsor.

### Recipient or parental organism

The GM vaccine comprises of two components, the parental organisms of which are:

- **a)** A field isolate of Mannheimia haemolytica originally cultured from bovine pneumonic lung tissue.
- **B)** A field isolate of Pasteurella multocida originally cultured from pneumonic lung tissue. This strain is highly virulent and is capable of replication in the bovine lung.

### Host/vector system

**Not applicable.**

### Origin & function

**a)** The GM vaccine comprises of two components. These are derived from the parental strains indicated above, but have had genetic material coding for major virulence markers removed such that the Mannheimia haemolytica produces a truncated and ineffective leukotoxin and the Pasteurella multocida has a defective capsule.

### Evaluation of foreseeable effects

The host range of this strain of Mannheimia haemolytica, is strictly limited to reminants. The isolates appear to be host specific and neither bovine nor ovine isolates readily cause disease in other host species. In contrast, Pasteurella multocida can be found as a commensal organism in the respiratory and digestive tracts of a wide range of domestic and wild animals. In terms of its potential to spread within the environment, the GM Pasteurella multocida can therefore be regarded as the most hazardous of these GMMs. Pasteurella multocida is classified by the ACDP as hazard group 2, a biological agent that can cause human disease. However, most Pasteurella multocida isolates appear to be specialises for virulence in the host of isolation and so not appear to be able to cause disease in a wide range of species. The parental organism was a field isolate originally cultured from pneumonic bovine lung tissue and it is therefore considered unlikely that the organism can readily spread to, or cause disease in humans. No genetic modifications were made to this strain prior to the specified gene deletion. The gene-deleted organism and therefore presumptively the parent has been shown to be susceptible to a wide range of antibiotics including ampicillin, oxytetracycline and penicillin.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable.**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Schedule 8 of the Contained Use Regulations 2000 requires that for a class 2 activity an autoclave be present in the building. We would like to apply for a derogation with respect to the above requirement pertaining specifically to the inoculation of vaccine in the contained animal facility. The building in which it is proposed to house the animals does not have an autoclave. Thus derogation is sought to transfer disposable materials used throughout the trial (such as syringes, gloves etc.) either to an autoclave such that they can be sterilised prior to disposal or directly to the incinerator. Sharps will be transferred in suitable sharps containers, whereas other material will be double-bagged the outside surfaces of which will be cleaned with 70% ethanol or appropriate chemical disinfectant prior to removal from the containment facility.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All disposable material such as gloves, masks, syringes, protective clothing etc. will be incinerated or autoclaved prior to disposal. Since no shedding of the GMOs is expected straw bedding from the pens will be composted. The composting procedure would entail removing bedding on a weekly basis and transferring to a compost heap. Composting would be allowed to proceed for a minimum of 6 months. The protective clothing will remain within the accommodation until the end of the experiment.
at which point it will be disposed of by incineration. Wellington boots will be cleaned in a Foot and Mouth Disinfectant (FAM - Manufactured by Evans) both prior to entry and exit of the facility.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This project involves a vaccine trial using the Moredun model of Pasteurellosis. No GMO will be created at the Moredun, but instead the GMOs concerned will be shipped to the Moredun from the sponsor as a freeze dried preparation. Inoculae will be prepared in a Class II hood prior to transport to the animal facilities in a secure container. Once inside the animal containment rooms syringes will be used to deliver the vaccine subcutaneously. This appears to represent the greatest risk in this particular project, although it is not expected however that either of the strains used will be pathogenic to humans. Nevertheless PPE, particularly masks, must be used to protect individuals during the vaccination process. Once injected it is not expected that the GMOs will be shed by the animals, (the sponsors have evidence to this effect). Although it might be expected that Pasteurellosis in its natural form may be spread by aerosol, the committee felt it was reasonable not to require that the animal accommodation be kept as negative pressure with respect to the outside environment given that there was likely to be no shedding of the GMOs. Similarly given that no GMOs are expected to be shed from the immunized animals the committee were happy that all bedding (together with associated animal waste) can be composted.

Project Additional Information

Purposes of the contained use
Production of diagnostic tests for infection with jaagsiekte sheep retrovirus (JSRV) and development of vaccines against JSRV/ovine pulmonary adenocarcinoma in sheep.

Recipient or parental organism

B) Cultured mammalian cell lines including sheep cells (Choroid plexus (CP) cells, JS7, JS8), human cells (HEK293, 293T, HeLa, A549), murine cells (NIH3T3) and cells of other species including monkey (Cos-7), rat, hamster (BHK), cow, rabbit and deer cells. Cultured ovine and bovine primary cells including epithelial cells, dendritic cells and peripheral blood mononuclear cells.

Host/vector system
a) bacterial cloning vectors:
   pBluescript II (Stratagene)
   P GEM and derivatives
   other plasmid vectors listed in b), c) d) and e) below.

b) Bacterial protein expression vectors,
   pIVEX2 series (Roche)
   p TrcHis2 series (invitrogen)
   pGEX series (Amersham-Pharmacia)
   pBAD-HIS (Invitrogen)
   pMV10
   Pmal-2c (New England Biolabs)

c) Mammalian expression vectors
   pCI series (Promega)
   PGeneSwitch (inducible system, Invitrogen)
   PcDNA series (Invitrogen) and derivatives pβ-DNA (contains the chicken β-actin promoter instead of CMV-IE promoter)
   pIREShyg3 (Clonetech)
d) Murine leukaemia virus retroviral vectors pBabe-Puro (with pHIT60 MLV Gag-Pol and VSV-G or JSRV Env). HIV and EIAV derived lentiviral vectors.

E) JSRV retroviral vectors: JS-AP-ENV (pCMV-JS-GPP and pCMV2JSRV21ΔCP2).

**Origin & function**

The inserted genes are the protein coding regions and regulatory elements of the exogenous and endogenous strains of JSRV, and of the 2 strains of ENTV. Complete wild type and mutant JSRV proviruses and reporter genes.

**Virus protein coding domains:**

- **Gag** - This is a polyprotein encoding the structural proteins of the viral core. Subdomains of Gag will also be cloned separately, namely MA (matrix protein), PP (phosphoprotein), CA (capsid), NC (nucleocapsid).

- **Pol** - This is a polyprotein encoding the viral enzymes. Subdomains of Pol that will be cloned include DU (deoxyuridine triphosphatase), PR (protease), RT (reverse transcriptase and ribonuclease) and IN (integrase).

- **Env** - This viral polyprotein encodes the structural glycoproteins of the viral envelope. Subdomains of Env that will be cloned separately are SU (Surface protein) and TM (transmembrane protein). SU and TM proteins may also have transforming activity when expressed in mammalian cells.

- **Orf-X** - Predicted viral protein of unknown function.

**Regulatory domains:**

The JSR and ENTV untranslated 5’ and 3’ regions, including the LTRs encode regulatory functions such as transcriptional promoter and enhancer elements packaging signals and splicing signals.

**Molecular clones of replication competent JSRV:**

Currently there are 2 versions of this. The first (pJSRV²¹) contains the complete JSRV provirus. The second is a modified version, denoted pCMV2JS²¹ in which the U3 region of the viral 5’LTR has been substituted with the CMV-IE promoter (derived from pcDNA3 by PCR). These proviruses will be used to transfect mammalian cells in order to produce infectious virions and to evaluate cells for permissive replication. Mutants of these clones will also be constructed and studied.

**Reporter gene sequences:**

- Alkaline phosphatase, enhanced green fluorescent protein, firefly luciferase, β-galactosidase gene sequences.

**Evaluation of foreseeable effects**

The most hazardous GMM in programme will be mammalian cultured cells infected or transfected with wild-type JSRV or derived strains. JSRV is not recognised as a human pathogen and therefore such cells present a hazard to the environment only. Sheep inoculated with wild-type JSRV or mutant JSRV virions present no greater risk than a naturally infected clinical case of OPA.

The greatest risk for human health will be mammalian expression vectors (including viral and plasmid vectors) carrying the JSRV env coding sequences under the control of a eukaryotic promoter. This is because the product of this gene is a putative oncogene. If inoculated into humans, such vectors could result theoretically in expression of Env proteins in the recipient's cells and present a risk of transformation. Evidence from studies in mice suggest that a functional immune system reduces this risk (Wootton et al, (2005), Nature 434:90-7). Retroviral vectors used in this programme will not be replication competent and therefore have no risk of spreading to persons other than those directly handling the vectors.
Bacteria expressing the JSRV Env or TM protein represent the most hazardous groups of bacterial GMMs. However, although the JSRV Env glycoproteins have been implicated in the transformation of type II pneumocytes, such proteins expressed in bacteria will not have post-translational modifications and are therefore unlikely to retain such a function. In addition, these proteins are unlikely to be transforming when applied externally to cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from full category 2 facilities for the animal experiments.

The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator. [JSRV-Env pseudotyped retroviruses can be inactivated by more than 99.7% by 50% ethanol solution in as little as 10 seconds (Coli et al., 2001, J.Virol.75, 8864-7).]

JSRV is a pathogen of sheep, causing OPA. Experimental data has shown that virus produced in vitro demonstrates the same phenotype as virus harvested from lung fluid naturally OPA-affected sheep, but is much less efficient at reproducing OPA. In OPA-affected sheep the main risk of transmission comes from those that produce lung fluid as it is well described that this fluid contains large amounts of infectious virus. This fluid is produced when there is significant amount of tumour in these animals. It is very rarely produced in animals experimentally infected with JSRV derived from lung fluid and has not been seen in any of the animals infected with tissue culture derived JSRV. Indeed the animals which have been infected with invitro derived JSRV mostly had minimal tumour, not visible by gross pathology but detectable histopathologically. Therefore, when OPA is reproduced experimentally but without allowing late stage disease and production of fluid to occur, the risk of transmission of the virus is significantly reduced.

It is assumed that JSRV is transmitted by aerosol. However it is thought that close contact between animals is necessary for transmission to occur. It has been our experience from about 20 years working with the disease that sheep housed in the next stable (i.e. the other side of a solid wall) do not succumb to OPA. We regulary have field cases of OPA being brought to the Institute as a source of lung fluid and tissues for our research. These are housed in similar buildings to the one we propose to use here. Despite the fact that the clinical cases are producing virus, the veterinarians regard, the risk of transfer to the other sheep is low. This includes those sheep involved in long-term experiments. From this risk assessment, animal containment rooms will not be held at negative pressure relative to immediate surroundings, In addition, filtration of air is not required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid laboratory waste: Autoclaved in-house

Liquid laboratory waste: Autoclaved in-house or treated with Tri Gene disinfectant and disposed in general drainage. Trigene is quoted as having a 100% kill rate for enveloped viruses (1:100 dilution, for at least 1 hour) [MediChem Website]

Previous analysis has shown that no JSRV RNA can be detected in bedding of inoculated animals. Therefore animal waste and solid bedding will be disposed of by composting.

After post-mortem, animal carcasses will be disposed of by incineration. Tissue retained at post-mortem will be processed and jandled as laboratory waste. Samples remaining at the end of the experiment will be destroyed by incineration.
This connected programme of work is designed to replace all the individual projects previously notified to the committee (and the HSE) over the last 5 years as well as those transferred from the "old" GMO regulations in 2000. The committee felt that the research outlined in the risk assessment was appropriate to be considered as a "Connected Programme" of work. The committee were in overall agreement that the work requiring level 2 containment had been correctly identified and that there were no major exceptions or omissions. Clarification was sought regarding whether the expression of the Env gene in bacterial systems should also be handled at containment level 2. This was not thought necessary as there is no evidence that bacterially produced Env could be oncogenic since it does not have the appropriate post-translational modifications. The committee were also happy that the in vivo work had been adequately assessed and that "conventional" animal housing would be appropriate. Such experiments may require a derogation to be sought and previous communications from the HSE about notification of such experiments checked (see notification GM172/03.1). The committee did not require to see the proposal again and agreed that notification to the HSE could proceed.

CU2 Project Title
Connected programme of work to study the pathogenesis of ruminant gamma-herpesviruses.

Class 2
Culture Vol Class 2 < 1 Litre
Consent Granted Not Applicable

Non-GMM

Project notified under transitional arrangements

Tick if notifying a connected programme of work Y
Project Additional Information

Purposes of the contained use

(1) Studies towards elucidating the pathogenesis of ruminant gamma herpesviruses; Characterisation of individual genes and their products, analysis of gene function and the analysis of virus-host receptor interactions.

Recipient or parental organism

The Escherichia coli strains 1M109, DH5u, SIIRE-2 and XL-10 for sequencing and expression studies. Strains 517 pir, DH5ci, 05243, GS500, JM109, DHIOB, DS941, pirSl7 X, GS243, OS500, SWIO2, SW1O5, SW1O6 for BAC cloning. S 17-1 and Electrocomp Genehogs (trfA) E. coli (Invitrogen) for transposon insertion. These are all derivatives of the E. coli K-12 strain and are therefore considered to be disabled or non-colonising hosts. They are considered non-pathogenic to humans and will only survive in the environment for a limited time. Mammalian cell lines: Commonly used laboratory cell lines such as CHO, BHX, HEK293T, COS-1, COS-7, NIH 3T3 and Jurkat T cells will be used for expression of selected genes and for analysis of gene function. In addition bovine turbinate (BT) and embryonic bovine lung (EBL) cell lines will be used for propagation of recombinant viruses, Virus-infected large granular lymphocyte cells lines may also be used for the analysis of gene expression and function. All of these cell lines are considered to be especially disabled hosts and will not survive outside the tissue culture environment.

Host/vector system

a) Bacterial cloning vectors:
   pBluescript II (Stratagene)
   pGEM and derivatives (Promega)
   pCR series cloning vectors (Invitrogen)
   BAC vectors pBe1oBAC, pBluelox and derivatives Other plasmid vectors listed in (b), (c) and (d) below.

b) Bacterial protein expression vectors,
   pIVEX2 series (Roche)
   pIRHis2 series (Invitrogen)
   pGEX series (Amersham-Pharmacia)
   pBAD-HIS (Invitrogen)
   pTrxFus (Invitrogen)

c) Mammalian expression vectors
   pcDNA series and derivatives (Invitrogen)
   pCR series expression vectors (Invitrogen)
The inserted genetic material will include protein coding regions and regulatory elements of ruminant herpesviruses, particularly Ovine herpesvirus-2 (OvHV-2) and Alcelaphine herpesvirus-1 (AlHV-1); genes of particular interest are listed below. Additionally, host genes encoding proteins that may interact with or be regulated by viral gene products will also be studied (e.g. natural killer cell receptors and their ligands). Molecular clones of entire viral genomes will be manipulated in recombinant bacterial artificial chromosome vectors to allow the contributions of specific genes to virus pathogenesis to be studied in vitro and in vivo and to allow the development of attenuated viruses for vaccine development.

Reporter gene sequences:

- Alkaline phosphatase, greenlyellow/redcyan fluorescent proteins, firefly luciferase, -galactosidase gene sequences.

Epitope tags: FLAG, HA, myc, 6xHis, thioredoxin.

Evaluation of foreseeable effects

The most hazardous GMM in this programme, with respect to both human health and the environment, will be the recombinant vaccinia virus vCB21-R. In a penissive tissue culture host this virus will produce infectious particles that are capable of forming lesions in healthy individuals and causing severe disease in immunosuppressed individuals. Note that all use of this vaccinia virus will be either to produce virus to carry out fusion assays or in the fusion assays themselves, All assays will end-point, so that the virus will not be continuously cultured at any point and growing stocks of virus-infected cells will be kept to a minimum. All work with recombinant vaccinia viruses will be carried out at containment level 2.

Recombinant herpesviruses produced in this programme may replicate to high level in tissue culture and could become environmental contaminants following an accidental release. However, the consequences of such a release are unlikely to be significant. OvHV-b infects most sheep in the UK and superinfection with a recombinant virus is unlikely to be effective. AlHV-1 is restricted to exotic hosts - wildebeest,
hartebeest — and is unlikely to productively infect any host in the UK. Infection of MCF-susceptible hosts by recombinant AIHV-1 or OvHV-2 resulting in MCF would require a significant breach containment, but even in such cases further spread of virus is unlikely as these viruses do not replicate productively in disease- susceptible host species. None of the gene products to be expressed in this programme are likely to have deleterious effects on the environment or on human health either as isolated proteins or expressed in mammalian cells or bacteria. Ruminant gamma-herpesviruses do not appear to have oncogenic activity, unlike primate herpesviruses, and cellular transformation has not been described as a property of any MCF virus gene product. Bacteria expressing conserved herpesvirus antigens such as glycoproteins represent the most hazardous group of bacterial GMJls. Such bacteria might elicit an inappropriate/cross-reactive immune response against human herpesviruses. However, the expressed proteins will not have appropriate post-translational modification and so the likelihood of adverse reaction is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from full category 2 facilities for the animal experiments. The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% alcohol and transferred directly to the incinerator. Herpesviruses can be inactivated by more than 99.9% in 35% alcohol solution in less than 10 seconds (Croughan & Behbehani, 1988. J. din. Microbiol, 26: 213-215)

It is assumed that MCF is caused by aerosol or contact infection of susceptible species with AIHV-1 or OvHV-2. Studies of MCF in experimental animals carried out here over many years have shown that transfer between susceptible species is negligible. In addition, experimental intranasal infections with OvHV-2 have shown that infection of cattle is much less reliable than that of bison, even with doses of over 10^8 genome equivalents (Taus et al. 2006. Vet. Microbiol, 116: 29-36). This supports our view that the infection of susceptible hosts with MCF viruses constitutes a naturally-contained system. From this risk assessment, animal containment rooms will not be held at negative pressure relative to immediate surroundings. In addition, filtration of air is not required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid laboratory waste: Autoclaved in-house.
Liquid laboratory waste: Autoclaved in-house or treated with Virkon disinfectant (or validated alternative) and disposed in general drainage. Virkon is quoted as having a 100% kill rate for enveloped viruses (5% fmal concentration, for at least 30 minutes) [www.antechh.com]

MCF is a disease with unusual aetiology. The species in which these viruses replicate are not susceptible to disease, while those species that do get MCF do not appear to produce any infectious virus. Therefore horizontal spread of virus between MCF-susceptible animals is unlikely and animal waste and soiled bedding will be disposed of by composting.
After post-mortem, animal carcasses will be disposed of by incineration. Tissue retained at post-mortem will be processed and handled as laboratory waste. Samples remaining at the end of the experiment will be destroyed by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Moredun Institute GMSC agree with the assignation of these studies to category 2 containment. We also support the request for derogation as described above.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To determine the safety of a modified BVDV type 1 and 2 vaccine in non-target species. Containment level 2 required due to genetically modified nature of the material.

**Recipient or parental organism**

Bovine Virus Diarrhoea Virus type 1 and 2

**Host/vector system**
Origin & function

The attenuated viruses contained in this vaccine product were produced by deletions in the region coding for the polyprotein, no additions have been made to the genome. All the manipulations and production of the infectious viruses were performed in Dr Myers laboratory in Germany (Institut fur Immunologie, Friedrich-Loeffler-Institut d-72001 Tubingen Germany). The viruses contained in the vaccine have previously been worked with at the Institut of Animal Health at Compton where the work was conducted at containment level 2 in naturally ventilated buildings.

The virus mutants exhibit a deletion of the overwhelming part of the genomic region coding for the N-terminal protease NPRO and a deletion of codon 349, which abrogates the Rnase activity of the structural glycoprotein Erns.

No new sequences have been introduced into the mutated viruses. No transfer of wild-type sequences to related micro-organisms have been reported.

No genes are inserted into the BVDV genome, deletions that have been shown to attenuate the virus have been made as detailed in "Meyers G, Ege A, Fetzer C, von Freyburg M, Elbers K, Carr V, prentice H, Charleston B, Schurmann EM: Bovine viral diarrhoea virus: prevention of persistent fetal infection by a combination of two mutations affecting Erns RNase and Npro protease. J Virol. 2007 Apr;81(7):3327-38"

Evaluation of foreseeable effects

BVDV is one of the common causes of infectious abortion in cattle. It is also associated with a wide range of diseases from infertility to pneumonia, diarrhoea and poor growth. BVDV is on of the most important viral causes of disease in cattle in the UK.

BVDV is a member of the family of pestiviruses. Diseases associated with other pestiviruses include classical swine fever and border disease in sheep. Pestiviruses infect cloven hoofed stock only. BVDV has been found in pigs and sheep (indeed many cases of border disease are caused by BVDV not border disease virus).

The organism does not replicate in the environment outside of a host animal and would not be expected to survive for long in the environment and is inactivated by a wide range of disinfectants, including Vikon (1:100 dilution).

In a previous study parenteral injection of the GM BVDV strains in calves produced little or no viraemia. Aerosol transmission has not been assessed with the genetically modified viruses, but lack of transmission of wild type virus has been demonstrated in 2 studies by Niskanen et al. Whereby none of the animals housed with animals during the acute phase of infection with wild type BVDV seroconverted to the agent, even when nose-to-nose contact was forced (Niskanen et al. 2000 & Niskanen et al. 2002) These studies showed that cattle acutely infected with non-cytopathic BVDV are highly inefficient transmitters of the disease.

Approximately 90% of the cattle in the world have evidence of exposure to BVDV, with no reported cases of human disease. Pestivirus has been detected in man, however there is no evidence that the virus will cause disease in humans or even immunosupressed humans, although seroconversion to BVDV has been reported (Gianpaspero M et al, Arch.Virol. 7:53-62). The deletions in the genome of the manipulated viruses are highly unlikely to result in a change in tropism. Thus it is considered that there is no risk to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from full category 2 facilities for the animal experiments.

The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with Virkon and transferred directly to the incinerator or autoclave. (see section 12 , below)
Transmission of the GMOs to other animals will be restricted by housing of experimental animals in Tange Box accommodation (Level 2 contained accommodation with natural ventilation). Staff will enter the animal rooms from the laboratory side and prior to entry into animal area, protective suits will be put on, and wellington boots will be changed to those designated for use in each room only. Gloves will be worn when handling animals or material from the room. On completion of the procedures, gloves and other consumable items will be replaced in a yellow bag for incineration. Bags will be placed inside another bag and sealed, then sprayed with Virkon prior to transport to the incineration facilities.

All equipment used to handle virus will be held in Virkon (1:100 dilution) for at least 18 hours prior to incineration or transfer to an autoclave. Sharps will be placed in a burn bin, the sealed burn bin will be incinerated.

At the end of the study the room will be sprayed with a 1:100 solution of Virkon. After 24 hours, the waste will be removed to the midden on site and the rooms will be washed with 1:100 Virkon solution or another suitable disinfectant.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

MRI GMSC reference GM09/07b (revised): "Evaluation of Safety in non-target species (pig and sheep) of a genetically modified type 1 and type 2 BVDV vaccine candidate".

The committee agreed that category 2 containment is appropriate. The containment measures planned for this experiment are suitable and will ensure that the GMM is not transferred to other animals.

Project Ref 172/09.2
The majority of Campylobacter species are human pathogens that typically cause self-limiting enterocolitis of varying severity. Many Campylobacters reside in the intestinal tract of various animal species without apparently causing disease and are important zoonotic pathogens through contamination of meat, food products and the environment. Some Campylobacter species exhibit host and/or tissue preference and include C. fetus subsp. Fetus, C. fetus subsp. Venerealis, C. hominis, C. hyointestinalis and C. lari.

In man, Campylobacteriosis is the leading cause of foodborne illness in developed countries and causes much morbidity and mortality in the developing world. Disease is commonly attributed to C. jejuni and C. coli with the former being the commonest bacterial foodborne pathogen both in terms of number of cases of diarrhoeal disease reported via reference laboratories and morbidity related to working days lost and the economic consequences of infection (http://www.hps.scot.nhs.uk/giz/campylobacter.aspx and www.hpa.org.uk). Diarrhoeal disease due to this organism ranges from the acute (the main presentation) to chronic and is typically self-limiting in healthy persons although may be more severe or prolonged in the immunocompromised. Normally disease is managed by fluid replacement and antibiotics are not routinely used therapeutically. Infection can also have significant long-term consequences approximately 1 in 1000 cases subsequently developing Guillian Barre syndrome or Miller Fisher syndrome which are neuropathies associated with particular serotypes of C. jejuni. It is estimated that Campylobacter infection is a priority for DEFRA, Food Standards Agency (FSA) and BBSRC within the UK and EFSA (European Food Standards Agency) across the European Economic Community.

Despite the importance of Campylobacter spp. Including availability of three C. jejuni genome sequences, genomes from four other Campylobacter species (C. lari, C. concisus, C. curvus and C. hominis) factors and mechanisms contributing to disease pathogenesis are comprehended poorly. Improving such understanding is a key step in improving control and reducing the risk posed by these common foodborne pathogens.

We propose to examine the contribution of selected C. jejuni components by use of recombinant proteins, and tagged, reporter and mutant strains. The main focus will be cell surface and secreted components.
The three activities can be summarised as:

I) Cloning of specific PCR- or restriction enzyme-derived fragments from Campylobacter spp. Genomic DNA into plasmid cloning vectors for expression of recombinant proteins.

II) "Tagging" of wild-type strains to generate "WITS" (wild-type isogenic tagged strains) to monitor population dynamics during infection.

III) Transformation, mutation and (where required) complementation of selected genes for which the purpose is to demonstrate the role of gene products.

Recipient or parental organism

C. jejuni is a human pathogen (Hazard Group 2) and all strains are potentially infectious to humans. In the event of infection with C. jejuni, disease is self-limiting (typically recovering in 2-5 days) and does not usually require antibiotic treatment; if treatment were required on clinical grounds, erythromycin or a fluoroquinolone is used. These organisms are handled at containment level 2 and good microbiological practice should ensure negligible risk.

Host/vector system

Generation of mutants, tagged or reporter strains involves use of plasmids and introduction of antibiotic resistance genes, at least as an intermediate step. Plasmids used for tagging and mutagenesis are non-replicating in recipient Campylobacter strains and are only retained by homologous recombination under antibiotic selective pressure; complemented strains and reporter constructs can be generated both by insertion of target into the chromosome or on plasmids such as pMW10 which can replicate. Several resistance genes have been employed in genetic manipulation strategies including CAT (chloramphenicol acetyl transferase), KanR (kanamycin) and TetR (tetracycline). Naturally-acquired resistance to each of these agents has been reported in clinical isolates of Campylobacter and carriage of any of these resistance genes would not affect treatment since erythromycin or a fluoroquinolone are preferred for treatment, and then only in cases where disease is severe or prolonged. Where possible, unmarked mutants (from which the antibiotic resistance gene has been excised) will be produced, although such an approach is not routinely employed with Campylobacter. Genetically manipulated strains are expected to retain the pathogenicity of the parent strains and present no additional infectious hazard.

Origin & function

Genes being targeted compromise mainly surface and secreted (putative and known) proteins as well as key metabolic, regulatory or modifying factors. Mutants and other GMMs generated are expected to be less virulent or of equal virulence to the parental strain. Many preceding studies support this assertion - there are no reports of enhanced infectivity or pathogenicity conferred by mutation of genes in Campylobacter strains. Methods for complementation have recently been developed and are being increasingly used for verification purposes. Complementation with a copy of the wild-type gene returns strains to parental gene complement hence does not increase the hazard through promotion of virulence. Some experimentation may require monitoring of gene expression using reporter constructs and methods for doing so in Campylobacter have been developed.

Evaluation of foreseeable effects

GMMs generated are expected to be less virulent or of equal virulence to the parental strain. Many preceding studies support this assertion - there are no reports of enhanced infectivity or pathogenicity conferred by mutation of genes in Campylobacter strains. Genetic manipulation requires use of antibiotic resistance genes to enable selection - these genes are derived from naturally-occurring bacterial resistance genes. Resistance to each of the possible antibiotics used for selection (chloramphenicol, tetracycline, kanamycin) occurs in clinical environment isolates of Campylobacter species and these differ from drugs of choice for treatment.

A main purpose of this GM is to inactivate genes; hence, if transfer were to occur, any recipient would receive a non-functional gene. Complementation with a copy of the wild-type gene returns strains to parental gene complement hence does not increase the hazard through promotion of virulence. Reporter constructs are based on promoter regions of genes which are non-coding regions with reporter genes such as b-galactosidase (lacZ), green fluorescent protein (GFP) or site specific recombinase none of which are known to provide any advantage to recipients. No novel, harmful phenotype is expected from these manipulations.

Campylobacter spp. Are microaerophilic (i.e. require reduced O2 and increased CO2 levels relative to atmosphere for growth) and cannot replicate aerobically or at ambient temperatures so there will be no replication of the organism in the environment. Any introduced genes are not expected to confer benefit to environmental survival hence the hazard is no greater than the wild-type parent strain.

Containment procedures as outlined for risk reduction for human health should be followed.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Campylobacter species are defined primarily as human pathogens although risk of infection is low in healthy adults, including laboratory personnel. All manipulations of Campylobacter species will be on a small scale, and all handling is carried out in a microbiological safety cabinet at Containment Level 2, therefore exposure to bacteria is minimised. All materials in contact with the organisms are decontaminated by disinfection or autoclaving. All workers will have a copy of the relevant risk assessment, will be appropriately trained and will be expected to work to Good Practice standards. All waste materials and products will be disinfected or autoclaved before disposal.

The Moredun research Institute GMSC reviewed the risk assessment "Characterisation of Campylobacter species" (Our ref GM09/12)

The committee agreed that category 2 containment is appropriate for the proposed work. The containment measures proposed are sufficient to ensure that the risk of exposure to the GMMs is extremely low.

Project Ref 172/10.1

Date Ackn'd 19/01/2010
CU2 Project Title Genetic modification of a common non-pathogenic parasite of cattle
Class 2
Culture Vol Class 2 < 1 Litre
Class Volume Class 3-4

02/03/2022 Page 4484 of 15326
The majority of cattle harbour a non-pathogenic parasite throughout much of their lives. This parasite is sustained at low-levels without affecting productivity in beef and dairy herds. By utilizing the genetic tractability of these parasites, we aim to develop this parasite as a potential delivery system for antigens or other bioactive molecules in cattle. Our aims are to develop a vaccine-vehicle for the expression of recombinant antigens in cattle.

A common non-pathogenic parasite of cattle.

The organism is a ubiquitous parasite specific to cattle: it cannot infect humans or other animals. Although widespread in cattle herds of Europe and North America, the parasite is non-pathogenic. Indeed, incidence levels of ~80% have been recorded in the absence of clinical signs or effects on productivity with there being extremely few reported incidences of this parasite ever being associated with disease, this being only in severely weakened animals. Reinforcing its non-pathogenic status, the parasite is not listed as a specified animal pathogen by DEFRA. Moreover, there is no evidence that the parasite suppresses the immune response of the host.

The inserted sequences are protein products of two eukaryotic pathogens, Babesia spp. and Dictyocaulus viviparus. These are required to be found in the context of the intact whole organism to generate pathogenicity and disease. There are no anticipated consequences of expression of the selected inserted and expressed genes and protein products.

There are no predicted hazards associated with the plasmid and phage vectors employed. All vectors used are based on commercially available vectors. Vectors are non-mobilisable on the basis of being Bom-, mob-, tra-.

All existing vectors are based, as a background, on the pGEM plasmid series with modifications only occurring by insertion into the pGEM polylinker sites. Vectors developed from these, or related vectors with similar control sequences may also be used as they become available. The list of potential expressed heterologous antigens to be used are:

- Babesia antigen
- Babesia antigen + a parasite surface targeting signal
- Babesia antigen + a parasite secretory signal
Dv ACE1
Dv ACE1+ a parasite surface targeting signal
Dv ACE1+ a parasite secretory signal

Evaluation of foreseeable effects

No hazards to human health are anticipated. The parasite is non-pathogenic in its natural host, cattle. Although widespread in cattle herds of Europe and North America, the parasite is non-pathogenic. Indeed, incidence levels of ~80% have been recorded in the absence of clinical signs or effects on productivity with there being extremely few reported incidences of this parasite ever being associated with disease, this being only in severely weakened animals. Reinforcing its non-pathogenic status, the parasite is not listed as a specified animal pathogen by DEFRA, and pre-screening of a sample of 16 cows at MRI has identified that all cattle already harbour existing infections. The modified parasites to be used in these studies have been engineered to express an antibiotic resistance gene (to allow selection of transformants); however this is not a drug used to treat cattle commonly. The parasite itself can be transmitted only by inoculation of infected blood by biting flies; to exclude access of these vectors to experimental cattle, all animals will be housed in high containment facilities where flies cannot obtain access. The parasites do not form spores and do not produce pathogenic products. They cannot survive outside of blood or tissue culture media and are killed in water.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The parasite is spread by blood-feeding flies. Cattle will be kept under conditions inaccessible to such vectors. The parasite is not shed from experimentally infected cattle. Nonetheless, all cattle waste will be subject to treatment. Firstly, all liquid waste will be autoclaved and all solid waste will be bagged and incinerated.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Reference GM09/09: Connected programme of work. "Genetic modification of a common non-pathogenic parasite of cattle".

The committee agreed that the use of the HSU facility to ensure containment of the GMM is entirely appropriate. The Committee approved this programme of work at class 2 containment.

Project Containment

02/03/2022
Purposes of the contained use

Bacterial chondronecrosis with osteomyelitis (BCO) caused by Staphylococcus aureus is the most common cause of lameness in studied flocks of commercial birds and a major economic burden on the global broiler poultry industry. By population genetic analysis, we have discovered that the vast majority of cases of BCO worldwide are caused by a single poultry-specific subtype of S. aureus which has undergone a recent human to poultry host jump followed by genetic adaptation to its new host and wide dissemination (Lowder et al, PNAS 106: 10545-19559, 2009). We have sequenced the complete genome of a representative isolate (ED98) and discovered that several novel mobile genetic elements (MGE) including 2 prophages, 2 plasmids and a pathogenicity island have been acquired since separation from a human progenitor strain. The MGE encode several putative virulence factors not previously identified among human S. aureus strains, including a thiol protease, phospholipase and a novel superantigen. We have examined the distribution of the MGE among a panel of poultry S. aureus isolates and found that they are widely distributed among poultry strains including strains from distinct unrelated clonal lineages. We propose to examine the role of the acquisition of specific MGE in adaptation of S. aureus to poultry in a chicken model of BCO.

All genetically modified S. aureus strains will be generated in the laboratory of Dr. Ross Fitzgerald (Centre of Infectious Diseases, Chancellor's Building, Little France).
Infection challenge experiments of broiler chickens will be carried out at the Moredun Research Institute. Broiler chickens will be infected with S. aureus by intravenous inoculation and by aerosol exposure in isolators. Necropsy, blood and tissue sampling will be carried out in the procedure rooms of the Moredun Research Institute animal facilities. Samples will be brought for follow-up analysis to the Easter Bush Veterinary Research Centre and processed in BSL2 laboratories.

Recipient or parental organism

The project will involve genetic deletion of specified MGE from a wild type poultry clinical isolate of S. aureus in order to test the role of the MGE in the pathogenesis of S. aureus during experimental infection of poultry. In addition, we will introduce the specified MGE into a non-poultry adapted strain of S. aureus of human origin to determine if it confers a survival advantage or contributes to increased virulence in a poultry host.

The wild type S. aureus poultry strains to be modified are strains CIX2 an ED98 or similar strains of the same genotype. The S. aureus strains of human origin include strains MR1, RN4220, SH1000 and strain Newman or other well-characterized strains

Host/vector system

The main plasmid vector used for construction of deletion mutants will be pMAD, an erythromycin resistant strain designed specifically for allele replacement of target genes. By the nature of the allele replacement procedure, the erythromycin marker is used to detect the single cross-over event but is lost after the double cross-over event and so is not maintained in the recipient strain which contains a ‘silent’ mutation. Other vectors routinely used for complementing mutations, or for reporter fusions for tracing infections may be used including pE194, pTS1/2, pCU1, pT181, pSK265, pCL84, pG+Host, members of the PCN shuttle vector series and derivatives of all of these. Additional novel plasmid vectors may be used as they become available.

Origin & function

The inserted genes are associated with several different MGE which have been identified in wild type strains of poultry S. aureus. Many genes encoded in the MGE are of unknown function. However, a description of each MGE and any homology with putative or known virulence factors is provided (see Table 1 of the attached risk assessment form).

Evaluation of foreseeable effects

1) Potential hazards to human health
S. aureus is ACDP hazard group 2. As discussed, the recipient strain will either be of human or poultry origin, each specialised for its own host. Poultry strains have lost the function of several genes and are deleted for several MGE involved in human disease pathogenesis. Accordingly, they are unlikely to be as pathogenic for humans as human-adapted strains, although zoonotic transfer cannot be ruled out. The human strains which have acquired poultry-specific MGE are unlikely to be more pathogenic for humans as the MGE have only been found in association with poultry strains previously and are likely to encode avian-specific functions. The pathogen is usually transmitted through physical contact but infections are opportunistic and usually require a compromised immune system or broken skin for invasive entry. Antibiotics are available for treatment of infection for all strains used in the current study and the antibiotic sensitivity is known for all strains to be employed.

2) Potential hazards to the environment
The recipient microorganism is a commonal strain of poultry which occasionally causes opportunistic infections of poultry. As such the release of wild type or MGE-deleted strains would not represent a novel hazard of potential threat to poultry health. Human strains which have acquired MGE may in theory be more fit for survival in chickens but are not likely to be as well adapted for birds as existing poultry specialized strains which have undergone extensive genetic adaptations to a poultry host. S. aureus is non-pathogenic for plants.

To protect against hazards to human health and the environment all experiments will be carried out under biosafety category class 2 containment. Accordingly, the following protective measures will be taken:

Personal protection:
Personal protection (gloves, face-masks, hair cover and appropriate laboratory clothing) will be used at all times to minimise the risk of infection. In the unlikely case that an accidental laboratory infection occurs affected persons can be treated with antibiotics. For all strains that will be employed in the current study the antibiotic sensitivity is
known. Medical emergency staff can be advised for treatment accordingly. Staff will be made aware that if they feel any adverse effects after working with the chickens they should seek medical attention immediately and inform the medical staff of the organism involved.

Waste management:
All waste and bedding from the infected birds will be bagged and autoclaved or incinerated. Carcasses will be placed in sealed, strong plastic bags which will be surface decontaminated before carriage to the incinerator in plastic bins/trolleys with lids. The carcasses will be placed directly into the incinerator within the bags. Any other material used for the experiments (e.g. scalpels, needles, syringes, gloves, face masks) will be inactivated by autoclaving or incineration.

Disinfection of contaminated surfaces, floors and equipment:
TriGene Laboratory Disinfectant can be used for treatment of Staphylococcus aureus including MRSA and VISA at a dilution of 1:100 for heavy soilage and high-risk areas. A contact time between 10-30 min is indicated to be sufficient for disinfection.

Special containment for aerosol infected birds:
All animals infected by the aerosol route will be maintained in poultry isolators (e.g. BioFlex® B50 Rigid Body Isolator) throughout the experiment to ensure containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No application for derogation from full containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste and bedding from infected birds will be bagged and autoclaved or incinerated. Carcasses will be placed in sealed strong plastic bags which will be surface decontaminated before carriage to the incinerator in strong plastic bins/trolleys with lids. The carcasses will be placed directly into the incinerator within the bags. Any other material used for the experiments (e.g. scalpels, needles, syringes, gloves, face masks) will be inactivated by autoclaving or incineration. All equipment used for inactivation of GM material is under regular monitoring and calibration procedures. Records of autoclave/incinerators operations are being produced and kept as required.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dear A

The MRI GMSC has reviewed your risk assessment entitled “Staphylococcus aureus-host interactions in experimental infection poultry”

The first point raised regards transport of the material between the university and here. Please note that the packaging must comply with UN2814.

Part d) i) Experiment 2. It was noted that the experimental protocol on the proposers project license states: “Birds will be infected 1 day post hatching and maintained in the isolator for a maximum observation period of 3 week. After this period they will be released into biosafety class 2 maintenance rooms and monitored for another 40 days.” However, the GM risk assessment states that “the chickens will be infected and maintained in isolators thus ensuring containment” implying that the birds will remain in isolators throughout.

The committee therefore requests clarification regarding the length of time that the birds will be maintained in the isolators. Justification should be given if they are to be removed into class 2 rooms. The aerosol infection process will obviously contaminate the surfaces of the isolator and also the birds skin and feathers with the bacteria. Information on the likely survival time of S. aureus in this environment should be supplied.

Part d) viii) An additional sentence should be added stating “Staff should be made aware that if they feel any adverse effects after working with the chickens they should seek medical attention immediately and inform the medical staff of the organism involved.”

Part 3.

All aspects of this project are assigned to class 2.

Please make these changes to the risk assessment document and return it.

In addition, a “pathogen fact sheet” as you suggested previously would be very helpful. The document can be put up on the wall for all the staff working with the birds to see.

Yours sincerely

DR C C
Chair,
Moredun Research Institute Genetic Manipulation Safety Committee.

The updated risk assessment and procedures reviewed by the MRI GMSC at a meeting on 28/06/2010. The committee agreed that these are now appropriate for both the laboratory and the in vivo work proposed.

### Project Additional Information

**Purposes of the contained use**

Novel viral vectors will be developed from the ovine retroviruses for use as gene delivery vectors for use in vitro and in vivo

**Recipient or parental organism**

b) Cultured mammalian cell lines including sheep cells (Choroid plexus (CP) cells, JS7, JS8), human cells (HEK293, 293T, HeLa, H820), murine cells (NIH3T3) and cells of other species including monkey (Cos-7), rat (208F), hamster (BHK), cow, goat, rabbit, cat and deer. Cultured primary cells including cultured ovine, caprine and bovine epithelial cell, dendritic cells and peripheral blood mononuclear cells.

c) Sheep, mice, cows, mice and rabbits for in vivo studies

**Host/vector system**

a) Bacterial cloning vectors:
   - pBluescript II (Stratagene)
   - pGEM and derivatives
   - pCR2.1
b) Mammalian expression vectors
   - pCI series (Promega)
   - pIREShyg3 (Clontech)
   - pEGFP-C1, pEGFP-N3 (Clontech)
   - pCAGneo (a derivative of pClneo containing the chicken B-actin enhancer-promoter in place of the CMV promoter-enhancer)
   - Other plasmids encoding retroviral vector components listed in (c) and (d)

c) Murine Leukaemia virus retroviral vectors pBabe-Puro (with pHIT60 MLV packaging construct and VSV-G or retroviral Env proteins). HIV lentiviral vectors (pLenti system (Invitrogen)).

(d) Novel retroviral vector systems derived from ovine retroviruses

Origin & function

Retrovirus vectors will be developed based on existing molecular clones of infectious ovine retroviruses using a standard 3-plasmid transient transfection system similar to those in routine use derived from MLV and HIV.

The plasmids used will be:
   (i) Gag-Pol expressing plasmid (packaging construct)
   (ii) Env expression plasmid
   (iii) Vector plasmid

Reporter gene sequences including alkaline phosphatase, enhanced green fluorescent protein (and variants), firefly luciferase, and β-galactosidase will be incorporated to facilitate vector development.

These vectors will be used to study vector (and parent virus) function in cells and tissues from various species, including sheep, goats, cows, rabbits and mice.

Evaluation of foreseeable effects

The most hazardous GMM in this programme will be novel retroviral vectors derived from ovine retroviruses. These new vectors are replication-incompetent and are capable of a single round of infection. We therefore expect them to be at least as safe as using existing and well-characterised retroviral vectors derived from HIV-1 and MLV.

Two general hazards are associated with retroviral vectors: formation of replication-competent retrovirus (RCR) and vector mobilisation. RCR can be generated through recombination events during the transfection step of vector production. Recombination occurs due to regions of sequence homology between the different plasmids used to make the vectors. To minimise this risk, prior to in vivo studies we will design the vectors to eliminate as far as possible any regions of homology, by codon optimisation of the packaging vectors. PCR and infection assays will be used to measure the production of RCR. The hazards to humans associated with a breakdown of containment are small, given that ovine retroviruses are not human pathogens and any RCR generated would be a defective version of these viruses.

Vector mobilisation poses a theoretical hazard to the environment, by rescue of vectors following co-infection with wild-type viruses. However, we will develop self-inactivating vectors for in vivo use thereby minimising the risk. Even if vector mobilisation were to occur, the vectors themselves are replication incompetent and the effects are likely to be negligible in comparison to the effects of the wild-type viruses themselves.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
We request derogation from full category 2 facilities for the animal experiments.

Animals that have been inoculated with retroviral vectors will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator. (Retrovirus vectors can be inactivated by more than 99.7% by 50% ethanol solution in as little as 10 seconds (J Virol. 75:8864-8867). The vectors to be used are replication defective ("one-hit") and unable to spread from the inoculated recipient. Therefore, bedding will be disposed of by composting. Previous analysis using wild-type viruses has shown that viral RNA cannot be detected in bedding of inoculated animals using quantitative real-time PCR (please refer to previous correspondence, notification reference GM172). Animal carcasses will be disposed of by incineration. Tissue taken at post-mortem will be processed and handled as laboratory waste.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid laboratory waste: Autoclaved in-house.

Liquid laboratory waste: Autoclaved in-house or treated with 5-10% TriGene disinfectant and disposed in general drainage. Trigene is quoted as having a 100% kill rate for enveloped viruses (1:100 dilution, for at least 1 hour) [MediChem website]

Animal waste: The vectors to be used are replication defective ("one-hit") and unable to spread from the inoculated recipient. Therefore, bedding will be disposed of by composting. Previous analysis using wild-type viruses has shown that viral RNA cannot be detected in bedding of inoculated animals using quantitative real-time PCR (please refer to previous correspondence, notification reference GM172). Animal carcasses will be disposed of by incineration. Tissue taken at post-mortem will be processed and handled as laboratory waste. Samples remaining at the end of the experiment will be destroyed by incineration.

Animal Units | Large Scale Activities | Human Clinical Applications
Project Additional Information

Purposes of the contained use
To detect mycoplasmal, microbial and/or extraneous agent contamination in a Sponsor’s Sample. The intention is that the modified virus seeds will be prepared by the Sponsor and shipped to Moredun for testing by the Biosafety Division at Moredun Scientific. The material will be shipped to Moredun as a ready to use test material for sterility, mycoplasma and extraneous agents testing (all according to European Pharmacopoeia). A summary of the work to be undertaken is detailed in the attached Risk Assessment.

Recipient or parental organism
Baculovirus (infectious to insect cells) - Master seed viruses produced on Sf+ insect cells.

Recipient strain is a polyhedrin-negative Autographa californica multiple nuclear polyhedrosis virus (AcMNPV).

In nature, AcMNPV particles are occluded in a polyhedron, a protective matrix consisting predominantly of the protein polyhedrin, which permits survival in the environment and efficient spread to new hosts. The Sponsor’s constructs are polyhedron-negative, limiting potential survival in the environment and spread to insects.

Host/vector system
Baculovirus vector Bac.VD43 (Sample name Bac. VD43 P4 WSV). Polyhedrin-negative.

Origin & function
Bac.VD43 encodes the human LPLS447X gene, expressing a natural variant of human lipoprotein lipase (LPL). Human LPL is a key enzyme in the metabolism of triglyceride-rich lipoproteins. It mediates hydrolysis of triglycerides in chylomicrons and very-low-density lipoproteins, and protects against excessive rises of triglycerides after meals.

**Evaluation of foreseeable effects**

No GMM is being constructed. The activities all involve the use of a previously generated, stable baculovirus vector, Bac.VD43.

Baculoviruses are rod-shaped dsDNA viruses found mainly in insects. Autographa californica multiple nuclear polyhedrosis virus (AcMNPV), is the type species of the nucleopolyhedrovirus genus, and is the most extensively studied and well used baculovirus vector. Baculoviruses are ubiquitous. Insects, and some crustaceans, are the only known natural hosts. Thus, the virus is not considered a hazard to humans or animals.

In nature, AcMNPV particles are occluded in a polyhedron, a protective matrix consisting predominantly of the protein polyhedrin, which permits survival in the environment and efficient spread to new hosts. The Sponsor's recombinant baculovirus is polyhedrin negative, limiting potential survival in the environment and spread to insects.

The construct was generated using a plasmid in which the polyhedrin gene is largely deleted, thus reversion to wild-type is not considered likely. As baculoviruses are insect viruses, without known homologues in humans or animals, it is unlikely that complementation or rescue to a polyhedrin-positive status could occur during the planned work, or following accidental inoculation of an operator. In the event of environmental contamination, recombination with wild-type baculovirus due to dual infection of an insect host, resulting in rescue of the polyhedrin gene, would be expected to result in deletion of the inserted sequence. Thus, no more pathogenic variant would be expected to arise.

The LPL gene is expressed under the control of the cytomegalovirus immediate early promoter. Therefore, following infection of mammalian cells, it is possible that high level expression of this gene could occur. There is no known toxicity associated with expression of this protein. Following accidental exposure of an operator, or infection of mammalian cells, the baculovirus would not replicate and spread. Therefore, within a human/animal host, expression would be expected to be transient, and high and/or sustained systemic expression of LPL is unlikely. Expression of LPL is not expected to alter the host range or pathogenicity of the baculovirus host.

The inserted sequences also include a woodchuck hepatitis virus posttranscriptional regulatory element (WPRE), to enhance transgene expression. Woodchuck hepatitis virus (WHV) is a member of the family Hepadnaviridae, of which Human hepatitis B virus is the prototype. The WPRE element overlaps with the coding region for the X protein, and some versions of this element are therefore capable of expressing part of this protein. The precise function of the X protein is uncertain. It is required for efficient infection and replication in vivo, and it has been shown to activate and repress gene transcription, and display anti-apoptotic and pro-apoptotic, and anti-proliferative and proliferative activity, depending on the assay systems used. It has been suggested that the X protein plays a role in the development of liver cancer. Although there is no evidence that the X protein is directly oncogenic, studies have shown that it may act as a cofactor for oncogenesis. Due to the lack of detailed knowledge in this area, it is recommended by the SACGM that constructs containing WPRE elements that could express part of the X protein be classed as GM level 2 or higher.

The pX open reading frame is not mutated in this construct. Therefore, in the absence of data to provide assurance that there is no protein expression from this element, it should be considered possible that part of the X protein could be expressed following infection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste will be soaked in at least 1% Virkon solution for a minimum of 2-3 hours – any plasticware that has been soaked will then be incinerated on site. All solid waste and waste and bedding from the animals will be bagged and autoclaved or incinerated. Animal carcasses will be placed in sealed strong plastic bags and will be...
placed directly into the incinerator within the bags. All carcass and waste bags will be surface decontaminated before carriage to the incinerator in strong plastic clinical waste bins/trolleys with lids. Any other material used for the experiments (e.g. scalpels, needles, syringes, gloves, face masks) will be inactivated by autoclaving or incineration. All equipment used for inactivation of GM material is under regular monitoring and calibration procedures. Records of autoclave/incinerators operations are produced and retained for reference.

The MRI GMSC discussed the risk assessment for this work (our ref GM10/22). The baculovirus construct could potentially express the woodchuck hepatitis virus X protein which may be oncogenic or a co-factor for oncogenesis. Because of this uncertainty the GM should be considered as of potential risk and therefore cat 2 containment should be applied.

### Purposes of the contained use

To detect mycoplasmal, microbial and/or extraneous agent contamination in a sample submitted by a client. The intention is that the GMO will be prepared by the client and shipped to Moredun for testing by the Biosafety Division at Moredun Scientific. The material will be shipped to Moredun as a ready to use test material for sterility, mycoplasma and extraneous agents testing. A summary of the work to be undertaken is detailed in the accompanying Risk Assessment appendix 1. Any modified test material remaining at the end of the study will be incinerated or returned to the sponsor, however it is not envisaged that there will be any material remaining.

### Recipient or parental organism

Examples of host/vector systems which may be submitted for testing are shown in the accompanying Risk Assessment Appendix II.

The majority of recombinant proteins intended for therapeutic use, or for use as vaccines are generated using mammalian or insect cells. Most are expressed using immortalised CHO cells, but other recombinant cell lines based on NS0, BHK 293 and human retinal cells have gained regulatory approval for recombinant protein production. In all instances the recombinant cell lines will be well characterized and suitable for the production of biopharmaceuticals for human or animal use.

### Host/vector system

All of the vectors used for generating the above cell lines will be standard expression vectors designed for stable integration into the host cell genome, based on well-characterised E.coli cloning vectors such as pBR322 pr pUC. Stably integrated vectors would be considered non-mobilisable, unlikely to spread from the host cell and therefore unlikely to increase the risk to the host.

A wide range of virus systems may be used to generate the virus vectors or attenuated viruses submitted for testing, based on hazard group 1 or 2 agents: eg baculovirus, retrovirus, adenovirus, herpesvirus, Vaccinia virus and other pox viruses such as fowlpox, canarypox, modified vaccinia virus (Ankara), Japanese encephalitis virus (all replication incompetent). Lentivirus vectors may be based on hazard group 3 pathogens (eg HIV) but only replication incompetent vectors containing minimal lentivirus genes will be employed and these are considered GM activity Class 2.

### Origin & function

Examples of inserted genes or nucleic acid sequences that may be present are given in the accompanying Risk assessment Appendix III. In most instances the inserted genes will encode therapeutic antibodies, including monoclonal antibodies, vaccine antigens or standard detectable or selectable markers and would not be expected to be toxic.

Vaccine antigens typically represent structural or surface proteins derived from the target microorganism and are usually not biologically active. There may however be some exceptions and some virus proteins may directly contribute to cytopathology in the virus from which they are derived.
Hazards may exist with respect to the risk of GMMs submitted for testing and therefore a cautious approach to classification will be taken. It may not always be possible to predict all the functions or potentially harmful effects of novel therapeutic products or vaccines, especially where clinical data is limited. In instances where there is a level of uncertainty, a worst case scenario will be applied. For example, if the level of gene expression for an insert is unknown, high level constitutive expression will generally be assumed.

Further examples of dealing with potential hazards are shown in the accompanying Risk Assessment Appendix III and IV.

---

**Purposes of the contained use**

PRRSV is endemic in the UK and European pig herd and results in considerable economic losses in the sector as well as considerable welfare issues for individual animals on infected properties. In piglets, PRRSV can result in loss of condition, inappetance, an acute and extensive pneumonia (coughing, sneezing, increased respiratory rate), diarrhoea and in some cases lameness may. In breeding sows, there can be a short period of inappetance and some respiratory signs. However, more importantly, there can be reproductive failures with increased still births, abortions and mummification of piglets, as well as increased mortality in piglets that are born up to 30% smaller.

There are a number of PRRSV vaccines currently available for use. However, more effective vaccines will result in considerable savings for the animal health sector as well as an increase in the welfare of pigs. The goal of this project is to determine whether any of the vaccine candidates show any efficacy in the prevention or reduction of clinical disease and virus shedding following an artificial challenge with PRRSV.

The vaccine candidates which will be tested in this project are considered to be the next generation of PRRSV vaccines which if successful, should increase the protection offered in the pig herd against PRRSV.

**Recipient or parental organism**

When compared to the parental strain, the vaccine candidates show attenuation in vitro as reflected by delayed viral growth and/or by increased induction of the immune system. It appears reasonable to expect that these aspects of in vitro attenuation will show corresponding effects of attenuation also in vivo.
### Host/vector system

None

### Origin & function

The parental strain as well as the vaccine candidates based on this strain, originate from a genotype I (EU) PRRSV field strain.

### Evaluation of foreseeable effects

When compared to the parental strain, the vaccine candidates show attenuation in vitro as reflected by delayed viral growth and/or by increased induction of the immune system. It appears reasonable to expect that these aspects of in vitro attenuation will show corresponding effects of attenuation also in vivo.

The attenuated vaccine candidates are considered to be less hazardous that the parental strain, which itself is not considered to be hazardous to humans or the environment. All vaccine candidates have had similar modification/deletion therefore none are considered to be more hazardous.

PRRSV is not considered to be harmful to humans and the genotype 1 strains are not detailed on the DEFRA website as being of particular concern within this country for animals, as the disease is already endemic in the UK. However as not all pigs herds are affected by PRRSV currently, it is not desirable for this modified virus to be released into the environment, especially as the pathogenicity of the GM PRRSV is not as yet ascertained. The modification of the parental strain is not considered to have increased the risk of any infection in humans. In-vitro testing of the GMO vaccine candidates has indicated that the modification has reduced the infectivity of the candidates, which should reduce further any possible concerns.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from full category 2 facilities for the animal experiments.

The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Due to the GMO nature of the vaccine candidates, and the potential for spread of the vaccine candidates or the wild type challenge to other pigs on site, it is recommended that a containment level of 2 is applied for this study. The modification of the wild type parental strain will reduce the infectivity to the environment and other pigs on site. However, containment level 2 will be required due to the more virulent nature of the wild type challenge material which will be used to assess the efficacy of the vaccines. The European genotype 1 strains of PRRSV are not detailed on the DEFRA list.

Liquid and solid laboratory waste will be disposed of according to standard Moredun protocols for disposal of infected material. (SOP EMS/PROC/009). Material used in the laboratory will be disinfected under a Class II microbiological cabinet and placed in yellow bags for onsite incineration. Liquid waste (including unused vaccine material) will be disposed of following overnight disinfection with Virkon.

Waste from infected animals will be treated with Virkon and allowed to dry before being disposed of by composting following standard site procedures for disposal of infected animal waste. If conditions are right (about 40°C, pH 7.5) the virus can survive from days to weeks. However, it is very susceptible to adverse conditions, especially drying, and will die off within hours as conditions change from optimum. On the usual pig-associated fomites (plastic, steel, wood, straw, clothing, slurry etc.) at normal environmental temperatures (25-27°C) PRRS virus survives less than a day but it can survive in water for up to 11 days (Benfield et al, 1999a). Thus, normal clean-up procedures with disinfection and drying will kill the virus. The PRRS virus is susceptible to all the commonly used disinfectants including chlorhexidine, formaldehyde, chlorine, iodophors, sodium hydroxide, quaternary ammonium compounds, and the phenolics.
At the end of the study the animals will be transported to the post mortem facility in a sealed vehicle (or sealed containers) where they will be euthanased and then samples will be removed for further analysis. The vehicle used to transport the animals will be cleaned with an appropriate disinfectant (such as 1:100 Virkon or FAM) prior to transport of any other animals. All samples collected will be placed in sealed containers and then placed in sealed bags prior to transport to Moredun Scientific where they will be stored prior to shipment to the Sponsors facility. All personnel will wear appropriate protective clothing which will be incinerated onsite on completion of sampling. All carcasses will be incinerated on site on completion. The post mortem facility will be washed disinfected on completion of work using a suitable disinfectant (as above).

The controls that are proposed will ensure that the GMO’s are contained. No infectious material will be transported off site other than those samples required by the sponsor for further analysis.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID  

Date of Significant Change  

Project Additional Information

Purposes of the contained use

To develop novel reagents for the control of pneumonia disease caused by these bacteria in bovids

Recipient or parental organism

Pasteurella multocida
Mannheimia haemolytica

Host/vector system

Deletion mutants of Pasteurella multocida or Mannheimia haemolytica

Origin & function

Origin is form naturally occurring outbreaks of disease (pneumonic pasteurellosis in UK calves or haemorrhagic septicaemia in buffalo and cattle in India in the case of Pasteurella multocida or pneumonic pasteurellosis in UK calves in the case of Mannheimia haemolytica) with the intention of producing attenuated strains.

Evaluation of foreseeable effects

The mutated strains will be attenuated and are not expected to have any deleterious effects. Wild-type P. multocida has been reported rarely to cause infections in humans either through dog or cat bites or in immuno-compromised individuals. There have been no reports of human infections with M. haemolytica. Transformation will reduce rather than increase the pathogenic traits of the organism and the planned gene disruption will either have no effect, or decrease the pathogenic capability of the GMM. The risk to humans or the environment is low

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during these studies will be rendered non-infectious by chemical disinfection or autoclaving and disposed of by on-site incineration or via a licensed clinical waste contractor according to the procedure documented and held at the Institute. Chemical disinfection methods will be monitored to ensure that the correct solution strengths are used. Internal temperature and pressure readings will be taken during sterilisation cycles from all autoclave equipment that alarm in the event of a
All solid laboratory waste will be bagged and surface-disinfected in containment before being taken for sterilisation by autoclaving and disposal. Contaminated liquids will be disinfected by adding Virkon powder and leaving for 2h before disposal via the drains. All infected animals will be killed and, along with bedding and solid excreta, bagged and surface-disinfected in containment and taken directly for incineration. Liquid excreta will be sterilised by heat before disposal to drains. Any plastic waste will be autoclaved on-site prior to disposal via incineration or by licensed clinical waste contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

This proposal was deemed to be fairly straightforward. Clarification was sought on the curing of all "non-native" plasmid sequences from the attenuated strain after which approval was given for the proposal to be forwarded to the HSE as requiring Level 2 containment.

**Project Additional Information**

**Purposes of the contained use**

The purpose of this work is to investigate the mechanisms by which Streptococcus spp. colonise and persist within the host, with particular attention to production diseases of farmed animals. In the course of this work, genetic manipulation of streptococci using recognized methods will be conducted, in order to fulfil the tenets of 'Molecular Koch's Postulates'.

**Recipient or parental organism**

The GMO's to be created will include non-pathogenic Escherichia coli laboratory strains, used as hosts to facilitate the construction of recombinant plasmids for downstream mutagenesis of streptococcal spp. GM E. coli will also be used as means of expressing clone streptococcal genes to facilitate recombinant protein production. All work in E. coli is considered Class 1, and no hazards are anticipated.

GM streptococcal strains will be constructed by targeted allele-replacement mutagenesis of target genes, or by random-insertion mutagenesis to identify novel phenotypes (in vitro). The foreseeable effects of this activity will be varying levels of attenuation of the recipient strains. Extensive in vitro analysis of GM strains will ensure that no strain of enhanced virulence is used for downstream studies.

**Host/vector system**

E. coli strains for routine cloning will be standard, non-pathogenic E. coli K12 derivatives. Furthermore, non-pathogenic E. coli B21- derivatives will be used for production of recombinant streptococcal proteins.

Streptococcal hosts will be naturally-occurring wild-type bacteria isolated from cases of disease, predominantly in farmed animals. The focus of the work is broadly against streptococcal diseases of veterinary importance, and it is anticipated that it may include Streptococcus uberis, Streptococcus agalactiae, Streptococcus dysgalactiae, Streptococcus suis, Streptococcus equi, Streptococcus iniae and Streptococcus parauberis, among others (dependent upon availability of funding for the work).

The vectors used for cloning and expression of streptococcal sequences in E. coli will be commercially-available plasmids, including pTOPO, pPCR-Script, pET-15b and pTrEx.

The vectors to be used for mutagenesis of streptococci will be pG+host 9 and its derivative pGh9:ISS1. pG+host 9 is derived from a naturally-occurring plasmid in non-pathogenic Lactococcus spp. The plasmid has been subjected to hydroxylamine mutagenesis, such that the plasmid-encoded repA gene has been altered. Consequently, the RepA protein, which is responsible for initiating replication of the plasmid at host-cell-division, is unstable above 28°C, meaning that replication of the plasmid within streptococci can be controlled by manipulation of the growth temperature.
pGh9:ISS1 is identical to pG+host 9, with the exception that it contains a cloned sequence corresponding to the Streptococcus agalactiae ISS1 insertion element. This insertion element drives the random integration of the plasmid into the chromosome of host streptococcal cells, allowing the creation of libraries of random mutants which can be screened in vitro to identify phenotypes of interest.

**Origin & function**

The genetic material to be exploited in this work will originate from naturally-occurring wild-type streptococcal species, isolated from cases of clinical disease. The streptococcal genes will encode proteins known (or suspected) to contribute to pathogenesis. The overall purpose of this work is to create modified derivatives of wild-type streptococcal strains which are deficient in the production of specific proteins, so that the contribution of these proteins to virulence can be assessed by comparing wild-type and isogenic mutant derivative strains using defined experimental approaches.

**Evaluation of foreseeable effects**

The streptococcal GM strains to be created in this work will contain altered sequences for individual genes. Following allele-replacement mutagenesis, the sequence of target genes will be altered such that the encoded proteins are either abrogated or reduced in their biological function. These mutants will be otherwise identical to their wild-type parent strains, and will not have antibiotic resistance determinants or other exogenous sequences not normally associated with wild-type streptococcal strains. As such, the expectation is that the GM streptococci will have reduced, or at worst equivalent pathogenicity to the wild-type strains from which they derive.

Similarly, GM strains created by random insertion mutagenesis will be devoid of plasmid 'backbone' sequences (including antibiotic resistance determinant) at the end of the mutagenesis procedure, such that genes will be disrupted by the ISS1 element remaining within the chromosome. This is a naturally-occurring element which does not encode any additional traits. It is highly-unlikely that this procedure will result in strains of increased virulence; rather attenuation is expected as compared to wild-type parent strains, and at worst no difference will be observed. Irrespective, extensive screening of random-insertion mutants will be conducted to ensure that no strains of enhanced virulence are used in downstream studies.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from full category 2 facilities for the large animal experiments.

The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Laboratory work: Virkon will be used for all laboratory disinfection (as per the manufacturer's instructions), since this disinfectant is active against a wide range of micro-organisms (including streptococcal species) and is not inhibited by organic materials (as may be present in culture media, clinical samples, etc.) All solid waste material resulting from this work will be autoclaved prior to disposal, while all liquid waste material will be treated with a 3% solution of Virkon for at least 2 hours prior to disposal to drain. Laboratory surfaces and equipment will be disinfected with a 1% solution of Virkon for 10 min prior to rinsing with water.

Animal work: For small animal (rodent) work, all bedding will be double-bagged in nylon bags and swan-neck sealed prior to autoclaving to exit the laboratory. This waste will then be incinerated on-site. For large animal work, the amount of waste is impractical for autoclaving; however, extensive shedding of GMOs is not anticipated. Disinfection of animal facilities and equipment will be conducted by soaking animal bedding and accommodation in the iodophor disinfectant FAM30, which is DEFRA approved for such activities, is active against a wide range of micro-organisms and is not inhibited by the presence of organic materials. Disinfected bedding will be composted, while facilities and equipment will be further high-pressure steam-cleaned. The GM streptococcal strains used for animal work will be extensively-characterised prior to introduction into animals, and will contain 'clean' gene mutations causing the abrogation of or reduction in the biological function of the encoded proteins. There will
be no exogenous DNA sequences present within these GM streptococci which are not naturally associated with wild-type strains. Consequently, these GM strains represent no risk to the environment beyond that associated with naturally-occurring strains, and hence the control measures proposed are equivalent to those used for work involving the Hazard Group 2 wild-type parent strains.

The Moredun GMSC discussed and approved the risk assessment for this connected program if work (Our ref: GM13.24). The committee agreed that the only GMOs derived from wild-type strains that have been shown not to be shed in urine or faeces should be employed in cattle studies. They also agreed that only GM strains that were predicted from in vitro studies to have lower or at least no greater than wild type virulence would be employed in any in vivo studies.

### Project Additional Information

#### Purposes of the contained use

This new vaccine contains the Glycoprotein G from the rabies virus and will be used to immunise horses against rabies. Rabies is 100% fatal in horses and infected horses can theoretically infect humans through bites. A vaccine to immunise horses against the virus would therefore be of significant benefit to both horses, and potentially humans.

#### Recipient or parental organism

The parental strain is Parapoxvirus ovis which has been highly attenuated by passaging 135 times in embryonic lamb kidney cell cultures. The final harvest was plaque purified and cultured 38 times in bovine embryonic lung (EBL) cells. The virus harvest from the 38th pass was used to inoculate Bovine Kidney Cells (BK-KL-3A) and identified as Orf, 38.BEL/1.BK-KL-3A, A11070, 18 April, 1994. This material was then passaged five times on Bovine Kidney Cells (BK-KL-3A) then the virus was adapted to Vero cells. The virus was plaque purified three times by end point dilution. The plaque purified virus was used for the generation of beta galactosidase recombinant parapoxvirus. The beta galactosidase recombinant parapoxvirus was used for the generation of a recombinant parapoxvirus expressing the G gene of the vector virus.

#### Host/vector system

The parapoxvirus strain used as a vector was extensively attenuated by:

- more than 170 passages leading to attenuation by rearrangement of limited terminal regions of the genome which is accompanied by gene deletion (E2L) (Cottone et al., 1998).
- the substitution of the amino acid isoleucine (position 115) in the viral IL-10 (virulence factor) which is described to be very critical for retaining the stimulatory activity of human IL-10 (Rziha et al., 2003).
- deletion of the VEGF-E gene (virulence factor of parapoxviruses) and three further regions of its genome (Rziha et al., 2000).

#### Origin & function

The gene inserted in the parapox vector virus is the rabies virus G gene. Expression is under control of a synthetic early-late poxvirus promoter eIP-1 designed for protein expression in the mammalian cell. No expression will occur outside of the mammalian cell host. The intended function is to elicit a protective immune response against rabies virus infection.

#### Evaluation of foreseeable effects

When compared to the parental strain, the vaccine candidate shows attenuation in vivo and is considered to be less hazardous than the parental strain.
Although the parapoxvirus vector was demonstrated to be safe in permissive and non-permissive animals (see above), there is no data available for humans. However, the risk of infection to humans near the site would be effectively zero, except for the risk of needlestick injury when the animals are injected with the vaccine candidate. In humans, direct contact with another infected person or animal is the normal route of infection with virulent field virus and involves a substantial transfer of infectious virus through a cut or other break in the skin. Due to its high attenuation the vector used in this study is avirulent in the most permissive species, sheep. In addition, horses are a non-permissive species for parapoxviruses which mean that the vector will not replicate and be shed by the host.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**N/A**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from full category 2 facilities for the animal experiments.

The animals will be housed under category 2 containment conditions in except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with 70% ethanol and transferred directly to the incinerator or autoclave.

Due to the more specific handling and housing requirements for horses there are only a few specific areas within the Moredun Group animal accommodation which are capable of housing horses. The accommodation that will be used is a self contained facility with secure access, changing facilities and a double barrier layer (internal pen within the interior of the building) which has sufficient facilities to allow safe handling and maintenance of horses.

Horses are non-permissive hosts for this virus and this will ensure that the GM virus will not be shed by the animals and therefore the bedding and animal waste will not be contaminated. For this reason we request derogation to allow bedding and animal waste to go to the midden for composting without prior treatment.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Sharps** will be stored in sharps bins and disposed of on site by incineration
- Clinical waste will be stored in clinical waste bags and disposed of by incineration.
- Providing derogation is granted, bedding waste will be disposed of by composting as the virus will not be shed by the animals and therefore the bedding will not be contaminated.
- All personnel will wear appropriate protective clothing which will be incinerated onsite on completion of sampling.
- Blood waste (contained in blood tubes) during the study will be disposed of into clinical waste bags which will be disposed of by incineration.
- At the end of the study the animals will be in the cat 2 animal accommodation and incinerated on site. Carcasses will be transported to the incinerator in a covered trailer which will be sprayed down with FAM afterwards.
- All samples collected during the study will be placed in sealed containers and then placed in sealed bags prior to transport to Moredun Scientific where they will be handled and stored under cat 2 containment conditions prior to shipment of the samples required by the sponsor for further analysis, e.g. sera. These should not contain any infectious material but nevertheless the samples will be shipped to the Sponsors facility as a "biological substance category B".

The controls that are proposed will ensure that the GMO is contained.

---

**Is an emergency plan required according to regulation 20?**  
**N**

**If yes, tick to confirm that it is attached to this form**  
**N**

**Tick to confirm that you have attached a risk assessment to this form**  
**Y**
The Moredun GMSC discussed and approved the risk assessment for this project (Our ref: GM13.25).
Given that the vaccine candidate does not replicate in the animal or human host the GMSC felt there was negligible risk from the GMO except at the time of injecting the animals. Even then the risk of harm arising from needlestick exposure to this GMO is very low.
It was discussed whether Category 2 containment measures were more than required but it was agreed that this was justified because the original parapoxvirus from which the attenuated vector virus is derived is classed as BSL2 under SAPO rules.

Project Additional Information

02/03/2022
**Purposes of the contained use**

The objective of this work is to confirm the safety of a mutant Salmonella enterica serovar enteritidis isolate, scheduled for vaccine development, when administered to colostrum-deprived piglets. The vaccine is intended for use in chickens, however, as chickens do not generally present clinical signs following S. enteritidis infection, it is necessary to conduct the testing in a sensitive species. Prior to any additional research work being conducted, it is necessary to confirm the safety of the modified isolate.

<table>
<thead>
<tr>
<th>Recipient or parental organism</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host/vector system</td>
<td>None</td>
</tr>
</tbody>
</table>

**Origin & function**

No genes have been inserted. A total of three genes have been deleted which are involved in the conversion of shikimic acid to chorismic acid, in recombination in the cell and regulation of genes associated with UV damage recovery and DNA repair, resistance to low pH and bile, and flagelin production.

**Evaluation of foreseeable effects**

Although the vaccine candidate has been shown to have attenuating characteristics relative to the originating wild type strain, no assessment has been carried out of its ability to infect or cause disease in humans. It will be assumed for the purposes of this study that human infection is a possibility and biosecurity and control procedures will be utilised to this effect.

Salmonella infection in humans and pigs may result in acute gastroenteritis with sudden onset of abdominal pain, diarrhoea, nausea and vomiting. Salmonella infections usually resolve in 5-7 days and often do not require treatment unless the subject becomes severely dehydrated or the infection spreads from the intestines. In colostrum deprived piglets these symptoms may be more severe and may result in the requirement for intervention by veterinarians.

The genetic modifications encompass the deletion of genes coding for proteins involved in the multiplication, survival or virulence of salmonellae in the host (mammal or chicken). As such it is anticipated that any alteration of existing traits will only give rise either to a deletant with an attenuated phenotype or of equivalent virulence to the parental strain.

The genes are only mobilisable by transducing phage or recombination. In the unlikely event of this happening the receiving strain would lose its ability to produce flagellin and or survive in vivo. This would not be considered as having the potential to increase its virulence.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from full category 2 facilities for the animal experiments.

The animals will be housed under category 2 containment conditions except that an autoclave is not available in the same building. We request derogation such that material leaving the containment facility may be bagged, sprayed with an appropriate disinfectant (Anistel 1:100) or fumigated and transferred directly to the incinerator. Anistel is confirmed as effective against a wide range of microorganisms including Salmonella spp.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Salmonella enteritica serovar enteritidis is classified as an ACDP hazard group 2 organism. The proposed deletions will not increase this classification, and may reduce it.
However, as the strains are untested in humans the containment level will be maintained as level 2.

Animals will be housed in specific pathogen free (SPF) rooms within the High Security unit (HSU) at Moredun and waste will be disposed of following the standard waste management procedures within the unit. Solid laboratory waste will be disposed of by incineration following disinfection in Anistel (1/100) overnight. Liquid waste will be disinfected with Anistel (1/100) overnight. Anistel (1/100) has a wide spectrum of activity and is effective against Salmonella spp in both liquid and solid waste at this concentration (see information attached for activity and dilution details from the manufacturer). Dilution for the different materials will be as specified in manufacturers instructions.

The animal phase of the work will be conducted in SPF rooms following the standard containment procedures which should be more than sufficient to provide appropriate level of protection. All personnel entering the animal rooms will be required to wear FFP3 face masks and gloves as well as Tyvek suits and wellington boots which will remain in the rooms. All handling of infected animals will be conducted in the SPF rooms by suitably trained staff. The animals will be inoculated by the oral route using graduated syringes and applicators as appropriate.

All animal waste material produced, including bedding will be bagged and either surface sprayed with a disinfectant overnight (Anistel 1:100) or fumigated then incinerated as per standard procedures. In the laboratory, all material will be handled under a Class II microbiological cabinet with gloves and lab coats being used. Any consumable items that are used will be disinfected in Anistel (1/100) overnight followed by disposal into clinical waste bins which will be incinerated onsite. All animal products (i.e. faeces) will be disposed of in clinical waste bags for incineration.

### Project Additional Information

**Purposes of the contained use**

Pleuropneumoniae caused by Actinobacillus pleuropneumoniae (APP) is a severe disease in pigs which has a significant impact on the pig industry. Therefore, a high demand for a low cost and efficacious vaccine against all APP serotypes exists. In this project a number of genetically modified vaccine strains for induction of protection against APP will be tested to confirm whether it induces an immune response and subsequently the vaccines may also be tested to confirm whether it is effective in the prevention or reduction of clinical symptoms / pathology following artificial challenge with Actinobacillus pleuropneumonia.

**Recipient or parental organism**

- **Strain 1:** Salmonella typhimurium SL1344 parental strain (not attenuated) isolated from infected cattle (Hoiseth et al. 1981 Nature). S. typhimurium is a leading cause of human gastroenteritis and is used as a mouse model of human typhoid fever. Strain SL1344 is a histidine auxotroph generated from strain ST4/74 which was originally isolated from the bowel of a calf with Salmonellosis.

- **Strain 2:** Escherichia coli strain 5 (isolated from tonsils of healthy pigs). The strain is not attenuated in any way.

**Host/vector system**

GM vector bacteria were developed from the above S. typhimurium and E. coli strains by genetically modifying them to remove the gene cluster encoding the O-antigen biosynthetic pathway (rfb) so that they do not express endogenous O-antigen.

**Origin & function**

- **Kan resistance gene:** aminoglycoside phosphotransferase
A gene cluster encoding the O-antigen biosynthetic pathway of A. pleuropneumoniae was inserted, replacing the endogenous equivalent in each recipient strain. The intended function is to express the A. pleuropneumoniae specific O-antigen on the surface of the bacterial vector as a potential vaccine against APP.

ApxI, II or III truncated proteins (ApxI/II/III surf.fusion derived from APP).

All Apx toxoids are considered as virulence factors acting in the lung on destroying lung tissue and killing neutrophils and macrophages. These toxins are considered to be a major player in typical lung lesions observed for APP infection. ApxI and ApxII are hemolytic and cytotoxic. ApxIII is strongly cytotoxic to porcine neutrophils and pulmonary alveolar macrophages. However, truncated proteins will be expressed according to the following publications: ApxI truncation: Seah et.al. Nov. 2002 Infection and Immunity p. 6464-6467; ApxII truncation: Kim et.al. 2014 Bioscience, Biotechnology, and Biochemistry (74) p. 1362-1367; ApxIII truncation: Kwang 2004 Vaccine 22 (2004) 1494-1497. The truncated proteins are expected to induce neutralising antibodies but are not expected to exhibit any toxicity. No side effects were reported when used for vaccination in mice.

**Evaluation of foreseeable effects**

The E. coli_5 strain was an isolate from healthy pigs however, as a potential human pathogen, the isolate is characterised as ACDP 2. For pigs this strain was harmless, however a risk for humans cannot be excluded since there are no data or cases described.

Salmonella typhimurium is listed as a human pathogen hazard group 2 in the ACDP list. It is considered that as a maximum, infection of humans may result in similar symptoms to wild type Salmonella typhimurium infection.

The integrated O-antigen biosynthesis genes in the genome do not encode for toxins, potential oncogenic proteins, allergens or growth modulators. These genes are solely present for the synthesis of specific glycans.

The single sugars synthesized get linked to each other and transferred onto Lipid A. This glycan – lipid A complex defines the lipopolysaccharide (LPS).

The integrated Apx toxoids are derived from cytotoxic, haemolytic precursor proteins. The truncation of these are expected to result in loss of toxicity according to the literature however the truncated proteins bound on the surface of vaccine strains have not yet been tested for their toxic potential. One version of the Apx toxoids (ApxII) was tested in its truncated version by injection into pigs in an animal trial performed by Malcisbo. No side effects were observed when pigs received a dose of 400ug protein.

A risk of the transfer of the Kan resistance gene to wild type bacteria via horizontal gene transfer cannot be completely excluded but the likelihood of this is very low as the resistance gene is integrated into the bacterial genome rather than a plasmid. Housing of the animals in contained BSL 2 accommodation will further reduce the risk of any potential transfer to wild type bacteria.

The risk of horizontal gene transfer of the O-antigen biosynthesis cluster of APP2 and the truncated Apx toxoids is the same as described for the Kan resistance gene. The replacement of the E.coli O-antigen biosynthesis gene cluster with the ApxI/II/III truncated proteins is not expected to increase the risks associated with infection by the GMO compared to the host strain. When the ApxII truncated protein purified from the bacteria was injected into pigs at a dose of 400ug, no clinical symptoms were observed. However, while confirmed to not be hazardous to pigs, no additional testing has been carried out to determine whether the encoded truncated Apx toxoids could potentially be harmful for animals or insects.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Laboratory waste (consumables such as pipette tips) will be disinfected for a minimum of 24 hours, in a microbiology class 2 safety hood, using a laboratory disinfectant (Anistel at 1/100 dilution), and then added to clinical waste bags which will be sealed and then incinerated either on site or at an approved off site facility as appropriate. As the material will be incinerated no process testing or monitoring measures will be put in place. It is expected that this method will result in 100% kill of the GM material.

Animal bedding waste will be double bagged in clinical waste bags, in the animal accommodation, which will be surface decontaminated following local protocols (sprayed with Anistel at 1/100 dilution and left overnight in the accommodation), before being incinerated either on site or at an approved off site facility as appropriate. As this material will be incinerated no process testing or monitoring measures will be put in place. It is expected that this method will result in 100% kill of the GM material.

Animal carcasses will be double bagged in clinical waste bags while in the animal accommodation (which will be surface decontaminated as above) before being incinerated either on site or at an approved off site facility as appropriate. As this material will be incinerated no process testing or monitoring measures will be put in place. It is expected that this method will result in 100% kill of the GM material.

The risk assessment entitled “Potential vaccine candidate testing against APP2 infection” (Our ref: GM18.04) was reviewed by the Moredun Research Institute GMSC. It was agreed that CL2 containment is appropriate for this work.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The purpose of this work is to identify and understand proteins of the protozoan parasite Toxoplasma gondii that perform a key role in the parasite's biology, in pursuit of antigens that can be used in the development of a novel vaccine to protect against infection. The removal of specific T. gondii genes for the development of attenuated strains.

**Recipient or parental organism**

Toxoplasma gondii

**Host/vector system**

Mice and sheep

**Origin & function**

Published CRISPR/Cas9 plasmids adapted for use in Toxoplasma gondii will be used in this work (e.g. Brown et al, Bio Protoc, 2018; Guerra et al, PLoS Path, 2018). These plasmids contain the Cas9 gene and sgRNAs (guide RNAs) under the expression of T. gondii promoter sequences. They also contain ampicillin resistance markers for propagation in E. coli. The 20bp sgRNA sites within these plasmids will be modified by PCR to generate sgRNA sites for T. gondii genes-of-interest. Following tranfection in T. gondii, expressed sgRNAs and Cas9 will bind to specifically designated sites in the T. gondii genome and facilitate a double strand break. This work will be performed in T. gondii that have already been modified to lack the ku80 gene, meaning that non-homologous recombination does not take place in these
background strains. Therefore, it will be necessary to co-transfect these strains with a repair template. Repair templates will be generated to facilitate positive selection of genetically modified T. gondii. These repair templates will be designed with 5' and 3' homology arms flanking gene sites targeted for CRISPR/Cas9 DNA breakages. They will contain a sequence encoding genetic tags (e.g. HA, myc, GFP, YFP) or a resistance marker (HXGPRT, providing resistance to mycophenolic acid or pyrimethamine-resistant DHFR, DHFR*). Resistance markers will facilitate positive selection of modified strains when cultured in the presence of mycophenolic acid or pyrimethamine. Because pyrimethamine is the primary treatment for toxoplasmosis, other selectable markers will be considered before the use of the pyrimethamine-resistance DHFR cassette. Where possible, Cas9 plasmids transiently expressing a bleomycin-resistance gene (Guerra et al, PLoS Path, 2018) will be used for strain selection, given the transient nature of resistance in these transfected populations (as opposed to permanent resistance).

**Evaluation of foreseeable effects**

The GMMs generated in this work are not expected to gain virulence. This is because tagging of the genes with commonly used non-hazardous tags should not provide a gain-of-function. Furthermore, the deletion of genes predicted to be essential in T. gondii should result in attenuation of the parasite and complementation of deleted genes is not expected to increase parasite virulence compared to wild-type strains. However, insertion of a resistance markers (e.g. DHFR* cassette) will result in the development of drug-resistant parasites (e.g. pyrimethamine resistance in the case of DHFR* cassette integration). This approach has become an established protocol worldwide in labs implementing CRISPR/Cas9 gene editing in T. gondii (Shen et al, 2014, mBio; Sidik et al, 2016, Cell; Sidik et al, 2018, Nature Protocols). Pyrimethamine is an inhibitor of dihydrofolate reductase. Treatment with this inhibitor blocks the folic acid synthesis pathway and therefore interferes with DNA and RNA synthesis, resulting in parasite death. Parasites containing a DHFR* gene will no longer die in response to pyrimethamine treatment.

Application of Δku80 T. gondii parasites as background strains is now widespread, with many studies documenting their use as a background for more efficient genetic modification of the organism. For example, it is stated in a report by Fox et al (2011, Eukaryotic Cell) that “a Δku80 genetic background enables a higher-throughput functional analysis of the parasite genome to reveal fundamental aspects of parasite biology controlling virulence, pathogenesis, and transmission”. They also show in this study that the number of parasite cysts present in the brains of mice is not significantly different between Pru (wild type) and a Pru Δku80 strain. Huynh and Carruthers (2009, Eukaryot Cell) also directly showed that deletion of the ku80 gene in T. gondii (RH strain) increases transfection efficiency with inserted genes and gene tags, due to an ablation of non-homologous recombination in Δku80 parasites.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For in vitro and ex vivo work:

Toxoplasma gondii is in biological hazard group 2. All work with the parasite will be performed in a containment level 2 laboratory. Parasite samples will be decontaminated with 1% virkon for a minimum of 60 minutes, liquid waste decanted and discarded down the drain and solid waste subsequently autoclaved. Note, in an in vitro assay to demonstrate effective killing with virkon, no parasites were found to be viable (unable to invade and replicate within host cells) following treatment with 0.1% and 1% virkon for 1 hour. Therefore, treatment with virkon was found to be an effective method for killing T. gondii parasites in vitro (performed by Dr David Smith at Moredun Research Institute, 2020).

For in vivo work:

Any animals infected with GM T. gondii strains generated in this work will be euthanized and destroyed following experimentation and therefore GM strains will not be able to enter the environment. Euthanized mice and sheep will be disposed of by incineration according to section 12 of Moredun Standard operating procedure CLIN/PROC/018:Handling, transfer and Disposal of Waste Containing Hazard Group 2 Pathogens generated within the HSU.

It is also worth noting that non-felid mammalian hosts are "dead end" hosts for T. gondii, in that the parasite cannot be shed from the host and therefore will not enter the environment.
The Moredun Research Institute Genetic Manipulation Safety Committee reviewed the risk assessment and agreed that CL2 is appropriate for this work.

**Project Additional Information**

**Purposes of the contained use**

The objective of this study is to provide information relating to the efficacy of a number of genetically modified Campylobacter jejuni vaccines strains (Salmonella Typhimurium presenting C. jejuni N-glycan on its surface) in the control of Campylobacter infection and shedding in broiler chickens.

Campylobacter species including C. jejuni, are endemic in many chicken flocks in the UK and worldwide (including both layer breeds and broiler breeds). While these bacteria rarely cause clinical disease in the birds, except in cases where the birds are under stress or have preexisting clinical conditions, they are commonly associated with cases of food poisoning in humans through contact with infected eggs and meat, often due to insufficient cooking. A Campylobacter vaccine, capable of reducing bacterial shedding by birds would reduce environmental contamination which would potentially reduce the risk of zoonotic infection.

**Recipient or parental organism**

Salmonella Typhimurium SL1344 parental strain isolated from infected cattle (Hoiseth et al: 1981 Nature); SL1344 is the genetic marked version of the parental strain. Salmonella Typhimurium SL1344 has a natural streptomycin resistancy (encoded on the plasmid pRSF1010).

**Host/vector system**

None

**Origin & function**

**Vaccine 1:**

The following genes of C. jejuni N-glycan biosynthesis cluster were integrated downstream of pagC in a non-coding area of the parental strain (S. Typhimurium SL1344):

- gene: gne  UDP-Glc 4-epimerase
- gene: pglK  ABC-transporter
- gene: pglH  (1→4)-GalNAc transferase
- gene: pglJ  (1→3)-Glc transferase
- gene: pglB  oligosaccharyltransferase
- gene: pglC  Undecaprenyl phosphate bacillosamine 1-phosphate transferase

Tetracycline resistance gene: Tetracycline resistance efflux pump

The natural promoter of the C. jejuni N-glycan biosynthesis cluster was exchanged with the proD promoter (Davis et al. 2010, Nucleic acids research, Vol. 39(3), p1121-1141).

ATPase (apy) encoded in the genome of vaccine 1:

-ATPase gene fused C-terminally with an HIS (histidine) tag is integrated in the non-coding region downstream of the rfaL gene of SL1344

**Vaccine 2:**

The following genes of C. jejuni N-glycan biosynthesis cluster were integrated downstream of pagC in a non-coding area of the parental strain (S. Typhimurium SL1344):

- gene: gne  UDP-Glc 4-epimerase
- gene: pglK  ABC-transporter
- gene: pglH  (1→4)-GalNAc transferase
- gene: pglI  (1→3)-Glc transferase
The integration of the ATPase apy should, based on literature (Proietti et al. 2019 Nature Communications (10)250), increase the recognition of the S. Typhimurium vaccine.
strain in the gut of chicken and increase the rate of clearance of the bacteria from the gut. This hypothesis needs to be verified in the planned animal trials. The deletion of the tetracyclin and streptomycin resistance in vaccine 2 and 3 results in the sensitivity of these strains towards both antibiotics.

A risk of the transfer to wild type bacteria via horizontal gene transfer cannot be completely excluded but the likelihood of this is very low as for all three vaccines, the genes/gene cluster are integrated into the bacterial genome rather than a plasmid. Housing of the animals in contained BSL 2 accommodation within the high security unit will further reduce the risk of any potential transfer to wild type bacteria.

The modifications proposed are expected to result in GMOs of similar potential hazard as the wild-type counterparts. Containment Level 2 accommodation should be enough to minimize the risk to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory Waste. Laboratory waste, including liquid waste will be disinfected using Anistel at a 1:100 dilution for a minimum of 5 minutes. Laboratory waste will be placed in sealed containers (sealed bottles or clinical waste bags –double bagged) which will be sprayed with 1:100 Anisitel once sealed. Containers will be placed in locked clinical waste bins for removal and disposal by an approved external commercial contractor.

Bird carcasses will be double bagged in yellow clinical waste bags which will be sprayed with 1:100 dilution of Anistel and then placed in sealed plastic containers for disposal by an approved external commercial contractor. As birds don’t produce large volumes of liquid waste, blocking the drains in animal pens and use of absorbent bedding material (sawdust) will be sufficient to absorb any liquid waste. Bedding will be double bagged in yellow clinical waste bags which will be sprayed with 1:100 dilution of Anistel and then placed in sealed plastic containers for disposal by an approved external commercial contractor.

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment

The Moredun Research Institute Genetic Manipulation Safety Committee have reviewed your risk assessment “Assessment of efficacy of genetically modified Campylobacter jejuni vaccine strains in a broiler hen model” (Our ref GM21.03) and have agreed with your assessment that the work should be done at containment level 2. Please note that a notification to the HSE is required and the work must not commence until acknowledgement of receipt of the notification by HSE is received.

Historical Significant Changes: TRANSFERRED TO GM 80 (21/6/07).

Project Additional Information
### Purposes of the contained use

To prevent exposure of the workers to class 2 GMM

### Recipient or parental organism

Commercially available replication-defective serotype V adenoviral expression system (e.g., Becton Dickson AdenoX system) lacking E1 and E3 genes.

HEK 293 cells which express E1 genes necessary for packaging the virus will be transfected with adenoviral DNA to generate a replication-defective adenovirus.

The virus will be used to infect primary cultures of ovarian cancer and cancer cell lines.

### Host/vector system

Adenovirus as described above.

### Origin & function

Adenovirus as described above.

### Evaluation of foreseeable effects

No foreseeable effects are anticipated with the use of replication-defective adenovirus type V per se. Adenovirus type V is a common respiratory pathogen, and immunity in humans is believed to be lifelong. The parental virus is considered a class 1 agent.

Therefore, any hazard that arises will depend on the nature of the insert. The insert will be shRNA directed to genes identified through micro-array analysis of ovarian cancers and the work to identify these genes is ongoing. A risk assessment will be conducted for each gene which we intend to knockdown, once the identity of the genes is known. However, since the genes identified by the microarray studies are expected to promote a malignant phenotype, interfering with their expression by RNAi is unlikely to promote malignancy. Nevertheless, we may choose to inhibit the expression of genes whose function is not fully understood and for which the effects are not wholly foreseeable.

### Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

Not relevant.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work will be conducted within a containment level 2 laboratory using a class 2 microbiological safety cabinet. Liquid waste will be treated with chloros at a final concentration of 3% for 12 hours prior to sterilisation by autoclave. Solid waste will be soaked in 10% chloros overnight. Both solid and liquid waste will be collected by the central sterile supplies department and sterilised by autoclave.

### Is an emergency plan required according to regulation 20?

N

### If yes, tick to confirm that it is attached to this form

N

### Tick to confirm that you have attached a risk assessment to this form

Y
The risk assessment has been reviewed by the local GMM Committee who have made no additional comments that have not been included in the risk assessment.

Project Ref 173/07.1

The aim of the project is to use genetically engineered Lentiviruses to produce metastatic models that express a Luciferase marker enzyme and enable the tumours to be visualised in vivo. Cell signalling pathways that are involved in maintaining the metastatic phenotype will be

Class 2  < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

TRANSFERRED TO GM 80 (21/6/07).

purposes of the contained use

To prevent exposure of the workers to Class 2 GMM.
Recipient or parental organism

E.Coli (recA)
DH5 alpha
A commonly used strain with a long history of safe use.

Host/vector system

The following plasmids will be utilised
pFIV-34N
PVSV-G
pSIF1-H1-Puro™shRNA Expression Vector

Origin & function

Our intention is to introduce the luciferase gene into the appropriate established tumour cell lines using an Expression system based upon a Feline Immunodeficiency Virus (FIV) obtained from a commercial source (System Biosciences Inc). The FIV lentiviral expression systems circumvent the possible recombinant issues that normally arise with the use of HIV vectors. We also intend to use the FIV-based short hairpin RNA and double promoter – siRNA Cloning and Expression Vectors that will target selected gene sequences and enable us to produce stable tumour cell lines.

To create functional pseudoviral particles, the lentivector containing the expression construct is co-transfected with the packaging plasmids into the producer cell line. The packaging cells replicate the expression construct and package it into the pseudoviral particles. The pseudoviral particles will then be used to infect (or transduce) target cells and express effector or reporter molecules but cannot replicate within target cells because the viral structural genes are absent and the LTRs are designed to be self-inactivating upon transduction.

Following transduction into the target cells, the expression cassette is reverse transcribed and integrated into the genome of the target cell. After integration, the expression cassette continuously and stably produces high levels of effector or reporter molecules in target cells. Target cells stably expressing the effector molecule will be isolated using the selectable marker contained in the expression vector construct (e.g. puromycin or copGFP). The transduced cells will be assayed for gene breakdown or luciferase production using specific assays, immunoblotting or by flow cytometry. Infected cells will be assayed in vitro and in vivo to determine the effect of knock down or expressed genes on their metastatic potential.

The cell lines that will be transduced are all established human tumour cell lines either derived by the Tumour Biology and Metastasis Team or from ATCC. These will include MDAMB435 (breast), DU145 (prostate), MTSP 12-H (mesothelioma)

Evaluation of foreseeable effects

The feline immunodeficiency virus (FIV) was originally isolated from cat blood. Despite common close exposure of humans to FIV through contact with domestic cats (including bites, scratches, etc), no human infection or disease has ever been associated with FIV.

The lentiviral expression systems are made with a split-genome conditional packaging system which acts as a built in device against the generation of productive recombinants. The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev), and the corresponding proteins are expressed from different plasmids (for HIV-based packaging plasmids) lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus. None of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal – therefore, the lentiviral particles generated are replication-incompetent.

The packaging plasmids are transfected into the 293TN producer Cell Line. In the unlikely event these cells were accidentally injected the risk of pathogenesis is very low due to the recognition of the cells by the immune system as being foreign.
A deletion in the enhancer of the U3 region of 3' LTR ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Evaluation of foreseeable events:**

The feline immunodeficiency virus (FIV) was originally isolated from cat blood. Despite common close exposure of humans to FIV through contact with domestic cats (including bites, scratches, etc), no human infection or disease has ever been associated with FIV.

The lentiviral expression system are made with a split-genome conditional packaging system which acts as a built in device against the generation of productive recombinants. The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev), and the corresponding proteins are expressed from different plasmids (for HIV-based packaging plasmids) lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication virus. None of the HIV-1 genes (gag. Pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal - therefore, the lentiviral particles generated are replication- incompetent. The packaging plasmids are transfected into the 293TN Producer Cell Line. In the unlikely event these cells were accidentally injected the risk of pathogenesis is very low due to the recognition of the cells by the immune system as being foreign. The infected human cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. In our risk assessment, the modified viruses should not pose a serious risk to the environment. These viruses are extremely unstable, inactivated by detergent, UV light and ethanol, and would not survive outside of the laboratory environment. Animals containing the previously infected human cells are safe to the environment as they would be unlikely to survive outside the laboratory because of their severe immune defect. There is no potential to transfer the GMO to other organisms outside of the experimentally manipulated procedures outlined.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Protective clothing and gloves will be worn at all times. All staff are trained in the good laboratory practise and are fully aware of the Institute local rules for containment level 2 laboratories. Work surfaces, including the inside of microbiological safety cabinets, will be suitably disinfected after use. Centrifugation will only be performed in sealed tubes to prevent aerosols. Sharps will not be used. Liquid waste, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with a QAC based disinfectant (Tresolin K). Plastic pipettes will be soaked in 5% Chlors prior to removal by CSSD. Solid waste will be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Supernatant will be collected and human tumour and epithelial cells will be exposed to the supernatant in conditions to promote infection. Virus preparation will be certified free of replication competent virus (see below). These cells will then be assayed in vitro and/or injected into animals to measure their oncogenic potential.

Once the lentivirus has infected the cells it should not be able to replicate. In order to test this we will plate NIH3T3 (murine) or ECV304 (Human) cells into 6 well plates (5x10^4/well). Next day we will add 1ml of either fresh or frozen (-70°C) viral supernatant (supernatant 1) (Vector+gene+GFP) plus 2g of polybrene (8mg/ml stock) and incubate overnight. The following day the cells are washed with medium and replaced with fresh medium. After 24 to 48 hours the infectivity will be assessed by assaying the % positive GFP cells. The cells will grow for a further 4 to 6 days (splitting cells if necessary) and overnight supernatant harvested (supernatant 2) from confluent cells. This will allow amplification of the virus.

Plate NIH3T3 or ECV304 cells in a 6 well plate (5x10^4/well) and leave overnight. Add supernatant 2 plus polybrene as before. In addition include as a positive control supernatant 1 plus polybrene. Wash cells next day and add fresh
Question: why are NIH3T3 or EC304 cells being used for the viral activity assay? Are these the cell lines in which studies will be performed?

I thought human tumour cell lines were going to be used for these studies in which case shouldn't these be the cell lines tested for viral activity?

Answer:
Your assumption is correct that no viral particles should be present. This assay is about ensuring that any viral particles there would be detected. I understand that these cell lines are highly sensitive to infection by any virus. DH5 á

It is not clear to me from the proposal what their animal models or the cell lines actually are.

I am only being vague on this issue because we have many animal models and cell lines that we hope to use and I don't wish to be limited by naming just a few.

Initially there will be MDAMB435 (breast), DU145 (prostate), MSTO 12-H (mesothelioma)

The work is categorised as containment level 2 and yet there are not any level 2 labs in the McElwain.

The proposed laboratory (room 019) has been inspected by members of ICR's Health and Safety and has been

Historical Significant Changes

Historical Date of Additional Info MERGED WITH GM774
**Project Additional Information**

### Purposes of the contained use

- Molecular cloning and expression, of Porphyromonas gingivalis genes encoding extracellular protease, enzymes involved in protein modifications, lipopolysaccharide biosynthesis, and outer membrane proteins in Escherichia coli.
- Manipulate the above constructs for insertional mutagenesis of genes putatively involved in protease and outer membrane protein expression, and post-translational modification and re-introduce into Porphyromonas gingivalis.

### Host/vector system

**Escherichia coli** K12 derivitives (XL-1 Blue, XL10 Gold, SCS110, SURE, Stratagene), general cloning hosts, will be used. The strains are attenuated, sensitive to bile salts and are unable to survive in the alimentary canal. Porphyromonas gingivalis (see above) will be used for complementation of mutated genes.

E. coli - Plasmids pUC18 - derived (Amp(r), LacZa - pUC18, pUC18notI, pK18) will be the general cloning and manipulating vectors. For expression of poly his-tagged recombinant proteins JFQ- derivitives (commercially known as pQE80, Qiagen) will be used to direct controlled (inducible by Isopropyl-D thiogalactoside, IPTG) expression under ptac or pT5 promoter, respectively.

Porphyromonas gingivalis - pNJR12 (tet(r) Bacteroides/Porphyromonas - E.coli) shuttle plasmid will be used; the plasmid is known to replicate autonomously as a low copy number (<10 copies per bacterium). Alternatively, manipulated genes will be integrated into the genome via the homologous recombination using erythromycin encoding cassette (from pVA2198).

### Origin & function

Chromosomal DNA will originate from Porphyromonas gingivalis and will encode orthologues of: Proteases specific for extracellular arginine - peptide bonds (Lys-gingipain) Proteases specific for extracellular lysine peptide bonds (Arg-gingipain) Outer membrane proteins . Enzymes involved in lipopolysaccharide (LPS) biosynthesis, glycan transferases.

The open reading frames (orfs) will be amplified, cloned and manipulated (by insertion of a specialised macrolide-lincosamide cassette, erm) in E. coli with the main intention of inactivating the corresponding gene in Porphyromonas gingivalis via homologous recombination. These mutants will be assessed, biochemically and genetically, to ascertain their contribution to the metabolism, survival and pathogenicity of Porphyromonas gingivalis.

Some of these orfs will be specially cloned for controlled expression in E. coli for subsequent production of antiserum for studies of protein expression in Porphyromonas gingivalis.

Another set of orfs will be cloned into pNJR12 and introduced into Porphyromonas gingivalis to compliment corresponding mutations to assess interconnecting metabolic pathways.

### Evaluation of foreseeable effects

The genome of Porphyromonas gingivalis W83 has been sequenced by The Institute of Genomic Research (http://www.tigr.org/) and annotated (http://www.tigr.org/tigr-scripts/CMR2/GenomePage3.spl?database=gpg) so only known orfs will be cloned. Protease gene constructs have previously been shown not to yield active enzyme in E.coli. However, expression of active enzymes from some constructs cannot be ruled out. Expression of Porphyromonas gingivalis proteins in E.
coli is unlikely to make the host more pathogenic than Porphyromonas gingivalis itself. Inactivation of Porphyromonas gingivalis genes is expected to lead to metabolic defects that should result in attenuated and poor viability of the bacterium. Complementation of Porphyromonas gingivalis should lead to restoration of normal activities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All relevant containments are in place to minimise the potential of any risk. All materials (pipette tips, plates, glassware, tissues, gloves, etc) that are contaminated with bacteria or nucleic acids will be thoroughly soaked in 5% Hycolin then autoclaved, or autoclaved directly, and disposed via the College in accordance with departmental containment level 2 safety regulations.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Project Ref 174/01.2

Date Ackn'd 30/11/2001

CU2 Project Title USE OF REVERSE GENETICS TO CREATE AN ATTENUATED INFLUENZA VIRUS

Class 2

CultureVolClass2 < 1 litre
Project Additional Information

### Purposes of the contained use
To produce an attenuated influenza virus that could be used as a live attenuated vaccine against current strains of influenza virus. Current influenza virus vaccines are only about 70% effective, live attenuated virus vaccines like those we are trying to develop may be more effective.

### Recipient or parental organism
The extensively studied PR8 strain of the influenza virus will be used as the recipient influenza strain. The PR8 strain of influenza virus is highly attenuated and does not cause disease in humans. Influenza viruses are classified as ACDP category 2 pathogens.

### Host/vector system
Plasmids containing the cloned genes of influenza virus strain PR8 are being generously donated by Professor Brownlee (Sir William Dunn School of Pathology, University of Oxford). The plasmids are pPoli-PB2-PR8, pPoli-PB1-PR8, pPoli-PA-PR8, pPoli-HA-PR8, pPoli-NP-PR8, pPoli-NA-PR8, pPoli-M-PR8, pPoli-NS-PR8, pPoli-Sapl-Rib, pcDNA-PB1-PR8, pcDNA-PB2-PR8, pcDNA-PA-PR8, pcDNA-NP-PR8. These plasmids are all pUC18 derivatives. These will be transfected into either Vero (African Green Monkey) cells or 293T (Human kidney) cells. Recombinant virus will then be retrieved from these transfected cells (see Fodor E, et al. Rescue of influenza A virus from recombinant DNA, J Virol 1999; 73:9679-9682).

### Origin & function
The introduced genetic material will be the influenza virus neuraminidase and haemagglutinin genes cloned from recent strains of the influenza virus such as A/New Caledonia/11/99. Mutations will be added to these cloned genes to attenuate the virus. Alterations to the neuraminidase gene have been shown to lead to a reduction of virulence (see Solarzano et al. Reduced levels of neuraminidase of influenza A viruses correlate with attenuated phenotypes in mice, J. Gen Virol 2000: 81 Pt 3: 737-742). The recombinant virus will thus contain all the PR8 gene segments except those encoding the neuraminidase and haemagglutinin which will come from a recent strain of the influenza virus. The introduced gene products will be expressed on the surface of the recombinant influenza virus and are intended to act as antigens to provoke a protective immune response to any later challenge by the wild type influenza virus.

### Evaluation of foreseeable effects
The influenza virus normally causes an upper respiratory infection in humans, however, the attenuated PR8 strain is non-pathogenic in humans. The mutations we add to the influenza virus genome are intended to be stable and to attenuate the virus. The haemagglutinin and neuraminidase proteins have been shown to be non-toxic to humans and have been used extensively in vaccines. Vaccines are available to protect against influenza virus infection and there are antiflu drugs such as Tamiflu and.

---

**Date Ceased:** 01/09/2009

**Non-GMM Consent Granted:** not applicable

**Historical Significant Changes:** MERGED WITH GM774

---

02/03/2022

Page 4549 of 15326
Relenza.

Influenza viruses pose limited environmental risk as they are degraded quickly in the environment (UV, desiccation), the genetic modifications we perform will not change this.

Work with the mutated influenza virus being conducted in Microflow Biological Safety Cabinets in a category 2 GLP laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste produced containing recombinant influenza virus will be treated with Basol a quaternary ammonia compound based detergent. This detergent is known to very rapidly destroy lipid encapsulated viruses such as influenza. To ensure a one hundred per cent kill the waste containing the recombinant virus will be left in the basol for 24 hours. The waste will then be disposed of down the sink. This is a standard technique for disposing of influenza waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Both the parent virus and the neuraminidase and haemagglutinin proteins from recent strains have a history of safe use in humans.

Project Ref 174/02.1
Project Additional Information

Purposes of the contained use

Molecular cloning of Pseudomonas aeruginosa genes encoding metalloproteases, serine proteases, genes involved in type III secretion systems and genes involved in cobalamin (vitamin B12) biosynthesis in Escherichia coli.

Construction of insertion mutants of the genes mentioned above in Pseudomonas aeruginosa.

Recipient or parental organism

The origin of DNA will be the gram-negative bacterium Pseudomonas aeruginosa.

The genome of P. aeruginosa has been sequenced in a collaboration among the Cystic Fibrosis Foundation, the University of Washington Genome Center and Pathogenesis Corporation (http://www.pseudomonas.com/).

In P. aeruginosa the mutated genes are unlikely to confirm any advantage relative to the wild type strain; complemented strains are expected to restore wild type gene activities.

Host/vector system

Escherichia coli JM109 strain a K12 derivative will be used as a cloning host.

This strain is attenuated, sensitive to bile salts and unable to survive in the gut.

E. coli S17-1 a mobilising strain that carries the transfer function of the plasmid RP4 integrated in its chromosome will be used as the host for the plasmid pEX100T carrying the disrupted P. aeruginosa genes.

The vectors used in this project are:

pUC18, pUC18NotI. Non-mobilisable vectors

pUCP18-Escherichia-Pseudomonas shuttle vector. Non-mobilisable
pEX100T-gene replacement vector, mobilisable. The P. aeruginosa genes cloned in this vector are interrupted by the insertion of a gentamicin resistance cassette.

pUCGm-source of the gentamicin resistance, GM R cassette.

Origin & function

Chromosomal DNA will originate from Pseudomonas aeruginosa and will encode orthologues of:
- Metalloproteases
- Serine proteases
- Genes involved in Pseudomonas aeruginosa type III secretion system
- Genes involved in cobalamin (vitamin B12) biosynthesis

The open reading frames will be amplified, cloned and manipulated (by insertion of a gentamicin resistance cassette) in E. coli with the main intention of inactivating the corresponding gene in P. aeruginosa via homologous recombination. These mutants will be assessed, biochemically and genetically, to ascertain their contribution to the survival and pathogenicity of P. aeruginosa.

The above open reading frames will be cloned into pUCP18 and introduced into P. aeruginosa in order to complement the corresponding mutations.

Evaluation of foreseeable effects

The E. coli JM109 strains carrying the cloned P. aeruginosa genes should not be more hazardous than the P. aeruginosa host. In P. aeruginosa the mutated genes are unlikely to confer any advantage relative to the wild type strain. Complementation of P. aeruginosa should lead to restoration of normal activities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All relevant containments are in place to minimise the potential of any risk.
All materials (pipette tips, plates, glassware, tissues, gloves) that are contaminated with bacteria or nucleic acid will be thoroughly soaked in 5% Hycolin autoclaved and disposed via the college in accordance with the safety regulations.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Suggested comments by the local Genetic Modification Safety Committee have been incorporated in this and the attached document.
**Project Additional Information**

**Purposes of the contained use**

Molecular cloning of Helicobacter pylori genes encoding proteolytic enzymes of H. pylori identified using a number of bioinformatic approaches.

Construction of insertion mutants of the genes mentioned above in Helicobacter pylori.

**Recipient or parental organism**

a) Escherichia coli DH5a (or similar K12 derivative) (supE44 [lacZYA-argF]U169 (80lacZ M15) hsdR17 (rk-, mk+) recA1 endA1 gyrA96 thi-1) that is recognised as a non-colonisung and disabled. It may be considered equivalent to ACDP category 1. It has limited survivability in the environment. Over expression strain: ER2566

02/03/2022
b) Helicobacter pylori SS1, 26695, J99 and NCTC 11637. All strains carry the Cag pathogenicity island and do not carry any virulence plasmids. 26695 and J99 are the 2 sequenced Helicobacter pylori strains. SS1 is the adapted mouse colonising strain and NCTC 11637 is the adapted Mongolian Gerbil colonising strain. All strains are ACDP category 2 and have very limited survivability in the environment.

Helicobacter pylori: The disruption of a gene with either cat or aphA3 is unlikely to confer any advantage to the wild type strain, apart from the introduction of the antibiotic resistance genes. Neither of these antibiotics have every been and are never likely to be part of treatment regimens for H. pylori infection. If strain cans be complemented, it will restore the Wild-type activities. Further, Large quantities of H. pylori must be ingested along with acid suppressive drugs to allow colonisation.

### Vector System

<table>
<thead>
<tr>
<th>Vector</th>
<th>Description</th>

<tr>
<td>pTyb</td>
<td>pTyb is a protein fusion vector with a T7 RNA polymerase expressed off a Lac Promoter</td>
</tr>
<tr>
<td></td>
<td>Overexpression of recombinant proteins will only occur upon addition of IPTG</td>
</tr>
<tr>
<td>pKatA</td>
<td>pGem with katA from H. pylori cloned into lacZ. katA::aphA3 (originating from Campylobacter coli)</td>
</tr>
<tr>
<td>pucCat20</td>
<td>puc19 vector containing cat originating from Campylobacter coli</td>
</tr>
</tbody>
</table>

None of the above vectors are replicated in H. pylori and will be used as suicide vectors.

### Host/vector system

Hosts will be E. coli

Escherichia coli DH5a (or similar K12 derivative) (supE44 (lacZYA-argF)U169 ( 80lacZ M15) hsdR17 (rk-, mk+) recA1 endA1 gyrA96 thi-1 relA1) that is recognised as a non-colonising and disabled. It may be considered equivalent to ACDP category 1. It has limited survivability in the environment. Over expression strain: ER2566

Genotype: F- -fhuA2 [lon] ompT lacZ::T7 gene1 gas sulA11 (mcrC-mrr)114::IS10 R(mcr-73::miniTn10-TetS)2 R(zgb-210::Tn10(TetS) endA1 [dcm].

### Origin & function

All genes identified as potentially encoding proteolytic enzymes of H. pylori will be cloned from the sequenced strain H. pylori 26695. These genes will be cloned into a vector and disrupted using an antibiotic resistance cassette, such as aphA3 or cat encoding kanamycin and chloramphenicol resistance, respectively (originating from Campylobacter coli). Once the genes have been disrupted in the vector, they will be introduced to H. pylori by transformation and incorporated into the genome by allelic exchange. Kanamycin and Chloramphenicol are not currently used and are unlikely to ever be used in therapeutic regimes for the treatment of H. pylori infection.

### Evaluation of foreseeable effects

Creating protease deficient mutants of H. pylori are unlikely to confer any advantage to the organism. It is more likely to compromise the pathogenicity of the bacterium.

Introducing virulence factors into the attenuated derivatives of E. coli K12 is likely to increase the potential virulence of the E. coli. The potential virulence of the E. coli will not exceed that of the Wild-type H. pylori.
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All relevant containments are in place to minimise the potential of any risk.
All materials (pipette tips, plates, glassware and gloves) that are contaminated with bacteria or nucleic acid will be thoroughly soaked in 5% (v:v) hycolin, autoclaved and disposed by incineration via the college in accordance with safety regulations, currently in use for ACDP hazard group 2 organisms.

Is an emergency plan required according to regulation 20?  N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

MERGED WITH GM774

Project Additional Information

**Purposes of the contained use**

A marker plasmid will be constructed to allow the monitoring of bacteria either by bioluminescence or fluorescence in the presence of a fluorescent substrate.

**Recipient or parental organism**

Recipient organisms: Escherichia coli K12, Salmonella typhimurium SAL1, Legionella pneumophila NCTC11191, Bacillus cereus NCT2599, Pseudomonas aeruginosa PAK and Burkholderia cepacia NCIMB9091; all are wild type identified laboratory strains. E. coli is ACDP cat. 1 all other organisms are cat. 2.

**Host/vector system**

Plasmid vector (pBBR1MCS4) confers ampicillin resistance and is only mobilisable when the RK2 transfer functions are provided in trans. Plasmid will be modified to also confer chloramphenicol resistance.

**Origin & function**

Firefly luciferase (luc+) from the commercially available plasmid pSR-luc+ or B-galactosidase (lacZ) amplified from the E. coli K12 chromosome will be cloned into the plasmid pBBR1-MCS4. These will allow us to determine the amount of bacteria adhered to eukaryotic cells either by luminescence (luc+) or fluorescent (lacZ).

**Evaluation of foreseeable effects**

Since the plasmid being constructed is only for use as a marker it is not expected to change the virulence properties of the recipients. Therefore a release of the GM organism would result in the same effect as a release of the unmodified organism.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All materials contaminated with GM bacteria will be soaked in 5% (v/v) hycolin (if not directly autoclaved), autoclaved and disposed of by incineration via the college in accordance with the safety regulations currently in use for ACDP hazard group 2 organisms.

Date of Significant Change

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
To investigate function of DNA replication, recombination and repair genes, and their role in antibiotic resistance acquisition.

**Recipient or parental organism**
Clinical and laboratory isolates of Streptococcus pneumoniae and other mitis group streptococci.

**Host/vector system**
Genes will either be cloned in E. coli vectors unable to replicate in streptococci in order to mediate incorporation into the pneumococcal/streptococcal genome, or cloned in shuttle vectors such as pVA838 and pVA981 which can replicate in pneumococci/streptococci. In some cases genes will be cloned to allow expression: pMSP3535 allows regulated expression in streptococci.

**Origin & function**

The intention is either to inactivate or to overexpress the genes in streptococci. In some cases genes will be inactivated by insertion of antibiotic resistance cassettes, and reporter genes will be inserted downstream of promoters to assess regulation of expression.

**Evaluation of foreseeable effects**
Modified S. pneumoniae and mitis group streptococci may have an increased mutation rate and some will carry additional antibiotic resistance genes. Hypermutable organisms are generally at a disadvantage due to the accumulation of errors. Clinical isolates known to have a wide range of mutation frequencies are not thought to be associated with increased virulence. There is potential for an increase in mutation to antibiotic resistance. Penicillin is usually the drug of choice for treating infection - penicillin resistance cannot be gained by point mutation, and none of the resistance cassettes to be used confer penicillin resistance.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All cultures and contaminated materials are autoclaved (effective 100% kill, monitored by regular servicing of autoclave and integrated chart recorder). After autoclaving, disposable solids are removed as clinical waste for incineration, and liquids are disposed of to drain.

Project Ref 174/06.2

Date Ackn'd 22/03/2006

Date Project Ceased 01/09/2009

Consent Granted Not Applicable

Project notified under transitional arrangements N

Investigation of interactions of enterohaemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) and cells of the organised lymphoid tissue of the human gut.

purposes of the contained use

Investigation of enterohaemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) can affect and modulate immune cells of the human gut by injecting proteins via a type III secretion system.
Laboratory derivatives of the E. coli strain EHEC 0157:H7. All strains are Shigatoxin-negative.

Laboratory derivatives of the E. coli strain EPEC 0127:H6. All strains are negative for the EspC enterotoxin.

Host/vector system

The strains to be used carry a plasmid (pFPV25.1) with the gene that encodes for green fluorescent protein (GFP) or the plasmid pCX340 with a gene that encodes with NleD ("Non LEE Encoded effector", an EHEC effector protein) fused to TEM-1 B-lactamase which serves as a reporter protein to directly show that a cell has received a signal via type III secretion.

One EPEC strain carried the pCX340 plasmid with the effector protein (TccP ("Tir-=cytoskeleton coupling protein") fused to TEM-1 B-lactamase which serves as a reporter protein to directly show that a cell has received a signal via type III secretion.

Origin & function

pFPV25.1 expressing the green fluorescent protein (GFP) allows direct visualisation of EHEC and EPEC by fluorescent microscopy.
pCX340 expressing NleD or TccP fused to TEM-1 beta-lactamase serves as a fluorescent-based reporter for cells which have received a signal via type III secretion.

Origin & function

Modification involves introduction of marker genes. These are expected to have no effect on the virulence of the host.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Please enter comments on the GM safety committee on the risk assessment

The comments were that if a member of staff suffers from diarrhea, the PI and the Health and Safety Officer will be notified. A restriction was made on the volume of media in which the organism was cultured (maximum 20 ml).
To make single base changes by site directed mutagenesis in 10 genes involved in replication of the live attenuated Oka Varicella-zoster vaccine virus.

Historical Significant Changes
MERGED WITH GM774

Project Additional Information

Purposes of the contained use
To determine the biological significance of wildtype alleles present in genes involved in replication that occur at significantly lower frequency in the original Oka vaccine preparation but appear to have been selected for in Oka Varicella vaccine viruses that cause rashes.

Recipient or parental organism
Attenuated Oka varicella vaccine virus present in Cosmids and in a BAC.

Host/vector system
Cosmids and BAC are already assembled containing the entire Oka varicella vaccine virus and will be transfected into E. coli to obtain sufficient titres.

**Origin & function**

Genes to be manipulated are involved in either DNA replication, gene expression or are of unknown function but are known to be expressed during latency and may include: Ie10 AND Ie62 (transactivator proteins), Membrane protein (ORF1), Stearoylated membrane protein (ORF 9), glycoprotein C (ORF14), latency expressed protein (ORF21), glycoprotein B (ORF31), ORF39 (unknown function), 50 (unknown function), Origin of replication binding protein (ORF51), Components of DNA helicase/primase complex (ORFs 6, 52, 55) ORF54 (unknown function), Uracil-DNA glycosylase (ORF59).

Mutated cosmids will be transfected into melanoma cells to produce transmissible recombinant virus.

**Evaluation of foreseeable effects**

Recombinant Oka vaccine virus from cosmids or BAC may have increased virulence compared to original Oka vaccine virus but are highly likely to remain attenuated compared to wildtype virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

This connected programme of work aims to investigate the neutralisation and tropism properties of different retroviruses. Both ACDP 2 and ACDP 3 retroviruses will be used including HIV 1 and 2, HTLV 1 and 2, SIV and MLV. Retroviral genes will be amplified from infected cell cultures or patient DNA and either full length molecular clones or plasmids containing different retroviral genes will be generated. Transfections into mammalian cell lines will result in either fully infectious or defective virus particles that are not transmissible.

Retroviral full length molecular clones will be propagated in E. coli K12 derivatives and in human cells. E. coli K12 derivatives are disabled and non-colonising. Mammalian cell lines will be used but these will not come from worker. Fully infectious virus will be made following transfection of these plasmids into mammalian cell lines. The foreseeable risk for work with these full length molecular clones is the production of infectious virus. Transfections and all subsequent work with these retroviruses will be done in a CL3 laboratory.

Host cell lines and primary cells including: T-cells, fibroblasts, epithelial cell lines, primary peripheral blood mononuclear cells and macrophages. All cell lines and primary cells will not be from any authorised workers. The bacterial hosts for expression vectors will be disabled E.coli K12 derivatives. The cloning plasmid vectors will include TOPO vectors, pcDNA3.1, pCAGGS, pNL4.3 delta env, pMDG (VSV-G envelope vector) pCNG (packaging plasmids) and pHIT60 (MLV gag/pol vectors). Vaccinia virus.
expressing T7 RNA polymerase: VR2153.

### Origin & function

Retroviral genes amplified from DNA from patients will be cloned into mammalian expression vectors following cotransfection into mammalian cell lines either fully infectious virus will be made of defective, non-transmissible virus capable of only a single round of infection will be made. The intended function is to study the neutralisation and tropism properties of these chimeric infectious or pseudotyped viruses.

The vectors to be used include pCGNCG (Sonoeka et al 1995), PCSGW, pSVIII, pCAGGS, pCR-Blunt II and pCR 2.1. Packaging vectors include p8.3, p8.91. Full length molecular clone vectors include pNL4.3, p89.6 and pHXB2. The envelope deleted plasmid can be pNL4.3 delta env. These retrovirus vector systems are standard laboratory reagents.

The intended function of the plasmid expression vectors, retroviral expression vectors and the general material inserted in them is to change the level of expression of viral and/or host proteins in the cell. This will result in the production of cells and viruses with altered properties.

### Evaluation of foreseeable effects

The bacterial strains used for all plasmid propagations are disabled in key bacterial functions and are unable to survive in the environment or pass genetic material onto host bacterial flora following a breach in containment. Expression of the retroviral full length molecular clones could cause infection if injected intra muscarily in sufficient quantities. These clones will only be grown in a maximum culture volume of 100ml and sharps will be forbidden in this laboratory area in order to minimise the above risk.

PPE in the form of Howie lab coats, goggles and disposable gloves will also be worn. The plasmids used for the generation of pseudotyped retroviruses split the retroviral genome into separate plasmids such that virus production is only initiated when all plasmids are present in a mammalian cell line. These plasmids are always propagated separately to minimise the risk. No mammalian cell culture is present in the CL2 molecular biology laboratory where this work is carried out. The risk of naked DNA is considered to be negligible.

The recipient cell lines and primary cells which are not from person who work in the laboratory are known to be free from human pathogens ACDP2-4 groups. These cells have limited survivability in the environment and have serum and nutrient requirements that would not likely be met outside laboratory tissue culture. Transfection of the full length molecular clones results in fully infectious virus that is capable of infecting a worker. Recombination between the plasmids for the pseudotyped viruses could also result in infectious virus though this is very unlikely. The risk is managed by carrying out transfections into mammalian cells and all subsequent work in a CL3 laboratory. A Code of Practice details all working practices for this laboratory. All staff must be fully trained by an experienced worker and copies of all training records kept. All work with cell cultures is carried out in a Class 1 microbiological safety cabinet which is tested every 6 months. Access to the laboratory is controlled by card. Sharps are forbidden. Vaccinia virus is used to boost the expression of retroviral envelopes. In order to limit the exposure of workers to those only involved in the work directly, it will be handled in the CL3 laboratory where access is controlled and a separate class 1 microbiological safety cabinet and CO2 incubator can be dedicated to this work. Workers with vaccinia virus will be fully apprised of the risks prior to working with the virus as per the attached risk assessment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Containment Level 2:**

Bacterial waste: All GMMs are inactivated in 5% Trigene for at least 16 hours before disposal or autoclaved followed by incineration as per college practice.

**Containment Level 3:** All disposable plasticware is soaked in 5% Trigene in microbiological safety cabinet for at least 16 hours prior to disposal. All plasticware is then placed in double autoclave bags and autoclaved directly out of the CL3 laboratory before being sent for incineration. A temperature of 134°C is maintained for 15 minutes in the autoclave to sufficiently kill all life exposed to this treatment. Two double ended autoclave bags are present in the CL3 laboratory. The efficacy of Trigene has been
tested using a blue spot beta-galactosidase assay for HIV infectivity. No infection could be detected following staining 3 days later.

Project Ref 174/08.1

Investigation of neutralising antibodies and anti-viral compounds on hepatitis viruses and the effect of chronic infection on the response to treatment.

Class CultureVol  Class 2 Culture Volume  Class 3-4
Class 3 < 1 Litre 100ml

Non-GMM Consent Granted
Yes

Project notified under transitional arrangements  N

Historical Significant Changes
MERGED WITH GM774

Significant Change ID
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Chronic infection with the hepatitis viruses is an important cause of morbidity and mortality. This connected programme of work aims to investigate the biology of the viruses and potential agents useful in treatment and prevention of infection. Both HBV and HCV will be investigated as will co-infection of HCV and HIV and the effect of HCV infection on HIV virus production and other properties. Viral genes from infectious clones or patient samples transfected into cell lines will result in either fully infectious virus or non-transmissible defective virus particles.

**Recipient or parental organism**

Full-length or partial viral DNA will be cloned into Ecoli. Transfection of full-length RNA or plasmid DNA, or partial length DNA co-transfected with a defective retroviral plasmid construct into mammalian cell lines or primary cells will be used. These will not come from any laboratory worker. The foreseeable risk for work with these full-length molecular clones is the production of infectious virus. Viral RNA will be produced and stored in the CL3 laboratory as will transfections and all subsequent work with these constructs.

**Host/vector system**

Host cell lines and primary cells including: fibroblasts, hepatoma cell lines, and primary cell, T-cells, peripheral blood mononuclear cells and macrophages. All cell lines and primary cells will not be from any authorised workers. The bacterial hosts for expression vectors will be disabled E.coli K12 derivatives. The cloning plasmid vectors will include TOPO vectors, pGEM, pcDNA31, pCAGGS, pNL4.3 delta env, and pSVIII.

**Origin & function**

The intended function of the genetic material is to introduce it into mammalian cells so that it becomes possible to study the neutralisation of the hepatitis viruses and their effect on the functions of the cell. Hepatitis genes will be amplified from infected patients and will be cloned into mammalian expression vectors and following cotransfection into mammalian cells defective, non-transmissible virus capable of only a single round of infection will be made. The vectors to be used include the mammalian expression vectors pSVIII, pCAGGS and pNL 4.3 delta env. Other vectors include pGEM Teasy and the TOPO vectors pCR-Blunt land pCR2.1. Full-length RNA from a plasmid containing cloned JFH1 will be used to transfect mammalian hepatoma cell lines (Wakita et al, 2005). This is known to transfect successfully and produce infectious virus particles. Mutations of this construct or constructs from other genotypes or of mixed genotype will also be used. Further, these HCV expressing cell lines will be infected with HIV and other retroviruses to study the effects on HIV biology. These experiments will result in the production of cells and viruses with altered properties. A well characterised hepatoma cell line which is already transfected with the hepatitis B virus, and produces viral particles into the tissue culture medium, will also be used (Sells et al, 1987)

**Evaluation of foreseeable effects**

The bacterial strains used for all plasmid propagations are disabled in key bacterial functions and are unable to survive in the environment or pass genetic material onto host bacterial flora following a breach in containment. The plasmids used for the generation of pseudotyped retroviruses split the retroviral genome into separate plasmids such that virus production is only initiated when all plasmids are present in a mammalian cell line. These plasmids are always propagated separately in disabled E. coli K12 derivatives to minimize this risk. No mammalian cell culture is present in the CL2 molecular biology laboratory where this work is carried out. The risk of naked DNA is considered to be negligible. Co-transfection of the envelope deleted retroviral plasmid, a plasmid containing a marker gene and the cloned envelope genes into a mammalian cell can result in a single cycle infectious virus which is not transmissible. To mitigate the risk of infection co-transfection and all subsequent work will only be carried out in a CL3 laboratory covered
by a code of practice which details all working practices for this laboratory. All staff must be fully trained by an experienced worker and copies of all training records kept. All work with cell cultures is carried out in a Class 1 microbiological safety cabinet which is tested every 6 months. Access to the laboratory is controlled by card, Sharps are forbidden. Cell lines expressing full length clones of the hepatitis viruses produce small quantities of infectious virus. All such culture and the subsequent experiments will be carried out in a dedicated CL3 laboratory under its code of practice as described above. All work with HIV viruses will be carried out in a CL3 laboratory with a COP detailing all work practices.

[The recipient cell lines and primary cells which are not from persons who work in the laboratory are known to be free from human pathogens ACDP2-4 groups. These cells have limited survivability in the environment and have serum nutrient requirements that would not likely be met outside laboratory tissue culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment Level 2:
Bacterial waste: All GMMs are inactivated in 1% Virkon or 5% Trigene for at least 16 hours before disposal. Plates will be autoclaved followed by disposal in the clinical waste as per college practice.

Containment Level 3:
All fluid waste is inactivated in 1% Virkon or 5% Trigene for 16 hours prior to disposal. All disposable plasticware is placed in double autoclave bags and autoclaved within the CL3 laboratory prior to disposal in the clinical waste as per college practice. The performance of the autoclave is tested every 6 months under a service contract. The autoclave is also monitored for each run through its printout and the inclusion of Thermolog chemical integrator strips (Bennett Scientific) to the load.

Project notified under transitional arrangements N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Production of normal and truncated forms of the mouse and human prion protein within a bacterial expression system. The expressed proteins will be used in the development of diagnostic assays to the prion protein from a range of tissues, in particular blood, brain and lymphoreticular tissue.

**Recipient or parental organism**

E.coli BL21 strain classified as broadly similar to disabled, non-colonising K12 strains under laboratory use providing the insert is unlikely to modify bacterial pathogenicity (ACGM guidance, Newsletter 30, November 2001).

**Host/vector system**

pET vector, mobilisation defective.

**Origin & function**

Mouse and human PrP sequences is derived from host cDNA libraries amplified by PCR. The sequence will encode full-length or truncated normal prion sequence.
Evaluation of foreseeable effects

Recombinant prion protein (PrP) is not, of itself, a toxic or hazardous substance. It is unlikely to be hazardous to the environment. The bacterial strain E.coli BL21 has a history of safe laboratory use and is broadly similar to genetically disabled E.coli strains such as K12 and its variants. It is not able to survive in or colonise a host organism. The plasmid used for cloning and expression is defective in its ability to mobilise.

Expression of PrP in the bacterial host will be into inclusion bodies within the bacterium and will not be in a conformation that is similar to the infectious prion. If, in the unlikely scenario that the GMM containing the PrP construct was able to survive and colonise a host, the expressed PrP is unlikely to be hazardous. However, random pathogenic isoform. For this reason additional containment measures are considered sensible. The work is classified as a class 2 activity. As an additional precaution the work will be carried out in a containment level 3 laboratory. The containment measures taken should minimise any escape of the GMM from the laboratory or accidental exposure of the operator.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Evaluation of foreseeable effects

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This contained use activity will take place in a containment level 3 laboratory and all procedures for treatment of GMO waste will be the same as used for decontamination of pathogenic prion protein. Liquid waste is treated with sodium hypochlorite (minimum concentration of 20,000ppm available chlorine) for at least 1hr then discarded into the laboratory sink and washed into the drain with copious amounts of water. This treatment has been validated in our laboratory and shown to kill all (100%) E.coli cultures under conditions of practical use.

Solid waste us placed into the unsealed autoclave bags and autoclaved at 134°C for 20 minutes. Autoclaved waste is placed into 60L sealable rigid containers and sent for incineration as clinical waste using a licenced external contractor. The autoclave is validated annually and serviced at regular intervals.

Project Additional Information

Purposes of the contained use

To investigate the role of red blood cell adhesion molecules, red cell membrane Band 3 complex proteins, apoptotic pathway proteins, signalling molecules, transcription factors and the role of protein trafficking and internalisation and autophagy of these molecules in human erythropoiesis (red blood cell production).

Recipient or parental organism

1. Lentivirus-based plasmids will be propagated in laboratory strains of the bacterium E.coli. There are no foreseeable effects except that the OMM will be transformed to antibiotic(ampicillin) resistance to facilitate selection. The OMM will not express the target genetic material and, like the parent bacterial strain, will be unable to survive outside the laboratory nor colonise mammalian gut.
2. Lentivirus-based transduction particles will be produced in a cultured, human, embryonic kidney cell line. There are no foreseeable effects - the OMM will not express the target genetic material, will be cultured transiently and will be unable to survive outside the laboratory.
3. Cultured, human, haematopoietic, progenitor cells and cultured, human, haematopoietic cell lines will be transduced using these particles and thus rendered resistant to an antibiotic (puromycin) to facilitate selection. The GMIVI will express the target genetic material but will be unable to survive outside the laboratory.

Host/vector system

1. Lentivirus based plasmid vectors: Transfer vectors - pLKO. 1, Sigma, St Louis, USA or pTRIP transfer vector, Charneau et al., Gene Ther. 2001, 8(3):190-8; packaging vectors (Sigma Mission shRNA or psPAX2, Charneau et al., Gene Ther. 2001, 8(3):190-8) and envelope vector, (pCMV VSV-G, Sigma, St Louis, USA) will be propagated in XL-I blue E. coli cells.
2. Lentivirus-based transduction particles will be produced in HEK293T, a human embryonic kidney epithelial cell line.
3. The ultimate host will be cultured, human, haematopoietic, progenitor cells or cultured, human, haematopoietic cell lines. These cells will be transduced using lentivirus-based transduction particles produced as above.

Origin & function

Genetic materials are small, inhibitory RNA sequences or eDNA sequences for the human genes of the proteins listed below:
1. Green fluorescent protein — a control protein used to determine multiplicity of infection values and to demonstrate effectiveness of transduction or knockdown protocols.
2. Cell adhesion molecules - found on many normal human cells and expressed during erythroid development (e.g. ICAM-4 [CD242]; Lutheran blood group protein [CD239]). Tetraspannins - cell adhesion accessory molecules found on many normal human cells and expressed during erythroid development (e.g. CD81; CD82; CDI5I). Band 3 (CD233 the chloride/bicarbonate exchange transport protein) macrocomplex molecules. Includes some red blood cell restricted molecules such as the blood group active proteins glycophorin A, ICAM-4 and Rhd/CE; Rh associated glycoprotein and other, more widely expressed, proteins such as CD47. Includes associated structural/cytoskeletal proteins such as ankyrin and its isoforms and protein band 4.2 and also cellular proteins involved in the efficient trafficking of Band 3 and associated proteins. The overall function of the complex is gas-exchange between the red cell and tissues.
4. Other well characterised mammalian membrane transport proteins found on red blood cells (including Kidd blood group active protein [urea transporter]; glucose transporter Glut-I and CD98 an amino acid transporter).
5. Red cell membrane proteins that form structural complexes involved in the maintenance of red cell integrity (including glycophorin C and associated cytoskeletal proteins such as protein band 4.1, actin and spectrin).
6. Transcription factors - these control gene expression in a tissue dependent manner and thus direct cell differentiation and function. Examples are well characterised human haematopoietic transcription factors GATA-1, KLF 1 and Spi-1. Haematopoietic transcription factors will be targeted. These molecules are normally expressed during erythroid differentiation but inappropriate or mis-timed expression (such as in this case where expression will be driven from a viral promoter) or knockdown of expression by siRNA may result in arrest of normal differentiation and therefore transformation of the target cell to immortality. For this reason, certain transcription factors such as Spi-1 may be considered as oncogenic or leukaemogenic and their encoding sequences as oncogenes.
7. Intracellular signalling molecules with a role in erythropoiesis. Target molecules include kinases and phosphatases of the Src and MAP pathways.
8. Proteins involved in apoptotic pathways in erythroid cells. Includes pro-apoptotic proteins such as Bak/Bax, BH3-only proteins, caspases, Fas & FasL and associated signalling molecules such as GSK-3. The intended use is to enable the study of loss of function or rescue of function of the targeted proteins within a tissue culture, laboratory model of human red blood cell maturation (erythropoiesis).

Evaluation of foreseeable effects

It is predicted that the GMOs produced in this study will have very similar characteristics to the host cells or organism. E.coli cells used to propagate plasmid vectors will be transformed to antibiotic (ampicillin) resistance but will not express proteins encoded by the inserted genes within the vectors. Human embryonic kidney packaging cells will produce lentivirus-based transduction particles. Transduced, target, haematopoietic cells are predicted to be silenced for expression of the gene target sequence or to over-express the sequence but other characteristics are predicted to remain the same as the host cells. None of the GMOs will be capable of survival outside the exacting conditions of culture used in the laboratory. The system is designed such that virus that is capable of replicating within host cells is not produced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
No plants or animals will be used in this study.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Bacterial cultures, petris dishes, tips, etc. contaminated with bacterial strains will be collected in an autoclave bag, an indicator strip will be placed inside so that the indicator “dot” can be seen and autoclaved for 30 minutes at 125°C. Degree of kill 100%. The bag will be inspected and if the indicator strip has changed colour, thus verifying the temperature and duration of heat treatment, the bag will be disposed as clinical waste for incineration by a contractor. The autoclave is serviced annually.
2. Spent tissue culture medium and tissue culture plastic will be treated for 5 minutes with an equal volume of 2% w/v “Virkon” (dipotassium peroxodisulphate, Antec International, Sudbury). Validated by manufacturer to give 100% kill of lentivirus and validated in user’s laboratory to give 100% kill of cultured mammalian cells. Liquid waste will be disposed to drains and waste plastic ware will be disposed as clinical waste for incineration by a contractor.

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The project, with an outline risk assessment (part one of attached risk assessment form) was presented to the Institute’s genetic modification safety committee on 8th January 2008. The committee agreed, in the light of advice provided by HSE specialist inspectors during their inspection in July 2007, that this was not a class 1 project and that a more detailed risk assessment and minimum level 2 containment was required. The risk assessment was completed and sent to committee members by email with an invitation to comment. Comments were favourable and one committee member suggested segregation from other work in the laboratory by further containment within a vented tray designed to contain any potential spill or contamination of the exterior of labware. This has now been included in the risk assessment.

The project, its risk assessment and examination by the GMSC and notification to HSE will be communicated to all staff via the local Health and Safety Committee and the “Local Services Group” as required by the legislation.

CU2 Project Title HUMAN IN VITRO MODELS OF CARCINOMA DEVELOPMENT AND PROGRESSION

Class 2
Culture Volume Class 3-4 < 1 litre

Non-GMM Consent Granted not applicable

---
**Project Additional Information**

**Purposes of the contained use**

To use retroviral transduction to introduce genes into normal human epithelial cell lines that will disable the activity of tumour suppressor proteins and provide a model for studying carcinoma development in vitro.

**Recipient or parental organism**

Disabled retrovirus will be produced by transfecting the pLXSN vector engineered to contain a) the HPV 16 E6 gene (pLXSN16E6) (Halbert et al 1991; J Virol 65:473-478) and b) a full-length p53 mutant which acts as negative-dominant inhibitor of wild-type p53 (Gottleib et al, 1994; EMBO J 13:1368-1374) into the PT67 packaging cell line. The retrovirus will be used to infect normal human epithelial cell lines derived from urothelial, breast, colonic, ovarian, prostate and Fallopian tube origins. Following infection, transduced cells will be selected by neomycin resistance and supernatant from the transduced cells will be screened to demonstrate absence of infectious retrovirus. There are no anticipated risks for the environment as all vectors and host strains are incapable of survival outside specialist laboratory conditions. The only perceived risk would be if a research worker were exposed to the infectious virion through an open wound or via a mucosal epithelial surface as this could result in the introduction of genetic material into exposed cells of the research worker. However, this risk is extremely low because of the safety protocols used to limit exposure of the research worker to retrovirus and because gene integration can only occur in proliferating cells. In addition, the retrovirus is disabled and the chance of genetic recombination or complementation to restore infectivity is minimal. This means that following initial infection, the retrovirus is incapable of producing further infective retrovirus and hence cannot lead to widespread or systemic infection.

**Host/vector system**

**Vector**

pLXSN (from Clontech). This vector is derived from Moloney murine leukaemia virus and contains the MoLV 5'LTR and 3'LTR and has a neomycin resistance cassette. A packaging signal and part of the gap gene is downstream from the 5'LTR. This is a replication deficient viral vector that does not produce infectious virus.

**Host**

a) Packaging cell line

Amphotrophic packaging cell line PT67 obtained from Clontech. In this cell line the gag, pol and env viral genes have been introduced separately making it extremely unlikely that an active retrovirus will be produced due to recombination.

b) Normal human epithelial cells

These cells have not been genetically modified to limit their ability to colonise or infect humans and would therefore be categorised as a wild-type host. However, the immunophenotype of human cells from an individual and the inability of the cells to survive outside defined culture conditions means that they may be categorised as a...
disabled host. It is important that normal cell cultures derived from personnel in the laboratory are not used.

**Origin & function**

- a) the HPV16 E6 gene (pLXSN16E6) the product of which binds and target wild type p53 for ubiquitination (Halbert et al 1991; J Virol 65:473-478) and

**Evaluation of foreseeable effects**

Disablement of the functions of the p53 tumour suppressor protein is likely to mimic the early events of malignant transformation of human epithelial cells. Thus, normal cells so treated must be considered premalignant, with enhanced oncogenic potential, posing a similar risk as human tumour-derived cell lines. All cultures involved in this work will be carried out in laminar flow cabinets and culture supernatants will be tested for the presence of infectious virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Packaging cell lines and normal human epithelial cells are unable to survive outside defined culture conditions, meaning that they can be categorised as a disabled host.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Once the genetically modified epithelial cells have been produced and shown not to produce infectious virus they will be classified as Class 1 as they pose no risk to the environment or to human health.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated plasticware will be decontaminated overnight in 2% Virkon and autoclaved before disposal to waste. All liquid waste will be decontaminated with 2% Virkon (final concentration) overnight before disposal to drain.

Initially, this project was overcautiously classified as a Class 3 activity, on the basis that the work involved the use of oncogenes. However GMSC discussion and subsequent comments/advice by HSE Inspectors resulted in a re-classification to Class 2.

It was decided that the hazards associated with this activity would be adequately contained using containment level 2 measures.

### Project Additional Information

**Purposes of the contained use**

To study the biology of the proteins encoded by human papillomavirus and to relate the biological properties to the structural properties of the viral proteins and the human cell proteins with which they associated.

**Recipient or parental organism**

Disabled Retrovirus will be produced by transfecting the pLNCX and pLXSN vectors into a packaging cell line (3T3 mouse cell based)

**Host/vector system**

**Hosts**

3 types of host will be used:

1. **E.coli**
   
   (a) E.coli K12 based strains are recognised as non-colonising and disabled, posing very low/negligible risk to both human health and the environment. These will be used for the growth and amplification of all plasmid vectors.
   
   (b) E.coli BL21 and AD494 will be used for protein expression. BL-type strains may represent a potential hazard since they are non K-strains and potentially infective. However there has been no evidence of adverse effects after 11 years of use in this laboratory.
2. Insect - non viable outside the tissue culture laboratory and pose a negligible hazard.
3. Mammalian cells - non viable outside the tissue culture laboratory and pose a negligible hazard.

Vectors:
The proposed vector systems pose a low hazard to humans or the environment. The greatest potential risk would be from transfer of antibiotic resistance rather than expression of the foreign gene.

(a) pET series plasmids (non-mobilisable)
(b) pT7Blue series (non-mobilisable)
(c) pGEM series (non-mobilisable)
(d) baculovirus transfer plasmids pVL-type and pBac series - These baculovirus vectors are deleted for the polyhedrin gene and incapable of survival or replication outside the insect cell in tissue culture. Although capable of infecting human cells these vectors can not replicate in these cells.
(e) Plasmids containing mammalian promoters for transfection into mammalian cell lines and recombination into retroviruses.

Origin & function
This activity will use human papillomavirus (HPV) or bovine papillomavirus (BPV) gene coding for E1, E2 (E4, E5), E6, E7, L1 and L2 PV proteins and human cellular proteins E6 - associated protein (E6-AP), and P53.
PV-encoded proteins are expressed from 8-10 viral genes and are responsible for recruiting the functions of the infected host (mammalian epithelial) cell towards maintenance and replication of the viral genome. The E1 and E2 proteins are responsible for viral replication and transcription and are expressed at low levels in infected cells. E4 and E5 are concerned with facilitating exit of viral particles from cells. L1 and L2 are the virus capsid proteins which coat the viral DNA to form virus particles.

Evaluation of foreseeable effects
Expression of E1, E2, E4, E5, L1 and L2 genes in any system constitutes a low hazard. Expression of E2 (and probably E1) in mammalian cell systems at even moderate levels results in death of the expressing cell and no detectable protein product. Ingestion of purified protein is also unlikely to pose a significant risk since the proteins would be readily digested and unable to enter cells in a functional form. Also, since a large proportion of the human population has had a PV infection, many individuals already possess antibodies to PV proteins.

The PV proteins E6 and E7 pose a greater potential hazard as these proteins are responsible for cellular transformation when expressed in a dysregulated manner in the infected epithelial cells. E6 and E7 genes will be expressed in separate vectors to minimise the potential risk. The risks from the purified protein would be low for the same reasons outlined above.

pLNC X and pLXSN vectors could infect and express foreign genes in human tissue but should pose a low hazard due to the cellular toxicity of the PV genes and their inability to replicate. They are deleted for replication functions and require propagation in specific (non-human) helper cell lines in which complementing genes are expressed from separated cassettes thus minimising the risk. All vectors used to generate the recombinant retroviruses are standard strains, and have been in safe use for more than 9 years.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Contaminated plasticware will be autoclaved before disposal of waste. All liquid waste will be decontaminated with 2% Virkon or presept (2000ppm chlorine) (final
concentration) overnight before disposal to drain.

Is an emergency plan required according to regulation 20?

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

For most activities this project is a borderline Class 1/2.  The decision to opt for Class 2 was a result of the use of retrovirus vector combined with potentially very large quantities of biologically active protein for crystallisation studies.

To assess the relative efficiencies of promoter fragments to target mammalian cells for expression of indicator genes (to assess targeting) and bacterial/viral genes (of no known pathological activity) as prod rug activators.

**Recipient or parental organism**

Replication disabled adenovirus will be produced in cultured human embryonic cell lines (eg 293 cells) and inserted genes expressed in primary human cell cultures. The adenovirus is disabled through deletion of the Ad2 E1 gene and cannot replicate in cells which do not contain a fragment of Ad2 adenovirus (eg 293 cells). Disabled baculoviruses are defective in the polyhedrin gene and other critical genes and can only replicate effectively in cells other than the highly adapted host insect cell lines (eg SF9 and SF21) used in the laboratory. The disabled baculovirus will be produced in these standard insect cell lines and used to infect and express transgenes in primary human cell cultures.

**Host/vector system**

4 types of host will be used:

1. **E.coli - E.coli** K12 derived, recA strain DH5a is recognised as non-colonisung and disabled, posing very low/negligible risk to both human health and the environment.
2. **Insect cells** SF21 and Hi5 (for baculovirus production). Insect cells are very unlikely to become established in a human host following accidental exposure unless the individual is severely immunocompromised.
3. **Mammalian cell line** HEK293 (for adenoviral production). The HEK293 cells were derived from human embryonic kidney cells by transformation with sheared human Ad5 adenoviral DNA. The HEK293 are very unlikely to become established in a human host following accidental exposure unless the individual is severely immunocompromised.
4. **Experimental target cells.** Cultured human cell lines and primary human cells. These are also very unlikely to become established outside of the laboratory environment.

Human cells HEK293, experimental target cells and insect cells are non-viable outside the tissue culture laboratory environment and pose negligible hazard to the environment.

**Vectors:**

1. **Bacterial shuttle vectors**
2. **pUC/AdenX/expresson cassette bacterial plasmids**
3. **parental and recombinant baculovirus DNAs (within the insect cells)**
4. **Recombinant AdenX/expresson cassette adenoviruses**
5. **recombinant baculoviruses**

**Origin & function**

3 types of expression cassette will be cloned into the viral vectors.

1. reporter genes encoding luciferase or the fluorescent proteins EGFP or DsRed2 placed under the control of cloned fragments of promoter sequences from specific human genes (primarily those expressed in the prostate such as PSA, PSMA and PSCA or the minimal CMV promotor as a positive control).
2. Cloned tumour-suppressor and prodrug activating genes (wild type or as fusion constructs with sequences encoding EGFP or DsRed2) under the control of minimal CMV promotor or of cloned fragments of specific human genes as described above.

3. Hybrid GP64 membrane proteins in baculovirus containing growth factor receptor recognition peptides to facilitate attachment of BV to human cells.

### Evaluation of foreseeable effects

**Summary**

Most of the experimental procedures in this activity using adenoviral and baculoviral gene transfer systems constitute a very low risk to humans or the environment. Procedures involving handling of high titres of infectious viral particles constitute a potential risk to humans working within the laboratory, though minimal risk to other personnel or the environment.

**Genes**

Products of the reporter genes EGFP, DsRed2 and luciferase are known to have low toxicity and no transforming activity even when expressed at relatively high levels in human cells. Ingestion of these proteins, expression within a person following exposure to bacterial hosts carrying intermediate constructs of the expression vectors, or expression within a person's cells following exposure to infective (non-replicative) virus, are therefore unlikely to present a significant health risk to humans or the environment.

The risk of insertion, by homologous recombination, of part or all of the expression cassette into the genome of a person accidently exposed to the recombinant virus is considered negligible. However, the most likely outcome of this would be apoptosis of the affected cell, with no discernible effects upon human health.

There is a higher risk associated with the use of tumour suppressor genes. However, tumour suppressor peroteins inhibit cell growth and by their nature suppress rather than activate tumorigenesis. The proteins are not likely to have deleterious effects through ingestion or expression within a person following exposure to bacterial hosts carrying intermediate constructs of the expression vectors. Expression of the native form of tumour-suppressor proteins within a person's cells following accidental exposure to infectious non-replicative virus is likely to cause only growth inhibition of the affected cells, again with no discernible effects upon the health of the affected person.

Greatest hazard would come from infection with virus carrying a dominant-negative mutant form of the tumour-suppressor gene or from disruption of normal tumour-suppressor gene function in infected cells through homologous recombination with expression cassette. Known dominant-negative mutants of tumour suppressor genes will be avoided.

**Vectors**

The bacterial shuttle vectors and the pUC/AdenoX/expression cassette plasmids pose a low hazard to humans or the environment and as they will be used in recA host bacteria, genes from these plasmids are unlikely to be transferred to other bacteria or organisms in the laboratory or the environment.

There is a risk of insertion of part of the adenoviral or baculoviral sequence into the host cell by homologous recombination, causing disruption to normal regulation of the host cell's proliferation or survival mechanisms. However, Baculovirus vectors are deleted for the polyhedrin gene and are incapable of survival or replication outside the insect cells in tissue culture. The AdenoX viruses are double-deletion mutants (E1 and E3) and are thus incapable of replication outside helper cells such as HEK293. The double deletion also considerably reduces any risk of intracellular recombination with naturally occurring adenovirus to form replication competent hybrid virus particles.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Contaminated plasticware will be decontaminated overnight in 2% Virkon and autoclaved before disposal of waste. All liquid waste will be decontaminated with 2% Virkon (final concentration) overnight before disposal to drain.

**Purposes of the contained use**

To use genetically modified plant viruses, tobacco rattle virus (TRV) and potato virus X (PVX) to induce RNA silencing (see Ratcliff et al, 2001, Plant Journal 25:237-245)

**Recipient or parental organism**

Two plant RNA viruses will be used: tobacco rattle virus (TRV) and potato virus X (PVX). These viruses exist in the UK and are not insect or pollen transmitted. Viral vectors based on these two viruses have been made by the laboratory of Dr David Boulcombe, Sainsbury laboratory, John Innes Centre, Norwich. Essentially the viral vectors are cDNA copies of TRV or PVX with added multiple cloning sites.

**Host/vector system**

The host plant will be Nicotiana benthamiana. Infection will be via Agroinoculation. The viral cDNA clones are carried in Agrobacterium binary vectors and therefore toothpick inoculation will be used to initiate infections. The viruses are not pollen or insect transmissible. Transmission within the containment facility would require mechanical inoculation.

**Origin & function**

Fragments (<300 bp) of plant cDNAs will be inserted into the PVX or TRV vectors. Replicating plant viruses have the capacity to induce RNA silencing of host genes. Therefore when a plant is infected with a virus carrying a particular sequence, the corresponding host gene will be switched off. This is an established technique referred to as virus-induced gene silencing (Boulcombe et al, 1999, Curr. Opin. Plant, Biol. 2:109-113; Ratcliff et al, 2001, Plant Journal 25: 237-245).

For this project, the inserted host fragments will be from genes involved in DNA methylation, chromatin changes and unknown functions. The gene fragments are not designed to produce protein products.

**Evaluation of foreseeable effects**

There is expected to be no danger to human health from the genetically modified plant viruses since these are essentially wild-type viruses that carry RNA sequences of plant genes. The inserted gene fragments are not designed to produce protein products.

The main risk of this work is in the potential to initiate virus infections outside of the containment glasshouse facility. It should be noted that both PVX and TRV are found in the UK and typically produce mild symptoms. The genetically modified viruses will be fully infectious and are expected to retain the same properties as the unmodified parental virus in terms of host range and symptomology. The viruses to be used are not insect or pollen transmissible or seed transmissible in Nicotiana benthamiana. The main route of transmission is mechanical and is therefore should be easier to contain than for viruses that can be spread via a vector.

Any plant host genes that share greater than ~90% sequence identity with the sequences carried by the virus will be switched off by the process of virus-induced gene silencing. Thus in addition to the normal viral symptoms, infected plants may show phenotypes of gene silencing though this would be limited to the plant species from which the gene fragment was derived. The gene silencing phenotypes will depend upon which gene is carried by the virus and could range in severity from no visible change to lethality. It is possible that the modified viruses will be less fit than the parental viruses and so there may be selective pressure for the viruses to lose the inserts. If this occurred then the modified virus would revert to the parental form.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All level 2 measures will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste material generated will be infected plant material, soil, Agrobacteria-contaminated items such as toothpicks and agar plates, and gloves used to handle plants. All waste material will be autoclaved at 134 degrees C for 15 minutes using a regularly serviced and validated machine. Autoclaving under these conditions is expected to produce 100% kill however the inactivation procedure will be monitored (by assessing the infectivity of autoclaved material) at quarterly intervals.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

It was noted that a class 2 activity classification was justified on the basis that the work involves the use of recombinant plant viruses. It was felt that although the overall risk to the environment was low, full application of containment level 2 control measures would provide satisfactory protection.

CU2 Project Title USsing GENETICALLY MODIFIED PLANT VIRUSES AS VECTORS FOR INDUCING RNA SILENCING OF HOST GENES.

Class 2

CultureVolClass2 < 1 litre

Consent Granted not applicable

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Experiments using genetically modified plant viruses Tobacco Rattle Virus or Potato Virus X and plants infected with them.

**Recipient or parental organism**

Two plant RNA viruses will be used: the tobacco rattle virus (TRV) and potato virus X (PVX). These viruses exist in the UK and are not transmitted by insects or pollen. Viral vectors based on these two viruses have been constructed in the laboratory of Yale University USA, Sainsbury Laboratory, John Innes Centre, Norwich. The viral vectors consist in cDNA copies of TRV or PVX with multiple cloning sites for the insertion of plant sequences.

**Host/vector system**

The host plants will be species in the genera Nicotiana and Lycopersicon, with a concentration on N. benthamiana and L. esculentum. Infection will be via Agroinoculation. The viral DNA clones are carried in Agrobacterium binary vectors and therefore toothpick inoculation will be used to initiate infections.

**Origin & function**

Genetic material consisting of short plant gene fragments (<300bp) will be inserted into the PVX and TRV vectors. Replicating plant viruses have the capacity to induce RNA silencing in host genes. Any plant host gene sharing more than 90% nucleotide sequence identity with the plant gene fragment could theoretically be switched off by the process of virus-induced gene silencing (VIGs). This methodology is well established and applied widely to identify the function of plant genes - see Baulcombe (1999) Curr Opin Plant Biol 2, 109-13, Ratcliffe et al. (2001) Plant J 25, 237-45, Liu et al. (2002) Plant J 30, 415-29. For this project, the cloned DNA fragments will be chosen to target genes specifically expressed in the epidermis of host plants, in order to identify among them those that are associated with epidermal differentiation processes.

**Evaluation of foreseeable effects**

Hazards arising directly from the inserted gene product. The inserted genetic material will be fragments (<300pb) of plant genes predicted to encode proteins that specifically accumulate in the epidermis. The process of virus-induced gene silencing could theoretically switch off any plant host gene that shares more than 90% identity with the plant gene fragment. However, it must be noted that VIGs has been shown not to be active in all plants, even in those in which TRV and PVX replicate and carry genes of the host plant (unpublished test - Sainsbury Laboratory, Norwich). If the receiving environment was exposed to virus used in this activity. VIGs could only theoretically occur in tomato, since only Lycopersicon and Nicotiana sequences will be used, and Nicotiana species are not grown commercially in the UK. Mutations in epidermal-expressed genes have been shown to result occasionally in loss of plant fitness, usually through lower male fertility and less efficient surface water exchanges - see Chen et al (2003) Plant Cell 15, 1170-85, Todd et al. (1999) Plant J 17, 119-130. Such mutations affect all epidermal tissues, whereas VIGs will cause most potential defects in the epidermis of tissues arising 2 to 3 weeks after inoculation. Silenced plants will at worst have partially defective epidermal function, which is unlikely to have any significant effect on their fitness.

Survivability, hazards from the infectious nucleic acids

Partial plant epidermal gene sequences are not expected to alter viral survivability, since they are essentially additional untranslated genomic RNA in the recombinant virus. No recombinant plant protein product is expected to be produced and no hazard to human health is anticipated.
Likelihood that the GMM could cause harm in the event of the environment being exposed
It is extremely unlikely that the recombinant virus would infect plants in the receiving environment since the virus is transmitted by mechanical inoculation only. In the very unlikely event that infection did occur, the resulting level of harm would also be low - defects on some of the epidermal surfaces of plants containing epidermis-expressed genes sharing the appropriate level of sequence identity.

Fitness of genetically modified viruses
In some cases, inserted plant sequences may cause a reduction of viral fitness due to the additional burden of replicating these sequences. This may increase the selective pressure for the viruses to lose the inserts. We do not expect that additional genomic RNA will increase fitness of the virus.

Hazards arising from the alteration of existing pathogenic traits (e.g. alteration of host range or tissue tropism)
No change in host range or tissue specificity is expected for the recombinant viruses as the inserted sequences are not expected to produce a protein product. Since our research will be limited to epidermis-expressed genes, VIGs may result at worst in defects in epidermal cell morphology or biochemistry, which are not expected to have an effect on viral pathogenicity.

Hazard to humans necessitating additional containment measures
There is no identifiable hazard to humans from these recombinant plant viruses.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste material will include infected plant material, soil, Agrobacterium-contaminated materials such as culture tubes, culture flasks, toothpicks, agar plates and contaminated gloves. All waste will be treated appropriately according to its category. Contaminated plant material and soil will be double-bagged at the source prior to autoclaving. All waste will be autoclaved at 134°C for 15 minutes using a regularly serviced and validated machine. Autoclaving under these conditions is expected to produce 100% kill, although assessing the infectivity of autoclaved materials at quarterly intervals will monitor this inactivation procedure.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Following the debate over the suitability of Containment Level 2 for the first activity that we notified involving VIGs, this further activity (albeit an unrelated activity by a different research group) was reviewed by the GM Safety Committee with interest! The GM safety committee inevitably felt that the theoretical risk was greater compared to the original activity given that the work intends to apply the VIGS technique on Lycopersicon esculentum. However, the committee felt that level 2 containment measures, which aim to minimise release of GM material, were still appropriate for this activity for the following reasons. Firstly, the likelihood of tomato crops becoming infected, in the unlikely event of the environment being exposed, remains very low since the virus is transmitted by mechanical means only. Secondly, the level of harm to any tomato plant that is both infected and displaying VIGs symptoms is also considered low - affected plants displaying only mild symptoms. At worst, the silenced plants are anticipated to have a partially defective epidermal function, which would not significantly impair fitness.

Following advice from the HSE, the committee agreed that since there was a possibility that the resulting modified organism could still cause harm, this activity did not satisfy the regulatory definition of self-cloning. The committee agreed that containment measures required for Class 2 activities would provide adequate containment. It was also suggested that, if available, the group leader should consider using a departmental containment level 3 facility for liquid culture manipulations. Although not strictly required for containment of this GM activity, the use of such a facility would offer the advantage of avoiding the use of the shared facility currently used.

Project Additional Information

Purposes of the contained use
The project will analyse the biofilm formation process at a molecular level with the goal of identifying genes or processes that can be targeted in the development of new antimicrobial strategies specific for biofilms. This involves constructing mutants, analysing the ability of these mutants to form and disperse from biofilms, and identifying
the underlying reason for their altered properties. In addition, GMM will be constructed that will facilitate analysis of genes expression during biofilm formation using fluorescent proteins (Gfp, Yfp, Cfp).

Recipient or parental organism

Research will be carried out with bacterial species that are normally commensal isolates of the gastro-intestinal tract: Klebsiella pneumoniae, Pseudomonas aeruginosa, Proteus mirabilis, Enterococcus faecalis. These species however are also causative agents of urinary tract infections, and in many cases have been associated with urinary catheter related infections. They will be mutagenized so that they carry mutations in single genes.

Host/vector system

In addition, GMM will be constructed that will facilitate analysis of genes expression during biofilm formation using fluorescent proteins (Gfp, Yfp, Cfp).

Origin & function

The mutants are made in the parental bacterial species.

In addition, to characterize the genes of interest, they will be cloned and propagated in a E. coli K12 strain (MG155), a non-colonizing bacterial species that is commonly used for this purpose. The cloned genes are not expected to alter this strain with regard to its ability to propagate and survive in the environment.

Evaluation of foreseeable effects

Mutants of the various bacterial species will be selected for their altered ability to adhere to surfaces and to each other, and for altered growth in the environmental micro niche(s) present in a biofilm. Based on the literature, in most cases this will be associated with specifically a decrease in the relevant capacity, which will also negatively affect their ability to colonize. The parental organisms are considered opportunistic pathogens, and this can reasonably be expected to be the same for the GMMs. Thus, they will not pose a health risk for healthy individuals.

The genes clones into E. coli K12 isolates are not expected to alter this strain with regard to its lack of ability to propagate and survive in the environment, since it contains mutations that incapacitate it.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid G waste will be autoclaved on site. A 100% "kill" degree is achieved, which is monitored by periodic viability testing for CFU of waste material. Annual servicing and validation of autoclaves occurs.

GM solid waste and liquids are stored in bins in the laboratory and then taken for autoclaving in another part of the department in sealed, leak proof contains. Treated material is finally disposed of in normal refuse bins for collection by local authorities.
This project was approved as a Class 2 activity, requiring control measures from containment level 2, on the basis that it involved the use of several ACDP hazard group 2 organisms. It was agreed that genetic modification of these organisms did not result in additional hazards to human health or the environment.

### Project Additional Information
## Purposes of the contained use

Expression and manipulation of Schistosoma mansoni proteins with putative immunomodulatory or unknown functions.

## Recipient or parental organism

- **Echerichia coli** strains, eg BL21 or JM109
- **Pichia pastoris** strains, eg X-33 or GS115
- Chinese hamster ovary cells
- Insect cells, eg SF21 or High Five cells

All hosts are non-pathogenic and pose negligible risk to human health.

## Host/vector system

- **E. coli** vectors include pUC, pET, pGEM-T
- **P. pastoris** vector to be used is pPICz
- CHO cell vector to be used is pcDNA4/70
- The Bac-N-Blue baculovirus will be used as a vector with the insect cells

All vectors are either mobilisation defective (eg pET) of non-mobilisable (eg pGEM-T) and are considered to pose a negligible risk to human health.

## Origin & function

The genes to be cloned originate from the human blood fluke *S. mansoni*. The intended function of these gene products is unknown unless significant homology to a protein from another species is detected. It is our hypothesis that some of these proteins may have immunomodulatory function.

## Evaluation of foreseeable effects

GMO constructs will be used for the expression and manipulation of *S. mansoni* proteins. It is anticipated that in most cases the GMOs will be no more hazardous to human health and the environment than the unmodified organisms. This will apply for GMO constructs involving gene inserts of known function eg alkaline phosphatase. However, some of the gene inserts will encode products of unknown function or possibly products with homology to putative immunomodulators. In a minority of cases, it is thought that expressed proteins may, for example, be allergenic. The overexpression of proteins in bulk fermentation cultures (up to 10 litres) and processing of samples with centrifugation and sonication/homogenisation are factors which could increase risk of exposure to proteins with potentially harmful (eg allergenic) properties. As a precautionary measure, it is therefore considered appropriate to apply full Containment Level 2 measures for activities involving the bulk culture of proteins of unknown function, which may have potentially harmful properties.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

## For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

## Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Solid** - Solid waste for disposal will be bagged and autoclaved before disposal. Kill level for these procedures is effectively 100%.
- **Liquid** - Liquid waste will also be chemically treated with Virkon, and autoclaved prior to disposal in designated sinks. Again, the kill level for these procedures is effectively 100%.
Periodic viability checks will be performed after both solid and liquid waste disinfection to validate effectively 100% kill levels. Annual validation of autoclaves are performed.

The possibility of some GMOs expressing proteins with potential immunogenic properties was the key concern of the GM Safety Committee. It agreed that as a precautionary measure, full containment level 2 measures should be applied to the bulk expression of recombinant proteins to control the risk to human health from this potential hazard. The Committee also requested further details on measures to be applied to control the risk of exposure during sample processing using techniques of sonication or centrifugation.

Non-GMM Consent Granted: Not Applicable

Project notified under transitional arrangements: N

Tick if notifying a connected programme of work: N
The purpose of this project is to develop a tool to monitor specific gene activity in cells grown in tissue culture. The approach will be to use a commercially-available system whereby the promoter of the gene of interest is inserted upstream of a fluorescent reporter gene. The lentivirus system has been selected as it will allow highly efficient, stable expression.

Disabled lentivirus will be produced whereby reporter genes encoding luciferase or the fluorescent proteins EGFP or DsRed2 will be placed under the control of cloned fragments of promoter sequences from specific human genes (generally those known to be expressed primarily in the bladder, such as UPK2) or the minimal CMV promoter as a positive control. This will enable us to monitor by fluorescence or luminescence when a particular gene is expressed in the modified cells grown in tissue culture.

An expression cassette (pENTR-5'TOPO) containing promoter of interest and entry vector (pENTR-ORF) containing the reporter gene construct will be amplified in E. coli K12. The cassettes will then recombined using the multisite gateway technology (Invitrogen) into a plasmid containing a disabled lentivirus backbone sequence (pLenti6/R4R2/V5-DEST) in E. coli DB3.1 as host, then propagated in 293FT cells to produce replication-incompetent lentivirus. Tissue cultured mammalian cells (including 293T) are unable to survive outside defined culture conditions, meaning they are categorised as a disabled host. The disabled lentivirus will be used to infect mammalian cells so that expression of the reporter genes (encoding luciferase or the fluorescent proteins EGFP or DsRed2) is regulated from cloned promoter sequence fragments.

EGFP and DsRed2 are derived from Aequoria victoria (EGFP) and Discoma species (DsRed2), respectively. They are proteins commonly used as reporter proteins as they are non-toxic, fluorescent and not expressed by mammalian cells. Luciferase is commonly derived from firefly and renilla and luciferase assays are commonly used to quantitatively assess promoter activity when combined with a foreign promoter or fragment thereof.

We anticipate that fluorescent reporter protein will be expressed in mammalian cells that have active promoter sequence (eg of the correct cell type and differentiation stage). Specific promoter sequences will be selected and cloned on the basis of restricted transcriptional activity to specific cell types and/or stage of differentiation. For example, the uroplakin II gene promoter which is active in terminally-differentiated human urothelial cells. Usually, such promoters would drive expression of gene products required for tissue-specific or differentiated cell function, but in this case they will be cloned upstream of reporter genes in order to monitor activity of the promoter in
The products of the reporter genes EGFP, DsRed2 and luciferase have been shown to have low cytotoxicity and no transforming activity even when expressed at relatively high levels in human cells. Ingestion of proteins, expression within a person following exposure to bacterial hosts carrying intermediate constructs of the expression vectors, or even expression within a person's cells following accidental exposure to infectious (non-replicative) virus, are unlikely to pose a significant health risk. The greatest hazard would come from the unlikely event of insertion, by homologous recombination, of part or all of the expression cassette into the genome of a person accidentally exposed to the recombinant virus. The outcome of such an event cannot be predicted with absolute certainty, although the result of introducing a highly tissue-specific promoter would not be anticipated to be significant and it might be anticipated that such a cell would be eliminated by the host immune system. The proteins are not likely to have deleterious effects through ingestion or expression within a person following exposure to bacterial hosts carrying intermediate constructs of the expression vectors. The highest risk would be from disruption of normal tumour-suppressor gene function in infected cells through homologous recombination with the expression cassette. Risks to the environment are considered negligible: the host cells used are non-viable outside the laboratory and the lentivirus vectors, which are disabled through absence of LTRs in the ViralPower packaging mix, are therefore only expressed in the producer cell and never packaged into virions. The resulting viral particles after mixing with virapower packaging mix are replication-incompetent.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- a) Contaminated plasticware will be decontaminated overnight in 2% Virkon and autoclaved (effectively 100% kill) before disposal to general waste. The autoclave is subject to annual testing and validation using thermocouples, and routine use of chemical indicator tubes.
- B) All liquid waste will be decontaminated with 2% Virkon (final concentration) overnight before disposal to drain.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The committee agreed that this was a CL2 activity based on the current guidance for work involving a 3rd generation replication incompetent Lentiviral expression system. It was felt that the modification would not present further significant hazards to human health or the environment. Indeed, since the GMO is unlikely to cause human disease, the possibility of this activity being graded as Class 1 was considered. However, it was agreed that CL2 should be applied as a precautionary measure, and consistent with recommended containment level for work with these Lentiviral vectors.

#### Project Containment
Purposes of the contained use

Generation and recombinant lentiviruses for overexpression of cDNAs, shRNAs and genomic promoter reporter genes by lentiviral transduction of mammalian cells to identify novel signalling pathways and proteins regulating the activity of connective tissues cells and stem cells and their influence on tissue function in health and disease.

Recipient or parental organism

Replication defective lentiviruses will be produced in cultured human embryonic cell lines (HEK 293 FT) and inserted genetic material (cDNAs, shRNAs or genomic promoter sequences) expressed in mammalian primary cells and cell lines. Virions will be generated by co-transfecting HEK 293 producer cells and plasmid constructs containing the recombinant lentiviral expression cassettes and plasmids supplying helper functions and genes encoding structural and replication proteins in trans (eg gag, pol and rev).

Host/vector system
Host cells to be used include: E. coli K12-derivatives (eg Stb13, INV. F and TOP10), HEK-293 cell line (for lentiviral production) and cultured mammalian cell lines and primary cells (experimental target cells, including material derived from humans). Vectors to be used include: Bacterial sub-cloning vectors (eg pENTRIA, PCR2.1), lentiviral expression cassette vectors (eg pLenti6/V5-DEST, pLenti6/BLOCK-iT - DEST), lentiviral packaging plasmids (eg pLP/VSVDG, pLP1) and resulting recombinant lentiviruses.

3 types of expression cassette will be cloned in the vectors.
1. Reporter genes encoding luciferase, lacZ or fluorescent proteins (eg EGFP, dsRED2) under the control of cloned promoter fragments derived from specific target genes.
2. cDNAs encoding specific genes of interest under the control of the CMV promoter expressed as native wild-type proteins, fluorescent fusion constructs or truncated/mutated variants with constitutively active or dominant negative activity.
3. Small oligonucleotides encoding shRNAs targeting specific genes of interest under the control of the U6 RNA polymerase promoter to induce and determine the effects of gene knockdown.

Genes and promoters of interest include:
A: Receptors, ligands/cytokines and transporters. Receptors, ligands and transporters include those for glutamate (eg NMDAR1, NMDAR2A-D, NMDAR3, GluR1-4, KA1 and 2; GluR5-8 and mCluRs, GLAST, GLT-1, vGLUT1), Wnt (eg Wnt1, Wnt5a, sFRPs, Frizzled, Kremen, LRPs/6, Dickkopf), Notch (Notch 1-4, Jagged), BMP (eg BMP-2) and hedgehog signalling pathways (hedgehog, patched, smoothened). Other receptors, ligands and cytokines with suspected regulatory functions in the control of cell differentiation/function will also be studies (eg RANK, PTH-R, estrogen receptor TGF-, IL-1, IL-6, RANKL, TPO, OPG)

B: Matrix, structural and exocytotic proteins. These proteins include normal constituents of the cell matrix (eg osteocalcin, Type 1 collagen, osteopontin), adhesion molecules (eg APP, neurexins, syndecans, integrins) signalling specific structural proteins (eg receptor interacting proteins; PSD-95, GSKAP, SHANK, Homer) and molecules involved in neurotransmitter release (eg SNAP25, VAMP, syntaxin).

C: Enzymes and transcription Factors. These proteins include those involved in the termination of cholineric signalling (eg AChE, bChE and their C-terminal derivatives), with roles in intracellular signal transduction (eg TIP60, glyceraldehyde - 3-phosphate dehydrogenase, alkaline phosphatase, CaMKII, PKB, eNOS, nNOS presenilins, ADAM10) or enzyme co - regulators (Nct, Pen-2, APH-1). Transcription factors (eg TCF-1, NFE-2, c-FOS, CBFA-1, SMAD4, Gli-1) and repressors (SuiFU, Groucho) activated by cell signalling pathways or that control gene expression in connective tissues will also be studied.

D: Intracellular signalling components. These include molecules required for intracellular signal transduction (eg FRAT/GBP, -Catenin, Dishevelled, Adenomatous Polyposis Coli, Axin/Axil Conductin, GSK-3, Fu, Fe65)

Evaluation of foreseeable effects

Bacterial subcloning vectors, recombinant lentiviral expression cassette vectors and lentiviral packaging plasmids are non-mobilisable and lack essential loci required to mediate DNA transfer from one host to another. Lentiviruses have a history of safe-use and are replication defective, engineered to lack essential genes required for packaging and replicative activity. These are only expressed in the producer cell line and are supplied on separate plasmids which lack regions of homology and LTRs, safeguarding against recombination events that could lead to restoration of these functions in viral progeny. Since packaging and replicative genes are never packaged into the viral genome infective viruses are incapable of undergoing further rounds of replication and can be considered as mobilisable defective. Deletion of the 3' LTR (U3) of the pLenti expression plasmids also results in self inactivation of the virus after transduction into host cells rendering the lentivirus further incapable of producing a packageable viral genome following integration into the host genome. No new replication defective-competent virus can be produced following transduction of host cells. E. coli K12-derivatives used for subcloning (eg Stb13, INV. F and TOP10) are disabled hosts and are non-pathogenic, non-reversional and are unable to colonise the human gut. These strains are unlikely to survive outside the laboratory where they would be subjected to sub-optimal growth conditions (nutrients and temperature) and pose a very low/negligible risk to human health or the environment. HEK-293 (used for virus production) and target mammalian cell lines have a history of safe use, are unlikely to establish outside the laboratory and pose a very low/insignificant risk to human health or the environment. Primary cells are of unknown pathogenicity and will be considered to be pathogenic. Cells are unlikely to colonise the worker except under conditions of severe immunocompromisation.
Lentiviral particles exhibit a wide species tropism and although they could survive for several weeks under non-laboratory conditions, they are replication defective and therefore pose a low-risk to the environment. Some of the cloned gene products are oncogenes or have tumour suppressor activity and although ingestion of these proteins, expression or shRNA gene knockdown within a person following accidental exposure to E. coli or infectious (non-replicative) virus is unlikely, it does constitute a low risk to human health. The greatest hazard is likely to arise from incorporation of cloned gene products/shRNAs into the genome of the worker accidentally exposed to the virus. The most likely outcome of this would be apoptosis of the infected cell or growth retardation, but may include increased risk of cellular transformation for oncogenes. Some oncogenes can act independently which increases the risk posed by the insert, however the overall chances of exposure to workers protected by full biosafety containment level 2 measures (causing oncogenic transformation) is very low, since the virus will be unable to establish in the worker and the virus is unlikely to come into contact with or penetrate the skin, buccal, oesophageal or intestinal mucosa which represent the most likely routes of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated plasticware (culture dishes, pipette tips, centrifuge tubes etc.) and culture medium used for viral production/transduction will be chemically disinfected by soaking in 1% Virkon solution or 5% Chlorus bleach (5g/L available bleach) for 24 hours. Waste will be double-autoclaved, bagged, clearly marked biohazard and transported to the autoclave in a leak-proof container. Autoclaving is performed on a 20 minute steam sterilisation cycle. The degree of kill achieved is 100% as validated by the manufacturer. Autoclaving efficiency is routinely monitored by thermolog monitoring and dummy loads ensuring that the autoclave is operating for the correct time at an appropriate temperature and pressure. Autoclaves are service annually and validated using thermocouples. Sterilised autoclave waste is placed in a disposal bin for removal to a designated landfill site.

Please enter comments on the GM safety committee on the risk assessment

The committee agreed that this was a Class 2 activity based largely on the current guidance for work involving a 3rd generation replication incompetent lentiviral expression system, and also because of the oncogenic nature of some of the inserts. Although it was felt that there was a theoretical possibility of oncogenes integrating into a cell genome of an exposed individual, the risk of this happening and leading to cancer formation was considered low. In addition to the use of physical control measures from CL2, the committee stressed the importance of applying good safety management practices for this activity, and asked the group to consider using alternative facilities from those proposed, which are often busy and shared with several groups.

02/03/2022
The overall aim of the research programme is to understand the pathogenesis of infectious diseases of major public health importance (e.g. leishmaniasis, pneumoniae), with specific reference to understanding the balance between protective immunity and immunopathology. The results of our research will be of value in the design of new vaccines and therapeutics.

In this GMO project, we will use viral vectors in three main contexts: i) to introduce genes encoding various reporter proteins (luciferase, EGFP, DsRed etc) into mammalian cells in vitro. These "reporter tagged" cells will be used for in vitro experiments and / or be transferred into rodents (by adoptive transfer into normal mice or by bone marrow transplantation) to allow visualisation and tracking of immune responses; ii) to introduce genes encoding potential vaccine antigens / adjuvants into mammalian cells in vitro. These cells will be introduced into rodents by adoptive transfer and / or bone marrow transplantation to enable the efficacy of various vaccination protocols to be assessed; iii) to introduce the genes encoding reporter proteins, vaccine antigens / adjuvants directly as gene therapy in rodents in vivo. The main vectors of choice for these projects will be lentiviruses. This GMO project will utilise pre-constructed lentiviral or adenoviral vectors, obtained either commercially or from other laboratories in the UK or elsewhere.
Non-replicating lentiviruses and adenoviruses will be used to introduce genes into rodent cells, which will then be either studied in vitro or transferred into rodents for further study. In some cases, viral vectors will be directly administered to rodents. The viral vectors will encode for proteins that "tag" cells to allow their detection and with no known influence on function (e.g. fluorescent proteins), or they will encode proteins which may be targets of protective immunity or may help to enhance immunity (i.e. adjuvant molecules).

Host/vector system

The GMO will be constructed in and obtained from the laboratories of our collaborators or commercial suppliers. GMO will normally be obtained as pre-titered viral concentrates.

The lentiviral vectors are disabled by deletion within the 3' LTR which prevents production of packageable virus genomes once the virus has integrated into the target cell. Additionally, the recombinant lentiviral genome contains no viral structural genes so these cannot be expressed in the target cell. The adenoviral constructs are deleted at both the E1 and E3 regions and hence are replicative deficient.

Origin & function

"Reporter" proteins (e.g. EGFP, DsRed, luciferase) will be obtained from commercial sources or other laboratories and are not known to have any activities that are directly toxic or detrimental to the health of humans or animals.

The vaccine "antigens" will encode an antigen from a micro-organism causing human disease e.g. Leishmania. The function of these antigens will be to induce immune responses against the target micro-organism, and they will not be known toxins or other molecules likely to have detrimental effects on human or animal health. The function of the "adjuvant" proteins is to enhance immune responses by manipulating the host immune response. These will be cytokines (e.g. GM-CSF) which are normally made by humans and rodents, and which are often, but not exclusively, are already in clinical use.

Evaluation of foreseeable effects

Adenovirus and lentivirus can infect human cells but all viruses contain multiple deletions are unable to replicate and produce virions except in specialised laboratory host cells. Adenovirus can cause minor respiratory tract disease but because of the mechanism of viral attenuation it cannot cause a pool of replicative virus, so disease in humans would be very minor.

Principle routes for accidental infection with viruses would be needlestick injury or aerosol production.

The expressed reporter gene products and vaccine antigens are not known to have adverse affects on human health, even in the unlikely event that they are expressed for prolonged periods. The antigens have a remote possibility of causing allergic reactions if the individual has been exposed previously and developed specific allergy. Most rodent cytokines to be used in this study are species specific and have no activity on human cells. In cases where species cross-reactivity exists, clinical data suggests that transient exposure of humans to such cytokines would have no derious adverse effects. Long term exposure is unlikely as rodent cells harbouring virus would not survive in humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be adjusted to a final concentration of 10% Trigene for > 24h before being autoclaved at 134°C for 15 minutes at 27psi pressure, the degree of kill is effectively 100%, see nore below.

Solid waste will be placed directly into a stainless steel discard autoclave box, lined with 2 autoclave bags. These boxes will be sealed and labelled before being
autoclaved at 134C for 15 minutes at 27psi pressure, the degree of kill is 100%.

Autoclave validated by the manufacturers initial commissioning, bi-annual service and calibration of waste programme conditions (print out each run kept for with lab
records).
Any glass and other “sharp” material will be disposed of in a “sharps-bin” and taken for incineration.
70% ethanol will be used to clean non-disposable materials and surfaces.
Transfer of experimental material between labs will be in a leak-proof, impact-resistant container.
Lab coats will be autoclaved before laundering.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The committee felt that the viral vectors presented negligible risk to human health and the environment and could potentially be handled at Containment Level 1. Further
detail was requested on the nature of the cytokines and possible effects on human health if exposure occurred. It was concluded that although this activity presented
negligible risk to human health or the environment, Containment Level 2 should be applied as a precautionary measure, and consistent with current guidance and other
activities at York using 3rd generation replication incompetent vectors.

Project Ref 177/07.1

Date Ackn’d 05/01/2007

CU2 Project Title Identifying and characterizing the molecular basis of pathogenesis and persistence in

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4
This project addresses both the regulation and role of factors in foodborne bacterial pathogens that enable them to persist in animal hosts and be successful as a pathogen in human hosts. Specifically the project aims to elucidate regulatory networks of cell surface factors used in serotyping (O-antigens) but may expand to include factors under the control of phase variation (adhesins for example) that may adversely affect serotyping. The project will also address the biological role of these factors, and how they may affect virulence. These questions will be addressed for Gram negative bacterial pathogens associated with food poisoning. The initial focus is on Salmonella, but the study may expand to include genes from the few Escherichia coli strains (pathogens) that have a similar transmission route and virulence as Salmonella.

Recipient or parental organism

Two types of GMM will be generated for this project, one where E. coli K12 is the recipient, and second where the recipient is the pathogenic isolate Salmonella. Our studies will generate GMM of the Gram negative foodborne bacterial pathogens that mainly cause gastroenteritis, initially of Salmonella. Strains will excluded which code for toxins that render them highly pathogenic and thus resulting in more severe disease, as will those strains that have a high probability to cause systemic disease (Salmonella: serotypes with high probability of causing enteric disease in humans (notably typhus, paratyphoid A and cholera is excluded). Any strains that have been identified as MDR (multidrug resistant) will not be used as recipient. E.Coli pathotypes that may be used as donor of DNA E.coli: enterohaemoragic E coli (EHEC) will be excluded.

Importantly, genes from one pathogenic species or strain will not be expressed in a different pathogenic species or strain, thus limiting the possibility of increased risk.

Host/vector system

Mutations (deletion or insertion) in single genes will be constructed. Genes will be cloned into non-transmissible plasmid vectors. Importantly, genes from one pathogenic species or strain will not be expressed in a different pathogenic species or pathogenic strain, thus limiting the possibility of increased risk.

Origin & function

The genetic material will be derived from Salmonella strains (non-typhoid) and Salmonella phage, and may expand to include genes from E.coli pathotypes that have a similar transmission route and virulence as Salmonella (thus EHEC excluded). The functional groups of genes targeted for mutation will be regulatory proteins, LPS modifying enzymes, adhesions and outer membrane proteins. No toxins will be cloned.
Standard reporter genes will be introduced into the parental strains (including Green fluorescent protein (Gfp) and derivatives from Aequorea victoria and LacZ (beta-galactosidase) from E.coli).

**Evaluation of foreseeable effects**

Based on current state of knowledge, the probability that the mutations will not affect virulence or decrease virulence is high, and the probability that virulence is increased is low. After infections, disease is a multi-factorial process, and bacterial genes must be expressed at the appropriate time and location during infection for the bacterium to cause disease. The worst-case scenario is that the GMM has a higher incidence of progressing from gastroenteritis to systemic disease, but no scenario is known for this to occur as a result of a single mutation or expression of a single gene.

Natural occurring infections of these species are mainly associated with contaminated food or water, and thus with oral ingestion, and mainly cause gastroenteritis. In rare cases infection can lead to systemic disease, mainly in immune suppressed individuals, very young and the elderly. In the laboratory setting the main risks for the GMM are also ingestion and parental infection.

Salmonella: All serovars can cause disease in humans. The broad host range strains to be used in this work mainly cause gastroenteritis, which is a self-limiting disease, and needs to be treated with antibiotics (fluorquinolones are considered optimal). Any strains that have been identified as MDR (multidrug resistant) will not be used as GMM, since this would severely limit treatment options in the very unlikely case systemic infection does occur. The main concern is ingestion and parenteral infection. This applies to the select E.coli strains as well.

The GMMS will have the same risk factors as the recipient strains where the recipient is the pathogenic isolate. Where E.coli K12 is the recipient, the risk will be the same or lower as for the original donor. Thus, the GMMS are considered to present a low to moderate risk to human health and low risk to the environment. All containment level 2 control measured will be applied together with the principles of GMP and good occupational safety and hygiene.

Measures include use of protective clothing (Lab coat), gloves, sterilizing all liquid and solid contaminated waste and use of disinfectants to clean work surfaces.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid and solid GM waste will be autoclaved. GM solid waste and liquids are stored in bins in the laboratory and then taken for autoclaving in the same building in leak proof containers. Solid autoclaved material is finally disposed of in normal refuse bins for collection by local authorities; liquid autoclaved material is disposed of in the sink. The degree of "kill" is effectively 100%.

Autoclave is validated by the manufacturers initial commissioning, bi-annual service and calibration of waste programme conditions (print out of each run kept for with lab records). Periodic viability testing for CFU of waste material.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee concluded that the GMOs produced by this activity would not result in organisms that were more harmful than the corresponding unmodified organisms. The assessor was asked to make it clear that there was no possibility of introducing unknown toxin genes into E.coli K12, and emphasise that a safety cabinet would be used for procedures likely to generate aerosols.

**Project Additional Information**

The overall aim of the research programme is to understand the mechanisms that govern the innate immune response to pathogens that are associated with infectious diseases of major public health importance. In this GMO project, we will use human herpesviruses and self-inactivating lentiviral vectors to dissect the role of non-coding
**RNAs in immunity.**

Human herpesviruses used in the project will include Kaposi's sarcoma herpesvirus (KSHV), Herpes Simplex virus 1 (HSV-1), and human Cytomegalovirus (CMV). These viruses will be used for in vitro challenge of mammalian cells. The mouse herpesvirus MHV-68 will also be used for similar in vitro experiments. Some of these viruses (such as in the case of KSHV strain used) are engineered to encode for reporter proteins (such as EGFP, luciferase etc). These tags are introduced in the viral genome in such ways so they do not affect viral infectivity or replicator. Self-inactivating lentiviral vectors (pSIN vector, previously used in similar projects elsewhere) will be used for the introduction of human protein-coding genes and non-coding RNAs into primary human cells. These viruses are replication-deficient and virions are not produced from infected cells. Virions are produced through a triple transfection method (lentiviral plasmid + packaging protein plasmid) into a permissive line such HEK293T cells. The separation of the three plasmids ensures that the lentiviral plasmid alone (the fragment of DNA that is integrated in host genome after lentiviral infection) is not capable to replicate. The genes delivered with the lentiviral vectors include non-coding RNAs, signalling proteins, and RNA-binding proteins.

**Recipient or parental organism**

Herpesviruses and self-inactivating third generation lentiviruses will be used to infect mammalian cells (rodent or human, primary, immortalised or transformed. The lentiviruses will encode for fluorescent tags or human genes with a role in immunity. The used herpesviruses are engineered to carry fluorescent or luminescent tags.

**Host/vector system**

Wild-type herpesviruses (Kaposi sarcoma herpesvirus, herpes simplex virus 1, human cytomegalovirus ) engineered to contain reporter cassettes (EGFP, luciferase etc. These reporter genes do not affect virulence of the used viruses.

HIV-based self inactivating lentiviral vectors containing inserts encoding for human genes (non-coding RNAs, signalling proteins, RNA-binding proteins etc). These viruses are incapable of replication due to deletion of their LTR regions as well as structural gene. Individual gene inserts are unlikely to represent any significant hazard.

**Origin & function**

Lentiviruses with tag or gene inserts will be constructed in our laboratory or provided by collaborators. Production of lentiviral particles involves a triple transfection procedure in HEK-293T cells, to achieve one round of replication. The main purpose of using these constructs is to test the role of individual non-coding RNAs and proteins in the regulation of the innate immune response in human primary cells, and identify protective pathways from infection.

The herpesviruses will be grown in our lab or obtained by collaborators. None of the engineered viruses displays increased virulence. The purpose of using theses pathogens is to probe mammalian cells and analyse their anti-pathogen responses.

**Evaluation of foreseeable effects**

Human herpesviruses are used in this project. At the titres used, these viruses are unlikely to cause primary infection of humans. In the extremely unlikely case of injection of a high number of latently infected cells in a human, these cells would be most likely cleared by the immune system.

The lentiviral vectors used contain multiple disabling mutations. None of the host cells or inserted genes could complement or replace the disabled genes. All components for producing lentivirus virions are encoded separately on three different plasmids. The herpesviruses used do not establish permanent infections in vitro and at the doses used are not likely to infect humans. In the extremely unlikely event of injection of the low lentiviral particles preparations used, it is highly unlikely that any cells will become infected and that the gene inserts could cause alone any harm to humans.

The used pathogens and lentiviral products do not have any known toxic or transforming activities in the amounts and forms used. MicroRNAs and RNA-binding proteins have been implicated in disease but the safe usage of low titre, replication deficient lentiviral vectors ensure the practically risk-free use of these genes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste is sealed in double autoclave bags and subsequently autoclaved (134°C for 15 minutes at 27psi) before disposal. Liquid waste is decontaminated in Virkon or Precept followed by autoclaving before disposal. These procedures lead to 100% killing of used viruses, as monitored by growth curves. Autoclave printouts will be checked after cycles of solid decontamination. Autoclaves are regularly serviced.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The committee noted that work with 3rd generation replicative incompetent, self inactivating Lentiviral vector with inserts unlikely to cause harm, presents negligible risk and could be justified as a Class 1 activity. The possibility of the expression cassette integrating within infected cells and activating harmful genes was raised. However, it was noted that additional biosafety features of the lentiviral vectors reduces this risk. In addition, exposure of worker to levels of virus high enough to cause e.g. tumourigenesis following exposure would be unlikely during normal laboratory based manipulations.

It was agreed that the activity should be assigned to Class 2 on the basis that the work involved the use of Herpes Viruses (Hazard Group 2), capable of causing harm to humans. However, it was noted that the risk of infection from these viruses was low, especially with the application of Containment Level 2 measures and GMP.

Project Ref 177/19.1

Date Ackn’d 01/05/2019

CU2 Project Title Use of reporter genes to characterise plant resistance/susceptibility to fungal and bacterial plant pathogens endemic to the UK

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Consent Granted

Date Project Ceased 02/03/2022
### Project Additional Information

#### Purposes of the contained use

The goal of the research is to understand plant-pathogen interactions to improve plant resistance to biotic stress. Plants will be infected with GM pathogens harbouring reporter genes to follow the dynamics of infections during time as well as under different genetic and environmental conditions. Infections of plant material will be small scale only, typically involving infecting leaf material detached from plants.

#### Recipient or parental organism

The GMM will be mainly necrotrophic fungi such as Botrytis cinerea and Sclerotinia sclerotiorum as well as, possibly, bacteria (e.g. Pseudomonas syringae). All these pathogens are endemic to the UK, and the genetic modifications that they may harbour are reporter genes such as the innocuous Jelly-Fish-Green-Fluorescent-Protein.

#### Host/vector system

Lattuca sativa (lettuce) and Arabidopsis thaliana will be the main plant used for pathogen challenges.

#### Origin & function

The jellyfish Green Fluorescent Protein (GFP) gene will be the main reporter gene to be used. Work could also include the use of other commonly used reporter genes such as human B-glucuronidase (GUS) and firefly luciferase. These genes/proteins are well characterised and have a history of safe use and widely used in bacterial, animal and plants research.

#### Evaluation of foreseeable effects

GMMs to be used present no/negligible risk to human health and a low risk to the environment. The plant pathogens to be used infect a wide range of mono and di-cotyledonous plant species. However, these pathogens are endemic species to the UK (i.e. already present in the wild) and, hence, do not represent a new environmental hazard. The genetic modification with reporter transgenes will not increase the pathogenicity nor host range of the organisms in the event of accidental exposure of the environment. The reporter transgenes themselves are innocuous to both the pathogen and the host plants (as well as to humans). As such Containment Level 2 measures (applied in general laboratory and plant growth facilities) will be appropriate to reduce risks associated with these plant associated GMMs to an acceptable level.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal:
All waste materials are subject to autoclave treatment that should give 100% kill. All autoclave runs are monitored to ensure they achieve the correct temperature, pressure and time. In addition, autoclave cycles are validated by annual independent thermocouple testing to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time.

Solid Waste: plastic waste and infected plant leaf material will be contained within two robust “autoclave bags” and autoclaved (loads exposed to a cycle of 134°C for at least 15 minutes) in the departmental autoclave facilities. Autoclaved solid plastic waste and plant leaf material is transferred to 'tiger bags' and collected by a contractor for deep landfill disposal.

Liquid Waste: waste spore suspension and liquid cultures will be contained in glassware and be autoclaved in the central departmental autoclave facility (liquids exposed to a cycle of 134°C for at least 15 minutes). Autoclaved liquid waste is disposed of to drain with copious amonous of cold water.

Disinfection: Culture/spores spillages will be decontaminated by wiping the contaminated areas with virkon or chloros in accordance with suppliers instructions.

Is an emergency plan required according to regulation 20?  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

It was questioned why the overall classification of the activity was Class 2 (low risk to human health and the environment) rather than Class 1 (no, negligible risk) given that B. cinerea is a fungal pathogen ubiquitously found in the environment affecting many plants, and commonly used reporter gene labelling (such as GFP) will not alter the hazardous properties of the fungal pathogen. However, it was noted that work involving the use of a GM plant pathogen would normally be Class 2, in line with the GM ‘Compendium of Guidance’ which states that GM activities involving plant pathogens cannot typically be deemed to present ‘no / negligible risk’ (i.e. Class 1) and would require application of some CL2 measures such as an autoclave in the building / restricted access arrangements (i.e. Class 2). It was felt that the application of Containment Level 2 measures for plant associated GMMs would provide appropriate containment. The small scale nature of the activity, typically involving infecting detached leaf material contained in plant growth rooms / cabinets, further reduces the risk associated with the activity.

The need to notify another Class 2 activity involving GFP labelling of microorganisms was also questioned. However, it was noted that whilst the University had previously notified activities involving the use of GFP labelled human pathogens (e.g. P aeruginosa and other similar HG2 organisms) the scope of the notification did not cover GFP labelled plant pathogens.

Project Additional Information

Purposes of the contained use

These contained uses represent the extension of an existing notified contained use activity (involving Leishmania and Trypanosoma parasite species that are naturally transmitted by direct inoculation) to include parasites (e.g. Trypanosoma cruzi and Toxoplasma gondii) that can be transmitted via mucous membranes or orally (T. cruzi / T. gondii), as well as direct inoculation (T. cruzi).

Specifically, the purpose of the T. cruzi activity is to:

- To study the T. cruzi parasite and T. cruzi-specific immune responses and associated pathology during the course of T. cruzi infection in animal models. To test the efficacy of novel vaccines and drugs for Chagas Disease in animal models of infection
- To culture T. cruzi parasites in vitro in mammalian cell lines for generation of crude antigenic extracts and to study the phenotype of mutant parasites.
- To clone T. cruzi genes into plasmid vectors (engineered for prokaryotic or eukaryotic expression) to express and purify the target proteins for further analyses.
- To target specific T. cruzi genes for disruption (by homologous recombination or CRISPR/Cas9) to generate null, loss-of-function mutants or for over-expression to generate gain-of-function mutants for phenotypic analyses, by the introduction of antibiotic resistance genes into chromosomal sites in the genome of T. cruzi parasites.

The purpose of the T. gondii (and possibly other apicomplexa protozoa) activity is to:
Study the molecular genetics and biochemistry of *T. gondii* and its interaction with the mammalian host. The activity will involve introducing recombinant plasmid DNAs (containing parasite and bacterial sequences) into *Toxoplasma* tachyzoites by nucleofection, and target specific genes for disruption (using CRISPR/Cas9) to generate null, loss-of-function or gain-of-function mutants by the introduction of antibiotic resistance genes into chromosomal sites in the *Toxoplasma* genome. The transgenic parasites produced will be characterised according to nucleic acid and protein content, metabolism, cell cycle, viability and cell structure and infectivity in cultured mammalian cells. Transgenesis will be confined mainly to manipulations within genera i.e. insertion of *Toxoplasma* genes into *Toxoplasma* strains. Intergenera transgenic manipulations and insertion of genes encoding reporter proteins may also be performed.

<td>The kinetoplastid parasite <em>Trypanosoma cruzi</em> (ACDP Hazard Group 3 human pathogen) is the causative agent of Chagas disease. The human and environmental risks from genetically modified <em>T. cruzi</em> generated by this activity are considered to be no greater than wild type. Gain of function phenotypes may be generated, although it is unlikely that any gain of function mutants will be any more virulent to, or cause different disease tropisms in humans than wild type. Where inter or intra genera gene transfer is performed, no additional risk is foreseeable.</td>
</tr>
</tbody>
</table>
Drug resistance genes will be used as selectable markers to generate loss of function or gain of function mutants. However, these do not provide resistance to commonly used anti T. cruzi drugs.

Risk to the environment as a result of loss of containment is negligible: lab adapted strains to be used can only be maintained on complex media at a narrow temperature range outside of a mammalian host; use of non-mobilisable cloning vectors; susceptible mammals need to be directly inoculated with parasite, and the natural insect vector (the triatomine bug- essential hosts necessary for the lifecycle progression and transmission of the parasite) is absent from the UK environment.

Application of CL3 measures are considered appropriate to provide effective containment for the protection of human health and the environment.

T. GONDII ACTIVITY

Toxoplasma gondii (ACDP Hazard Group 2 human pathogen) is a protozoan parasite responsible for Toxoplasmosis. The human and environmental risks from genetically modified T. gondii generated by this activity are considered no greater than wild type.

No risks are associated with the plasmid vectors. The DHFR encodes resistance to a currently used drug (Pyrimethamine) which is used clinically to treat toxoplasmosis. However, the likelihood of recombination into human cells upon infection is effectively zero. Furthermore, the DHFR is a selection marker used more rarely. In the case it is used, the DHFR encoding gene will be flanked by LoxP sites and the gene will be excised by transient electroporation with Cre recombinase after transgenic parasite selection. This reduces the chances of accidental exposure of the lab personnel to pyrimethamine-resistant parasites.

None of the genes that are ectopically expressed are expected to increase the risks associated with the host strain of T. gondii. Genes do not encode the production of any toxins or allergens, they do not increase virulence or change tropism. Previous studies have generated numerous parasite lines expressing heterologous genes or mutated version of endogenous genes. None of these parasites showed any increased virulence in assays (growth rate in cell culture). Likewise, many other labs in the field use the same system, including for studies in animals and report no increased virulence. On the contrary, it is often observed that parasites are attenuated due to the type of genetic manipulations performed.

Application of CL2 measures are considered appropriate to provide effective containment for the protection of human health and the environment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

T CRUZI ACTIVITY

Full Containment Level 3 measures will be applied for all higher risk T. cruzi work activities (includes T. cruzi culture and sample preparation, and all infected animal related work activities). However, lower risk work activities involving downstream sample analysis of live parasites (includes microscopic imaging, imaging of whole infected animals) will use Containment Level 2 facilities in the 'Cell & Imaging Lab' associated with the Biology 'Technology Facility'.

These facilities do not have the following features typical of CL3: room maintained at negative pressure; room sealable for disinfection; HEPA filtration on extract, an observation window. However, T. cruzi is not transmitted via the airborne route.

Downstream processing of parasite preparations / infected tissue samples / whole (anaesthetised) animals involves the application of routine, well practiced procedures associated with microscopic and imaging systems. Only small volumes (no more than 8mL) of parasite, infected cell preparation will be involved; samples will be double contained during transport in robust, sealed containers, and samples will be maintained, where practicable, in sealed containers or covered (e.g. on the microscope slider holder) during analysis. Once a sample is mounted on a microscope, the incubation chamber will be closed and any additional samples resealed in the transport box. For
some experiments, it may be necessary to remove the lid or add samples to the wells (e.g. drug or reagent addition). Any such manipulations will be kept to a minimum and limited to simple sample addition steps.

Application of a high standard of working practices will be applied at CL2 to maintain effective control of exposure. Use of these CL2 facilities will be supplemented with key working practices also applied for handling T. cruzi samples at CL3, as detailed in a Code of Practice. All individuals directly or indirectly associated with downstream sample analysis at CL2 will receive recorded training on key practices detailed in the CoP. Key practices include the wearing of protective gloves and eye / face protection when handling infective samples; avoiding use of sharps, routine disinfection of work surfaces and equipment following use. In addition, temporary signage (warning of a biological hazard and restriction of access to authorised persons only) will be displayed on the outside of the door of the CL2 room to be used for sample analysis, before work begins. All samples / waste materials will be returned using double containment to CL3 for inactivation.

Movement of infected animals between CL3 containment rooms and multiphoton microscopy room (CL2) for intra-vital imaging will be done in IVC cages, mice will be anesthetised before leaving CL3 BSF rooms, maintained anesthetised throughout the procedure and euthanized after completion of the procedure. Mice will be held in isolated containers at all times while in CL2, all materials and containers will be decontaminated before leaving the room, and carcasses will be taken back to CL3 BSF rooms for disposal.

Cell sorting of samples at CL2 will only be performed with inactivated (using a validated method) sample materials.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid GM waste will be generated and treated as describe below. All waste will be handled by authorised, trained personnel only.

Liquid GMM waste:
All liquid parasite waste material will be made safe by disinfection (using Distel (diluted 1:10, final volume) a disinfectant validated against Leishmania and Trypanosoma to give 100% kill) before disposal. Spent cultures and vessels will be treated with disinfectant for a minimum of three hours before pouring the liquid down lab disposal sink through a stainless steel sieve to catch any solid matter. The waste bottles are then rinsed and reused. Any caught waste matter is placed in an autoclave bag and treated as solid waste.

Solid GMM waste:
All solid waste material is subject to autoclave treatment (134°C for 15 mins at 27 psi pressure) that should give a 100% kill. All autoclave runs are monitored to ensure they achieve the correct temperature, pressure and time (machine cycle pass/fail run report). In addition, autoclaves are validated by annual indenpentant thermocouple testing to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time. Waste is be collected in metal autoclave bins and either autoclaved directly in the CL3 lab using a double-ended autoclave (T. cruzi solid waste), or securely transferred from the CL2 lab to the autoclave room within the same building (T. gondii solid waste). Autoclaved solid material is transferred to either ‘orange bags’ for ‘alternative treatment’, or ‘tiger bags’ for disposal as non-hazardous offensive waste for collection by a registered waste contractor.

Solid waste from the CL3 animal facility (BSF), (e.g. soiled bedding and food, blue roll, tubes and used gloves) will be inactivated by autoclaving. Animal carcasses / tissues samples will be stored in a freezer located within the containment suite until collected for clinical waste disposal via a registered waste contractor.

All solid waste materials associated with sample analysis of T. cruzi parasite material in the CL2 Technology Facilities will be returned to the CL3 lab using double containment for inactivation using the same waste disposal procedures applied to waste generated in the CL3 lab.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The GMSC agreed that the 2 activities could be covered by a Connected Programme of Work on the basis that T. cruzi and T. gondii are parasites that can both be transmitted via mucous membranes, as well as orally. Both organisms, therefore, require similar working practices (albeit at different Containment Levels) to effectively control risk of exposure. The existing notification for work with Leishmania and Trypanosoma parasites does not cover species that can be transmitted via mucous membranes or orally (T. cruzi and T. gondii). It was also noted that the activities are associated within a larger parasitology research group that use the same two research laboratory buildings. As such, both activities share the same suite of containment facilities, come under the same management system and apply the same waste disposal arrangements.

Generation of gain of function mutants (for example by over-expression of genes) was discussed. It was felt that manipulations would most likely lead to loss of virulence, rather than any gain of function resulting in further harmful properties.

The risk assessment / CoP refers to external validation data confirming the effectiveness of Distell disinfectant against Leishmania / Trypanosoma species. The Committee requested this to be supplemented with internal validation of Distil for T. cruzi cultures. Validation of the method used to inactivate T. cruzi for flow cytometric analysis in the CL2 lab will also requested.

It was concluded that overall this was a Class 3 activity, adequately contained with the application of both Containment Level 2/3 facilities and associated working practices.

**Project Additional Information**

**Purposes of the contained use**

To date most of our studies in this area have focussed on Streptomyces phages. Thanks to bacterial genomic sequencing we have hypothesised a more general nature to some of our discoveries and we now wish to test some of these theories. We now propose to use several known human pathogens in our research.

**Recipient or parental organism**

Several organisms will be manipulated; Salmonella typhimurium SL 1344 and LT2, Thermobifida fusca, Streptomyces sp. Mycobacterium smegmatis (mc2155), M. avium, M. marinum, M bovis BCG, E. coli K12.

**Host/vector system**

Chromosomal genes in S. typhimurium and in E. coli will be mutated using the lambda red pcr targeting gene replacement system; the red genes will be introduced via pKD20 or pKD46 or similar. Gene replacement in T. fusca and S. coelicolor will rely on homologous recombination via DNA introduced by mating on suicide vectors derived from E. coli ColE1 derived plasmids (eg pSET151). We also intend to use site-specific integrating vectors (eg pSET152). Mutations in the mycobacterial chromosomes will also be generated by homologous recombination with DNA cloned on suicide plasmid vectors or on phasmids. E. coli vectors used will be derived from ColE1, p15A, or defective lambda phage.

**Origin & function**

All the genes we will be studying were discovered through research on host-phage interactions. All the genes when mutated in S. coelicolor give an altered response to phage infection. Some of the genes (the pgl genes) are involved in a phage resistance phenotype in S. coelicolor whilst others (such as pmt1 and ppm1) are required to synthesise the phage receptor. In S. coelicolor the pgl genes involve proteins with the following predicted functions; a protein kinase (pglW), DNA methyltransferase (pgIX), an ATPase (pglY) and a protein of unknown function (pglZ). Homologues of these genes will be knocked out in S. typhimurium, T. fusca and in the genetic elements SXT and CTnR391 (derived from V. cholera and P. rettgeri respectively and transferred by conjugation into E. coli). In each case an antibiotic resistance marker (usually kanamycin, chloramphenicol, apramycin, hygromycin or spectinomycin resistance genes) will replace the pgl gene. The pgl homologues from these organisms will also be cloned into E. coli and Streptomyces. The pmt1 and ppm1 genes appear to be involved in a protein glycosylation pathway, which is common to all the actinomycetes. Pmt1 and ppm1 homologues (and other genes involved in the glycosylation pathway) in mycobacteria will be replaced by antibiotic markers, kanamycin or hygromycin. The pmt1 and ppm1 genes from mycobacteria will also be inserted in E. coli and streptomyces.

**Evaluation of foreseeable effects**

It is unlikely that any of these manipulations described here will result in any increase in the hazardous nature of these organisms. If anything their fitness will be reduced either due to sensitivity to phage infection or due to defects in synthesising key cell wall proteins. Indeed other people's attempts to knockout the pmt1 gene in M. tuberculosis so far have failed. The knockout mutants will contain antibiotic resistance genes but these will no confer resistance to any known therapy for any disease caused by the organisms in question. Cloning of the heterologous glycosylation genes in E. coli K12 strains or in Streptomyces is not likely to confer any degree of pathogenicity on these bacteria. We intend to use E. coli K12 containing the mobilisable SXT and CTnR391 elements which originate from V. cholera and P. rettgeri. These elements are known to encode several antibiotic resistance genes and several genes of unknown function. Given these known properties E. coli containing these
elements will be used under class 2 containment to eliminate any possibility of spread.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The class II safety cabinet will be used for manipulating Mycobacterium avium, M. bovis BCG and Thermobifida fusca at all times. This is because they are known to cause pulmonary disease and there is a clear danger of infection via an airborne route. For S. typhimurium, E. coli, M. smegmatis and M. marinum there is little danger from the airborne route and these organisms will normally be manipulated on the bench with protective clothing and gloves.

The class II safety cabinet will always be used whenever aerosols are expected, such as vigorous mixing or resuspending cells after centrifugation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Trigene kills E. coli, S. typhimurium, Streptomyces sp. T. fusca, M. smegmatis and 5% kills M avium and M Bovis BCG. We expect to get 100% inactivation and validation will be routinely tested. Information on testing of most of these organisms is described at http://www.medichem.co.uk/medical_products.html. Streptomyces sp and Thermobifida fusca are not mentioned in this information but we have performed our own tests on Streptomyces and found 1% Trigene to be sufficient for 100% killing. The concentration of Trigene for killing of T. fusca will be thoroughly tested before GM work begins.

In practice the lab will routinely use 5% Trigene for killing of liquid cultures and for disinfection of contaminated glassware and spills. Disinfection will take place in containers with lids for no less than 24 hours before disposal. Disinfected cultures and glassware will be disposed of down the sink with plenty of water.

Plates will be taped together, placed in a double autoclave bags, sealed and sent for autoclaving on the premises for sterilising.

Is an emergency plan required according to regulation 20?  
N

If yes, tick to confirm that it is attached to this form  
N

Tick to confirm that you have attached a risk assessment to this form  
Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  
N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee accepted the scientific procedures and hazard assessments as reasonable. They requested that only one type of disinfection should be used throughout the laboratories for simplicity sake, which we have implemented by converting to the use of Trigene. The committee also requested a clear statement of when the safety cabinet should be used and when it is safe to work at the bench.

The risk assessment was passed pending these changes. It was decided that the labs where the work will take place would be inspected for compliance with level 2 containment prior to receipt of microbes classified as ACDP hazard group 2.

**Purposes of the contained use**
* to map and sequence target genes in Leishmania species and Trypanosoma brucei, in relation to their chromosomal position and stability between genomes.  
* to clone Leishmania and Trypanosoma brucei genes into plasmid vectors engineered for prokaryotic expression: to express and purify the target proteins for further analyses.  
* to target specific genes for disruption (by homologous recombination) to generate null, loss-of-function of gain-of-function mutants for phenotypic analyses, by the introduction of antibiotic resistance genes into chromosomal sites in the genomes of non-infective Leishmania or T. brucei stages.

**Recipient or parental organism**
- E. coli K12 strains: eg E. coli BL21 (DE3) pLysS  
- Leishmania major MHOM/IL/81 Friedlin  
- Leishmania mexicana MNYC/B762/M379  
- Leishmania donovani MHOM/SD/62/IS-CL2D  
- Leishmania infantum MCAN/es/98/LLM-724

02/03/2022
### Host/vector system

For E. coli host:
- Plasmid vectors: pUC based such as the pBS, pSK, pGEX or pEt series
- Cosmid vectors: pWE15 (Strategene) or similar

For Leishmania/T brucei host:
- Plasmid shuttle vectors: pUC based such as the pBS or pSK series.

### Origin & function

The sources of parasite material (both Leishmania species and Trypanosoma brucei) are collaborating reference centres, both in the UK and abroad, that supply frozen samples in sealed containers for transport into the containment laboratory. Frozen material is stored in the vapour phase of liquid nitrogen until required for in vitro culture.

The genetic material from these parasites will be used:
- in gene mapping studies
- for expression studies to generate recombinant proteins for structural and functional analysis
- to generate null, loss-of-function or gain-of-function Leishmania or T. brucei mutants for phenotypic analyses

### Evaluation of foreseeable effects

Species of Leishmania are causative agents of human Leishmaniasis; the parasite species L. donovani, L. infantum, L. braziliensis are designated hazard group 3 ($ (ACDP categorisation). The remaining species covered by this notification, L. major and L. mexicana, are hazard group 2 (ACDP categorisation), as is Trypanosoma brucei, which is non-infective to man. In susceptible individuals, leishmaniasis is treatable (as detailed in the Code of Practice, June 1992).

The target genes for manipulation will be wild type Leishmania or T. brucei sequences that have been fully characterised by DNA sequencing. The products of these genes are not known to have a role in the progression of human disease but this possibility cannot be discounted for those genes coding for proteins of unknown function. The GMMs are unlikely to express proteins at a level significantly higher than wild type parasites that have not been genetically-modified.

The pathogenicity of Leishmania species and the hazard this imposes to experimental work in the Department of Biological Sciences is already covered by Codes of Practice for cultivation in culture (June 1992) and in animals (January 1993). Genetically-modified Leishmania will be subject to the same safety protocols; the environmental risk is therefore no greater than with unmodified parasites. The life cycle of Leishmania involves transmission of extra-cellular parasite stages between hosts by a sandfly vector, followed by intracellular maintenance within macrophages in the mammalian host. No other organism is known to be at risk from infection. There is no sandfly colony on the South Kensington site of Imperial College, so transmission of the parasite, by inoculation of infective parasites into susceptible mammalian hosts, is impossible.

Transgenic Leishmania will be resistant to one or more antibiotics but this is irrelevant to therapy against human leishmaniasis (for which pentavalent antimonials are the current drugs of choice). Transgenic T. brucei will also be resistant to one or more antibiotics but this is irrelevant as T. brucei is non-infective to man.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Table 1a Measure 2 Laboratory: sealable for fumigation. Justification - Parasites not transmissible through the airborne route.
GM waste is of 2 types: liquid and solid.

Liquid GMM waste: is treated by chemical disinfection, using Chloros diluted 1:10 (final concentration 10,000ppm available chlorine), with contact time > 12 hours. This gives 100% kill, as validated by testing described in the attached risk assessments.

Solid GMM waste: is autoclaved at 134 degrees C for 15 minutes at 27 psi pressure. This gives 100% kill, as validated by testing described in the attached risk assessments.

All clinical waste is sealed in bags and transported on robust trays from the containment facility to the autoclave, via the interlock hatch. This waste is handled by authorised personnel only. After autoclaving, the material is transferred to yellow bags for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The GMSC agreed with the classification and containment measures assigned to this project. Minor modifications were required to be made to the risk assessment form prior to notification to the HSE.

Project Additional Information

Purposes of the contained use

Campylobacter jejuni and Campylobacter coli are major human pathogens responsible for the majority of human cases of acute gastroenteritis in the UK. At present it is not possible to distinguish between pathogenic and non-pathogenic strains of Campylobacter as the mechanisms of pathogenicity are still not fully understood. The purpose of this work is to characterise virulence and survival properties of these organisms and to investigate the molecular basis for the variation of virulence (such as toxin expression) that is observed between strains. This work may lead to the identification of novel markers of pathogenicity that will facilitate pathogenic strain identification as well as provide information on the regulation of expression of the cytolethal distending toxin (CDT).

Recipient or parental organism

The resultant GMOs will include Escherichia coli strain TOPO10F', E. coli strain S17-1 ^ pir and other similar disabled strains of E. coli into which genes of Campylobacter origin will be cloned. These E. coli strains are hazard group 1 organisms and auxotrophic, therefore long-term survival outside of the laboratory and in the environment is unlikely. They are not pathogenic to humans and it is unlikely that the GMOs will have any increased virulence or survival capability compared to the wild type strains. Due to the low G+C content of C. jejuni and the differential codon usage between the two organisms it is unlikely that C. jejuni proteins will be efficiently expressed in E. coli.

In addition a range of Campylobacter jejuni and Campylobacter coli strains will be used as hosts for genomic constructs and mutagenesis studies. Campylobacter jejuni and Campylobacter coli are ACDP class 2 organisms. Wild type Campylobacter sp. Is ubiquitous in the environment and can survive in a wide diversity of locations including water, soil, etc. The infectious dose in humans is quite low (500 organisms) and once it has infected the host Campylobacter jejuni can colonise the guts of some animals and birds to high levels. Campylobacter jejuni and coli are pathogenic to humans (enteritis) but usually commensal in most animals and birds. Campylobacters are thought to just survive (persist) rather than multiply to high numbers in the environment and so if escape occurs contamination of the surrounding environment is likely to be low. The genetically modified Campylobacter strains are unlikely to be any more harmful to humans, animals or the environment than the wild type strains.

Host/vector system

Vectors to be used for the CDT expression studies include pMA20T, which is an adaptation of pGU0202, a shuttle vector for use in Escherichia coli and Campylobacter, which contains a Campylobacter-derived kanamycin resistance cassette (aph (3')-III as well as the mob gene and so is mobilisable between strains. The modification of this plasmid in pMA20T includes the insertion of a reporter gene, either the lacZ gene from E. coli MG1655, which encodes b-galactosidase, or gfp, which encodes green fluorescent protein, along the two oligonucleotide linkers to introduce termination sequences and restriction sites for cloning upstream of the reporter gene start codon.

Other vectors include pBR322, a mobilisation defective, general purpose cloning vector, which will not replicate in Campylobacter jejuni and other similar general purpose cloning vectors such as pCR2.1TOPO (Invitrogen), pUC18, pBluescript (Stratagene) and pCRScript (Stratagene) will also be used for the mutagenesis studies as these plasmids will not replicate in Campylobacter and so will act as suicide vectors in this host.

The transposon mutant library was created using an in vitro method of transposition, whereby exogenous transposase enzyme was added to the reaction mixture. This results in a relatively stable insertion as the transposon is unable to transfer in the absence of the transposase enzyme. The "plasmids" that result from the plasmid rescue are mobilisable, but only from a strain of Escherichia coli expressing the pir protein. Even if the plasmid was taken up by another organism it is unlikely, due to the
low G+C content of Campylobacter DNA, that Campylobacter proteins will be expressed in other organisms.

**Origin & function**

CDT promoter regions from Campylobacter jejuni strains will be used in this study. These DNA fragments (up to 1.5 kb in size) will not be expressed themselves but will drive expression of the reporter genes cloned into pMA20T in E. coli.

For gene expression in Campylobacter jejuni small fragments (ca. 300 bp) flanking the cdt promoter from the 5' end of the cdtA gene will be cloned into plasmid pBR322 along with the kanamycin resistance gene from Campylobacter coli, to allow homologous recombination to occur and the insertion of the reporter gene downstream of the cdtA promoter in the genome of Campylobacter jejuni strains, such as 11168, 81116, 81176, 01/35, 01/51, 01/41, AG, DF, 99/224, EX114, 99/419 and EF.

The lacZ reporter gene originates from E. coli MG1655 and the gfp reporter gene is originally from Aequorea victoria.

For the virulence studies genes from Campylobacter jejuni and Campylobacter coli that have similarity to other known virulence factors associated with toxins, invasion, adhesion, fimbrial expression, in vitro survival and other surface exposed proteins will be investigated. In addition any genes identified through the transposon mutagenesis as having a role in invasion or in vitro survival will also be cloned for further characterisation.

**Evaluation of foreseeable effects**

It is unlikely that the GMOs will have any increased virulence or survival capability compared to wild type strains. The Campylobacter jejuni strains will have insertions that are chromosomally located and so transfer of the antibiotic cassettes between strains is thought to be low. For gene expression studies in Escherichia coli, these will be carried out using pMA20T, which is mobilisable. However only putative promoter regions from Campylobacter jejuni will be cloned into this plasmid upstream of the lacZ gene, which encodes B-galactosidase, or the gfp gene, which encodes green fluorescent protein. Overexpression of either of these genes is not known to be harmful to humans, animals or plants. The campylobacter-derived kanamycin resistance gene is used routinely for insertional inactivation in Campylobacter jejuni as this antibiotic is not used for treatment of Campylobacter jejuni infections in humans or animals.

For the transposon mutagenesis the Campylobacter coli chloramphenicol resistance gene is used as a selective marker. This antibiotic is also not used to treat Campylobacter jejuni infections in either humans or animals. The mutants are unlikely to be any more harmful to humans, animals or the environment than the wild type strain, 01/51.

The genetically modified Escherichia coli strain that result from the cloning of various virulence and survival-related genes have the potential of being more harmful than the wild type strain, although this is unlikely. These strains are auxotrophic and so survival outside of the laboratory is unlikely (these Escherichia coli strains will all be handled in a class 2 laboratory). Also due to the low G+C content of Campylobacter jejuni compared with Escherichia coli and the differential codon usage between the two organisms it is unlikely that Campylobacter jejuni proteins will be efficiently expressed in Escherichia coli.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The experiments that will be performed will yield both solid and liquid waste.

Solid waste such as petri dishes, plastic pipettes and other plasticware will be placed in autoclave bags inside designated waste bins. This material will then be autoclaved in a secure containment level 2 laboratory and then incinerated by a local company.
Liquid waste from bacterial cell cultures will be collected in a designated glass container to a maximum volume of 500 ml and autoclaved. Larger volumes (>500 ml) will be split into smaller bottles (no greater than 500 ml) to allow efficient steam transfer. This will achieve 100% kill of the GMOs. Once cool liquid will be disposed of in a designated sink.

Work areas are disinfected with hycolin (a broad spectrum, phenolic disinfectant used at a working concentration of 2% v/v) to prevent dispersal to other areas.

Monitoring of autoclaves, etc, is carried out in accordance with the School of Biomedical and Natural Sciences’ safety policy.

Non-contaminated waste is disposed of separately from contaminated waste and sent for incineration.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation, and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by Prof. Mark G Darlison, who is Chair of the Genetic Modification (GM) Safety Committee and University Biological Safety Officer.

Project Ref 187/05.2

Date Ackn’d 27/09/2005  CU2 Project Title The use of different plasmid vectors and/or viruses encoding either whole, mutated or

Class 2  CultureVolClass2 < 1 Litre  CultureVolumeClass3-4
The purpose of the work is to use known novel tumour antigens to provoke and characterise immune responses in mice and in invitro models. These studies form the basis of preclinical work that may ultimately lead to the development of cancer vaccines. The work falls under the remit of the genetically modified organisms (contained use) regulations 2000 because it involves the manipulation of mutated tumour suppressor genes as well as genes encoding novel tumour associated antigens.

The parental organisms to be used include bacteria (E.coli strains XL1-Blue and TOP10, which are non-colonising, disabled derivatives of E.coli K-12) and well-characterised mammalian cell lines (mouse EL4/A2 lymphoma cells, the hamster fibroblast cell line BHK-21, and human aOs-2 osteosarcoma cells). After insertion of any of the "foreign" DNAs into any of the proposed hosts, none of the resultant genetically modified organisms (GMOs) will have an increased ability to colonise humans, animals or plants. Furthermore, the potential of any of the inserted sequences to be transferred to any other GMO is considered to be effectively zero.

The above parental organisms will be transfected with a number of different vectors. E.coli will be transformed with routine DNA cloning vectors such as pCRO-TOPO, pBluescript II SK +/-, pBR322 (CMV), pBR328, pcDNA3.1/Hygro (+/-) and pSP6. Mammalian cell lines will be transfected with eukaryotic vectors such as pBR322 (CMV), pBR328, pcDNA3.1 Hygro (+/-) and pSP6. In addition, the Disabled Herpes Simplex single cycle (DISC) virus and the Semiliki Forest Virus (SFV), which requires the use of a replicon plasmid and a helper plasmid, will be used.

The DNAs that will be inserted are murine and human truncated, mutated and full-length complementary DNAs (cDNAs) and genes that encode known and potentially novel tumour associated antigens. These cDNAs will derive from human tumour tissues such as prostate, and human-derived cell lines; some of these cDNA sequences will be provided by collaborators.

The DNAs encode proteins that either i.) potential oncogenes; ii.) up-regulated in tumours; or iii.) have not been charctorised. They include sequences encoding mutated p53 and HAGE, and sequences derived from expressed sequence tag (EST) database analysis.

The XL1-Blue and TOP10 E.coli strains are non-colonising, disabled hosts that will have no harmful effect on either human health or safety. The introduction of "foreign"
genetic material, using the vectors mentioned above, will not result in an altered host range and will not increase the ability of the hosts to colonise humans.

The mammalian cell lines do not pose a significant hazard to either human health or safety since they cannot survive outside the laboratory. If accidental penetration were to occur in normal healthy individuals, then these cells would be quickly rejected by the immune system. The introduction of "foreign" genetic material, using the vectors mentioned above, will not result in an altered host range and will not increase the ability of the host to colonise humans. Although some of the DNAs may have oncogenic potential, the proposed level of containment should reduce the risk, to human health and safety, to effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work with mammalian cells, and the DISC and Semiliki Forest viruses, will be carried out in class II cabinets in containment level 2 laboratories. This will control the risk, to human health and safety, and the possibility of accidental environmental release, to effectively zero. Waste will be disposed of according to the procedures laid down by the school of Biomedical and Natural Sciences' Microbiological Safety Officer, Dr Steve Hammonds (see http://www.ntu.ac.uk/life/sh/safety/).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The experiments that will be performed will yield both solid and liquid waste. Solid waste such as tissue culture flasks, plastic pipettes and other ware will be placed in autoclave bags inside designated waste bins. This material will be autoclaved in a secure CL2 laboratory, and then incinerated by a local company. Glass roller bottles will be soaked overnight in a mixture of 0.5% Presept/1% Teepol. Liquid waste from mammalian cell culture will be collected in a designated glass container, treated overnight with a combination of 0.5% Precept/1% Teepol, and then disposed of via a designated sink. Liquid waste from bacterial cell cultures will be collected in a designated glass container, treated overnight with 0.5% Presept/1% Teepol, and then disposed of via a designated sink. These measures ensure 100% kill. Monitoring of autoclaves, etc, will be carried out in accordance with the School of Biomedical Natural Sciences' safety policy.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The RA that is attached has been reviewed by 3 members of staff with expertise in GM, and revised in the light of recent comments that were made on it. The revised RA was then approved by all 3 original reviewers and signed off by Pro. Mark G. Darlison, who is the Chair of the GMSC and University BSO.

02/03/2022
The genotypic and phenotypic comparison of Yersinia enterocolitica from humans and animals.  

To investigate the role of various factors as potential virulence or host-specific colonisation factors in Y.enterocolitica.  This will involve mutation and complementation of genes identified via a previous comparative microarray analysis project.

Escherichia coli strain TOP10F' will be used for general cloning and the promoter expression studies as it is easy to use and readily available.  E coli strain S17-1 lambda pir will be used for conjugational transfer of suicide plasmids containing insertionally- inactivated target genes.  A variety of wild-type Y.enterocolitica will be used as hosts for homologous recombination with the introduction of antibiotic resistance markers.

The standard cloning vectors pCR2.1TOPO (Invitrogen) and pACYC184 (New England Biolabs) will be used for cloning and insertional inactivation of genes.  The R6K Ori suicide vector pKNG101 (Kaniga et al. 1991, Gene 109 (1): 137-141) will be used for homologous recombination in the target Y.enterocolitica strains.  Plasmid pMN402 (Scholz et al.2000, Eur J Biochem. 267: 1565-1570) will be used to construct promoter green fluorescent protein (GFP) fusions.

To investigate the role of various factors as potential virulence or host-specific colonisation factors in Y.enterocolitica.  Targeted genes are as yet unknown, though genes
with similarity to other known virulence factors such as toxins, adhesins, fimbriae, as well as regulatory elements are most likely to be investigated. In the majority of cases, the genes will be insertionally inactivated in Y. enterocolitica and the resultant phenotype studied. In some instances, non-coding regions upstream of the gene may be used to study expression of the factors via a reporter gene.

**Evaluation of foreseeable effects**

Wild-type Y. enterocolitica is pathogenic to humans and symptoms range from mild diarrhoea to mesenteric lymphadenitis. The disease is generally self limiting and severe disease is rare. Human infections are primarily due to consumption of contaminated dairy and meat products, in particular porcine food products, as well as contaminated water and occasionally contact with domestic animals. Y. enterocolitica is a commensal of animals. In this project, genes potentially important for colonisation and virulence will be targeted for insertional inactivation. Any resultant contact with animals should result in a reduced colonisation potential. If a genetically modified (GM) organism were to enter the human food chain, expression of virulence factors will be reduced, which in turn should lead to reduced levels of infection. All mutants will be screened for altered pathogenicity via an in vitro cell invasion assay, allowing the rapid identification of any hyper-virulent mutants. In the event that a mutation leads to increased pathogenicity potential, the disinfection and waste management strategies outlined in the attached GM risk assessment should minimise any danger to the environment. Most of the genes to be targeted in this study will be putative colonisation factors, which should decrease adhesion and, therefore, invasion of cells in vitro.

For gene expression studies in Y. enterocolitica, this will be carried out using pMN402, which is mobilisable. However, only putative promoter regions from Y. enterocolitica will be cloned into this plasmid upstream of the gfp gene (which encodes GFP). Overexpression of this reporter gene is not known to be harmful to humans, animals or plants.

The GM E. coli strains that will result from the cloning of various virulence and survival-related genes have the potential of being more harmful than the wild-type strain, although this is unlikely. These strains are auxotrophic and so survival outside of the laboratory is unlikely (note that all of the GM E. coli strains will be handled in a class 2 laboratory).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Laboratory procedures are in place to prevent the escape of GM Y. enterocolitica and/or GM laboratory attenuated E. coli strains. All personnel will be trained in “Good Microbiological Practice” and all work involving GM Y. enterocolitica as well as the GM E. coli strains will be carried out in a Containment Level 2 laboratory with restricted access.

Guidelines for working with hazard group 2 microorganisms are available as a document within the School of Biomedical and Natural Sciences (and a copy is attached to this notification). This document also contains details of how to deal with an accidental release and/or spillage of a hazard group 2 organism and this should, therefore, be read in conjunction with the attached risk assessment.

Howie laboratory coats and gloves will be worn when working with such organisms. Small culture volumes of up to 100ml will be handled on the bench using aseptic techniques. Work areas will be disinfected with hycolin (a broad spectrum phenolic disinfectant used at a working concentration of 2% v/v) to prevent dispersal to other areas.

Autoclaving of waste material will be carried out within the microbiology area.

In the unlikely event of escape, the E. coli organisms will not survive outside of the laboratory. If acquired by humans or animals, these organisms are unlikely to be any more hazardous than wild-type Y. enterocolitica strains already in the environment.
Monitoring of autoclaves, etc, is carried out in accordance with the School of Biomedical and Nature Sciences' safety policy.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been revised by three members of staff with expertise in genetic manipulation, and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by the chair of the Genetic Modification (GM) Safety Committee and University Biological Safety Officer. This attached Risk Assessment is directly linked to an application previously notified to the Health and Safety Executive, for work on Y.enterococolitica at the Veterinary Laboratories Agency in Surrey.

**Project Additional Information**

**Purposes of the contained use**

The primary aim of the project is to determine post-desiccation recovery in powdered infant formula of specified members of the Enterobacteriaceae using lux and gfp expressing strains. A secondary aim is to visualise the tagged organisms inside mammalian tissue culture cells. Banks of random gene fusion/mutants will be created via mating the recipient strain and E. coli SM10-pir pLOFKmgfp or pUT mini-Tn5 Km (transposon donor with promoterless gfp) to give rise to exconjugates. GFP and lux enables quantification of recovery desiccated cells (protein synthesis, and metabolism respectively). While gfp and lux reporter gene expression within these bacteria can allow a better understanding of invasion of host cells. Bacterial transformation with GFP and lux encoding plasmids (pDEST, pBRRMCS and pMN402) will be used to generate tagged organisms without mutagenesis. Bacterial strains expressing gfp or lux simplifies visualization and allows gene expression to be examined in single living cells. The inflammatory nature of Enterobacteriaceae will be examined with a HeLa cell reporter fusing the NFkB promoter to luciferase and galactosidase production to a Rous sarcoma gene promoter.

**Recipient or parental organism**

Enterobacter sakazakii, Ent. Cloacae, Ent hormaechei, Ent. Cancerogenus, Citrobacter freundii, C. koseri, Escherichia coli (containment level 2 and below), Esch. Vulneris, Pantoea agglomerans, Salmonella enterica, Hafnia alvei, Klebsiella pneumoniae and K. oxytoca are all Hazard group 2 bacteria that can be pathogenic to humans, specifically at risk populations such as neonates and immunocompromised individuals. They are colonising, non-disabled organisms that can survive outside the laboratory. All genetic modifications outlined in this proposal are not thought to increase virulence of any strain used in this study.

HeLa57 cells are cervical in origin and are classified as containment level 2 in the ECACC collection database.

**Host/vector system**

E.coli DH5α and E. coli SM10-pir (derivatives of E.coli K12) are hazard group 1 bacteria which are not pathogenic to humans, animals or plants. They cannot survive outside the laboratory but are recognised as 'disabled or non colonising' hosts for genetic manipulation; see the ACGM (2000) Compendium of Guidance. HeLa57A cells carry an NF-KB dependant promoter driving luciferase and a B-galactosidase gene driven by a Rous-Sarcoma promoter (Rodriguez et al 1999) and carrying a Gentamicin selective marker.

pRYluxCDABE contains the pRYluxCDABE genes from the soil bacterium Photorhabdus luminescens. This shuttle vector contains the specific origin of replication sequences for E.coli and a kanamycin cassette for maintenance within the host. Therefore this vector does not integrate or affect E.coli genomic DNA and can only be transformed into competent cells under defined laboratory conditions (Allen and Griffiths, 2001. JFP 64, 2058-62).

pFLOKmgfp- this pUT based plasmid contains the promoterless gfp mut2 gene, isolated from the jellyfish Aequorea victoria, genetically modified to improved fluorescence. The gfp gene and kanamycin resistance selectable marker gene is located on a transposon (Tn10) contained within a suicide vector such that, once the transposition event has occurred the vector is compromised and unable to replicate (Stretton et al. 1998. AEM 64, 2554-9).

pUT mini-Tn5 Km- this pUT based plasmid contains the promoterless gfp mut2 gene, isolated from the jellyfish Aequorea victoria, genetically modified to improve fluorescence. The gfp gene and kanamycin resistance selectable marker gene is located on a transposon (Tn5) contained within a suicide vector such that, once the transposition event has occurred the vector is compromised and unable to replicate (Stretton et al. 1998. AEM 64, 2554-9).

The transposase gene is located outside of the transposable element on the suicide vector. Following transposition the transposase is lost along with the delivery vector.
This increases stability of the mutation and makes transfer of the transposon into other organisms highly unlikely. Random and stable insertions into bacterial chromosomes has been demonstrated previously with this vector (Albertson et al., 1996. FEMS 140. 287-294).

pLUX GFP: this plasmid is based on pDESTR4-R3 (Invitrogen) and contains an ampicillin-resistance marker cassette, a T7 promoter linked to the gfp gene isolated from the jellyfish Aequorea victoria, genetically modified to improve fluorescence, and the luxCDABE operon. This construct has a pBR322 origin of replication and is non mobilisable, limiting the host range.

pBBRMCS lux: this plasmid is based upon broad host range plasmid pBBRMCS carrying kanamycin resistance in addition to luxCDABE. It is of incompatibility group N and could be mobilised by P group plasmids such as pRK2 and has a pBBR1 origin of replication (Lewis et al. 2005. J. Food Eng. 76, 49-52).

pMN402, carries hygromycin resistance, and the GFP+ gene fused to an HSP60 promoter. It is non mobile shuttle vector and has a broad host range to include both gram -positive and negative bacteria. It contains a PAL500 origin of replication and a ColE1 origin of replication (Scholz et al. 2000. Eur. J. Biochem. 267, 1567-1570).

Hela57A cells carry an NF-KB dependant promoter driving luciferase and a B-galactosidase gene driven by Rous sarcoma promoter and carrying a Gentamicin selective marker (Rodriquez et al. 1999. J. Biol. Chem. 274, 9108-9115)

Origin & function

The DNAs encode bacterial luminescence structural and regulatory genes from Ph. Luminescens and green fluorescent protein from the jellyfish A. victoria. The lux and gfp genes are well characterised marker genes. These genes will be biologically active though there is no identified hazard associated with their usage. The reporter genes encode products that are either constitutively expressed in the case of B-galactosidase, or subject to possible high levels of induction in the case of luciferase, neither is associated with any known hazard.

Evaluation of foreseeable effects

The host bacterium E. sakazakii, E. cloacae, and C. koseri are hazard group 2 organisms causing gastroenteritis in humans; E sakazakii and C. koseri can cause meningitis in low birth weight neonates (associated with ingestion of contaminated formula milk). They are colonising, non-disabled organisms that can survive outside the laboratory. However, these organisms are ubiquitous in the environment. There are no recognised hazards associated with GMO's constructed to contain luminescence or green fluorescent protein genes and they are also present naturally in the environment. The resulting genetic modifications are maintained in the host strain under the selective pressure of kanamycin, ampicillin or hygromycin. The addition of pRYluxCDABE and/or gfp is not likely to increase virulence, alter host range, or increase in the ability to colonise humans or animals. As stated above, transference of the antibiotic genes to other organisms is highly unlikely. Neither kanamycin, ampicillin nor hygromycin are first choice antibiotic for Enterobacter or Citrobacter infections. The HeLa cell line is cervical in nature and highly unlikely to survive outside the laboratory. The genetic alterations made in fusing luciferase expression to an NF-KB dependant promoter and fusing B-galactosidase expression to a Rous sarcoma promoter is unlikely yo improve survival inside or outside the laboratory, and transfer of the reporter genes or gentamicin resistance concurrent with these genes is highly unlikely to occur.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The use of the School 'Code of Practice for Microbiology' for category 2 work in containment level 2 laboratories and risk assessment will ensure that the GMO's will not be released into the environment. This will include training of personnel in the use of containment level 2 facilities, use of safety hoods aseptic techniques, the avoidance of aerosol production, laboratory coats to be worn within containment level 2 laboratories, maintenance of negative air pressure within the laboratory, the disinfection of...
working surfaces and equipment (for example, centrifuges), and autoclaving of all bacterial waste will be within the laboratory suite. Both 2% Hycolin, 2% Virkon and Presept will be available for any spillages, and appropriate measures would be taken in the event of spillages. The autoclaving of all waste material will be carried out within the microbiology area. In the unlikely event of escape, the modified GMO's are not likely to be maintained outside of the laboratory (due to the lack of positive selection pressure in addition to the high metabolic demand of ATP production for luciferase activity), in any event, do not represent a greater hazard than the wildtype organism to either humans, animals and plants. Implementation of the above safety measures should control risk of release/exposure to effectively zero.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by Prof. S. J. Forsythe who is the Chair of the Genetic Modification (GM) Safety Committee and Dr Matthew Smith, the University Biological Safety Officer.

Project Ref 187/12.1

Date Ackn'd: 27/01/2012
CU2 Project Title: The use of different plasmid vectors and/or viruses encoding telomerase reverse transcriptase to transfet primary cells and generate in house cell lines
Date Project Ceased: 02/03/2022

Class: Class 2
Culture Volume Class 2: < 1 Litre
Non-GMM: Consent Granted
Project notified under transitional arrangements N
The primary aim of work outlined in this document is to use commercially available vectors to immortalise human and murine cell lines. Normal human prostate epithelial cells and even primary prostate cancer cells have a finite lifespan. They undergo approximately 30 population doublings before becoming senescent (3). Immortalisation will enable long term culture and expansion of precious patient material which has otherwise proven difficult to maintain in culture.

Despite extensive work (by others) on the development of human prostate cancer cell lines, the proportion of cell lines that give rise to immortalised prostate cancer cell lines is still disappointingly low (3). Therefore, there are very few primary prostate cancer and normal prostate cancer cell lines which can be studied extensively to further our understanding of prostate cancer biology (4).

In future, we hope to have access to more fresh patient material, such as tissue samples from breast cancer patients. These will also be processed in the same manner, in order to separate different cell populations which will then be characterised and will undoubtedly require immortalisation to enable long-term culture.

The preferred method to immortalise cells is through the expression of the telomerase reverse transcriptase gene (TERT). Several groups have utilised hTERT in a standard procedure to immortalise primary cells and analysis of many TERT-immortalised cell lines has verified that the cells maintain a stable genotype and retain critical phenotypic markers (5).

References

Recipient or parental organism

Human cell Lines
The human cell line 293T, purchased from the ATCC, is free of pathogenic viruses and cannot survive outside its culture media. In addition, in the unlikely event of accidental contamination, the recipient's immune system would quickly reject these cells due to human leukocyte antigen (HLA) mismatch. No immunocompromised individuals will be permitted to conduct work described in this Risk Assessment. Normal human cell lines are considered to be especially disabled hosts (see the ACGM Compendium of Guidance) but they will, nevertheless, be grown in a containment level 2 laboratory.

Primary cells
None of the cells specified below can survive outside of their specified culture media. Furthermore, as stated above, in the unlikely event of accidental contamination, the recipient's immune system would quickly reject these cells due to human leukocyte antigen (HLA) mismatch. As with all clinical samples, there is a risk of hepatitis infections which is a potential hazard to human health therefore these cells are/will be handled very cautiously in a containment level 2 laboratory. With the adoption of good
laboratory practice and the growth of these cells in a containment level 2 laboratory there are minimal risks to human health.

Human Primary Prostate cells
Prior to processing, patient tissue samples are subjected to fungizone treatment and post processing the isolated cells are grown in the presence of penicillin/streptomycin to eliminate any fungal/bacterial contamination. The cells isolated from patient samples are grown as two separate cultures; epithelial and stromal. The epithelial cultures contain a mixture of basal, secretory luminal and neuroendocrine cells. The stromal (connective tissue) cultures contain a mixture of cells including fibroblasts, pericytes, endothelial cells and smooth muscle cells.

Human Primary Cells (other)
In future, we hope to obtain patient samples from other solid malignancies and matched benign tissue. These will also be subjected to fungizone treatment and post-processing the isolated cells will be grown in the presence of penicillin/streptomycin to eliminate any fungal/bacterial contamination. Depending on the tissue type, these will be processed in a similar manner to the prostate tissue samples in order to separate different cell populations for culture prior to immortalisation.

Host/vector system

pUMVC
This is a packaging plasmid for the Moloney murine leukaemia virus (MoMuLV) (a gammaretrovirus) constructs. This plasmid encodes gag and pol, two of the three major proteins encoded within the retroviral genome. Gag is a polyprotein which makes up the retroviral core (capsid). Pol encodes reverse transcriptase, an essential enzyme that carries out the reverse transcription process that take the RNA genome to a double-stranded DNA preintegrate form. The reverse transcriptase gene also encodes an integrase activity and an RNase H activity that functions during genome reverse transcription.

pCMV-VSV-G
This plasmid encodes the third major protein encoded within the retroviral genome; the envelope protein. This protein plays a role in association and entry of a virion into a host cell.

pBABE-neo-hTERT;
This is a mammalian retroviral expression vector encoding human telomerase reverse transcriptase. This plasmid is directly responsible for the immortalisation of the target cells.

The above vectors pose no threat to human health as they are only capable of giving rise to conditionally infectious virus. Hence, the virus produced will only be capable of infecting the host cells once as it is non-replicative.

The use of a three plasmid system to split the genomes of the helper plasmid greatly reduces the risk of replication competence occurring as a result of genetic recombination. The separation of the gag and pol genes from the env gene on separate plasmids greatly decreases the likelihood of replication competent retrovirus (RCR) generation as not only would recombination between the vector plasmid (which would give the packaging sequence) be required, but also between the two split plasmids (6).

6) Lentiviral vectors. Information and Biosafety considerations
Human telomerase reverse transcriptase is a catalytic subunit of the enzyme telomerase. Telomerase is a ribonucleoprotein polymerase which lengthens telomeres in DNA strands, thereby allowing senescent cells that would otherwise become post mitotic and undergo apoptosis to exceed the Hayflick limit and become potentially immortal, as is often the case with cancerous cells. Deregulation of telomerase expression in somatic cells may be involved in oncogenesis hence hTERT is oncogenic. Following successful transfection and integration of the hTERT gene into the genome of the target cells, the protein will be expressed and biologically active, thus rendering these cells immortal.

Origin & function

As stated, the virus generated through the construction with the three plasmids. (MoMuLV+hTERT) will only be conditionally infectious. i.e. the MoMuLV constructs have been engineered such that they are only capable of infecting cells once (as they are non-replicative). As such, in the unlikely event that they should enter the human body, the inserted DNA would only be produced temporarily and it would trigger an immune response leading to the detection and elimination of the cells producing the protein. Infection of host cells with the virus produced (MoMuLV+hTERT) will render them immortal; i.e. these cells will have acquired the ability to proliferate indefinitely. Immortalisation of host cells will not increase their survival outside the laboratory as they will still be unable to grow in the absence of defined culture conditions. Hence, the immortalised cells will not be more harmful. The expression of telomerase reverse transcriptase will not alter the host range of the host cells neither will it increase their ability to colonise humans, animals or plants. In the unlikely event that the immortalised cells should enter the human body, they would be rejected and eliminated immediately by the immune system which would recognise them as "foreign". The potential for the inserted sequences to be transferred to other GMOs is, with the application of good laboratory practice and the methods of containment described herein, considered to be effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The 293T cells, the primary cells and the MoM7uLV viruses (transfected with hTERT) will be cultured in plastic tissue culture flasks (a maximum of ten 50ml flasks at any one time). Plastic flasks and any disposable plastics used during the culture of these cells will be disposed of into a bin for immediate autoclaving followed by incineration. Other material, including glassware and disposable plastic pipettes etc., will be soaked overnight in a mixture of 0.5% Presept®/1% Teepol prior to autoclaving and/or disposal. The cells will be grown in a class II cabinet, with one cabinet dedicated to virus work. Both 0.5% Presept®/1% Teepol and 70% (v/v) ethanol will be available in the cabinet in case of any spillages. This is as recommended by the School Disinfectants Policy. As the cells will not be cultured on a large scale, there will be no risk of any large spillages. Consequently, it is highly unlikely that either cells or viruses would be released into the environment. In the unlikely event of escape, none of the modified GMOs would be able to survive outside of the laboratory. Accidental exposure will be prevented by the use of suitable personal protective equipment (PPE) including gloves, a suitable laboratory coat and, where necessary, a CN P2 v mask which provides protection against viral exposure. General adherence to good laboratory practice will also help to ensure that accidental exposure is avoided. However, in the case of accidental exposure, for example through puncture wounds, a trained first aider will be available to administer first aid. Our collaborators at the M. D. Anderson Cancer Centre (Houston, Texas, USA) have provided us with the information regarding the plasmids and will provide a detailed protocol/standard operating procedure (SOP) and any other information required upon approval of this Genetic Modification Risk Assessment. They have been very cooperative and will continue to provide assistance throughout the duration of this project.
Any new staff will be trained by a member of the laboratory according to the training program for tissue culture activities (developed by Dr E V; see the NTU School of Science training booklet, version 1.2 October 2006) with additional specific training by the named main investigation/supervisory team/laboratory manager involved in this project. Mr S R and Dr M M at the John van Geest Cancer Research Centre and Mr R D at the Anthony Nolan Stem Cell Bank have already used similar systems of production of viral particles in the view of transfecting primary cells as well as cell lines. These persons can provide training to work at a high safety standard.

In order to reduce the potential for mucosal exposure during transduction, those transducing the cells will be required to wear a CN P2 v mask which provides protection against viral exposure. As stated, all procedures involving live, immortalised cells will be conducted in containment level 2 laboratory in a category 2 hood where all culture media/liquids/disposable materials which associate with the cells will be carefully disinfected in 0.5% Presept®/1% Teepol overnight. Furthermore, any materials which contact the cells will also be disinfected with 0.5% Presept®/1% Teepol prior to autoclaving followed by incineration. These disposal and decontamination methods are in adherence to containment level 2 procedures. Therefore, the extremely unlikely release of live hTERT-expressing virus into the culture media would not present a significant hazard since the virus would be destroyed using the disinfection procedures described. All related experiments involving any material from the immortalised cell lines will be concluded in containment level 2 laboratories (there are ample facilities available at the JvGCRC as well as in the interdisciplinary Biomedical Research Centre).

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by Prof S J F who is the Chair of the Genetic Modification (GM) Safety Committee and Dr M S, the University Biological Safety officer.

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by Prof S J F who is the Chair of the Genetic Modification (GM) Safety Committee and Dr M S, the University Biological Safety officer.
The tumour-associated antigens studied in the John van Geest Cancer Research Centre (JvGCRC) are linked with tumour cell proliferation. Small interfering RNAs (siRNAs) processed from short hairpin RNAs (shRNAs) are a powerful way to mediate gene-specific RNA interference (RNAi) in mammalian cells. Different plasmid vectors and/or viruses encoding shRNA to silence/knockdown tumour-associated antigens will be used to transfect cell lines, produce virus particles and/or inject animals in order to assess the effects of shRNA on tumour cell proliferation both in vitro and in vivo. Also, lentiviral vectors are known to be a very efficient way of gene transfer because of their stable integration in non-dividing and dividing cells and long-term transgene expression.

A number of human cell lines purchased from the ATCC (American Type Culture Collection, USA) and ESTDAB (European Searchable Tumour line Database and Cell Bank, Germany) will be transfected in vitro or in vivo using different plasmid and virus vectors. The human cell lines will include: FM-82, a human melanoma cell line (Originally given by Prof. D. Schadendorff and well described on the ESTDAB website) and PC3, a prostate cancer cell line (Originally purchased from the ATCC) and the prostate cancer cell line OPCT-1 (obtained from Onyvax, Ltd).

Recipient or parental organism

Prokaryotic hosts: Attenuated and non-colonising hosts, such as the disabled E.coli K12 strains XL1-Blue (Stratagene) and TOP10 (Invitrogen), will be used to bulk up DNAs of interest. These bacteria are unable to survive outside of laboratory conditions.

Eukaryotic hosts: Human cell lines, such as FM82 or PC3 cells will be used. These cells are free of pathogenic viruses, and cannot survive outside their culture media. In addition, in the unlikely event of accidental contamination, the recipient's immune system would quickly reject them because of the human leukocyte antigen (HLA) mismatch. No immuno-compromised individual(s) will be permitted to carry out work described in the Risk Assessment. Normal human cell lines are considered to be especially disabled hosts (see the ACGM Compendium of Guidance) but they will, nevertheless, be grown in a containment level 2 laboratory.

Animals: Non-obese diabetic / severe combined immuno-deficient (NOD/SCID) mice will be used. These mice lack B cells, T cells and NK cells, and only survive in a sterile environment. Lentiviral transduction particles, used in a tumour model, are not pathogenic or transmissible, and will not affect these mice. Furthermore, encoded shRNA are under the control of human promoters and will not be expressed in murine cells. NOD/SCID mice will be handled in a containment level 2 laboratory and will be kept in individually ventilated cages. Other immuno-compromised mice may be used in the future.
SureSilencing™ shRNA plasmid for human DDX43 (SA Biosciences, Cat Number: KH11719N): This plasmid is designed to specifically knockdown the expression of DDX43 by RNA interference under stable transfection conditions after performance of the appropriate enrichment or selection procedures. The vector contains the shRNA under control of the U1 promoter and the neomycin resistance gene for the selection of stably transfected cells.

BLOCK-iT™ inducible H1 RNAi entry vector for human T21, primarily, and other potential tumour-associated antigens in the future (Invitrogen, Cat Number: K4920-00 and K4925-00): This vector facilitates tetracycline-regulated expression of a shRNA of interest from an H1/TO RNAi cassette for use in RNAi analysis in mammalian cells. It provides a rapid way to clone double stranded oligonucleotide duplexes encoding a desired shRNA target sequence (e.g.: to target T21) into an entry vector containing an RNA polymerase III-driven expression cassette.

Mission™ shRNA lentiviral transduction particles against DDX43 (Sigma, Cat Number: SHCLNV-NM_018665). The lentiviral transduction particles are produced from a library of sequence-verified lentiviral plasmid vectors for human genes. The libraries consist of sequence-verified shRNAs cloned into the pLKO-puro vector. Unlike murine-based MMLV or MSCV retroviral systems, self-inactivating replication-incompetent lentiviral-based particles will permit efficient infection and integration of the specific shRNA construct into both dividing and non-dividing mammalian cells.

BLOCK-iT™ lentiviral RNAi expression system for human T21, primarily, and other potential tumour-associated antigens in the future (Invitrogen, Cat Number: K4925-00). This expression system facilitates the creation of a replication-incompetent lentivirus that delivers an inducible shRNA of interest to dividing or non-dividing mammalian cells for RNAi analysis.

pGreenFire™ Pathway Reporter Lentivectors Cat. # TR0XX Series (System Biosciences) has a dual reporter system consisting of GFP and Luciferase. These can only be expressed when the relevant transcription factor is present within the cell. This vector will be used to transfect mammalian cell lines in order to report the expression of a particular transcription factor and to sort and study the cell populations according to GFP expression. pGreenZeo lentivectors are third generation HIV lentiviral vectors which are designed to maximize their biosafety features. These HIV-based vectors falls within NIH Biosafety Level 2 criteria because of the possibility of recombination with endogenous viral sequences to form self-replicating virus or of insertional mutagenesis.

Origin & function

The DNA inserted into the cells encodes a shRNA designed to silence tumour-associated antigens such as HAGE or T21 in human tumour cell lines. Each shRNA is or will be inserted downstream of a modified human promoter, respectively, allowing the entire shRNA to be produced. It is believed that shRNA do not have any oncogenic or other harmful properties.

pGreenFire™ Pathway Reporter Lentivectors express copGFP reporter gene followed by the self-cleaving T2A peptide and the firefly luciferase gene under the control of a pathway-specific TRE. Other than GFP and luciferase, no other proteins will be expressed as a result of the transduction with these lentivectors.

Evaluation of foreseeable effects

The potential for the inserted sequences to be transferred to other GMOs is, with the application of good laboratory practice and the methods of containment described herein, considered to effectively zero. However, future users will have to possess a working knowledge of viral and tissue culture techniques, lipid-mediated transfection, and the RNAi pathway.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The different tumour cell lines and the lentiviruses will be cultured either in plastic flasks (a maximum of ten 50ml-flasks at any one time). Plastic flasks will be disposed of into a bin for autoclaving and then incineration. Glass bottles will be soaked overnight in a mixture of 0.5% (w/v) Presept® / 1% (v/v) Teepol. Cells will be grown in a class II cabinet, with one cabinet dedicated to virus work with both Presept® and 70% (v/v) ethanol available in the cabinet in case of any spillages.

Plasmids containing the shRNA of interest will be grown in E.coli in a containment level 2 laboratory. Bacteria will be cultured either on agar plates (typically 15ml volume) or in liquid medium (a maximum of 250ml). Cultures will be stored in 1 ml-volume (under glycerol at -80°C).

Lentiviruses will be injected (either using a syringe or a gene gun) in NOD/SCID mice in a class II cabinet by a trained Personal License Holder. The latter will follow the rules set up by the Home Office Codes of Practice for the housing and care of animals. Needles will be discarded in sharps bin for autoclaving and incineration. Moreover, mice are kept in individually ventilated cages providing an effective barrier protecting animals from airborne contaminants and users from injected replication-incompetent lentiviruses. Mice will be monitored two to three times a week and will be sacrificed if any symptoms arise or when the tumours reach a size of 1cm² according to the Home Office guidelines.

Any spillages will be dealt with as recommended by the School Disinfectants Policy, which is available on the Microbiological Safety website. In addition, the implementation of the Code of Practice for Working with Hazard Group 1 Microbes will ensure that the bacteria and the viruses will not be released into the environment. For this, personnel will be trained in Good Laboratory Practice, aseptic technique, the avoidance of aerosol production, and the disinfection of working surfaces and equipment. All waste will be autoclaved and incinerated. Consequently, it is highly unlikely that either cells or viruses will be released into the environment.

New staff will be trained by a member of the laboratory according to the training programme for tissue culture activities (See the NTU School of Science Training Booklet). An up-to-date list of GM users will be maintained. In the unlikely event of escape, none of the modified GMOs will be able to survive outside of the laboratory.

Accidental exposure, for example through puncture wounds, will be treated by a trained first aider.

### Project Additional Information

**Purposes of the contained use**

The project aims to generate a transposon mutant library of Helicobacter pylori laboratory strains including 60190 and SS1 to identify genes involved in outer membrane vesicle production and virulence. Additionally, H. pylori mutants lacking key virulence factors including VacA, CagA, CagE, catalase, PPT, GGT will be brought to Nottingham Trent University from collaborator institutions or generated in-house if necessary, and the same virulence factors will be cloned into E. coli for overexpression, mutagenesis and purification.

**Recipient or parental organism**

H. pylori is a recognised human pathogen, but is considered as hazard group 2 because it is unable to persist in the environment for more than a very short time. Adult acquisition is extremely rare, and volunteer studies have shown that large volumes of active culture are needed along with deliberate stomach acid suppression with drugs to cause infection.

**Host/vector system**

Hosts: Escherichia coli DH5α and B834 or closely related strains; these are hazard group 1 strains that are recognised as 'disabled or non-colonising' hosts for genetic manipulation; see the SACGM Compendium of Guidance. E. coli DH5α and B834 are K-12 derived laboratory strains that are non-colonising and disabled, therefore not considered pathogenic to humans, animals or plants. As strains have auxotrophic requirements unlikely to be met outside laboratory culture, the survival of bacteria in the
Vectors: pBR322-derived vectors such as pJET (Fermentas) and pET series plasmids will be used for cloning and expression of H. pylori virulence factor genes in E. coli. For targeted mutagenesis in H. pylori, the target H. pylori genes will be cloned into pBR322-based plasmids then disrupted in vitro with a chloramphenicol or kanamycin resistance marker before transformation back into H. pylori for mutant generation by homologous recombination and marker rescue. These vectors are mobilisation defective and there are no known hazards associated with their use.

For transposon mutagenesis in H. pylori, a transposon based system will be used to introduce random insertion mutations into the H. pylori genome with a chloramphenicol resistance marker. The transposon system will use GPS plasmids and transposase enzyme to mutagenize H. pylori chromosomal DNA in vitro, which will then be transformed back into H. pylori for mutant generation by homologous recombination and chloramphenicol or kanamycin marker rescue. The GPS plasmids are not able to replicate in normal laboratory strains of E. coli and there are no known hazards associated with their use.

The virulence factor genes to be cloned include the VacA and CagA toxins (harmful to human and mammalian cells, CagA may be oncogenic, VacA is immune modulatory). CagE which is part of the Type IV secretion system used to deliver CagA to human cells, catalase and other proteins with diverse effects on human immune cells including GGT and PPT. These proteins will be overexpressed in E. coli and purified in their biologically active forms. The activities of these virulence factors may be harmful to human cells and may become allergenic upon repeated exposure. CagA may have oncogenic effects once inside human cells, but requires delivery into cells via a complex multi-component bacterial secretion system so the risks associated with handling the purified toxin in isolation are considered to be low. All proteins will be produced in small quantities (typically less than 1 mg) under containment level 2 using appropriate PPE (gloves, lab coat) and Good Laboratory Practice including precautions to prevent aerosolisation, to minimise the risk of exposure of workers to the bacterial products.

Origin & function

The virulence factor genes to be cloned include the VacA and CagA toxins (harmful to human and mammalian cells, CagA may be oncogenic, VacA is immune modulatory). CagE which is part of the Type IV secretion system used to deliver CagA to human cells, catalase and other proteins with diverse effects on human immune cells including GGT and PPT. These proteins will be overexpressed in E. coli and purified in their biologically active forms. The activities of these virulence factors may be harmful to human cells and may become allergenic upon repeated exposure. CagA may have oncogenic effects once inside human cells, but requires delivery into cells via a complex multi-component bacterial secretion system so the risks associated with handling the purified toxin in isolation are considered to be low. All proteins will be produced in small quantities (typically less than 1 mg) under containment level 2 using appropriate PPE (gloves, lab coat) and Good Laboratory Practice including precautions to prevent aerosolisation, to minimise the risk of exposure of workers to the bacterial products.

The antibiotic cassettes that we propose to use as selectable markers to facilitate inactivation of genes in H. pylori will confer resistance to kanamycin or chloramphenicol. Neither of these are used in either the treatment or prophylaxis of H. pylori infection.

Evaluation of foreseeable effects

Cloning of H. pylori virulence factor genes into E. coli: Addition of H. pylori virulence factor genes has the potential to increase the pathogenicity of the host E. coli strains, for example via the production of VacA toxin which is harmful to human cells, but overexpression of one virulence factor in isolation would not confer upon the E. coli host strains the ability to infect humans, animals or plants. It is unlikely that any DNA sequence will confer on the E. coli host a significant increase in fitness or pathogenicity due to the multiple disablements present and the multifactorial nature of pathogenicity. Furthermore, expression will be controlled at a low level. The resultant DH5α and B834 strains carrying H. pylori virulence factor genes are not expected to have altered host ranges and will not be able to survive outside of the laboratory. As a precaution, E. coli strains containing H. pylori virulence factor genes will be handled only at containment level 2.

Transposon mutagenesis in H. pylori and targeted mutagenesis to disrupt specific virulence factors: Generation of chloramphenicol or kanamycin resistant H. pylori mutant strains would not affect treatment options, because other antibiotics are used in treatment of H. pylori infections. Introduction of additional antibiotic resistance markers is considered unlikely to affect therapeutic potential in the extremely unlikely event of a laboratory acquired infection.

Since the mutations introduced will cause loss of function of H. pylori genes, most mutants are anticipated to have reduced or unchanged virulence. However, mutation of regulatory genes which may co-ordinately control expression of a number of virulence factors has the potential to generate strains which may express elevated levels of some gene products. Mutation of regulators is considered highly unlikely to result in a strain which will have significantly enhanced virulence given the multifactorial nature of the infection process.

H. pylori is a fastidious, microaerophilic organism which cannot grow in atmospheric oxygen so the potential for transmission and environmental contamination with this organism is very low. We will not be using modified forms of any gene that is not already widely prevalent in the wild-type strain populations, except where a modification is designed to specifically reduce the activity of the encoded product (e.g deletion of protein domains, functional motifs etc.). In the unlikely event that survival of the GMO was sufficient for gene transfer to occur, any such transfer to a wild type microorganism would either not confer a greater virulence attribute than was already prevalent in the
population or would be a redundant duplication of existing genetic material.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The use of "Good Laboratory Practice" and containment level 2 will ensure that the GMOs will not be released into the environment. Measures taken will include the training of personnel in "Good Microbiological Practice", aseptic techniques, the avoidance of aerosol production, etc., the disinfection of working surfaces and equipment (for example, centrifuges), and autoclaving of all bacterial waste. 2% New Hycolin, 2% Virkon and Presept will be available for any spillages, and appropriate measures would be taken to ensure adequate disinfection. The autoclaving of all waste material will be carried out within the containment level 2 laboratory. In the unlikely event of escape, the GMOs will not be able to survive outside of the laboratory and, in any event, will not be hazardous to either humans, animals and plants. Since E. coli DH5α and B834 are non-colonising and H. pylori requires a large infective dose, the risk to humans, animals and plants can be considered to be effectively zero. Hosts and GMOs will be cultured on agar plates (typically 15 ml). Broth cultures will be no larger than 250 ml in volume. Cultures will be stored in 1 ml volumes (under glycerol). Accidental exposure through puncture wounds will be treated by a trained first aider. Implementation of the above safety measures should control the risk of release/exposure to effectively zero.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by the Chair of the Genetic Modification (GM) Safety Committee and the University Biological Safety Officer.

Human Clinical Applications
**Project Additional Information**

**Purposes of the contained use**

The broad interest of our laboratory is to determine the changes in the epigenome and cellular signaling that occur in inflammatory diseases and cancer, identify novel targets and investigate therapeutic applications. This project aims to utilise disabled, replication incompetent retroviral and lentiviral systems to deliver genes of interest as cDNA or shRNA against individual genes into mammalian cells for their subsequent analysis in a broad range of cell-based and biochemical assays. Viral mediated methods for transduction of cDNAs into cells provides a very valuable tool for the production of cells stably expressing a gene, short hairpin- or micro-RNA of interest into the host genome.

**Recipient or parental organism**

Cloning strains of bacteria derived from E. coli K12: MACH1, DH5a and Sbtl3, are non-pathogenic, non-hazardous. They do not carry the well-recognized pathogenic mechanisms required by strains of E. coli that cause the majority of enteric infections. These strains are considered to be non-pathogenic and unlikely to survive in host tissues and cause disease. Exposure through eyes and skin may cause irritation with susceptible persons.

**Host/vector system**

Host Cell Lines: Containment level 1 (CL1) human cell lines: NCM356, NCM460 (InCell) immortalised colonic cell lines and HCT116, HT29, CaCo2, SW480, SW620, SW48, LS123, RKO, DLD1 (ATCC) colorectal cancer cell lines, Capan1, PANC1, BxPC3, MiaPaca2, Capan2, CFPAC1, AsPC1, HPAFII (ATCC) pancreatic cancer cell lines, SKHep1, HepG2 (ATCC) liver cancer cell lines. These are established, dissociated mammalian cell lines, no human hazards exist. All cell lines were purchased from ATCC and InCell and are virus-free certified.
Containment level 2 (CL2) SNU475, SNU387, SNU398, SNU449, Hep3B (ATCC) human liver cancer cell lines. These cell lines contain Hepatitis B virus (HBV) as assessed by PCR. Hepatitis is spread through contact with blood and blood products or contaminated hypodermic needles.

Containment level 2 (CL2) HEK293T/17 (ATCC) and AmphoPack-293 (Clontech) cell lines will be used for the production of lentiv- and retro-viruses, and amphotropic viruses, respectively. They give high titres when used to produce viruses and have been widely used for retroviral production, gene expression and protein production. These cell lines contain adenovirus genetic material and HEK293T also contains Simian Virus 40 large T antigen (SV40T). Because these cells do not contain the complete viral genome for the respective viruses the risk of generation of these viruses by these cells is extremely low.

The self-inactivating vector systems or AmphoPack-293 cells will be used to generate replication defective viruses. Genes for replication and structural proteins are absent in the packaged viral genome since genes are supplied by other plasmids in packaging cells. Viral genome contains only the region between the 5’ and 3’ LTR’s. Vectors contain self¬-inactivating 3’ LTR.

Hazards associated with these vectors are summarised as: stable expression of transgenes, insertional mutagenesis and potential for generation of replication competent virus. Replication defective vectors that cannot infect human cells can generally be considered class 1. For replication defective retroviruses and lentiviruses capable of infecting human cells, if the risk assessment demonstrates they are adequately attenuated, it is possible to designate the activity as class 1 :- Factors supporting this classification will include: low risk of generation of RCV (e.g. a third generation packaging system), self -inactivating (SIN) LTR and non-harmful insert. However, contaminated sharps represent a significant hazard, and their use should be excluded for vectors that can infect human cells, if the activity is to be designated class 1.

Origin & function

The inserted sequences are capable of encoding biologically active proteins which may be potentially pathogenic to humans if mutated. The eukaryotic vector systems are optimised for physiological level expression of protein. The DNAs are highly unlikely to alter the pathogenicity or properties of the bacterial host cell. Enforced expression of such sequences in human cell lines, will not affect the malignant properties of the cells. Neither the DNA, encoded protein, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment. The GM microorganisms are incapable of surviving outside of the laboratory environment. Retroviral and Lentiviral particles are very labile, and unstable when exposed to air. In addition, they are very labile at high temperatures and can be disabled effectively with disinfectants (such as Virkon) or 10% bleach solution in water.

Primary Hazards associate with ingestion via the oral route, droplet exposure of the mucous membranes, inhalation (through respiratory droplets), and contact/hand-to-eye transfer. Special hazards: Generalized infections can occur in immunocompromised individuals. Exposure to this agent can cause serious infection in the congenitally immunocompromised, in patients undergoing immunosuppressive treatment for organ and tissue transplants and for cancers, and in human immunodeficiency virus-infected patients.

GM bacteria have a reduced ability to colonise beyond the intestine and reduced persistence compared with pathogenic strains. Laboratory procedures are in place to
prevent the escape of E. coli strains carrying GM plasmids. All personnel will be trained in good microbiological practice and work is carried out in a containment level 2 laboratory with restricted access (CELS206).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Handling and manipulation of naked DNA will require the wearing of lab coats and disposable gloves. Laboratory coats and nitrile gloves will be worn when working with GM bacteria. Work areas have impermeable surfaces and will be disinfected with freshly prepared Virkon (working concentration of 1% v/v) routinely and after spills to prevent dispersal. Media, cells, and cell lysates will be decontaminated using freshly diluted bleach (final dilution 1:10, minimum 30 minute contact time), or autoclaved before disposal in the sewer, to ensure that the environment is not contaminated with plasmids carrying antibiotic resistance genes or other potentially harmful genes.

All human cell lines have the potential risk of producing unidentified human viral pathogens. Human cell lines, whether designated by the source company as CL1 or CL2 will be cultured in a Class 2 biological safety cabinet using level 2 precautions. Any cell lines infected with the viruses will be handled using level 2 precautions in a laboratory containment level 2 room (CELS205), accessed by card only. All virus work will be performed in bespoke Class 2 microbiological safety cabinet. The specific cabinet will be labelled for virus production and use and increased risk of HepB. All personnel using the bespoke safety cabinet and tissue culture incubator will be immunised against Hepatitis B and will also have their resistance levels checked via an antibody titre test. Users will be experienced in proper pipetting techniques, pipetting down the side of the tube with no forceful expulsion, to reduce aerosol generation. For centrifugation, closed, screw-capped tubes and centrifuge cups with aerosol resistant lids containing O-rings will be used to contain aerosols. Any pipetting will be performed with filter tips, to minimise contamination of instruments, and only plastic pipettes will be used to minimise sharps risk. Pipettes and racks will not leave the biosafety cabinet. Good laboratory practice will include lab coat, eye ware (safety glasses or Face shield), waterproof gloves (nitrile rubber, butyl rubber); designated tissue culture lab coats. Use of double gloves when working with virus supernatants following production in packaging cell lines will reduce the risk of user contamination. Functional, molecular analyses will follow multiple passages of cells transduced with lentiviruses, while cell extracts (RNA, protein) will use reagents that inactivate viruses (Phenol, dithiothreitol). Extensive hand washing will be enforced after working with viruses. All users under this GM will be trained and supervised for these procedures prior to being given clearance for work. Log of personnel involved in virus production and usage, with all information related to the specific procedures and dates will be kept in the lab. 1% Virkon disinfectant and 70% ethanol for workplace and spillage decontamination will be used. Either 1% Virkon or 10% bleach, will be applied before disposal for at least 30 minutes for inactivation of any virus-containing media cultures, pipettes, tips and culture dishes. Microbiological safety cabinet will be in addition treated with UV for 1 hour after the completion of virus-related work. All biological waste will be autoclaved of prior to disposal.

Toxin-antitoxin (TA) modules function on low-copy virulence and resistance plasmids as postsegregational killing systems; they ensure vertical transmission of a plasmid by killing or inhibiting the growth of any plasmid-free daughter cells. My previous work (McVicker & Tang, 2016, Nature Microbiology) has shown that the regulation of a given TA system can itself be adapted to the host environment in a similar way to the virulence genes it helps to maintain. However, the ability of TA systems to successfully
transfer between bacterial hosts and integrate into organisms that already possess their own TA modules (i.e. the ability of TA systems to promote or prevent horizontal transmission) has not been well-studied.

This project proposes two main aims:

1) To investigate the presence of novel or poorly-characterised maintenance elements on the virulence and antimicrobial resistance plasmids/mobile genetic elements of a range of E. coli isolates, to identify new potential targets for therapy and to understand the maintenance of virulence in these highly diverse organisms.

2) To study the contribution of maintenance elements to horizontal gene transfer as opposed to vertical transmission of mobile genetic elements.

These aims will be primarily achieved via the construction of artificial test vectors containing replication, maintenance and/or conjugation machinery from existing pathogens (though lacking the associated virulence genes) and the tagging of “wild” plasmids in existing pathogens with counterselectable markers to study their stability over time in long-term evolution experiments.

In addition to the above, any novel maintenance systems (e.g. TA systems) discovered will be subcloned onto common laboratory vectors and tested for their biological role in various bacteria (typically non-pathogenic E. coli cloning strains and the genes’ native host).

Recipient or parental organism

"Domesticated" laboratory strains of E. coli K-12, e.g. MG1655 and BW25113 derivatives of the Keio collection (Baba et al., 2006). These are non-mobilising, non-pathogenic, hazard group 1 organisms routinely used as model organisms or transduction donors. These strains may survive outside of controlled laboratory conditions but do not pose a significant risk to human health.

Cloning and overexpression strains of E. coli such as DH5α, TOP-10, BL21 and their derivatives. These are non-colonising, non-mobilising, non-pathogenic, hazard group 1 organisms routinely used in the laboratory for maintenance of vectors and expression of proteins for purification. These strains are unlikely to survive outside of controlled laboratory conditions and do not pose a risk to human health.

Verotoxin-negative E. coli O157:H7 (from NTU stocks). This strain is an enteropathogenic form of E. coli that has undergone toxin-disabling mutations to reduce its handling risk. The disabled strain is hazard group 2 and is able to cause self-limiting gastrointestinal infection in humans, though the possibility of more severe haemolytic disease caused by the parent strain has been eliminated. This strain is likely to survive in the environment and may colonise humans via the feco-oral route, but represents a significantly lowered risk compared to its wild-type parent. The pathogen is not airborne. No modifications proposed in this study are expected to increase its virulence or infectious route.

Pathogenic E. coli outbreak isolates obtained from Public Health England and other controlled sources: typically enteroinvasive, enteropathogenic, enteroaggregative or extraintestinal pathogenic E. coli of various serogroups. These organisms typically colonise via the feco-oral route and are not airborne pathogens. All strains are hazard group 2 or lower. In all cases these strains will have been subjected to PCR to confirm absence of known verotoxin genes; many have also been whole-genome sequenced. Nonetheless, strains will often be disease isolates that may cause gastrointestinal infection and diarrhoea with a range of severities (likely to be self-limiting and treatable in healthy human adults), or extraintestinal infection in immunocompromised individuals (unlikely to affect healthy human adults). Some isolates are naturally multi-drug resistant due to pre-existing genes. As disease isolates, these strains are likely to survive well in the environment and represent an acute infection risk in their unmodified form (Dallman et al., 2014; Newitt et al., 2016; Alkeskas et al., 2015). No modifications proposed in this study are expected to increase the virulence or infectious route of these strains.

Host/vector system

Hosts

No modifications proposed in this study are expected to increase the virulence or infectious route of these strains.

Vectors

Laboratory cloning vectors such as pUC19 (Yanisch-Perron et al., 1985) and derivatives. High-copy. Routinely used in the laboratory, non-harmful and non-mobilisable. Antibiotic markers present for selection. Limited host range.

Expression vectors such as pBAD33 (Guzman et al., 1995), pGM101 (McVicker & Tang, 2016) and pET derivatives (Novagen). Low- to medium-copy. Routinely used in the laboratory, non-harmful and non-mobilisable. Antibiotic markers present for selection. Limited host range.

Allelic exchange and recombinering vectors such as pKO3Blue, pKD series, pCP20 and derivatives (Cherepanov & Wackernagel, 1995; Datsenko & Wanner, 2000). Low- to medium-copy. Routinely used in the laboratory, non-harmful and non-mobilisable. Used to enhance genetic manipulation of the host chromosome or large plasmids. Some vectors (e.g. pKD46) promote heightened nonspecific homologous recombination in the host, but do not themselves provide recombination substrates that would cause an increase in virulence of any organism. Many vectors in this category are temperature-sensitive so can be cured as necessary. Antibiotic markers present for selection. Limited host range.

pSTAB vectors (McVicker & Tang, unpublished): de novo constructed “stability test vectors” derived from the replicons of large wild plasmids and containing antibiotic resistance markers for selection. Low-copy, non-mobilisable. Likely to have a limited host range, though this is unknown as the replicons to be used are not characterised. Specifically constructed to study plasmid maintenance elements in a safe and isolated context (separate from the virulence and multidrug resistance genes found on the wild plasmids from which their replicon sequences are cloned).

P1vir bacteriophage (Ikeda & Tomizawa, 1965): a lytic phage capable of transferring genetic material from one species/strain to another, routinely used as the vector for controlled generalised transduction. Bacteriophage cannot infect animals (including humans) or plants. P1vir does not survive well in the environment compared to ubiquitous wild equivalents and cannot undergo lysogeny (dormancy within a bacterial host), so the risk of spreading genetic material to unintended organisms, both within and outside the laboratory, is negligible given good microbiological practice.

Origin & function

In many instances, GM experiments to be carried out will involve the inactivation of existing genes on native virulence/resistance plasmids via the insertion (and subsequent removal or allelic exchange) of a defined antibiotic resistance cassette. The techniques used will include phage transduction and site-directed mutagenesis/recombineering (e.g. Datsenko & Wanner, 2000; Blomfield et al., 1991). The DNA to be introduced in this case will not be hazardous or increase an organism’s virulence, with the exception that antibiotic selection cassettes will necessarily increase the number of antibiotics to which an organism is resistant.

Identified toxin-antitoxin gene pairs may be cloned for analysis, either together or separately. The gene products will be biologically active but non-hazardous to humans. Toxins are generally cytoplasmic bactericidal or bacteriostatic (i.e. “suicidal”) molecules that interfere with processes such as bacterial replication/translation and are not expected to be secreted by the bacterial cell. Toxins are unlikely to have valid human targets and human exposure will be negligible. Antitoxins prevent the above toxic activity and are hazardous to neither the bacterial host nor human workers. No increase in virulence would be expected from the introduction of either of the above DNA sequences; instead, bacterial host fitness is likely to decrease.

Plasmid replicons will be cloned to study them in isolation. These sequences are themselves non-hazardous. Other plasmid maintenance and mobilisation elements (distinct from TA systems described above) may be cloned occasionally in order to study their effects in isolation. These sequences will not encode hazardous products but may modify the stability/transmission of pSTAB test vectors (which are themselves non-hazardous). Mobilisation experiments will only be performed using non-GM plasmids (i.e. the rate of genetic transfer will be identical to the naturally-existing population) or, if using a GM construct, carried out using non-virulence-gene-encoding pSTAB vectors in disabled, non-pathogenic strains. Under no circumstances will virulence/multi-drug resistance plasmids be intentionally/artificially mobilised by the genetic
Despite their tangential relatedness in terms of natural plasmid function, known virulence factors are not the subject of study in this project and will not themselves be intentionally cloned or expressed.

**Evaluation of foreseeable effects**

P1vir bacteriophage transductions will be carried out to move vectors and marked gene mutations between strains under controlled laboratory conditions, observing good microbiological practice. It is unlikely that virulence elements could be accidentally transferred in this manner, as only the desired transductants will survive due to the integration of a selectable marker. P1vir transduction is rare (on the approximate order of 10^-6 events per recipient cell) and therefore the risk of a miscellaneous, unintentional transduction occurring in tandem with an intentional one is negligible.

Where possible, resistance alleles for selection will be introduced into strains that do not already carry broad multidrug resistance, to limit any potential impact on therapy. Furthermore, no modification proposed by this project will directly increase the virulence of any hazard group 2 organism being studied. On the contrary, many modifications made to the hazard group 2 GMOs in question will cause a reduction in virulence/resistance plasmid stability. In the event that such a GMO escapes into the environment, it will be less effective at causing disease than its wild type equivalent. In the event that a plasmid has been made more stable by a modification, the resulting GMO is predicted to be unable to compete effectively with the wild type due to the increased burden of large plasmid replication.

The pathogenic enteric bacteria studied in this project are hazard group 2, able to survive in the environment and cause acute disease in humans. The genetic modifications to be made are not likely to increase any such organism's virulence or ability to survive in the environment.

It is conceivable that virulence plasmid or resistance plasmid stability or transmission rate may be affected by the genetic modifications to be made, though this will not be in excess of naturally-occurring plasmids within the genus. If plasmid stability increases, fitness of host bacteria is likely to decrease, encouraging out-competition of a GM organism by wild type strains outside of controlled laboratory conditions. Non-mobilisable, naturally-occurring virulence and multidrug resistance plasmids will not be intentionally/artificially mobilised by this work.

It is likely that the majority of modifications to be made to wild plasmids, and the majority of genes cloned onto vectors that will be introduced into wild strains, will in fact reduce virulence/resistance by causing defects in native plasmid replication/maintenance. Many vectors that will be transformed or transduced into wild strains will be incompatible with naturally-occurring plasmids (by virtue of a shared replicon) and so their selection will ensure the loss of the native virulence/resistance plasmid – hence, a decrease in infectiveness and potential risk, rather than an increase.

The introduction of antibiotic resistance cassettes in order to construct mutants or assay plasmid stability will necessarily increase the resistance profile of the organisms being studied. This is a known quantity that can be accounted for by good microbiological practice and by careful consideration of existing resistance alleles. Virulence will not be directly affected by these mutations. Indeed, the counterselectable marker to be introduced for plasmid loss assays provides an additional method of killing organisms that contain a GM plasmid (McVicker & Tang, 2016), therefore is more likely to reduce any associated risk rather than increase it.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GMOs will be handled in rooms rated sufficient for hazard group 2 containment. Staff will be fully trained in the handling of these organisms at this containment level. Precautions to be taken will include good microbiological practice, sufficient PPE (nitrile gloves, Howie lab coats, eye protection where applicable) and the disinfection of contaminated material by chemical agents (e.g. 2% Virkon, able to inactivate enterobacteria and bacteriophage within minutes, or 70% ethanol) and/or autoclaving. Waste disposal and spillages will be handled appropriately using the methods above, according to standard containment level 2 guidelines.
The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by the Chair of the Genetic Modification (GM) Safety Committee and the University Biological Safety Officer.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
Pseudomonas aeruginosa is an opportunistic human pathogen and an increasingly urgent problem in healthcare settings. In this project, the secretion of several P. aeruginosa autotransporters or type V secretion systems will be investigated. PlpD is a secreted phospholipase and the prototype of type Vd secretion systems in bacteria. This little-studied subclass of type V secretion appears to combine features of both type Va (classical autotransporters) and type Vb (two-partner) secretion systems. By making truncations, point mutations, domain replacements and fusions with other proteins, the effect on surface localisation of PlpD will be measured both quantitatively and qualitatively. The results will provide information on the regions important for PlpD autotransport, the direction of secretion (N- or C-terminus first), the topology of the proteins, and the requirements in the phospholipase domain for efficient secretion. In addition, the relationship between type Va, type Vb and type Vd secretion systems will be investigated. Specifically, the goal is to produce either an artificial type Vb secretion system from a type Vd secretion system, or vice versa, to functionally demonstrate the evolutionary relationship between the two systems. This will be done by separating the phospholipase domain from the translocation domain. In parallel, an artificial type Vd system will be attempted by fusing the secreted protein (LepA) with the translocator protein (LepB) from the LepAB two-partner secretion system of P. aeruginosa. In addition, various fusions of PlpD, LepA and LepB will be made to see which functions of the systems are needed for efficient secretion. Readout of successful secretion will be either surface display of PlpD or LepA, or presence of these proteins in the culture supernatant. The relationship between type Va secretion and type Vd secretion will be investigated by utilising a type Va-secreted phospholipase of P. aeruginosa, EstA, and performing domain swaps to study the interchangeability of the different domains.

All cloning steps will be performed in E. coli K-12 (DH5<sup>®</sup> or similar), which is a hazard group 1 organism. Expression of plpD (from P. aeruginosa PAO1 with E. coli codon optimisation), lepAB (from P. aeruginosa PAO1, native sequence), estA (from P. aeruginosa PAO1, native sequence) and their derivatives will be performed in the laboratory P. aeruginosa strain PAO1 (hazard level 2). P. aeruginosa is an opportunistic pathogen of humans, animals and plants, but generally does not pose a threat to healthy individuals. For expression, a strain lacking the endogenous plpD gene will preferentially be used (see https://www.frontiersin.org/articles/10.3389/fmicb.2019.00100/full), but the wild-type PAO1 will also be employed for some experiments.

Neither plasmid represents a significant hazard to humans or the environment.
The insert plpD from P. aeruginosa PAO1 codes for an outer membrane phospholipase. The phospholipase is non-toxic and the corresponding knock-out strain is not attenuated in virulence in a Galleria mellonella model (unpublished data), suggesting that the lipase is not a toxin virulence factor of P. aeruginosa. The proteins will be expressed in their entirety, as truncated or point-mutated variants, or as fusion proteins with (non-hazardous) marker proteins.

lepAB encode a two-partner secretion system of P. aeruginosa PAO1, where LepA is a secreted protease and LepB the outer membrane translocator protein. LepA has been reported to induce inflammatory responses and is implicated in virulence. However, in this work, only the TPS domain required for LepA secretion will be expressed, thus excluding the toxic protease domain. LepB will be produced in its entirety, as truncations, and as fusions with EstA, PlpD and LepA.

estA encodes an autotransporter esterase of P. aeruginosa PAO1 that has been implicated in the production of extracellular rhamnolipids, but overproduction of EstA reduces biofilm formation (see https://mic-microbiologyresearch-org.ezproxy.uio.no/content/journal/micro/10.1099/mic.0.037036-0#tab2). However, no direct toxic effects of EstA have been reported. The protein will be produced in its entirety, or parts of it as fusions with LepA, LepB or PlpD.

Evaluation of foreseeable effects

P. aeruginosa is ubiquitous in the environment and is an opportunistic human pathogen that can infect wounds and burns. It is also a significant pathogen of cystic fibrosis patients. However, it rarely causes disease in healthy humans. PlpD does not appear to have a significant effect on the pathogenic potential of P. aeruginosa. LepA, though an established virulence factor, will only be produces as a non-toxic fragment, whereas its partner LepB is not expected to have an effect on virulence apart from the secretion of LepA. EstA has no reported toxicity, and overproduction of this protein has opposite effects on two virulence-related phenotypes. Therefore, EstA overexpression probably does not increase the pathogenic potential of P. aeruginosa. The organism itself is classed as a hazard group 2 organism, and therefore will only be handled in CL2 facilities.

In the unlikely event of escape, the modified GMOs are unlikely to be to represent a greater hazard than the wild-type organism to either humans, animals or plants. All personnel are trained in Good Microbiological Practice and all work is carried out in a containment level 2 laboratory with restricted access. Any future students will receive full safety training for working in a CL2 laboratory and be under supervision of trained staff. Technical staff are already trained in GMO work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMOs will only be handled in a CL2 facility with restricted access, and handling the GMOs will make use of safety hoods and aseptic techniques, the avoidance of aerosol production, wearing of laboratory coats and nitrile gloves, maintenance of negative air pressure within the laboratory, the disinfection of working surfaces and equipment (for example, centrifuges) with BioCleanse, and autoclaving of all bacterial waste will be within the laboratory suite. Work areas have impermeable surfaces and are disinfected with new hycolin (a broad spectrum disinfectant used at a working concentration of 2% v/v) or BioCleanse at 1%. Waste disposal and spillages will be handled appropriately using the methods above, according to standard containment level 2 guidelines.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. - **Project notified under transitional arrangements**: No
- **Historical Significant Changes**: No

### Project Additional Information
Purposes of the contained use

Transglutaminase 2 (TG2) is a calcium-activated crosslinking enzyme which is involved in a variety of pathologies, including tissue fibrosis, cancer and neurodegeneration. Our research group at NTU has a long-standing expertise in the molecular and cell biology of transglutaminases, which is recognised internationally; our latest work in the area of kidney fibrosis was published in J Amer Soc Nephrol (Scarpellini et al., 2014; Furini et al., 2018). We aim to generate TG2 knock down (KD) clones starting from rat cells (e.g. immortalised kidney epithelial cells NRK52E or primary cells such as neurons and astrocytes) by viral transduction. Specifically, transduction-ready lentiviral particles will be acquired from Santa-Cruz Biotechnology, containing target specific constructs that encode shRNAs designed to knock down TG2 gene expression. Antibiotic selection (puromycin) will be applied to select KD clones post-transduction. The efficiency of TG2-KD will be assessed by either genomic PCR, western blotting and/or TG enzymatic activity assay.

References:

Recipient or parental organism

The resulting GMOs (TG2-KD clones) cannot survive outside the laboratory regulated conditions, and are unable to colonise humans, animals or plants, whereas the inserted sequence is highly unlikely to be transferred to other organisms. The hazard group of transfected rat immortalised and primary cells in vitro can be regarded as hazard group 1 due to the extensive and continuous SPF testing of the source animals and minimal infectious potential of the transfected cells.

Host/vector system

Hosts
NRK52E cell line (ATCC® CRL-1571™) is especially disabled, as it is unable to colonise the worker and contains no known adventitious agents, which are potentially harmful. Accidental injection of NRK52E rat tubular epithelial cells in humans will result in their destruction by the host immune-system, unless the host is severely immune-compromised. NRK52E cell line will not survive outside the laboratory environment.

Primary rat brain cells such as neurons and astrocytes, as well as other primary rat cells isolated from other tissues (e.g. kidney), are not considered hazardous. They will be isolated from specific pathogen free (SPF) animals, which are screened for Adenovirus and lesions associated with Herpes Simplex and Vaccinia. Moreover, rats are not susceptible to Baculovirus or Human Papilloma Virus. Neurons and astrocytes are not capable of infecting humans as a GMO; they are non-colonising and non-pathogenic to humans, animals or plants.

Vectors
TG2 shRNA lentiviral particles (sc-270266-V) consist of a pool of concentrated transduction-ready viral particles, containing 3 target-specific constructs that encode 19-25nt (plus hairpin) shRNA which is designed to knock down TG2 gene expression. Each vial contains 200 μl frozen stock, containing 1.0 x 10^6 infectious units of virus (IFU) in Dulbecco’s Modified Eagle’s Medium with 25 mM HEPES pH 7.3.

Hazards
Lentiviral Particles were developed by the supplier (Santa Cruz Biotechnology) using a 3rd generation packaging system with a single custom expression vector to ensure the particles are replication-incompetent and designed to self-inactivate following transduction (Dull et al., 1998). In summary, the structural and replication genes necessary to produce viral particles are separated onto multiple plasmids for enhanced safety. All wild-type virulence and accessory genes are deleted. A feature of a self-inactivating 3’ long terminal repeat (SIN/LTR) renders the resulting lentiviral particles replication incompetent. Lentiviral particles are packaged in producer 293T cells and, upon co-transfection of the plasmids, all required sequences are available to produce and package a viral particle containing the transgene of interest (in our case, sequences for the synthesis of shRNAs to knock down TG2 gene expression). Only the region between the viral LTRs of the transfer vector is packaged within the viral capsid. In the event recombinants arise, mutations or deletions can be configured within the undesired gene products to render any possible recombinants non-functional (Danos and Mulligan, 1988; Markowitz et al., 1990). In addition, deletion of the 3’ LTR on both packaging constructs further reduces the ability to form functional recombinants.

While the specific details of how these products are packaged is proprietary, this information is not necessary to utilize the Lentiviral Particles in a safe and effective manner. Despite the above safety features, use of HIV-based vectors falls within NIH Biosafety Level 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Indeed, the company recommends treating these products with Biosafety Level 2 tissue culture facilities.

In our project, we will be using these ready-to-use pre-made viral particles suitable to transfer the shRNA once, to transduce recipient cells. We will not deal with packaging vector and packaging cell line to produce the retroviral particles. These constructs have already been used to successfully transfect rodent primary cells lines (Pinzón et al., 2017).

References:

Origin & function

The shRNAs constructs which will be inserted are designed for gene silencing and do not encode for any protein. Although it is possible that the integrated DNA could be transferred by recombination with hidden viruses, NRK52E is a well-established epithelial cell line, and there are no reports indicating that these cells carry viruses. Similarly, the primary rat cell lines will be isolated from tested SPF animals, therefore free from pathogens. Information about the shRNAs constructs is proprietary.

Evaluation of foreseeable effects

TG2-KD cells will not survive outside the controlled laboratory environment. It is also not possible for them to survive in the human body, as they will be destroyed by the host immune system. KD of TG2 is not hazardous for cells, and TG2-KO mice are viable, without evident deleterious effects (De Laurenzi and Melino, 2001). On the contrary, the reduction of TG2 levels has been shown to be protective on cancer development and fibrosis (Mehta et al., 2010; Scarpellini et al., 2014; Furini et al., 2018), as well as in primary brain cells (Tucholski et al., 2006; Fujita et al., 2006), therefore the procedure should not have risks related to the gene knock-out.
It is unlikely that the resulting GMO will be released in the environment and it will not survive outside the regulated laboratory conditions. Standard practice for handling genetically modified organisms is a further step in delimiting the GMO within the laboratory. Cells will be grown according to the Training Programme For Tissue Culture Activities provided by the University.

All staff involved in this project have already received formal training and induction in cell and tissue culture activities and good laboratory practice by research technicians working in the biosciences department. This involved practice of cell culture (work in sterile conditions, handling of cells and tissue culture materials, cell passaging and freezing/storage), use and maintenance of the tissue culture facility and equipment (centrifuges, laminar flow cabinets, incubators).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Immortalised and primary wild type cells, lentiviral particles and TG2-KD clones will be cultured in a Class 2 biological safety laminar flow cabinet using level 2 precautions, in a laboratory containment level 2 room (Biomed 108), which is located in a department with restricted access (by ID card only), and is protected by a door equipped with a further code lock.

Users will be experienced in proper pipetting techniques, pipetting down the side of the tube with no forceful expulsion, to reduce aerosol generation. For centrifugation, closed, screw-capped tubes and centrifuge cups with aerosol resistant lids containing O-rings will be used to contain aerosols. Any pipetting will be performed with filter tips, to minimise contamination of instruments, and only plastic pipettes will be used to minimise sharps risk. Good laboratory practice will include lab coat, eye-ware (safety glasses or Face shield), waterproof gloves (nitrile rubber, butyl rubber); designated tissue culture lab coats. Use of double gloves when working with lentiviral particles will reduce the risk of user contamination. All personnel accessing the containment level 2 tissue culture room (where human cells are also cultured) will have been immunised against Hepatitis B, and will also have had titres checked to confirm that they responded to this immunisation.

Functional molecular analyses will follow multiple passages of cells transduced with lentiviruses, while cell extracts (DNA, RNA, protein) will use reagents that inactivate viruses (phenol, dithiothreitol). Extensive hand washing will be enforced after working with viruses. Log of personnel involved in virus production and usage, with all information related to the specific procedures and dates will be kept in the lab.

For workplace and spillage decontamination, both 5% CHEMGENE HLD4L disinfectant and 70% ethanol will be used. Either 5% CHEMGENE HLD4L or 10% bleach will be applied before disposal for at least 30 minutes for inactivation of any virus-containing media cultures, pipettes, tips and culture dishes. Laminar flow cabinet will be further treated with UV for 1 hour after completion of virus-related work. All disposable plastic-wear and solid biological wastes will be disposed into bins for autoclaving (lined with an autoclave bag) and autoclaved according to standard operating procedures. Liquid waste will be inactivated using CHEMGENE HLD4L (at a final concentration of 5% v/v) and allowed to disinfect for 24 hours. The same spillage measures will be applied during any live cell imaging or analysis (e.g. with a microscope or other device). If a puncture wound was to occur, medical attention will be provided by first aid trained staff and wounds will be cleansed thoroughly.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by, the University Biological Safety Officer.

## Project Ref 187/21.1

**Date Ackn’d**: 28/05/2021

**CU2 Project Title**: Transduction (gain-or loss of function) of primary mouse epidermal keratinocytes and skin stem cells using overexpression and knock-down shRNAs/ORF lentiviral particles

**Class**: Class 2

**CultureVolClass2**: ≤ 1 Litre

**Non-GMM Consent Granted**: Consent Granted

**Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

## Project Additional Information

**Purposes of the contained use**

Our research group at NTU focuses on the investigation of molecular regulators in skin during development, wound healing, cancer and ageing. We will isolate and characterise mouse skin stem cells (SCs) after gain-or-loss of function of molecular regulators. We hope to enhance our understanding by using shRNA lentiviral particles to either knockout or overexpress our genes and non-coding RNAs (e.g. Long non-coding RNA/microRNAs) of interest in mouse cells (primary mouse epidermal keratinocytes) and FACs-sorted skin-SCs. Our lab has past experience of using lentiviral particles gained at University of Bradford, UK and published in leading scientific...

The protocol will involve isolation of mouse skin cells (primary epidermal keratinocytes) and skin stem cells via Mo-Flo-cell sorter (with the assistance of specialist technician Dr. Stephen Reed, John van Geest Cancer Research Centre, at NTU) and cells will be grown on culture dishes coated with either Matrigel or non-hazardous mouse fibroblasts cells (such as NIH/3T3, ATCC® CRL-1658™) as feeder cells and SCs grown in suitable medium for 2-4 days followed by transduction with viral particles.

Viral particles will be created using the Lentiviral Packaging Kits (Insight Biotechnology, UK; TR30037). The lentiviral transduction particles produced by this kit are replication incompetent. These viral particles will be used to either knock-down, using shRNA, and/or overexpress using ORF (open reading frame) of mouse genes such as Elf5 (for 24-72hrs). This will be followed by either silver or Rhodamine B staining of cells and quantification/analysis for colony forming ability (CF units) and/or, RNA and protein extraction for qPCR and western blot analysis.

Recipient or parental organism

The resulting GMOs (e.g. mouse Elf5 clones) cannot survive outside the laboratory regulated conditions, and are unable to colonise humans, animals or plant cells, whereas the inserted sequence is highly unlikely to be transferred to other organisms. The hazard group of primary cells in vitro can be regarded as hazard group 1 due to the extensive and continuous SPF testing of the source animals and minimal infectious potential of the transfected cells.

The hazard group of transfected HEK293/293T in vitro can be regarded as hazard group 2 that can be pathogenic to humans, specifically at-risk populations such as neonates and immunocompromised individuals. They are disabled/non-colonising, which cannot survive outside the laboratory.

Host/vector system

Hosts

HEK 293/HEK 293T (ATCC® CRL-1573/ATCC® CRL-11268) cell lines are sourced from human embryonic kidney and are epithelial in origin. HEK293/HEK293T are well characterised cells which cannot survive outside the laboratory and are recognised as 'disabled or non-colonising' hosts for genetic manipulation. Accidental injection of HEK293/HEK293T cells in humans will result in their destruction by the host immune-system, unless the host is severely immune-compromised.

Primary mouse epidermal keratinocytes and mouse skin stem cells are not considered hazardous. They will be isolated from specific pathogen free (SPF) animals (mice), which are screened for adenovirus and lesions associated with Herpes Simplex and Vaccinia. As these mice will be acquired from recognised mouses providers (Charles River or Envigo) they will arrive with SPF statement reports. Keratinocytes or skin-SCs are not capable of infecting human cells as a GMO; they are non-colonising and non-pathogenic to humans, animals or plants.

Vectors

We plan to use multiple gene versions of Lenti ORF/shRNA clone plasmids (knock-down, KD or overexpression), which will be sourced from a UK supplier (Insight Biotechnology Ltd, or Cambridge Biosciences, UK). For example, these lenti ORF clone’s expression plasmids (such as, Insight Biotechnology, UK; gene ID: mouse Elf5, cat number: MR203230L4) will be used in combination with the Lentiviral Packaging Kits (Insight Biotechnology, UK; TR30037) to create our ‘in house’ lentiviral particles. Elf5 role has been identified in other epithelial cells (e.g. mammary gland, kidneys) as a regulator of stem/progenitor cells for healthy development (Chakrabarti et al., 2012, Grassmeyer et al., 2017), while no role of Elf5 has been identified in skin cells. This procedure should not have risks related to the gene knock-out or overexpression to humans.

Transcriptional activation of these lenti-shRNA/ORF plasmids leads to the binding of the DNA sequences containing the consensus nucleotide core sequence GGA[AT], resulting in TK promoter activation, which drives expression of downstream gene clone insert (~762 bp). The contents of the Lentiviral Packaging Kit i.e. Packaging Plasmids, (Insight Biotechnology, UK; TR30037) are non-hazardous and cannot survive outside the laboratory environment. *Of note, the lentiviral transduction particles produced by this kit are also replication incompetent.

The structural and replication genes necessary to produce viral particles are separated onto multiple plasmids for enhanced safety. In addition, the third-generation lentiviral vectors described here are considered to be replication-incompetent and self-inactivating vectors, due to the number of essential genes that have been deleted from the third-generation lentiviral packaging system (Gándara et al., 2018).

A feature of a self-inactivating 3' long terminal repeat (SIN/LTR) renders the resulting lentiviral particles replication incompetent. Lentiviral particles are packaged in producer 293/293T cells and, upon co-transfection of the plasmids, all required sequences are available to produce and package a viral particle containing the transgene of
interest. Only the region between the viral LTRs of the transfer vector is packaged within the viral capsid. In the event recombinants arise, mutations or deletions can be configured within the undesired gene products to render any possible recombinants non-functional (Danos and Mulligan, 1988; Markowitz et al., 1990). In addition, deletion of the 3’ LTR on both packaging constructs further reduces the ability to form functional recombinants.

Despite the above safety features, use of HIV-based vectors falls within NIH Biosafety Level 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Indeed, the company recommends treating these products with Biosafety Level 2 tissue culture facilities, which we will do.

References:

Origin & function

The shRNAs/ORF clones (knock-down, KD or overexpression) constructs which will be inserted are designed for gene silencing and/or expression of the ORF gene with one or more epitope tags or with a fluorescent marker, which are replication-incompetent. Although it is possible that the integrated DNA could be transferred by recombination with hidden viruses.

HEK293/293T cells will need to be cultured in Biosafety Level 2 tissue culture facilities as they contain adenovirus 5 DNA (Ad5) at the left end of their DNA sequence. The cells express an unusual cell surface receptor for vitronectin composed of the integrin beta¬1 subunit and the vitronectin receptor alpha¬v subunit. The Ad5 insert was cloned and sequenced, and it was determined that a colinear segment from nucleotides 1 to 4344 is integrated into chromosome 19 (19q13.2). However, this cell line is not known to cause disease in healthy adult humans.

The primary mouse keratinocytes and skin-SCs will be isolated from tested SPF animals, therefore free from pathogens.

Evaluation of foreseeable effects

The resulting GMOs (e.g. mouse Elf5 clones) cannot survive outside the laboratory regulated conditions, and are unable to colonise humans, animals or plant cells, whereas the inserted sequence is highly unlikely to be transferred to other organisms. The hazard group of primary cells in vitro can be regarded as hazard group 1 due to the extensive and continuous SPF testing of the source animals and minimal infectious potential of the transfected cells. The hazard group of transfected HEK293/293T in vitro can be regarded as hazard group 2 that can be pathogenic to humans, specifically at-risk populations such as neonates and immunocompromised individuals. They are disabled/non-colonising, which cannot survive outside the laboratory.

Elf5-KD or overexpressing cells will not survive outside the controlled laboratory environment. It is also not possible for them to survive in the human body, as they will be destroyed by the host immune system and also the lentiviral transduction particles produced are also replication incompetent and therefore, Elf5-KD or overexpression is not hazardous to cells. Elf5 overexpression has no known effect on mice viability and health, while Elf5-knockout studies have shown no known effects on skin cells in mice (Choi et al., 2008, Grassmeyer et al., 2017), therefore the procedure should not have risks related to the gene knock-out or overexpression.

References:

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

It is highly unlikely that the resulting GMO will be released in the environment but in this scenario, it will not survive outside the regulated laboratory conditions. Standard practice for handling genetically modified organisms is a further step in delimiting the GMO within the laboratory. Cells will be grown according to the Training Programme For Tissue Culture Activities provided by the University and using the guide for Good Manufacturing Practice of lentiviral particles (Gándara et al., 2018). All staff involved in this project have already received formal training and induction in cell and tissue culture activities and good laboratory practice by the lead lab PI (Dr Mohammed Ahmed) and the research technicians working in the biosciences department. This involved practice of cell culture (work in sterile conditions, handling of cells and tissue culture materials, cell passaging and freezing/storage), use and maintenance of the tissue culture facility and equipment (centrifuges, laminar flow cabinets, incubators).

Immortalised and primary wild type cells, lentiviral particles and gene specific overexpression and KD clones will be cultured in a Class 2 biological safety laminar flow cabinet using level 2 precautions, in a laboratory containment level 2 room (Biomed 010), which is located in a department with restricted access (by pin door code). Only authorised user will have access to the code and room. Cell lines will be grown as 10X25ml flasks maximum.

Users will be trained and experienced in proper pipetting techniques, pipetting down the side of the tube with no forceful expulsion, to reduce aerosol generation. For centrifugation, closed, screw-capped tubes and centrifuge cups with aerosol resistant lids containing O-rings will be used to contain aerosols. Any pipetting will be performed with filter tips, to minimise contamination of instruments, and only plastic pipettes will be used to minimise sharps risk. Good laboratory practice will include lab coat, eye-ware (safety glasses or Face shield), waterproof gloves (nitrile rubber, butyl rubber); designated tissue culture lab coats. Use of double gloves when working with lentiviral particles will reduce the risk of user contamination. All personnel accessing the containment level 2 tissue culture room (where human cells are also cultured) will have been immunised against Hepatitis B and will also have had titres checked to confirm that they responded to this immunisation.

Functional molecular analyses will follow multiple passages of cells transduced with lentiviruses, while cell extracts (DNA, RNA, protein) will use reagents that inactivate viruses (phenol, dithiothreitol). Extensive hand washing will be enforced after working with viruses. Log of personnel involved in virus production and usage, with all information related to the specific procedures and dates will be kept in the lab.

For workplace and spillage decontamination, both 5% CHEMGENE HLD4L disinfectant and 70% ethanol will be used. Either 5% CHEMGENE HLD4L or 10% bleach will be applied before disposal for at least 30 minutes for inactivation of any virus-containing media cultures, pipettes, tips and culture dishes. Laminar flow cabinet will be further treated with UV for 1 hour after completion of virus-related work. All disposable plastic-ware and solid biological wastes will be disposed into bins for autoclaving (lined with an autoclave bag) and autoclaved according to standard operating procedures. Liquid waste will be inactivated using CHEMGENE HLD4L (at a final concentration of 5% v/v) and allowed to disinfect for 24 hours. The same spillage measures will be applied during any live cell imaging or analysis (e.g. with a microscope or other device). If a puncture wound was to occur, medical attention will be provided by first aid trained staff and wounds will be cleansed thoroughly.

Project Additional Information

Purposes of the contained use

The Interdisciplinary Science and Technology Centre (ISTEC) hosts researchers investigating adverse health related complications arising due to diabetes and metabolic disturbances. The key aims of this work are to determine the impact of modulating specific signalling pathways upon gene expression and cellular activity: factors that may underlie metabolic disease development and progression. The project leader Prof. Mark Christian’s research focuses on investigating key aspects of the biology of brown and white adipocytes. Brown adipocytes serve a unique function to "burn" fat rather than store it, as takes place in white adipocytes. By determining the key gene expression differences between these cell types gives new potential targets to increase energy consumption and promote weight loss. A key property of adipocytes is the storage of fat in lipid droplets. As these organelles are present in all cell types, albeit smaller than in adipocytes he is studying how lipid droplets are regulated in additional cell types including embryonic stem cells. Metabolic disease also causes deleterious pathologies that lead to the manifestation of a number of physical afflictions that impact the quality of life for the individual. These include chronic pain (Dr Hulse) and muscle atrophy (Dr Doig), degenerative conditions that to date lack effective therapeutic intervention. Deficiencies in metabolic capabilities of these tissues result in a decrease in physical attributes through loss of sensory perception of the surroundings and pain, as well as loss in muscle coordination and strength.

The program of work comes under these key aims: 1. Investigating the gene expression patterns during cellular differentiation and adaptation in adipocytes, muscle and neurons. 2. Evaluating signalling pathways that control cellular function in adipocytes, muscle and neurons. 3. Investigating the mechanisms that control lipid droplet dynamics in adipocytes and other cell types. Manipulations with viruses outlined below will be used to generate stable cell lines, over-express genes of interest (including GPR120, CIDEA) and knockout of genes expressing using Crispr/Cas9 gene editing technology. Lentiviral particles will be generated in-house (Virapower expression system) or purchased pre-made.

Recipient or parental organism

Cells that have been transduced with viral vectors which have then been allowed to integrate and the transduction medium changed are assigned to Class 1. The cell lines used are not viable outside the laboratory. Animals are SPF certified by the established provider. Additionally, animals are kept in appropriate housing cages and animal welfare is regularly monitored on campus to ensure animal health. Physical barriers are in place in the animal units such as appropriate caging, door barriers to prevent potential animal movement around the unit and/or outside the facility.

There are no recognised hazards associated with GMOs constructed using the above described DNA inserts. The resulting genetic modifications are maintained in the host strain under the selective pressure. Transference of the antibiotic genes to other organisms is highly unlikely.

Host/vector system

Hosts

Cell culture will be undertaken of cell lines confidently assigned to Hazard Group 1 being: human transformed embryonic kidney cell line (HEK-293), mammary gland cancer (MCF7), human adenocarcinoma cell line (HeLa), transformed primate kidney fibroblast cell line (COS-7), mouse adipocyte cell lines (e.g. 3T3-L1), mouse embryonic stem cell line (NIH3T3), rat adrenal gland pheochromocytoma (PC-12), murine muscle cell line (C2C12), human cardiac and muscle cell line (e.g. AC16, HL1, LCHN2), mouse primary cultures and mouse explants previously generated in-house including IMBAT and IMWAT pre-adipocytes. Primary cell culture (e.g. sensory neurons, cardiac myocytes) will be performed from rodents sourced from UK supplier.

Experimentation involving rodents will be performed upon Home Office authority, inline with the Animals (Scientific Procedures) Act 1986 legislation and approved Project License. Work will be performed in the designated establishment animal unit as setout in the Project license.

Lentiviral vectors are assigned as Class 2 GMMs, according to our current HSE notification. A system such as the Virapower Lentiviral Expression System will be used. The pLenti expression vector contains a deletion in the 3’ LTR (U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome. The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev). A subclone of HEK-293 (HEK293FT, ThermoFisher Scientific) that allows Lentivirus generation is assigned to CL2. We will generate stable cell lines (pre-adipocyte and myocyte) by transduction with ecotropic
retroviruses for transducing the SV40 Large T antigen. These retroviruses are not capable of infecting human cells and will be used to infect rodent cells. Thus, these viruses are safe for users.

E.coli Strains including K12, XL-1 blue, DH5a, TOP10, BL21, Stbl3. The host organism (E. coli strains listed above) is non-colonising and disabled and can be considered as equivalent to ACDP biological agents hazard group 1. Manipulation of plasmids in E.coli is a Class 1 GM contained use.

Vectors
pLP1: this plasmid contains an ampicillin resistance cassettes and a CMV promoter. This construct is a lentiviral packaging plasmid containing the HIV-1 gag and pol genes. It is non mobilizable and it is assigned to Hazard Group 1.

pLP2: this plasmid contains an ampicillin resistance cassettes and a RSV enhancer/promoter. This construct is a lentiviral packaging plasmid containing the HIV-rev gene. It is non mobilizable and it is assigned to Hazard Group 1.

pLP/VSIG: this plasmid contains an ampicillin resistance cassettes and a CMV promoter. This construct is a lentiviral packaging plasmid for expression of the vesicular stomatitis G glycoprotein. It is non mobilizable and it is assigned to Hazard Group 1.

pLenti6/V5: this plasmid (V49610 – Thermo Fisher) is for lentiviral based expression of a target gene in dividing and non-dividing mammalian cells. The vector has the CMV promoter for driving constitutive expression of the target gene and the blasticidin selection marker for stable selection in mammalian cells. C terminal V5 tag for quick detection. The plasmid is non mobilizable and it is assigned to Hazard Group 1.

Retrovirus:
pLNCX2, pLHCX, pLPCX does not contain the structural genes (gag, pol, and env) necessary for particle formation and replication. Vectors are mobilisation defective, all obtained from Parmjit S Jat (UCL).These plasmid allows the expression of the transcript for Ψ+ extended viral packaging signal and is selectable due to hygromycin resistance gene. This construct produces replication-incompetent virus.

Adeno-associated virus (AAV) is a non-enveloped, single stranded DNA viral vector that has no known links to human illness. It can infect both non-dividing and dividing cells and AAVs are thought to be non-pathogenic to humans as they lack the requisite helper virus to replicate. Under special conditions, AAVs can mobilise but this requires coinfection with a helper virus (e.g. Adenovirus or Herpes simplex virus). These will utilise promoters for constitutive expression including cell specific expression (e.g. synapsin, GFAP, CMV). Most activities with AAVs are low hazard and can take place safely at Containment Level 1.5. Grassmeyer J, Mukherjee M, deRiso J, Hettinger C, Bailey M, Sinha S, et al. Elf5 is a principal cell lineage specific transcription factor in the kidney that contributes to Aqp2 and Avpr2 gene expression. Developmental biology 2017;424(1):77-89.

The genes inserted into plasmids are non-pathogenic and encode transcriptional regulators (of the nuclear receptor superfamily including PPARs, ERRs, ER), transcripational co-regulators (including RIP140, PGC-1a), lipid droplet-associated proteins (CIDEA, CIDEB, CIDEc), signal transduction pathway regulators (RGS7), G protein-coupled receptors (e.g. GPR120), shRNA targeting RGS7 or other genes of interest will be used to knock-down gene expression. These genes, involved in cell signaling and lipid droplet biology, are not predicted to be harmful if over-expressed or if knocked down (e.g. by loss of tumour suppression).

Cas9 or similar emerging systems utilised for Crispr-mediated gene-editing utilising Cas9 protein and a guide RNA to modify gene expression/function. These are utilised with the delivery vectors as outlined. Cas9 protein has demonstrated no known toxicity whilst guide RNA function requires presence of Cas9 protein for function. The Cas9 gene has potential to cause off target effects. These will be minimised by co-expression of single guide RNA strands and the work will be assigned to Hazard Group 2.

Cellular actuators (e.g. Designer Receptors Exclusively Activated by Designer Drugs (DREADD), optogenetics) will allow specific targeted control of cellular activity. These are typically delivered via AAV vector and require exogenous activation via methods including administration of pharmacological agent (e.g. clonzine), eGFP, mCherry and similar utilised as fluorescent markers and gene fusions. These are going to be used to visualise the protein by fluorescence microscopy or to perform
The SV40 T antigen is an immortalising gene and has the potential to extend the proliferative life span of normal somatic cells. This risk is mitigated by using ecotopic retroviral vectors that cannot infect human cells.

### Evaluation of foreseeable effects

Cells that have been transduced with viral vectors which have then been allowed to integrate and the transduction medium changed are assigned to Class 1. The cell lines used are not viable outside the laboratory. Animals are SPF certified by the established provider. Additionally, animals are kept in appropriate housing cages and animal welfare is regularly monitored on campus to ensure animal health. Physical barriers are in place in the animal units such as appropriate caging, door barriers to prevent potential animal movement around the unit and/or outside the facility.

There are no recognised hazards associated with GMOs constructed using the above described DNA inserts. The resulting genetic modifications are maintained in the host strain under the selective pressure. Transference of the antibiotic genes to other organisms is highly unlikely.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**None**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All proposed research activity is outlined to be performed in ISTEC 135/139 and the Biological Support Facility. The containment level 2 laboratories and risk assessment will ensure that the GMOs will not be released into the environment. This will include training of personnel in the use of Containment level 2 facilities, use of safety hoods aseptic techniques, the avoidance of aerosol production, laboratory coats to be worn within containment level 2 laboratories, maintenance of negative air pressure within the laboratory, the disinfection of working surfaces and equipment (for example, centrifuges), and handling and disposal (e.g. autoclaving) of all the waste will be within the laboratory suite.

Waste will be decontaminated immediately or separated by folding over the top of autoclave bags at the end of the session. Solid waste inactivation will be ensured by collecting it in a separate autoclave bag, which will be sealed at the end of each session and immediately autoclaved at 121°C for 20 minutes. Liquid waste will be collected inside the hood in a disposable plastic container and treated with 1% Virkon or 5% Chemgene before disposal down the drains. Any spillage will be wiped with a paper towel containing 2% Virkon or 5% Chemgene. Dispose towels in autoclave bag, wipe contaminated area with ready-use trigger sprays of Chemgene HLD4L, which is effective against retroviruses. Appropriate handling of waste materials and consumables including plastics tips, cell culture flasks will be outlined such as handling of sharps through immediate disposal into designated sharp bins, no needle resheathing.

Environmental impact will be minimal due to containment in the laboratory and decontamination of any waste. Furthermore as this lentivirus is attenuated, it cannot propagate. For the work with E.coli, the genes investigated do not enhance the ability of the E.coli strain to survive or disseminate in the environment or to compete with other bacteria. The genes to be investigated show no pathogenicity towards plants or animal.

All the staff involved in the work will receive a CL2 facility induction followed by procedural training given by the designated trained member. Training records will be retained. Personnel are asked to update the PI if there is a change in their immunosuppression status. Work will be halted and alternative arrangements made if a lab worker is immunocompromised. All personnel will wear appropriate Personal Protective Equipment (PPE) (waterproof aprons, gloves etc) which will be provided and must be worn dealing with a spillage. Under normal lab conditions staff and students will wear lab coats, wear gloves and protective glasses. Hair should be tied back and no open toed shoes allowed. Also all staff and students should wash their hands as they leave the CL2 lab to maintain safety and hygiene.

Cell lines will be handled in lab 135 or 139 (ISTeC) using a class 2 biological safety cabinet, with all waste being treated as detailed above. A separate incubator will be dedicated for cells with virus particles in the supernatant. Virus particles are expressed from 5x10^6 HEK 293T cells in 10ml medium at maximum. All are harvested and either stored or used immediately to transduce host cells. For long term storage at -80°C, virus particles will be stored in screw cap cryovials in a box that is subsequently sealed in a plastic bag to contain the virus in case of freezer failure, storage will be in a dedicated drawer of the -80°C used for Class 2 work only. The autoclaving of all waste material will be carried out within the lab 135 and 139 area (ISTeC). In the unlikely event of escape, the modified GMOs are not likely to be
maintained outside of the laboratory (due to the lack of positive selection), in any event, do not represent a greater hazard than the wild type organism to either humans, animals and plants. Implementation of the above safety measures should control the risk of release/exposure to effectively zero.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment

The risk assessment that is attached has been reviewed by three members of staff with expertise in genetic manipulation and revised in the light of comments that were made on it. The revised risk assessment was then approved by all three original reviewers and signed off by Dr Matthew Smith, the University Biological Safety Officer and chair of the GM Safety Committee.

CU2 Project Title EXPRESSION OF HUMAN TISSUE TRANSGLUTAMINASE IN MAMMALIAN CELLS  

Class 2  

Consent Granted not applicable  

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 litre  

Non-GMM  

Project notified under transitional arrangements
### Project Additional Information

**Purposes of the contained use**

To elucidate the proposed function of tissue transglutaminase (tTG) in the binding to and stabilisation of the extra cellular matrix.

**Recipient or parental organism**

mammalian cell lines including tumour cell lines of murine and human origin.

**Host/vector system**

For expression of tTG in mammalian cells vector systems will include mammalian expression vectors such as pSG5 under which the enzyme is constitutively expressed. For more controlled expression of the enzyme vectors using the tetracycline regulating promoter will be used. The expression vectors will be produced and purified using disabled E. coli eg. JM109.

**Origin & function**

Cell lines and genetic material is available at The Nottingham Trent University, other vectors will be purchased by from commercial sources. Transfected named cell lines and tumour cells will be observed for any phenotype changes especially those in the extra cellular matrix. Tumour cells are often deficient in tissue transglutaminase. Replacing this deficiency by transfection of the enzyme into the cells may have a number of affects on the malignant phenotype. Tumour cells transfected with tissue transglutaminase will be tested for any effects on tumour growth and progression in murine animal models.

**Evaluation of foreseeable effects**

The E.coli hosts to be used are well established disabled bacteria that are unable to colonise the tumour gut. Cultural transfected mammalian cells will not survive outside the tissue culture environment.

Human tumour cells and those transfected with tissue transglutaminase do have the possibility of surviving in the human body if immunologically compatible but only when injected in large quantities eg. $10^6$ (The six should be superscript) cell quantities.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Disposal of infected material will be supervised by staff specifically trained in the requisite techniques.

As Previous - Virkon and Autoclave (Copy from scripts).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

For studies involving the transfection of murine cell lines including murine tumour cell lines these should be undertaken under containment level 1.

For studies involving the transfection of human cell lines including tumour cell lines these should be undertaken under containment level 2.

Using these conditions the committee felt there was no risk to the environment and the risk to human health was minimal.

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**
To enhance anti-tumour immunity and develop strategies for developing cancer vaccines.

**Recipient or parental organism**
Mammalian cell lines, of murine and human origin.

**Host/vector system**
Viral vectors, including disabled adeno and Herpes expression vectors.

**Origin & function**
The vectors have been obtained from commercial sources (either under material transfer agreements or purchased from suppliers). Genes from either antigens (including mini gene sequences encoding immunogenic peptides) and cytokine/immune response genes are incorporated into the vector. Appropriate cell infection leads to gene expression.

**Evaluation of foreseeable effects**
Expression of genes in appropriate cell systems. Viruses are disabled and therefore the progeny are non-infectious. An extensive literature exists on the safety of disables HSV and Adeno viruses. Experiments are designed to evaluate the ability of gene products to activate adaptive and innate immunity to tumours. Expression of genes in the human body is possible, but viruses have limited replicative capacity, and gene products would have a transient effect on the immune system.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
In vivo: use of vectors will be restricted to the appropriate containment facilities (containment 2), and all experiments will conform to Home Office guidelines for the use of animals.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All waste material will be either inactivated with disinfectant and autoclaving, and animal waste will be prepared for incineration according to appropriate codes of conduct (approved by NTU safety services and the Home Office).
For studies involving the transfection of murine cell lines including murine tumour cell lines these should be undertaken under containment level 1. For studies involving the transfection of human cell lines including tumour cell lines these should be undertaken under containment level 2. Using these conditions the committee felt there was no risk to the environment and the risk to human health was minimal.

All material in solid form, plates, tubes etc. possibly contaminated with genetically manipulated organisms is autoclaved and then disposed of by commercial incineration. All liquid waste, maximum culture volume of 4 litres, is treated with chloros and then disposed of via the mains sewage.

The autoclave is regularly serviced and tested for performance. The efficiency of the deactivation is monitored by plating out liquid waste after treatment and by microscopic examination for the presence of bacteria.

For activities involving GMMs, describe the waste management measures which will apply to the activity
The maximum culture volume to be released at any one time is 500 ml (0.5 litre).

All waste containing GMMs is deactivated by autoclaving at 121 degrees C for 30 minutes. 15 minutes at this temperature is generally accepted as guaranteeing the sterility of autoclave contents but extra time is used at the University of Westminster for any biological waste to further ensure the efficacy of the decontamination process.

The autoclave is tested by the manufacturers (Astell) twice yearly using thermistors enclosed in the load and thermal print outs obtained of its performance. In addition, the autoclave is tested each day that it is used using Browne's tubes to ensure the correct operating temperature is reached. Also, control plates of culture media are incubated to test for their effective sterilisation and decontamination.

Project Ref 197/01.1

INVESTIGATION OF THE MOLECULAR BIOLOGY OF RESPIRATORY SYNCTITIAL VIRUS AND PARAINFLUENZA VIRUS TYPE 3 USING REVERSE GENETICS TECHNIQUES.

Historical Significant Changes

PROJECT CLOSED 2/4/07.
**Project Additional Information**

**Purposes of the contained use**

Human respiratory syncytial virus (RSV) and parainfluenza virus type 3 (PIV-3) are human pathogens, classed in category 2. The planned modifications are not expected to increase the pathogenicity or fitness of these viruses, or to alter their host range. Therefore, the major hazard associated with this project is the hazard inherent to the recipient PIV-3 and RSV. Containment of these viruses and their mutant derivatives is intended to reduce their risks to human health to effectively zero.

**Recipient or parental organism**

RSV is a class 2 pathogen, it generally causes mild or moderately severe upper respiratory illness, however, it can cause life threatening pneumonia or bronchiolitis in children and chronic cardiac and pulmonary disease, immunocompromised patients and the elderly. PIV-3 is also a class 2 pathogen, it generally causes mild upper respiratory tract illness, but can cause serious lower respiratory tract disease in infants, the elderly, and patients with compromised immune systems. Both viruses are transmitted by direct contact with contaminated surfaces or by large droplet spread. These viruses are unstable and do not persist long in the environment. RSV and PIV-3 are highly prevalent in the human population. 100% of individuals aged 5 years or more have been exposed to them, and reinfection can occur. Both viruses are members of the family Paramyxoviridae, and have genomes consisting of a single strand of negative sense RNA, replicated via a positive-sense intermediate RNA.

**Host/vector system**

The technique of reverse genetics is used to introduce site-specific mutations into virus genomes and is a powerful tool for examining virus biology. In the case of the paramyxoviruses, which have a genome of negative-sense RNA, this involves 'rescuing' virus from DNA copies of virus elements. Reverse genetics systems have recently been established for a number of negative strand RNA viruses, including RSV and PIV-3 (Collins et al, 1995, PNAS USA, 92: 11563-67; Durbin et al, 1997, Virology, 235: 323-32). There are two basic formats of the system: one in which the complete virus genome is used and one using a defective virus genome (minigenome). In the situation in which the complete virus genome is used, plasmids are constructed which encode the complete virus genome RNA and virus polymerase proteins. The plasmids are transfected into cells and expressed by T7 RNA polymerase generated from a recombinant vaccinia virus (modified vaccinia virus Ankara). The virus genome RNA that is expressed is transcribed and replicated by the virus polymerase proteins. This results in synthesis of the full complement of virus proteins and progeny genomes. The genomes are packaged into virus particles and released into the supernatant. This virus is infectious and can be propagated indefinitely.

In the situation in which a defective minigenome is used, a plasmid is constructed which encodes an RNA containing virus cis-acting sequences flanking a reporter gene, or genes, such as chloramphenicol acetyltransferase, luciferase, and green fluorescent protein. The minigenome plasmid is transfected into cells, which are co-infected with homologous virus. The virus polymerase proteins transcribe and replicate the minigenome RNA, resulting in reporter gene expression, and progeny minigenomes are packaged into virus particles. Thus, a mixed population of wild type helper and defective minigenome viruses is produced. The defective minigenome virus can be propagated indefinitely provided wild-type virus is present as a helper.

**Origin & function**

Plasmids that express individual virus proteins, minigenomes, and the complete virus genome were constructed in the laboratories of Drs Peter Collins and Brian Murphy (National Institute of Allergy and Infectious Diseases, National Institutes of Health) using cDNA generated from infectious virus RNAs.

In this study, complete PIV-3 and RSV genomes will be modified by introduction of a reporter gene (or genes) into the virus genome. Reporter gene sequence will be inserted into the RSV or PIV-3 genome, either adjacent to the virus promoter, between virus genes, or within virus genes to create virus-reporter fusion proteins. The reporter genes to be used are commercially available (eg. chloramphenicol acetyltransferase, luciferase, and green fluorescent protein). The purpose of introducing a reporter gene is to allow rapid analysis of virus gene expression using assays for the reporter protein. In addition, because the reporter gene is not essential to virus growth potentially deleterious mutations can be introduced into its flanking cis-acting sequences and assessed.

The intended function of the genetic material in the study is to introduce site-directed mutations (substitutions, insertions, deletions) into the RSV and PIV-3 non-coding sequences and genes to carry out structure-function analysis of cis-acting sequences and virus proteins. Mutations in cis-acting sequences will initially be assessed using the minigenome system. Then selected mutations will be introduced into complete virus genomes to generate mutant infectious virus, as described above. The mutant
viruses will be analysed using standard virological techniques and assays that monitor reporter gene expression.

**Evaluation of foreseeable effects**

The reporter genes to be inserted into the PIV-3 and RSV genomes encode well-characterised proteins that do not interact with either the virus or the host cell e.g., chloramphenicol acetyltransferase, luciferase, and green fluorescent protein, therefore insertion of these genes is not expected to affect virus pathogenicity or host-range. The impact of inserting foreign sequence into the virus genome would be expected to have either no effect on virus biology, or to attenuate the virus due to the increased genome length. Indeed, chloramphenicol acetyltransferase and green fluorescent protein have individually been inserted into the RSV genome previously, and the resulting viruses were slightly attenuated compared to wild-type RSV (Bukreyev et al, 1996, J Virol., 70: 6634-41; Hallak et al, 2000, Virology, 271: 264-75). RSV and PIV-3 will also be modified by introduction of site-directed mutations in the virus genomes, either in cis-acting sequences or virus genes. These mutations are likely to either attenuate the virus, or to have no effect on virus replication. In summary, the modifications to be carried out on RSV and PIV-3 are unlikely to generate viruses with an increased risk to either human health, or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste will be autoclaved at 121 degrees C for 20 minutes. This will result in effectively 100% kill. The autoclave to be used is validated annually by a Scottish Home and Health official using probes which are inserted into bottles or bags. Each autoclave run is monitored to ensure that the necessary temperature is maintained for the appropriate length of time (a printout showing this information is produced for each run cycle). Contaminated solid waste will be double bagged and placed in dedicated, heavy-duty, leak-proof containers. Liquid waste will be aspirated into Duran bottles (the aspiration system involves a 0.2uM filter between the catch bottle and the pump and a backup Duran bottle to collect any accidental overflow). Terminex will be added to the liquid waste in the Duran bottles to a concentration of 10% as a precautionary measure. Bottles will then be collected in designated leak-proof containers for autoclaving. The waste will be autoclaved promptly following removal from the category 2 facility. Once the waste has been autoclaved it will be disposed of with normal waste.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The Committee accepted information provided by Dr Fearns stating that the most likely mode of transmission of these viruses is by large droplets (unlikely to disperse a large distance) and direct contact. For this reason the Committee agreed that the laboratory, with the additional control measures specified by Dr Fearns, is adequate.

### Project Additional Information

**Purposes of the contained use**

Lentiviral and oncoretroviral pathogens including human immunodeficiency virus types 1 and 2 (HIV), simian immunodeficiency virus (SIV) and human T cell leukaemia virus type 1 and 2 (HTLV), or their molecular clones will be grown in tissue culture. The virally infected cells will be used for biochemical, genetic and molecular analysis of viral replication. In particular, recombinant viruses will be produced carrying mutations or substitutions in specific genes (including rev, tat, nef and envelope). We will assess the impact of these mutations or substitutiosn on viral entry into cells, viral infectivity, and viral gene expression.

**Recipient or parental organism**

HIV-1, HIV-2, SIV, HTLV-2 and HTLV-1 are ACGM hazard group 3 pathogens that cause, or have the potential to cause, life threatening disease in man. Therefore the appropriate minimum level of containment for infectious replication competent HIV-1, HIV-2 and HTLV-1 is ACGM containment level 3. Principal routes of transmission for wild type and GM viruses will be inoculation by sharps, contact with open wounds and exposure to aerosols containing high concentrations of virus. The recombinant defective viruses will be equally or less pathogenic or "fit" than the parental virus. Retroviruses such as HIV and HTLV are fragile and do not survive for long periods in the environment.

**Host/vector system**
specific viral genes will be modified by incorporation of mutations, or by substitution of viral sequences with heterologous reporter genes. Mutant viral genes will be produced by site-directed mutagenesis using sub-genomic non-infectious viral clones or CDNAs (this type of manipulation is permitted under our existing containment level 1 projects). The site directed mutants (deletions, insertions and substitutions) will be transferred into the full length molecular clones of HIV, SIV or HTLV. For HIV-1, HIV-2, and SIV we will produce recombinant viruses carrying mutations involved in the viral replication cycle; for example, envelope, REV, Tat, Nef and the viral long terminal repeats (LTR). For HTLV-1 and HTLV-2 we will also generate mutations in genes involved in viral replication; including mutations in envelope, Rex, Tax and the LTRs. We will also replace the HIV-1 envelope sequences with those for HTLV-1 env. We will examine the replication kinetics and replicative capacity of the mutant proviral clones.

We will also employ lentiviral vector technology (Kafri et al. 1997. Nature Genet. 17:314-7, Kafri et al. 1999. J Virol. 73:576-84, Poescia et al. 1998. Nature Med. 4:354-357) to transduce "wild type" or mutant gene products involved in the viral replication cycle into cells in tissue culture. We will examine the ability of the transduced gene products to inhibit or stimulate replication of "wild type" infectious HIV or HTLVs in a trans-dominant manner. In particular, we will investigate the effect of viral and/or cellular genes involved in viral entry and replication: for example, we will employ the viral genes listed above, and cellular genes involved in viral entry such as CCR5, CXCR4, CD4, or other host genes involved in viral replication such as CRM1/Exportin.

We will insert the following reporter genes into the HIV, SIV or HTLV genomes: firefly luciferase (luc), green fluorescent protein (GFP), bacterial hygromycin resistance, and the gene for human alkaline phosphatase (HPAP). We will insert these reporter genes into viral sequences required for viral replication such as the nef or env open reading frames of HIV. Recombinant provirus encoding reporter genes in place of envelope will be complemented in trans using plasmid vectors expressing envelope. The virions produced in the envelope complementation system will be competent for a single round of infection. In contrast, reporter genes incorporated at sites such as nef will be competent for infection and replication but will not "fit" than the parental virus. The reporter genes will allow us to readily follow infection and dissemination of virus in culture by simple assay techniques.

Evaluation of foreseeable effects

HIV-1, HIV-2, SIV, HTLV-1 and HTLV-2 are ACGM hazard group 3 pathogens. Therefore the appropriate minimum level of containment for infectious replication competent HIV-1, HIV-2, SIV and HTLV is ACGM containment level 3. Cell lines and primary lymphocytes will be deliberately infected with HIV-1, HIV-2, SIV, HTLV-2 or HTLV-1. The uninfected cell lines may be considered as greatly attenuated microorganisms and present no apparent hazard to laboratory workers or the environment. However, for primary human cells the risk from endogenous agents is high, and most importantly for deliberately infected primary cells and cell lines the hazard is also high. Therefore, all work with deliberately infected cells will be performed at the containment level appropriate for the infectious agent, in this case containment level 3. Infectious proviral clones will be modified by incorporation of mutations within specific viral genes. These mutations will likely reduce the infectivity and pathogenicity of the virus. Some mutations may confer altered infectivity (altered tissue tropism and/or rate of replication) to particular recombinants, however these mutations will not affect the principal route(s) of virus transmission or viral host range. Thus, the recombinant mutant virus will be equally or less pathogenic than the parental virus.

Recombinant lentiviral gene-transfer vectors will be used to transduce cells with wild type and mutant genes that are involved in viral replication. The effect of the transduced genes on infection and replication of HIV-1, HIV-2, SIV, HTLV-1 and HTLV-2 will be assessed. Recombination may occur as a rare event between the lentivector and the infectious wild type virus strains used, however the viral genomes produced through recombination will likely be equally or less fit or pathogenic than the parental wild type virus. Therefore, the containment measures used for infectious replication competent HIV and HTLV strains are also appropriate for containment and use of lentiviral vectors for gene transfer. Importantly, we will substitute the envelope sequences of HIV-1 with those of HTLV-1. Substitution of HIV-1 envelope with env from HTLV-1 will result in expanded tissue tropism for the recombinant HIV and the ability to enter non-human cell lines (Landau 1991. J Virol. 65:162). However, substitution of envelope is unlikely to expand the host range of the recombinant HIV because there are multiple blocks to HIV-1 replication in many non-rimate cell lines. Moreover, transmission of HTLV-1 occurs mainly by cell-to-cell transfer and envelope is primarily responsible for this phenotype (Delamarre, 1997. J Virol. 71:259), consequently HTLV-1 pseudotyped HIV particles exhibit reduced infectivity (Landau 1991. J Virol. 65:162-9.). Therefore, inclusion of HTLV-1 envelope sequences will...
reduce the fitness and attenuate the pathogenicity of the recombinant HIV. The routes of viral infection will not be altered by incorporation of HTLV-1 envelope, and the pathogenicity of the recombinant virus will be equal or less than the parental virus. For the reasons specified, the appropriate containment level for this recombinant virus is ACGM containment level 3.

The reporter genes to be used in this study (luciferase, GFP, HPAP, and bacterial hygromycin resistance) are derived from organisms that are not pathogens of man and the genes have no serious deleterious or toxic effects. The reporter genes are not virulence factors and will not increase the pathogenicity of recombinant HIV, SIV or HTLV. Importantly, the heterologous sequences will disrupt essential viral gene functions by insertional inactivation, resulting in attenuation of the recombinant proviral clones (Deacon et al. 1995. Science. 270:988-91; Lasky et al. 1987. Cell. 50:975-85). Incorporation of reporter genes, or mutant viral genes, will render the recipient virus equally or less pathogenic than the parental virus; indicating that ACGM containment level 3 is appropriate for this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

<table>

<tr>
<th>All containment measures for class 3 will be applied.</th>
</tr>
</thead>
</table>

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>Solid waste: All plastics, gloves, flasks, pipettes, tips etc. will be autoclaved before disposal. Immediately after use pipettes will be immersed in 10% Terminex II or Microsol3 (see below). Subsequently, pipettes and other solid waste will be placed in double autoclave bags, sealed with autoclave tape and placed inside robust plastic leak-proof containers. The waste will then be treated by steam sterilisation in an autoclave. Autoclaved solid waste will be identified as “clinical waste” and processed through the Ninewells Hospital route for disposal of clinical waste (heat treatment followed by landfill).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Liquid waste: All liquid waste will be treated by addition of Terminex II or Microsol3 (to 10% Vol./Vol.). Terminex and Microsol3 are detergent based anti-viral agents and, at the recommended concentrations, are effective against HIV, HTLV-1 and HCV (expected degree of kill for these viruses is 99.99%). Tubes, flasks, and plastic bottles containing Terminex-treated media will then be placed in double autoclave bags sealed with autoclave tape, and/or placed in leak-proof plastic containers (as appropriate), and treated by steam sterilisation in an autoclave. Autoclaved liquid waste will be flushed down the sink with copious amounts of water.</td>
</tr>
</tbody>
</table>

Autoclave: Waste will be autoclaved at 134 degrees C for 5 minutes for solid waste, and 121 degrees C for 15 minutes for liquid waste. The procedure will inactivate 100% of all retroviral particles and cell associated virus. Monitoring of chamber temperature will be carried out with an internal probe during each run. The monitoring procedure will be validated quarterly (to HJM2010) and when a new probe is fitted.

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed that any genetically modified retrovirus created during this work would have broadly similar properties to 'wild type' retroviruses. For this reason Committee accepted the adequacy of the containment measures to be adopted.
THE USE OF ADENOVIRAL AND BACULOVIRAL VECTORS FOR EXPRESSION OF PROTEINS AND RNAi CONSTRUCTS TO MANIPULATE SIGNALLING IN MAMMALIAN CELLS.

The technique will permit the identification of the molecular mechanisms used by insulin to regulate gene expression. Each molecule identified will be assessed further for potential as a therapeutic target for type 2 diabetes.

Replication defective adenovirus and baculovirus will be used. These agents have been modified to prevent their expansion in the absence of helper cells. They cannot reproduce or indeed survive outwith the contained environment. As we will use them to express proteins whose complete function is not yet known the project becomes class 2 categorised.

Recipients or parental organism

Project Additional Information
Host/vector system

The host systems for propagation of the recombinant, replication defective adenovirus are 293 cells (E1 transformed embryonic kidney cells) and 911 cells (E1 transformed human embryonic retinal cells). Cultured mammalian cells are regarded as being unable to colonise the worker provided that their own or a close relatives cells are not cultured (compendium of guidance 2000). They may be considered to be ACDP group 1 for the purposes of the contained use regulations. Baculovirus is propagated within the insect cell lines Sf9. The recombinant, replication defective virus will be used to infect established mammalian cell lines in which the virus is unable to replicate such as: rat hepatoma cells, isolated rat and mouse hepatocytes or neurones.

Origin & function

The following genes will be/have been placed in the replication defective adenovirus vector (see below for details of tene function): AGC protein kinases (active and dominant negative, DN), mTOR (active and DN), MEKK (active/DN), GSK3 (active/DN), insulin-regulated transcription factors (FKHR, HNF3, SREBP1c, others as they become known), protein phosphatases (PP1, PP2A), glucokinase, small G-protein Ras (DN), PH domain-containing proteins. In addition, we will insert RNAi constructs to specifically target protein sequences for degradation. Dealing with these insert sequences is necessary to dissect out their physiological function and identify their role in disease.

Mouse, human, rat, rabbit, S.Pombe, Zenopus Leavis, E.coli, S.cerevisiae are in the sources of donated DNA.

Function of inserted genes:
AGC kinases      signalling molecules that modulate hormone sensing
Protein kinase B, S6K, PKC, PDK1, AMP-activated protein kinase

Other kinases
mTOR        signalling molecule that regulates protein translation
MEKK       signalling molecule that regulates gene transcription
GSK3       signalling molecule that regulates multiple actions of insulin

Insulin-regulated transcription factors
FKHR        target genes unknown
HNF3      mediates insulin antagonism of glucocorticoid induced transcription
SREBP1c    regulates expression of tene involved in fatty acid biosynthesis

Protein phosphatases
PP1, PP2A  antoganise the action of protein kinases

Other proteins
glucokinase - rate limiting step in glucose sensing
small G-protein Ras - regulates multiple actions of growth factors.
Other signalling molecules found in the future to play a role in the action of insulin and action.

PH domains
Plekstrin Homology domains are lipid binding modules that confer specific lipid regulation to a large number (over 100) of cellular proteins (including PKB, PDK1, TAPPs, DAPPS).

Evaluation of foreseeable effects

The AdEasy Vector system will be used: adenovirus Ad5 E1E3 or Ad5 E1E3E4 deleted(). The host-vector system to be used does not generate replication efficient viral particles. The system has been modified (E1 region deleted) so as to prevent replication in human cells. Genes will be inserted into the site of the disabling deletion. This safeguards against the generation of replication competent recombinant adenovirus by homologous recombination with wild type virus. The baculovirus is an insect virus.
that requires a very high titre to insert genetic material into mammalian cells. It cannot replicate in mammalian cells. Expression of genetic material which interferes with cell signalling function will not allow the deleted virus to replicate. The presence of the genes indicated in this application will not change the infectivity or enable replication of the viruses. The possible consequences of expression of the inserted genetic material in man (see above) are such that the classification of the recombinant virus should be group II.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment with 70% ethanol has been shown to be an effective disinfectant for adenovirus, but we will also use an anti-viral aerosol (Mikrozid, S+M Rotherham) to clean work areas and equipment, and a viricidal disinfectant (Terminex II, Arrow, Derbyshire) to treat liquid waste.

Solid waste will be autoclaved (expected degree of kill 100%). It will be identified as clinical waste and processed through the Ninewells Hospital route for disposal of clinical waste (heat treatment followed by landfill). Liquid waste will be collected in the presence of the viricidal disinfectant Terminex II and will be autoclaved (expected degree of kill 100%) and then poured down the sink with copious amounts of water.

Monitoring the efficacy of the autoclave will involve completion of test sheets supplied by Scottish Healthcare Supplies (or an equivalent contractor). This requires keeping a record on the test sheet, for the first production cycle of the day, of the temperature inside the load, pressure and sterilisation time. A record of each production cycle will be kept. Weekly testing involves safety checks, vacuum leak rate test and test of automatic controls. Quarterly testing includes thermometric test for small and normal load and safety check, vacuum leak rate test, and test of automatic controls.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

At its meeting on 13 March 2002 Committee agreed that the facilities and procedures are adequate for the level of risk.

### Project Additional Information

**Purposes of the contained use**

This project will focus on mechanisms underlying cardiac resistance to stress as well as lung development and function. Uncovering intracellular signalling pathways mediating some of critical functions of the heart and lungs, as it will be done here, may further increase our understanding of heart and lungs and it may lead to novel and more efficient strategies in therapy of cardiovascular and pulmonary diseases.

**Recipient or parental organism**

Cells and tissues in vitro and in vivo will be used as recipients. All these recipients are well characterised such as Vero/293, HBE, CFBE, CHO, BHK cell lines, cardiomyocytes, rodent lung and heart tissue and others. All cells/tissues that we might use are well established for these purposes and have been routinely used in many laboratories over many years.

**Host/vector system**

Only commercially available disabled and well characterised viral vectors with a history of safe use such as pADEasy-1 (Stratagene) will be used. These viral vector systems can only propagate in special packing cell lines: in normal cells they can not replicate. Inserts will be cloned into the site of disablement and recombinant events leading to replication competent viruses are extremely unlikely given their design. Introduction of genes of interest into these vectors is very unlikely to alter the survivability, tissue tropism/host range, infectivity or alter virus effects upon other organisms and potential route of transmission. These vectors have been in routine and safe use in many laboratories over many years.
Origin & function

Genes that will be inserted into viral vectors encode proteins involved in intracellular signalling in heart and lungs such as lactate dehydrogenase, creatine kinase, diadenosine tetraphosphate hydrolase and others. In addition, mutant forms of these proteins will be also used when dominant-negative strategy is required, i.e. when it is intended to block a specific signalling pathway. All these genes will be cloned into disabled commercially available viral vectors (as described above) and they have not been reported to cause immortalisation or transformation of cells. In theory, some of the constructs might alter cell determination and cell growth. However, it should be pointed out that similar constructs have been used in other laboratories without any harmful effects.

Evaluation of foreseeable effects

The viral vectors used may infect a wide range of mammalian cells. In the case of retroviral vectors they can integrate into the host cell genome and stable express the gene of interest. It is extremely unlikely that adenoviral vectors will integrate into the host cell genome so expression of the recombinant genes will only occur in cells initially infected. Eventually it is likely that recombinant genes will be lost through natural degradation of episomal DNA in infected cells.

All the genes we plan to clone into disabled viral vectors encode intracellular proteins involved in normal signal transduction/cell regulation processes in lungs and heart. None of the gene products is known to have any effect on the infectivity, pathogenicity or replication of viral-based expression systems and similar constructs have been used without harmful effects in numerous other laboratories. It is highly unlikely that they could have any effect on the host range or tropism of the virus, since they do not encode proteins that are cell receptors or extracellular matrix proteins etc. The viral receptors are so specific that different types/strains of viruses use different receptors so that possibility of affecting the tropism or infectivity through expression of any recombinant protein is extremely low.

Some of proteins being expressed have the potential to interfere with intracellular pathways, and hence alter cell determination and growth. However, with the following key controls the residual risk is negligible:

1. Replication defective viral vectors are used to ensure proliferation occurs only in special packaging cell lines.
2. Containment Level 2 is applied to prevent infection of the worker or release into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste: autoclave then dispose of as controlled waste

Liquid waste: Add Terminex 10%, autoclave and then dispose of to drains.

Sharps waste: collect in an autoclavable sharps-safe container, autoclave then dispose of as clinical waste.

Reusable labware: autoclave if possible, otherwise disinfect with 1% Virkon overnight, rinse out to drains then place in normal wash-up stream. There must be no significant volume of liquid waste present, only trace contamination.

Chemically contaminated GM waste: disinfect with Virkon then treat as purely toxic chemical waste. There must be experimental evidence to support the efficacy of Virkon under the specific conditions of use.

Radioactive GM waste: Disinfect with Virkon then treat as purely radioactive waste. There must be experimental evidence to support the efficacy of Virkon under the specific conditions of use.
Committee reviewed this work on 12 May 2005 and agreed that facilities and procedures are appropriate.

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

To develop new therapies for clinically significant conditions.

**Recipient or parental organism**

A range of systems based upon well characterised micro-organisms given ethical approval for human use by Gene Therapy Advisory Committee will be used to deliver genetic material to patients. All these micro-organisms will be either disabled or attenuated variants of pathogens. They will include delivery systems derived from adenoviruses, poxviruses, Herpes Simplex Virus, and retroviruses. Other well characterised delivery systems may be used in future as this technology develops. There is no intention to develop new delivery systems under this notification.

**Host/vector system**

These delivery systems will be approved by Medicines and Healthcare Regulatory Authority for use in human patients. They will be manufactured using fully documented procedures with strict quality control measures.

**Origin & function**

At present the functions of genetic material used in gene therapy trials worldwide include: antigen, antisense, cytokines, deficiency, drug resistance, hormone, marker, oncogene regulator, receptor, replication inhibitor, ribozyme, cell suicide, and tumour suppression (Journal of Gene Medicine). It is likely that this technology will continue to be used to express genetic material with physiologically relevant functions.

**Evaluation of foreseeable effects**

Fully characterised disabled or attenuated micro-organisms (delivery system) will be used to introduce genetic material into human cells for therapeutic purposes. In all cases the GMO will be evaluated in a variety of experimental systems before it is introduced into patients.

Many of these delivery systems are derived from commonly occurring pathogens that large sections of the population will have been exposed to, and cleared from their system (e.g. adenovirus, HSV and vaccinia). Thus they will have pre-existing immunity. The genetic material will not restore pathogenicity of the delivery system or create a more virulent form, or alter its morphological properties (e.g. susceptibility to disinfectants, dessication or heat).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste heavily contaminated with GMM (e.g. syringe, vials, dressings) will be autoclaved (expected degree of kill 100%, autoclaved tested to HTM 2010 standard).

Other waste that could possibly be contaminated with GMM will be treated as Clinical Waste (Thermal treatment).

Standard laundry and cleaning regimes will be adopted for clinical areas.
After lengthy discussion and some minor modifications to the protocols the Committee agrees that the measures being taken are sufficient for the level of risk.

Please enter comments on the GM safety committee on the risk assessment

### Project Additional Information

#### Purposes of the contained use

To investigate at a molecular level biologically important pathways.

#### Recipient or parental organism

A variety of well characterised packaging cell lines that provide the genes deleted from viral vectors in trans either by way of the cells genome or by transfecting in complementing plasmids.

Well characterised and authenticated tissue culture cell lines.

Primary cells.

#### Host/vector system

A range of well characterised, commercially available systems as detailed in Section 2.6 to 2.12 SACGM Compendium of Guidance will be used as research tools. Most commonly, adenoviral, retroviral and lentiviral vector systems will be used.

This notification does not include research to develop new viral vector systems or to investigate virus life cycles.

#### Origin & function

Wild type and mutant forms of genes and genetic material that may have harmful effects (as detailed in Section 2.2 SACGM Compendium of Guidance) including known and putative oncogenes, growth factors, cytokines, non-coding regulatory elements, anti-sense constructs, and siRNA.

This notification does not include known TSE proteins.

This notification does not include expression of genes that are likely to alter properties of the viral vector such as its tissue tropism or host range, susceptibility to prophylaxis or survivability in the environment, nor are they likely to overcome disabling mutations.

#### Evaluation of foreseeable effects

Significant risks to human health arise during the generation of cell lines: once established the cell lines are unlikely to cause harm to human health or the environment.

1. **Risks arising from recombination/complementation events**

   The worst case scenario is that a replication competent virus expressing a harmful gene (e.g., oncogene) is generated either during manufacture of the infectious viral vector particle (i.e., between transfer vector and packaging cell line components) or through co-infection of a person with wild-type virus and viral vector. This scenario is unlikely given the number of recombinations events required.

   It is also possible that the transfer vector reverts to a replication competent virus. The level of risk depends upon the pathogenicity of the wild-type virus, and for high risk viruses this possibility is unlikely given the number of recombination events related to the packaging of the transfer vector.

2. **Risks arising from integration of viral vector into person's genome**

   It is possible that random insertion could lead to activation of cellular genes, disruption of important genes (e.g., tumour suppressor) or acquisition of a harmful gene (e.g., oncogene). The worst case is that permanent changes are induced in an infected cell resulting in tumourogenesis.

3. **Risks arising from inserted genetic material**

   Wild-type and mutant forms of genes and genetic material may have harmful effects (as detailed in Section 2.2 SACGM Compendium of Guidance) including known and putative oncogenes, growth factors, cytokines, non-coding regulatory elements, anti-sense constructs, and siRNA.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved (expected degree of kill 100%, HTM 20 10 standard), and then placed in the low risk Clinical Waste stream ie heat treatment by landfill.

Liquid waste will be treated with 10% Terminex before autoclaved (expected degree of kill 100%, HTM 20 10 standard) and then put to drain.

Trace contamination reusable labware and equipment will be autoclaved if possible - if this not possible then it will be disinfected with 1% Virkon overnight before being rinsed to drain.

Any waste that cannot be autoclaved (e.g., chemical or radiological contamination) will be disinfected with 1% Virkon overnight before being disposed of as Special or Radiological Waste.

### Project Additional Information

02/03/2022
### Purposes of the contained use

The work will involve mutating wildtype Erwinia amylovora strains using a suicide vector system. The mutations will be introduced to known virulence genes or likely virulence gene regulators, and will either insertionally inactivate the gene of interest or create a reporter fusion to monitor expression. Mutation of virulence genes will compromise pathogenicity, allowing the role of the virulence factor to be characterised. The reporter system will create merodiploid strains that posses both an unmutated copy of the gene and the reporter fusion (inactive) copy. The ability to monitor the expression of virulence/regulatory genes will help increase understanding of how transcription of such factors is modulated during the infection process.

### Recipient or parental organism

Erwinia amylovora is a gram-negative bacterium and a plant pathogen, causing the disease fireblight on a range of hosts including apple, pear and non-crop plants such as Pyracantha, Cotoneaster and Cratagus. E. amylovora poses no threat to human health being unable to grow at temperatures above 30 degrees C. Being a plant pathogen work on E. amylovora is covered by Plant Health licence No. GM/139/2001 (copy attached). The parent strain to be used for genetic manipulation is Erwinia amylovora strain CFBP1430 a French isolate. This strain has been used for some years and its virulence on apple seedlings has been extensively studied. CFBP 1430 is significantly less virulent than other wild-type strains in this system eg. The UK isolate strain OT1. Higher inoculum levels are required for induction of disease and symptoms are less severe.

### Host/vector system

The host strain used for introducing suicide vector systems into E. amylovora is the Escherichia coli K12 derivative SM10 pir. K12 derivatives are auxotrophic mutants and are non-colonising, disabled and unlikely to persist in the environment. SM10 pir is able to mobilise certain plasmids into host strains. The suicide vector systems use a series of mobilisable plasmid vectors containing the conditional oriR6K origin of replication, which can only replicate in host strains expressing the pir gene product. Mobilisation is directed from either an R2K or RP4 origin of transfer. These vectors are commonly used for mutagenesis of Gram-negative bacteria.

### Origin & function

The genetic material will be derived from E. amylovora. Genes will be isolated from either a cosmid library or by PCR amplification from E. amylovora chromosomal DNA. Genes of interest include known virulence genes such as members of the hrp gene cluster used to produce the Type III secretion system, the ams genes involved in biosynthesis of the polysaccharide amylovoran, and the dsp (disease specific) genes. In addition, certain transcriptional regulators postulated to be involved in regulation of virulence factor expression, may be used. These include the csrA gene involved in induction of carbon storage genes. The E. coli lacZ and GUS genes encoding B-galactosidase and B-glucuronidase respectively will be used to analyse transcriptional expression of E. amylovora genes. Both genes/gene products have been extensively characterised and are non-hazardous. These properties have led to their widespread use in cloning vectors and reporter systems.

Antibiotic resistance genes used for insertional inactivation and as markers on suicide vectors will be taken from commonly used E. coli plasmid/cloning cectors and will not encode resistance to antimicrobials in clinical use.

### Evaluation of foreseeable effects

Erwinia amylovora is unable to grow above 30 degrees C and so any GM strains represent no hazard to human health. Being a plant pathogen E. amylovora GM strains represent a potential hazard to host plants. However, for the development of disease symptoms extended periods of warm temperatures are required (above 25 degrees C). There is little likelihood of successful infection occurring in Scotland. Erwinia amylovora does not persist in the environment outside of the host plant and does not form spores. The proposed genetic modification will either result in insertional inactivation of known virulence factor/virulence regulator genes or in the generation of transcriptional reporter fusions.

Inactivation of genes will involve introducing a suicide vector, containing the virulence gene disrupted by the insertion of an antibiotic resistance gene cassette, into E. amylovora. The antibiotic resistance genes used will be against antibiotics not used clinically. As the suicide vector cannot replicate in E. amylovora it will insert onto the chromosome by recombining with homologous virulence gene sequence. A second cross-over event will delete the wild type copy of the gene and vector DNA sequence, leaving only the insertional inactivated gene on the chromosome. The resulting strain will be defective in the production of a virulence factor, which will reduce pathogenicity and thereby prevent infection of host plants. Insertional inactivation of regulatory genes may also compromise virulence. In addition, inactivation of regulatory genes such as csrA is likely to affect other physiological characteristics. In the case of csrA carbon storage will be affected, this will compromise the ability of the resulting
GMM to persist in the environment. As all vector DNA is removed during the second recombination event it is unlikely that any DNA possessing mobilisation function will persist in the GM strains. There is, therefore, minimal potential for GMM DNA to transmit to other organisms. Reporter fusion strains will possess virulence or regulator genes linked to the E. coli gene encoding either B-glucuronidase or B-galactosidase. The suicide vector used for these constructs will contain the promoter and part of the coding sequence of the gene of interest linked to the reporter gene. The resulting vector will be introduced by a single recombination event onto the E. amylovora chromosome. This will generate a merodiploid strain with both a wild type gene copy and a fragment of the gene of interest linked to the reporter. These strains are likely to retain virulence. The gene fragment linked to the reporter will produce a truncated, inactive protein. Both reporter genes have been fully characterised and are non-hazardous to humans and unlikely to influence the stability of the resulting strains in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information

**Purposes of the contained use**

The work will involve the isolation of recombinant plasmid (pUK42) from microbial cultures and the stable/transient transfection of this into mammalian cells. Cells expressing SV40 oncogenes (potential immortalised cells) will be isolated and characterised. Clones with the desired phenotype will be used for further studies. The expression and of immunological proteins and the behaviour of the cells in in vitro immunology experiments will be investigated.

**Recipient or parental organism**

The recombinant plasmid will be grown up in the E. coli strain DH5α which is recognised as being non-colonising and disabled and is not considered pathogenic to humans or animals (Woodcock et al. Nucl. Acid Res. 17, 3469-3478, 1998). The primate and non-primate primary cultures and cell lines to be used are free of any deleterious virus and are very unlikely to be able to survive without specialised media. Primary cultures of cells need specialist media to grow and often establishing the cells in culture is very difficult. It is very unlikely that these cells will be able to survive out with the specialist culture media and facilities used.

**Host/vector system**

The recombinant plasmid pUK42 is based on the plasmid vector pAT153 and contains the SV40 large T and small T antigen sequences, an ampicillin resistance gene and a neomycin resistance gene (FitzGerald et al. in Vitro Cell Dev. Biol. 30, 236-242, 1993). The recombinant plasmid will be grown up in the E. coli strain DH5α which is recognised as being non-colonising and disabled and is not considered pathogenic to humans or animals (Woodcock et al. Nucl. Acid Res. 17, 3469-3478, 1998). The SV40 large T and small t antigen gene products are well documented as being oncogenic, albeit weakly when compared to transforming oncogenes such as ras and
In pUK42, the SV40 sequences are under control of the endogenous promoter which supports strong transcription in a variety of cell types. The SV40 origin of replication is not present in pUK42 and so no self-replicating virus can be generated.

Origin & function

pUK42 is a plasmid derived from the vector pAT153 and which contains sequences from the SV40 virus (genes for small t and large t antigens) whose products are known to be oncogenic. No genetic manipulation of pUK42 will take place in the work herein notified; rather, genes of the plasmid will be expressed in primate and non-primate cells. Selected clones of transformed cells will then be used in experiments to investigate the biology of certain cell types.

Evaluation of foreseeable effects

Neither neomycin nor ampicillin are used clinically and thus the use of genes whose products confer resistance to these antibiotics in this work should not pose any health risk.

The immortalisation of cells donated by workers will not be permitted so as to limit the possibilities of the immortalised cells colonising individuals.

SV40 antigens and neomycin resistance protein would not be expressed in bacterial cells, so bacterial cultures would not be a source of these proteins. Exposure to SV40 large T and/or small t antigen proteins could conceivably result in oncogenesis. The following procedures are to be used to minimise this risk:

* mammalian cells to be cultured in class II cell culture cabinets on a small scale only in a specialist facility with locked doors.
* gloves and lab coats would be worn at all times
* sharps not be used during this work
* cells to be disposed of by autoclaving following overnight soaking of all plastic ware in a bactericidal and viracidal solution.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

**Purposes of the contained use**

To study:
- cellular response to herpesvirus infection (HSV-1, HSV-2, CMV, VZV, EBV, HHV-6, HHV-7, KSHV)
- cellular senescence and ageing
- cellular mechanisms of postherpetic neuralgia
- cellular mechanisms of arthritis
- cellular mechanisms of cancer progression

**Recipient or parental organism**
Various widely used and established human and mouse cell lines (e.g. HFF, U2OS, Hepatocytes, iPSC, hESC, human neurons, IMR90s, SW1353) will be obtained from reputable sources e.g. ATCC, ECACC etc., so information as to whether they have been screened for HIV, Hep B, Hep C and EBV will be available. As a result they are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. The cells will therefore not exert any foreseeable effects on human health. All primary cell lines will be routinely tested for mycoplasma.

To identify viral genes involved in cellular resistance to herpesviruses: mutant variants of human herpesviruses will be generated using BAC mutagenesis (Bacterial Artificial Chromosome) to insert marker or viral genes into the viral genome, delete viral genes from the genome and mutate viral genes within the viral genome by homologous recombination in E. coli. BACs are then transfected into mammalian cells to obtain infectious virus.

**Host/vector system**

**Host:** E.coli, cultured cell lines  

**vector:**  
- 2nd and 3rd generation lentiviruses or the CRISPR/Cas9 system (the need for contained use for CRISPR/Cas9 stems from the use of a lentiviral based delivery system of the components which target the genes).  
- A replication-deficient retroviral vector (pBABE-puro) will also be used to deliver the activated oncogenes such as RasV12 to the human fibroblast cell line IMR-90 (ATCC Number CCL-186) in order to induce senescence. This strategy will be utilized in order to investigate mechanisms of the senescence pathway.  
- human herpesviruses and their respective BACs  
- New Lentivectors: We will employ newer generation, commercially available vectors with improved biosafety properties as they become available to further minimise risk to users on an ongoing basis.

**Origin & function**

**Deleted/mutated genes:**  
- cellular genes involved in intrinsic defense to herpesvirus infection (e.g. Daxx, PML, ATRX, Sp100, SUMO, Ubc9 and others)  
- viral genes involved in intrinsic immunity and latency (e.g. HSV-1 ICP0, HSV-1 LAT, EBV-EBNA, KSHV-LANA and others)  
- genes involved in cell senescence (e.g. HIRA, p53, p16 and others)  
- genes involved in mechanisms leading to arthritis and cancer (e.g. p53, p53-like genes, PAR2)

**Inserted genes:**  
- marker genes including EGFP, EYFP, dTomato and others  
- substitution of homologous viral genes (e.g. HSV-1 ICP0 with CMV pp71)  
- senescent regulatory genes and genes associated with pathogenesis of arthritis

**Evaluation of foreseeable effects**

**Lentiviruses**

The lentiviruses used for gene knock down and mutation will be 2nd and 3rd generation lentiviruses, which are replication defective and depend on helper (containing gag, pol, rev) and pseudotyped packaging vectors. Only co-transfection of HEK-293 cells with helper and packaging plasmids leads to infectious progeny virus. Due to lack of helper functions in the target cells, infection with lentivirus does not lead to productive virus infection or virus release. All lentiviruses used are unable to replicate in a human host and contain a 3' self-inactivating (SIN) long terminal repeat.
pBABE-vector with onogenes will be transiently transfected into Phoenix cells, a 293T-derived packaging cell line that contains the Gag, Pol and Env viral proteins required for making active virus. Subsequently, viral supernatants produced by Phoenix cells will be used to infect human fibroblasts (IMR-90). Both the Phoenix packaging cell line and IMR-90 fibroblasts are used extensively in laboratories and have been screened and found to be negative for HIV, Hep B, Hep C and EBV. There is no risk from the infected cells. Cells are obtained from ATCC and have been rigorously characterized.

The "LentiCRISPR" vector systems utilise a replication-incompetent lentiviral vector chosen for expression of CAS9 and guide RNAs (Genome-Scale CRISPR-Cas9 Knockout Screening in Human Cells Shalem et al, Science 343, 84-87 2014).

(III) herpesviruses

All human herpesviruses are approved in the human pathogen hazard group 2.

Handling of (non-infectious) virus BACs falls within hazard group 1 and does not pose a threat to human health.

Handling of all infectious virus preparations and infected cells is restricted to within biosafety cabinets, wearing protective clothing at all times and including use of safety goggles where appropriate.

It is not anticipated that the deletions, mutations or insertions of viral genes will alter virus tropism.

Mutations within the herpesvirus genome are not expected to, and do not in general, lead to a gain of function. However, as a precautionary measure, virus growth and replicative ability will be assessed post mutation to ensure no gain of function has occurred.

All human herpesviruses lead to life long infections and careful attention will be given to all safety precautions associated with biosafety level 2 work with human herpesviruses.

HSV-1/-2: Infections can occur through lesions in the skin. Infections of the eye are can lead to herpes keratitis. Safety goggles will be worn at all times.

HCMV: Risk of foetal damage after primary infection during pregnancy. Pregnant women should not handle HCMV, but may continue to work in a lab where HCMV is being handled subject to risk assessment. Although the used lab strains AD169, Towne and Davis were originally live vaccine candidates and their ability to cause disease is expected to be attenuated, they may still cause harm, especially in pregnant women.

VZV: Potential fetal damage. Women who are or may become pregnant, if seronegative, should consider being vaccinated and restricted from working with VZV.

EBV: Low risk of laboratory acquired infection. No reports of laboratory acquired infection can be found in the literature.

HHV-6: No risk for immunocompetent hosts. Is the causative agent of exanthema subitum (roseola). May reactivate during pregnancy or in immunosuppression.

HHV-7: No risk for immunocompetent hosts. Is a constitutive inhabitant of adult saliva. Has been associated with exanthema subitum (roseola).

KSHV: No risk for immunocompetent hosts. Leads to tumour formation in HIV-1 infected hosts.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II suite, with access restricted to authorized and trained staff. Dedicated protective clothing is to be worn in Containment Level II areas at all times.

The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. Plastic ware will be used throughout and no needles or sharps will be used during virus preparation.

The use of the Class II biological safety cabinet will guard against exposure to aerosols.

All cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using desinfectant before removal from the Containment Level II suite for final disposal.

Solid waste will be double bagged in biohazard bags prior to removal from the Containment Level II suite and then autoclaved before final consignment of waste to the approved contractor.

**Project Additional Information**

**Purposes of the contained use**

Acquire pil mutants of *Ps.aeruginosa* from collaborators. Compare ability of wild-type and mutant *Ps.aeruginosa* stains to attach and invade cultured cells in vitro. Functional pili are normally required for virulence.

**Recipient or parental organism**

*Pseudomonas aeruginosa* strain PAK

*Ps.aeruginosa* rarely affects healthy individuals; occasionally it causes a mild, self limiting infection. It can cause serious and lethal infections in the immunocompromised. It is a cause of respiratory infection in people with cystic fibrosis. *Ps.aeruginosa* has a high level of natural resistance to many antibiotics so infections can be difficult to treat.

**Host/vector system**

The disrupted pilA gene in plasmid PRIC276 was introduced via conjugation into *Ps.aeruginosa* PAK. It is stabilised by the inclusion of a tetracycline resistance marker.

**Origin & function**

Isogenic pil mutants of *Ps.aeruginosa* PAK. *Ps.aeruginosa* rarely infects healthy individuals.
Evaluation of foreseeable effects

The mutant is not expected to be any more pathogenic than the wild-type organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory must be rendered free from contamination before re-use, discarding all repair. Whenever possible, contaminated articles must be autoclaved. Discard autoclaves operate at a minimum of 134°C for 30mins, (chart recorded every load) which must be checked at least annually by the use of recorded thermocouples. Autoclaved waste materials are then incinerated. When autoclaving cannot be used, because for example the nature of the material is heat sensitive or items are required for re-use, or complex laboratory equipment requires servicing, chemical disinfection will be used. When chemical disinfection is used, it is important that all surfaces come into contact with the chemical. Because different chemical disinfectants have different ranges of micro-organisms against which they are effective, only (site) approved disinfectants and procedures will be used. When large items of equipment need to be decontaminated, this can be carried out by fumigation with formaldehyde vapour. Sodium hypochlorite based disinfectants ("Chloros") are effective against Ps. aeruginosa and will be used for surface decontamination of items being transported between the microbiological cabinet and incubator/fridge. Hypochlorite solutions will be used to decontaminate small items used in the cabinet. Hypochlorite solutions at these concentrations will be used:

Surface disinfection 1000ppm
Discard jars 2,500 ppm (for a contact time of several hours/overnight)

Is an emergency plan required according to regulation 20? N

## Project Additional Information

**Purposes of the contained use**

Genes encoding *F. novicida* and *F. tularensis* metabolic enzymes, regulatory genes and possible virulence determinants will be isolated and inactivated by mutation. Mutated genes will be introduced into *F. novicida* by electroporation and cryotransformation using a suicide vector.

**Recipient or parental organism**

*F. novicida*

**Host/vector system**

Target genes will be isolated from *F. novicida* and *F. tularensis* and cloned into laboratory strains of *E. coli* prior to deletion or insertion mutagenesis. These modified genes will be introduced into *F. novicida*.

**Origin & function**

Genes from *F. novicida* and *F. tularensis* will be mutated such that gene function is lost to obtain attenuation.

**Evaluation of foreseeable effects**

The inactivation of key metabolic enzymes, regulatory proteins or virulence determinants, should result in reduced virulence of *F. novicida*.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair. Whenever possible, contaminated items will be autoclaved. Discard autoclaves operate at a minimum of 134C for 30 minutes, (chart recorded every load) which will be checked at least annually by the use of recorded thermocouples. Autoclaved waste materials are then incinerated.

When autoclaving cannot be used, because for example the nature of the material is heat sensitive or items are required for re-use, or complex laboratory equipment requires servicing, chemical disinfection will be used. When chemical disinfection is used, it is important that all surfaces come into contact with the chemical. Because different chemical disinfectants have different ranges of micro-organisms against which they are effective, only (Site) approved disinfectants and procedures will be used.

Where large items of equipment need to be decontaminated, this can be carried out by fumigation with formaldehyde vapour. Sodium hypochlorite based disinfectants ("Chloros") are effective against F.novicida and will be used for surface decontamination.

Hypochlorite solutions at these concentrations will be used:
* Surface disinfection - 1000ppm
* Discard jars - 2,500ppm (for a contact time of several hours/overnight)

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Project Ref 202/03.3

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
CLONING AND EXPRESSION OF MARKER GENES, PROMOTERS AND VACCINE CANDIDATE GENES IN STRAINS OF SALMONELLA ENTERICA SEROVAR TYPHIMURIUM AND SALMONELLA ENTERICA SEROVAR TYPHI.

Various vaccine candidate genes (e.g., protective antigen from B. anthracis, SOD gene from Francisella tularensis) and some promoters will be cloned into attenuated strains of S. enterica typhimurium and S. enterica typhi (purA and aroA) for vaccine study.

Some marker genes (e.g., firefly luciferase), and will be cloned into S. typhimurium LT2 for bacterial growth studies.

Recipient or parental organism

- S. enterica serovar typhimurium LT2: rpos mutation
- S. enterica serovar typhimurium SL2361 (aroA auxotroph derived from SL 1344 by imprecise transposon mutagenesis)
- S. enterica serovar typhimurium LB5010 (galE)
- S. enterica serovar typhimurium MT168 (purA auxotroph)
- S. enterica serovar typhi CVD908-htrA
- S. enterica serovar typhi BRD1116
- S. enterica serovar typhi Ty21a

Host/vector system

Initially, genes encoding foreign antigens will be cloned into laboratory cloning strains of E. coli (e.g., JM101, JM109, XLI-Blue), prior to transfer into Salmonella. The expression vectors used will be either non-mobilisable vectors (e.g., pUC series-based plasmids, pLG339-based plasmids, pBlueScript phagemids) or mobilisation-defective vectors (e.g., pBR322-based plasmids). Suicide vectors used for integration of foreign genes into the chromosome of the bacteria may be mobilisation-defective in E. coli (e.g., pHSG422) or self-mobilisable in E. coli pir (e.g., pHSG422) but will not be retained in Salmonella. The vectors may contain ampicillin, kanamycin or chloramphenicol resistance genes for selection.

Origin & function

Vaccine candidate studies in vitro and in vivo.
The various strains of S. enterica serovar typhimurium and S. enterica serovar typhi will contain, and in some cases will express, vaccine candidate genes and their products.

GMOs resulting from this notification will be based on attenuated strains of S. enterica serovar typhimurium and S. enterica serovar typhi which are of low pathogenicity for humans. Strains such as LT2, however, retain their ability to infect tissue culture cells. These strains have long histories of safe use in the laboratory.

The GMOs would have no effects on plants or bio-processes, although they may affect humans or other animals. They tend to be pathogenic for mice and humans at high doses. This risk of infection is considered to be very low. The organism will be handled in an ACGM level II laboratory, and inactivated before disposal. Accidental release under these conditions is unlikely.

Proteins being expressed from the GMOs are potential vaccine candidates. They have no known toxic effects, indeed PA is a component of the present human vaccine.

Wild-type salmonellae can survive for up to 70 days in the soil. The survival of the GMO is not likely to increase this time period. Transfer of genetic modification to other organisms is unlikely.

It is unlikely that the GMO will be fitter as a result of these modifications.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

Purposes of the contained use

Genes encoding Yersinia pseudotuberculosis metabolic enzymes, surface proteins, regulatory genes and possible virulence determinants will be isolated and inactivated by mutation. The effects of these mutations will be assessed in an appropriate animal model. Site directed mutagenesis of the organism performed using transposon
mutagenesis, based on Tn5 will also be evaluated.

Host/vector system

Target genes will be isolated from Yersinia pseudotuberculosis will be cloned into laboratory strains of E. coli (lambda pir strains such as Escherichia coli cc118  pir, or equivalent), prior to deletion or insertion mutagenesis. These modified genes will be introduced back into Yersinia pseudotuberculosis. Tn5 is carried by pUTminiTn5Km2 in E. coli SY327. E.coli cc118 has no known ability to infect immunologically competent humans, or plants or insects. Although not well characterised, it has a history of safe use in the laboratory and is regarded as non-pathogenic.

Origin & function

Genes from Yersinia pseudotuberculosis will be mutated such that gene function is lost to obtain attenuation.

Evaluation of foreseeable effects

The inactivation of key metabolic enzymes, regulatory proteins or virulence determinants, should result in reduced virulence of Yersinia pseudotuberculosis.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Purposes of the contained use**

Genes encoding the virulence determinants and potentially protective sub-units and possible virulence determinants will be isolated and inactivated by mutation. The effects of these mutations will be assessed in an appropriate animal model. Site directed mutagenesis of the organism will be performed using transposon mutagenesis or allelic replacement in a plasmid cured strain of B. anthracis. Further cloning on identified genes into E. coli strains will occur.

**Recipient or parental organism**

Bacillus anthracis has been studied for many years and the two major virulence determinants have been identified. A tripartite toxin is encoded by plasmid pXO1 and capsule is encoded by pXO2 (Mock M and Fouet A Annu Rev Microbiol. 2001;55:647-71.). Removal of one or both of these virulence determinants considerably reduces the risk to human health. For example vaccine strains of B. anthracis e.g. ST1 are non-capsulated variants which have lost pXO2. All genetic manipulations will be carried out in a plasmid cured strain of B. anthracis such as UM23CL2. These strains of B. anthracis are considered suitable for use in ACGM II laboratories and have a safe history of use. We aim to use the plasmid cured strains to investigate minor virulence determinants of B.anthracis by mutation. We will target genes which are implicated in virulence of other bacterial pathogens, with reference to the recently sequenced genome of Anthracis (Reed T et al Nature Vol 423 2003 pp81-86).

**Host/vector system**

Target genes will be isolated from B.anthracis will be cloned into laboratory strains of E.coli (lambda pir strains such as Escherichia coli cc 118 pir, or equivalent), prior to deletion or insertion mutagenesis. These modified genes will be introduced back to B.anthracis. Alternatively transposons harboured on suicide plasmids will be used to randomly mutate the genome (Ivins B et al Infect. Immun. Vol 56 (1) 1988 pp 176-191).

**Origin & function**

Genes from B. anthracis will be mutated such that gene function is lost to obtain a measurable phenotype.

**Evaluation of foreseeable effects**

The inactivation of key metabolic enzymes regulatory proteins or virulence determinants, should result in reduced virulence of B. anthracis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

B. anthracis is an ACDP level III bacterium. Fully virulent strains can cause disease in humans which if untreated may be fatal. Particular risk is associated with inhalational disease which is difficult to treat and fatal if treatment is delayed. We aim to use plasmid cured strains which have reduced virulence at ACGM II. All genetic manipulation will occur in this background.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair. Date of Significant Change

Project Additional Information

Purposes of the contained use

Listeriolysin is a cholesterol requiring cytolsin produced by Listeria monocytogenes. During Listeria infection LLO allows bacteria to escape from the phagolysosome.
Listeriolysin is a phagosome specific cytolsin which has a pronounced acidic pH optimum (Glomski et al., 2002). It also contains a PEST-like sequence which targets it for phosphorylation and/or degradation in the host cytosol (Decatur & Portnoy, 2000).
The gene encoding LLO from L. monocytogenes will be cloned, in frame, downstream of a strong promoter such as T7/tac or equivalent, so as to allow expression as a fusion protein in E.coli. The Llo gene will be expressed in E. coli and the resulting protein will be purified by column chromatography.
This protein will form a key component of the intracellular delivery project which is aimed at generating appropriate immune responses to vaccine subunits.

Recipient or parental organism

E. coli K-12 derivatives such as TOP10F'/DH5α or equivalent
E. coli B strain BL21 (and DE3 component are lysogens) of the bacteriophage DE3 and carry a chromosomal fragment containing the lacI gene, the lacUV5 promoter and the gene for T7 RNA polymerase. The pLysS plasmid encodes the T7 lusozyme used for stringent control of T7 RNA polymerase expression in DE3 host strains.
Commercially available expression vectors will be used (e.g. pGEX vectors (Amersham Biosciences) or equivalent). Vectors have a pUC/pBR322 origin of replication or equivalent, and a strong promoter induced via IPTG for expression. Plasmid encoded antibiotic resistance is to ampicillin. Genes cloned downstream of the strong promoter are expressed as GST/histidine fusion proteins. Vectors allow expression of fusion proteins with fusions at either the N or C terminus.

Host/vector system

E. coli K-12 derivatives such as TOP10F'/DH5α or equivalent
E. coli B strain BL21 (and DE3 component are lysogens) of the bacteriophage DE3 and carry a chromosomal fragment containing the lacI gene, the lacUV5 promoter and the gene for T7 RNA polymerase. The pLysS plasmid encodes the T7 lusozyme used for stringent control of T7 RNA polymerase expression in DE3 host strains.
Commercially available expression vectors will be used (e.g. pGEX vectors (Amersham Biosciences) or equivalent). Vectors have a pUC/pBR322 origin of replication or equivalent, and a strong promoter induced via IPTG for expression. Plasmid encoded antibiotic resistance is to ampicillin. Genes cloned downstream of the strong promoter are expressed as GST/histidine fusion proteins. Vectors allow expression of fusion proteins with fusions at either the N or C terminus.

Origin & function

LLO gene from L. monocytogenes

Evaluation of foreseeable effects

The DNA will be expressed under the control of an IPTG inducible promoter. However it is unlikely that the structural genes will be expressed to any significant level in the host without the addition of IPTG to induce gene expression.

Project Ref 202/04.2

Date Ackn'd CU2 Project Title Class CultureVol Class2 CultureVolumeClass3-4
03/11/2004 The genetic modification of Burkholder thailandensis, expression of recombinant Class 2 1-50 Litres
We aim to utilise Burkholderia thailandensis as a genetic model to allow identification of gene functions by mutational analysis. B. thailandensis is a non-pathogenic soil saphrophyte which occurs naturally in the environment and is isolated widely from soil and water in North-Eastern Thailand (Brett et al., 1997, Wuthiekanun et al., 1996, Sonthayanon et al., 2002). B. thailandensis is genetically similar to B. pseudomallei and B. mallei but lacks at least one pathogenicity island that is present in those species. B. thailandensis has a similar biochemical profile to B. pseudomallei but can be distinguished by substrate utilisation particularly L-arabinose assimilation. B. thailandensis strains can assimilate L-arabinose, are avirulent in experimental animals and are only found in the environment. All clinical isolates collected have been B. pseudomallei with one exception which is thought to have occurred by direct inoculation of a large amount of environment debris.

Target genes isolated from B. thailandensis will be cloned into laboratory strains of E. coli (lambda pir strains such as Escherichia coli cc118 pir, or equivalent), prior to deletion or insertion mutagenesis. Modified genes will be introduced back into B. thailandensis. Alternatively transposons harboured on suicide plasmids will be used to randomly mutate the genome. Suitability of plasmid DNA is limited by the use of appropriate selective markers. Those suitable for use with the organism are kanamycin, chloramphenicol and tetracycline. Non-antibiotic resistance markers might also be used (e.g. Sucrose sensitivity). Complementation of inactivated genes with DNA derived from the parent strain will be carried out.

In addition recombinant production of putative vaccine antigens will be carried out using suitable expression systems (E.g. pTRC99A).

Genes from B. thailandensis will be mutated such that gene function is lost to obtain a measurable phenotype. Function will be verified by complementation.

Genes amplified by PCR will be utilised in E. coli expression systems to produce recombinant vaccine antigens.

The inactivation of key metabolic enzymes, regulatory proteins or virulence determinants, should result in measurable phenotypes. Recombinant production of vaccine antigens will result in products for use as potential vaccine components.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

B. thailandensis and any resulting GMMs will be handled under ACDP/ACGM level II containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair. Whenever possible, contaminated items will bw autoclaved by validated means. Discard autoclaves will be checked at least annually by the use of recorded thermocouples. Autoclaved waste materials are then incinerated. When autoclaving cannot be used, because for example the nature of the material is heat sensitive or items are required for re-use, or complex laboratory equipment requires servicing, chemical disinfection will be used. When chemical disinfectant is used, it is important that all surfaces come into contact with the chemical. Because different approved disinfectants and procedures will be used. Where large items of equipment need to be decontaminated, this can be carried out by fumigation with formaldehyde vapour. Sodium hypochlorite based disinfectants ("Chloros") Hypochlorite solutions at these concentrations will be used:

- Surface disinfection: 1000 ppm

Project Ref 202/06.2

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Construction of gene knock-out mutants of Burkholderia cepacia complex bacteria by insertion of fluorescent reporters for use in investigations of natural genetic transformation events.

**Recipient or parental organism**

- E. coli JM109 (Promega)
- Burkholderia cepacia ATCC 25416, 17759, 9091, C2970, C3159, C1963, LMG C1964
- Burkholderia cenocepacia LMG 18863, LMG J2956, C1394 J415, C2836,
- Burkholderia multivorans LMG 13010, ATCC 17616, 7897, 7732
- Burkholderia stabilis LMG 14294, LMG 14086, 7639, 8088, 300, ERL 347, LMG 3172, LMG 3173, J1743, J493
- Burkholderia vietnamiensis LMG 10929, LMG 18836, 159, 638, 549, LMG C3175, ERL 126, C1704, J2963, C2978

All members of the Burkholderia cepacia complex have been implicated in infection of Cystic Fibrosis patients. However, B. multivorans (genomovar II) and B. cenocepacia (genomovar III) predominate. These organisms are not a major cause of disease in healthy individuals. B. cepacia was first isolated as the causative agent of soft rot in onions.

**Host/vector system**

- Vectors to be employed:
  - pTurboGFP-B: Commercially available prokaryotic expression vector from Cambridge Biosciences. Encodes Green Fluorescent Protein and ampicillin resistance. GFP is under the control of a T5 promoter/lac operator. Will be used as a source of GFP coding DNA.
  - pBR322: Commercially available vector. Encodes ampicillin and tetracycline resistance.
pJQ200: Suicide vector available from LGC. Only replicates in members of the enterobacteriacea. Encodes sacB and gentamicin resistance.

Hosts:
E. coli JM109 and members of the Burkholderia cepacia complex listed above (the latter will only be transformed with pJQ200). Stable plasmid inheritance in Burkholderia cepacia complex is not the desired outcome of these experiments.

Origin & function
Green Flourescent Protein under control of T5 promoter/lac operator and Fire-fly Luciferase under control of trp-lac fusion promoter. This genetic material will be used to create gene knock-out cassettes targeting oprC and zmpA of the Burkholderia cepacia complex.

Evaluation of foreseeable effects
Maximising expression of these flourescent reporters in Burkholderia cepacia complex will not be undertaken. The desired outcome is the knock-out of oprC, which codes for an antibiotic efflux pump protein and zmpA which codes for a protease in members of the Burkholderia cepacia complex. The oprC knock-out will result in an increased sensitivity to chloramphenicol and ciprofloxacin. The zmpA knock-out will result in reduced protease activity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair. Whenever possible, contaminated items will be autoclaved. Discard autoclaves operate at a minimum of 134C for 30 mins, (chart recorded every load) which must be checked at least annually by the use of recorded thermocouples. Autoclaved waste materials are then incinerated. When autoclaving cannot be used, because for example the nature of the material is heat sensitive or items are required for re-use, or complex laboratory requires servicing, chemical disinfection will be used. When chemical disinfection is used, it is important that all surfaces come into contact with the chemical. Because different chemical disinfectants have different ranges of micro-organisms against which they are effective, only (Site) approved disinfectants and procedures will be used. Where large items of equipment need to be decontaminated, this can be carried out by fumigation with formaldehyde vapour. Sodium hypochlorite based disinfectants ("Chloros") are effective against Burkholderia spp and E.coli spp and will be used for surface decontamination of items being transported between the microbiological cabinet and incubator / fridge. Hypochlorite solutions will be used to decontaminate small items used in the cabinet.

Hypochlorite solutions at these concentrations will be used:
Surface disinfection 1000 ppm
Discard jars 2,500 ppm (for a contact time of several hours / overnight)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
The Site GMSC accepted the risk assessment submitted to it, subject to acceptance by the HSE.

## Project Additional Information

**Purposes of the contained use**

Generation of Francisella tularensis subspecies holarctica Live Vaccine Strain (LVS) isogenic mutants: LVS genes including those encoding metabolic enzymes, regulatory
genes, virulence determinants, surface antigens, protein export systems, post-translational modification systems and genes involved in survival will be inactivated by mutation. Mutated genes will be introduced into LVS by electroporation or other suitable DNA delivery methods.

Generation of transposon mutants of LVS: LVS will be transformed with transposons such as Tn5, Tn7 or Himar1 and their modified derivatives, by electroporation or other suitable DNA delivery methods. Transposon mutants will be selected by phenotype.

Confirmation of essential genes: genes predicted to be essential for growth will be assessed by modified isogenic mutagenesis approaches, such as complementation with a second copy of the gene prior to inactivation, or placing the target gene under the control of a heterologous promoter allowing repression or induction of expression.

Altered expression of genes: genes may be constitutively expressed or over-expressed to induce attenuation as a result of deregulation of expression or attenuation as a result of a phenotype detrimental to bacterial survival. Only genes where aberrant expression is predicted to be attenuating will be expressed in this way. Classical virulence facotrs will be excluded.

Some attenuated mutants will also have coding regions from antigens known to increase protectivity in other organisms introduced into them prior to being assessed as potential vaccines.

Pseudogenes in LVS, but intact in fully virulent subspecies tularensis and holarctica strains, predicted to be anti-virulence loci may be restored to assess the impact on virulence.

Site directed mutagenesis of the organism may be generated to characterise selected genes of interest.

Mutants will be characterised in vitro and in vivo. Suitable in vivo models may include mammals, such as mice, or alternative lower order species such as Galleria.

Recombinant LVS, both wild type and mutants, expressing proteins such as GFP or luciferase, will be generated. This will facilitate procedures such as confocal microscopy of infected cells and whole body in vivo imaging of infection. Other recombinants expressing tagged proteins (e.g. FLAG_tags, His-tags) will allow the purification of selected fusion proteins, for example to investigate post-translational modifications or protein-protein interactions.

Complementation of mutants: Mutants which have at least one gene disrupted may be complemented. Reintroduction of the gene or genes mutated on a plasmid will allow check for complementation of any missing phenotype that occurred upon deletion. The purpose of this will be to prove that any phenotype found as a result of the deletion is due to the gene(s). Complementation of mutants has been reported using a stable plasmid and cognate promoter or heterologous promoters, but new tools may need to be developed for this organism.

Specialist equipment (particularly equipment invovled in intravital imaging) may be housed at containment level 3 and require use of wild type or mutant LVS at containment level 3. In this incidence, strains will remain within containment level 3 and may only be removed, to a lower containment level facility, if inactivated by an appropriate method (e.g. formalin fixation or heat-killing) and sterility checked.

**Recipient or parental organism**

Francisella tularensis subsp. Holarctica live vaccine strain (LVS)

Escherichia coli (lab strains such as K12 or B derivatives)

**Host/vector system**

Vectors suitable for use with LVS have been reported and will form the basis of tools to manipulate the organism. Mutational studies will utilise suicide vectors such as pSMP75, pMP590 and pDM4. These vectors typically include a multiple cloning site, origin of replication, transfer genes and a selective marker but are unable to replicate
in LVS. Some suicide plasmids may contain transposons which are capable of random insertion into the LVS genome (e.g. Tn5 carried out on pUTminiTn5Km2). Recombinant expression of proteins may be achieved by chromosomal integration or on plasmids which are able to replicate within LVS. These vectors may include pKK202, pEDL, pCT, pFNLT and pFNLT10 based plasmids. Some have a strong promoter upstream of the multiple cloning sites to allow expression of the cloned genes. Additionally some plasmids such as may include protein purification tags such as glutathione-s-transferase, FLAG and 6xHis. Other vectors may be developed for use with LVS after approval by the local GMSC.

Complementation or expression plasmids used would likely be similar to or part of the pFNLT10 or pFNLT plasmid series (derived from pTOPO/FNL10). Plasmids would be maintained in the cell using an antibiotic resistance gene e.g. chloramphenicol or kanamycin. The gene(s) being investigated would be under the control of an inducible or native promoter.

Selection of recombinant strains will typically be done using antibiotics such as kanamycin, chloramphenicol, tetracycline and ampicillin. Plasmids contain up to two antibiotic resistance genes. Combinations of antibiotics that are recommended for treatment of tularemia will not be used (specifically not tetracycline in combination with chloramphenicol). Alternative selective markers such as sucrose selection or lethal genes (e.g. DNA gyrase) may be used where conventional selection is not appropriate.

Genes will be amplified by PCR from LVS genomic DNA before cloning into appropriate vectors. This genetic material will be used to create mutagenesis or complementation constructs. Expression constructs may be expressed in recombinant E. coli for protein purification.

Heterologous genetic material from other organisms will include labels e.g. GFP, luciferase, and tags e.g. FLAG tags.

Genes of interest will include metabolic enzymes, regulatory proteins, virulence determinants and genes involved in environmental survival.

Evaluation of foreseeable effects

Each genetic modification procedure is individually assessed by the site GMSC. The predicted effect on virulence will be challenged to ensure that, as far as is reasonably practicable, there is not expected to be a rise in virulence compared to that of wild-type LVS. Similarly each genetic modification is assessed by the site GMSC to ensure that there is not expected to be an increase in environmental survival or impact on the environment of the genetically modified strain compared to the wild-type.

In general, it is considered highly unlikely that the inactivation of any given gene will result in an increase in virulence or any alteration to environmental impact. Indeed, it is likely that inactivation of genes will result in strains less able to harm humans, animals or the environment. Production of recombinant proteins in LVS for the purposes of complementation is considered to be highly unlikely to result in an increase in virulence or environmental impact beyond restoration to wild-type levels. Similarly, production of recombinant proteins for the purposes of vaccine production is unlikely to result in any increase in virulence or environmental impact due to the nature of the proteins being produced. As mentioned above, each genetic modification is assessed by the GMSC to ensure that this is the case.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair.

Whenever possible, contaminated items will be autoclaved. Discard autoclaves operate at a minimum of 134°C for 30 mins, (chart recorded every load) which will be
validated at least annually by the use of 12 point recorded thermocouples. Autoclaved waste materials are then incinerated. When autoclaving cannot be used, because for example the nature of the material is heat sensitive or items are required for re-use, or complex laboratory equipment requires servicing, chemical disinfection will be used.

When chemical disinfection is used, it is important that all surfaces come into contact with the chemical. Project Ref 202/13.2

Date Ackn'd 19/08/2013  CU2 Project Title Generation of mutants of ACDP level 2 alphaviruses

Class CultureVol Class 2 CultureVolumeClass 3-4

Class 2 < 1 Litre

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Project Additional Information

**Purposes of the contained use**

The aim of this work is to generate mutants of ACDP hazard group 2 alphaviruses including Semliki Forest virus (SFV) and Sindbis virus (SIN). Mutants may be generated using either the whole virus or cDNA copies of the viral genome. Mutants generated using plasmids encoding cDNA copies of the genome will be maintained in laboratory strains of E. coli. Virus will be produced from the cDNA genome by linearising the plasmid (by incubation with a compatible restriction enzyme) and reacting with T7 RNA polymerase. The RNA genome will be transfected into eukaryotic cells (by electroporation or commercially available chemical transfection reagents).

**Generation of mutants**

Generation of ACDP hazard group 2 alphavirus isogenic mutants: viral genes including those encoding structural proteins as well as enzymes, regulatory genes and virulence determinants will be inactivated by mutation (either site-directed or random mutagenesis).

Altered expression of genes: genes may be constitutively expressed or over-expressed to induce attenuation as a result of deregulation of expression or attenuation as a result of a phenotype detrimental to viral survival or replication. Only genes where aberrant expression is predicted to be attenuating will be expressed in this way. Classical virulence factors will be excluded.

Mutants will be characterised in vitro and in vivo. Suitable in vivo models may include mammals, such as mice, or alternative lower order species such as Galleria mellonella.

**Complementation of mutants**

Complementation of mutants: Mutants which have at least one gene disrupted may be complemented. Reintroduction of the gene or genes mutated on a plasmid will allow checks for complementation of any missing phenotype that occurred upon deletion. The purpose of this will be to prove that any phenotype found as a result of the deletion is due to the gene(s) deleted and not to polar effects on other genes and will also provide further insights as to the role of the gene(s).

**Expressing foreign genes**

Recombinant alphaviruses, both wild type and mutants, expressing fluorescent or bioluminescent proteins such as GFP or luciferase, will be generated. This will facilitate...
procedures such as confocal microscopy of infected cells and whole body in vivo imaging infection. Other recombinants expressing tagged proteins (e.g. FLAG-tags, His-tags) will allow the purification of selected fusion proteins, for example to investigate post-translational modifications or protein-protein interactions.

Specialist equipment (particularly equipment involved in intravital imaging) may be housed at containment level 3 and require use of wild type or mutant (hazard group or GM class) alphaviruses at containment level 3. In this incidence, strains will remain within containment level 3 and may only be removed, to a lower containment level facility, if inactivated by an appropriate method (e.g. formalin fixation or heat-killing) and sterility checked. If equipment for intravital imaging becomes available at containment level 2 work will be conducted within this facility.

Recipient or parental organism

ACDP group 2 alphaviruses including Sindbis and Semliki Forest Virus

Eserchhia coli (lab strains such as K12 or B derivatives).

Host/vector system

Plasmids suitable for use with SFV and SIN have been reported and will form the basis of tools to manipulate the viruses. Plasmids encoding cDNA genomes of SFV or SIN will be cloned into laboratory strains of E. coli prior to mutagenesis. Mutated plasmids will then be used to create genetically modified SFV or SIN. The vectors described for SFV and SIN are derived from pBR322-based vector and consist of the complete genomic sequence for the virus represented as cDNA and a unique restriction site for the linearisation of the plasmid prior to in vitro transcription of infectious genomic RNA replicas. Other vectors may be developed for use with either SFV or SIN after approval by the local GMSC.

Plasmids to be used in studies with SFV may include; pVA7, pSFV4 and pCMV-SFV4. In pCMV-SFV4 the SFV infection clone DNA (icDNA) is under the control of the CMV promoter. Plasmids to be used in studies with SIN may include; pTR339, pToto series and pTRSB which encode a full-length icDNA of SIN. SIN and SFV cDNA encodes non-structural genes (nsp1, nsp2, nsp3 and nsp4) and structural genes (capsid protein C, envelope proteins; E3, E2, E1 and 6K peptide). SFV and SIN non-structural and structural genes encode whole virus. Non-structural genes encode for proteins involved in RNA genome replication and structural genes encode for proteins that package the genome in a viral particle.

Selection of recombinant strains will typically be done using antibiotics. The plasmids described above confer resistance to ampicillin. Other vectors may be developed which confer resistance to other antibiotics after approval by the local GMSC.

Origin & function

Plasmids encoding cDNA genomes of SFV or SIN will be cloned into laboratory strains of E. coli prior to mutagenesis. This genetic material will be used to create mutagenesis or complementation constructs. Expression constructs may be expressed in recombinant E. coli for protein purification.

Heterologous genetic material from other organisms will include labels e.g. GFP, luciferase, and tags e.g. FLAG tags.

Genes of interest will include structural proteins, regulatory proteins and virulence determinants.

Evaluation of foreseeable effects

Each genetic modification procedure is individually assessed by the site GMSC. The predicted effect on virulence will be challenged to ensure that, as far as is reasonably practicable, there is not an expected increase in virulence compared to that of wild-type SFV and SIN. Similarly each genetic modification is assessed by the site GMSC to ensure that there is not an expected increase in environmental survival and are, therefore, determined to be a class 3 activity, the work will either (i) not be carried out or (ii) a significant change will be submitted. No work (with the proposed genetic modification) will be conducted until the significant change has been accepted.

Introduction of mutations (including silent mutations) into the SFV or SIN genome may have no effect or they may increase or decrease infectivity and pathogenicity due to preferred codon usage of the host. However, the aim of this work is not to purposefully derive SFV or SIN with increased pathogenicity or infectivity. For this reason, silent mutations (that change the nucleotide sequence and not the protein sequence) will be chosen that do not increase the level of codon optimisation for mammalian cells.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Lentiviral vectors will be used in vitro to mimic the entry of a range of hazardous viruses in a high-throughput manner. This will allow assessment of virus tropism as well as medical countermeasure screening.

Production of pseudotyped lentiviral vectors (Class 1 and Class 2 activities)

Production of second-generation, lentiviral vectors will be carried out by co-transfection of mammalian cells with three separate plasmids (Class 2 activity). These plasmids will be stored and propagated within standard laboratory E. coli cells (Class 1 activity). These plasmids encode a mini-genome (encoding a reporter gene), the HIV-1 structural and replication enzymes, and the donor glycoprotein respectively.

Use of pseudotyped lentiviral vectors (Class 2 activity before removal of virus, Class 1 after)

A range of mammalian cells will be transduced with the vector and then integration and expression of the reporter gene measured. As the hazard is posed by the input lentivirus vector, after removal of residual input lentivirus vector the transduced mammalian cells will be considered Class 1.
Recipient or parental organism

- Lentiviral vectors - based on HIV-1
- E. coli cells
- Mammalian cells

Host/vector system

- The mini-genome, HIV-1 structural and replication enzymes, and donor glycoprotein will be cloned into standard cloning plasmids, such as those based on pcDNA3.1 (driven by a CMV promoter) or a pUC19. These plasmids will contain either an ampicillin or kanamycin resistance marker.

Origin & function

- All genetic material will be synthesised de novo by commercial companies, obtained from collaborators, or cloned form pre-existing constructs.

- pCSFLW or equivalent: plasmid that produces the vector minigenome. The mini-genome consists of the HIV-1 LTR (with a deletion in the U3 region), the HIV-1 packaging signal and a reporter gene (such as GFP/luciferase) that is under control of an internal constitutive promoter (such as but not limited to the SFFV promoter). This mini-genome production is under control of the 5’ LTR of the vector minigenome. Function - provide mini-genome to be incorporated into lentivirus vector;

- pCMVΔR8.9 or equivalent: plasmid expresses the GAG and POL polyproteins under control of the CMV promoter; contains an ampicillin resistance gene. Function - provide HIV-1 structural proteins to form the capsid of the lentivirus vector;

- pCMV-ENV-X or equivalent: plasmid expresses the glycoprotein of choice (X) under control of the CMV promoter; contains either a kanamycin or ampicillin resistance gene. Function - provide the donor glycoprotein to pseudotype the vector.

Evaluation of foreseeable effects

- Genetic material in E. coli cells:
  None - presence of plasmids in bacterial cells will not result in transgene expression due to lack of bacterial promoters. Therefore no HIV, reporter or pseudotyping proteins are produced. In addition, all E. coli are laboratory strains which have multiple auxotrophic markers and are unlikely to survive in the environment; presence of the genetic material would create a metabolic burden.

- Genetic material in mammalian cells:
  Presence of all three plasmids will result in production of replication-deficient lentiviral pseudoviruses. Generation of a replication competent virus (RCV) would require multiple highly specific recombination events between three plasmids that do not contain homologous retroviral sequences, including repair of the deletion in the 3’ LTR. The risk of this is effectively zero. Mammalian cells cannot survive in the environment as they require a nutrient-rich growth medium, an optimal temperature and a narrow pH range. They are also susceptible to drying and UV exposure.

- Pseudovirus:
  Presence of pseudotyped glycoprotein would allow the pseudovirus to enter any cell that the glycoprotein donor virus would be able to infect. Whilst the pseudovirus is replication-deficient and the transgene is considered non-harmful, integration of the pseudovirus’ minigenome into the recipient mammalian cell genome has the potential to disrupt host genes or disregulate the expression of host genes. Retroviruses are enveloped viruses that are highly susceptible to dehydration and are rapidly inactivated outside the host. The pseudotyped glycoprotein could allow infection of an animal species if the glycoprotein was able to bind to the appropriate receptors, however the pseudovirus is completely replication deficient and any infection would be a dead-end event.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All specimens, cultures of micro-organisms, materials and equipment used in the microbiology laboratory and protective clothing worn in the laboratory will be rendered free from contamination before re-use, discarding or repair.

For ACGM class 1 and 2 activities, material will be inactivated with disinfectants such as sodium hypochlorite (10,000 ppm, disinfection upon contact), virkon (5%, disinfection upon contact) or ethanol (70%, 30 minutes contact time) before being autoclaved.

Where large items of equipment need to be decontaminated, disinfection will be carried out by fumigation with a suitable, validated disinfectant vapour (e.g. formaldehyde, VHP).

Make-safe autoclave cycles operate at a minimum of 134°C for 30 minutes, (chart recorded every load) which are validated 6 monthly by the use of 12 point recorded thermocouples. Autoclave cycle print outs are verified by staff before waste is removed from the autoclave. Autoclaved waste materials are then incinerated on-site.

CU2 Project Title STUDIES ON INFLUENZA A HAEMAGGLUTININ (HA) AND MATRIX (M) PROTEINS

Class Culture Vol

Class 2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

The work is designed to increase our understanding of the effects of variant influenza A proteins on virus growth and human immunity. Some of the GMMs may also be used to develop diagnostic tests.

**Recipient or parental organism**

The influenza A proteins will be expressed either after transfection into MDCK/Vero cells or other mammalian cells, or incorporated into recombinant influenza A virus and used to infect mammalian cell lines. The transfected cells will not pose any foreseeable environmental or human health hazard. The recombinant viruses will have pathogenicity equal to that of laboratory strains handled under ACDP 2 conditions.

**Host/vector system**

The host system used to manipulate the influenza A sequences will be the E.coli strain TOP10. The vector will be one of the non-mobilisable vectors pc DNA3 or p Pol Isap I Rib (based on PUC18). Additional plasmids will be transfected into mammalian cells pHMG-NP, pHMG-PB1, pHMG-PB2, pHMG-PA which carry genes for NP, PB1, PB2 and PA proteins, under the control of the route HMG (Hydroxymethylglutory1 - coenzyme A conductase) promoter.

**Origin & function**

The genetic material to be cloned will be from human and avian influenza A isolates grown in mammalian tissue culture or eggs. Both the HA and M protein genes will be cloned in separate experiments. The M gene constructs will be used to produce a recombinant virus containing the amantadine resistance associated M gene in a helper virus background. The growth characteristics of the recombinant virus will be studied. The HA gene constructs will be used primarily to produce HA containing cell lines. HA expressing mammalian cells will be used for development of an assay for the detection of antibody to avian HA.

**Evaluation of foreseeable effects**

The GMOs are:
1. E.coli host strains carrying HA or M genes for influenza A. These organisms can be handled safely under category 1 conditions. There are no foreseeable effects.
2. Mammalian cell lines carrying and expressing influenza A genes. These cell lines can be handled safely under category 1 conditions. There are no foreseeable affects.
3. Recombinant influenza virus strains with M genes from parental amantadine resistant virus. These virus constructs can be handled safely under category 2 conditions which are equivalent to those used to handle the parental virus. All laboratory workers involved are vaccinated against influenza and monitored by swabbing in the event of a flu like illness. The recombinant virus would be equivalent to current laboratory strains in virulence.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Autoclaving to kill (100%) of all discarded cultures and contaminated materials.
Level 2 was considered by the Committee to be appropriate for the work proposed. The Committee was concerned about the nature of the recombinant viruses. On consideration it was decided that they would be equivalent to laboratory strains that carry an amantadine resistance conferring gene. Such strains do not pose a significantly greater risk than amantadine sensitive strains, and do occur in nature spontaneously.

## Project Additional Information

### Purposes of the contained use

The work is designed to increase our understanding of the genes responsible for antibiotic resistance in bacterial pathogens. Some of the genes characterised in these studies may be used to develop reference tests to enable screening and epidemiological studies. Under this programme, we will also study genes involved in DNA mismatch repair, which potentially play a role in the emergence of mutational antibiotic resistance.

### Recipient or parental organism

In these experiments, (i) genes associated with antibiotic resistance will be cloned into antibiotic-susceptible, laboratory-adapted strains of the bacterial genera under investigation, or (kii) gene fragments will be used to ‘knockout’ genes of interest, including DNA mismatch repair genes, from clinical isolates of these genera.

The final GMOs will be considered to have pathogenicity equal to that of the original clinical isolates handled under ACDP 2 conditions. They do not pose any foreseeable environmental or human health hazard; the constructs will be less antibiotic resistant than many current clinical isolates.

### Host/vector system

1. pSUP, pKNOCK and pG+host suicide vectors with E. coli hosts, DH5α, pir, S17-1 pir, S17-1 pir, VE7108 for the site-directed inactivation of genes contributing to antibiotic resistance, or involved in DNA mismatch repair.
2. pBC SK+ for shotgun cloning of Acinetobacter DNA into laboratory-adapted Acinetobacter calcoaceticus strain TRP E27
3. Ready-to-use EZ::TN Transposomes (Epicentre) for random mutagenesis of clinical isolates of Acinetobacter
4. The pAT18/19/28 series of vectors for cloning and transfer of eg recA in enterococci.

### Origin & function

The material to be cloned will be derived from clinical bacterial isolates. This DNA will be ligated into appropriate vectors (see above and attached proposals), and will either be transformed directly into clinical isolates of interest, or, in the case of the directed ‘knockout’ studies, will be cloned and manipulated initially in E. coli strains (as detailed in the attached proposals), before being introduced into the clinical isolates of interest.

The characteristics of the final GMO (derived from the clinical isolate) will be investigated to determine the contribution of the cloned gene to the antibiotic resistance phenotype of the strain.

### Evaluation of foreseeable effects

E. coli host strains with the cloned genes/gene fragments. These organisms can be safely handled under category 1 conditions. There are no foreseeable effects.

Recombinant Acinetobacter clinical isolates carrying cloned genes associated with antibiotic resistance, or fragments thereof. These constructs can be safely handled under category 2 conditions, which are equivalent to those used to handle the parental clinical isolate. All laboratory workers are trained in the manipulation of potentially pathogenic bacteria. The virulence of the recombinant strains is considered to be equivalent to, or lower than, that of the parental clinical isolate.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Autoclaving to kill (100%) of all discarded cultures and contaminated materials.

Agreed that local GMSC will be consulted and new risk assessments completed should this work extend to genera other than Acinetobacter and Enterococcus.

Committee discussed the resulting GMs, but could see no reason why they should be more pathogenic than the original host isolates.

Discussed the possibility that Tn-mutagenesis in Acinetobacter could result in resistance genes on cassettes. As many resistance genes occur as cassettes in integrons in gram-negative species, this was not thought to pose greater risk than clinical isolates.

<td>Study of cellular response to measles virus with SSPE derived genes</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td>Non-GMM</td>
<td>Not Applicable</td>
<td></td>
</tr>
</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

This work is designed to increase our understanding of measles virus (MV) characteristics in the persistent MV infection, subacute sclerosing panencephalitis (SSPE). Comparing host cell responses to wild type and SSPE derived measles viruses may provide clues how MV can evade the host defence systems and the mechanism of SSPE. This knowledge may lead to possible treatments of the infection and prevention of SSPE.

**Recipient or parental organism**

- Cloning of PCR amplified measles virus (MV) genes M and F from acute and subacute sclerosing panencephalitis (SSPE) clinical samples into pCR 2.1-TOPO and/or pGEM T-Easy vectors systems.
- Addition of FLAG tag at the 5’-end of cloned gene by site directed mutagenesis.
- Transfer of gene fragment from the cloning vector into p(+)MV (a pBluescript KS(+) vector containing the entire MV anti-genome (Radecke F. et al, 1995, EMBO 14(23), p5773)) to replace the original gene.
- Co-transfection of 293-3-46 mammalian cells (293 human embryonic kidney cell line stably expressing MV N and P proteins and T7 RNA polymerase) with p(+)MV and a pTM1 including MV L gene.
- Rescue of viable virus expressing the gene isolated from clinical material.
- Comparison of biological activities of original and mutated viruses in cell culture.

**Host/vector system**

Vectors/host: The chemically competent host E. coli TOP10 (F mcrA (mrr - hsdRMS - mcrBC) 80 lacZ M15 lacX75 recA1 and deoR araD139 (ara - leu) 7697 ga/U ga/K rpsL (Str) endA1 nupG) is a disabled commercial strain, developed for safe convenient cloning. This strain carries a very low hazard due to its low potential to colonise animal/human hosts and its poor ability to survive outside the laboratory.

Plasmid pCR 2.1-TOPO (Invitrogen): a construct containing colE1 ori, f1 ori, kanamycin resistance, ampicillin resistance, lacZ, T7 promoter cloning site. It is a mobilisation defective product developed for safe cloning.

pGEM-T Easy (Promega): pUC ori, f1 ori, lacZ, ampicillin resistance.

P(+)MV: pBluescript KS(+) (Stratagene) containing MV anti-genome under T7 promoter control, pUC ori, f1 ori, lacZ, ampicillin resistance.

PEMC-La: pTM1 (Moss et al, 1990, Nature 348, p91) containing MV L polymerase gene controlled by the encephalomyocarditis virus internal ribosome entry site, pUC ori, f1 ori, ampicillin resistance.

**Origin & function**

The material to be cloned will be derived from clinical samples. This DNA will be amplified by PCR and cloned into an appropriate vector (see above). These genes will then be integrated in a MV reverse genetics rescue system to rescue whole virus.
The characteristics of the final GMO will be investigated to determine the contribution of the cloned gene on host cell response to the virus.

**Evaluation of foreseeable effects**

The host/vector system utilises E. coli and the plasmids pCR 2.1, pGEM, p(+)MV. The host is disabled and the vectors are non-mobilisable. No measles protein should be expressed in this procedure. This suggests that the containment level for working with host/vector should be ACGM 1.

Unmodified MV is a Hazard Group 2 pathogen for humans. SSPE derived tissues are handled in a class II microbiological cabinet in a level 2 laboratory. The modified virus is expected to behave like SS:PE derived virus and should therefore be handled under similar safety containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Autoclaving to kill (100%) of all discarded cultures and contaminated materials. The autoclaves are validated and have thermocouple tests on every run.

**Project Ref** 203/16.1
A Human Immunodeficiency Virus (HIV) retroviral vector system has been adapted to allow the cloning and study of viral genes from HIV-1.

### Project Additional Information

**Purposes of the contained use**

To generate recombinant HIV-1 pseudoviruses for use in the phenotypic and genotypic characterization of viral genes from HIV-1. Study areas include, but are not limited to, investigation of drug resistance and viral replication fitness. Additionally, the pseudoviruses will also be used as reference material for the evaluation and validation of next generation nucleotide sequencing assays.

**Recipient or parental organism**

Lentivirus parental organism: Human Immunodeficiency virus-1 (HIV-1), classified as ACDP hazard group 3. HIV-1 genes of interest or parts thereof will be derived from laboratory-adapted viruses, molecular clones or clinical samples. Plasmids are maintained in K12-derived multiply-disabled E.coli strains HB101, TOP10F, STBL and DH5a. All these strains have multiple functiona l deletions which minimise recombination events (eg. recA1) and render them auxotrophic and unable to survive in the environment (eg. LeuB, ara14, proA2, etc.). The absence of frameshifting, splicing and glycosylation machinery in these bacterial hosts coupled with the absence of prokaryotic promoter sequences in the plasmids precludes expression of HIV-1 proteins. Well-characterised HG1 human cell lines including SupT1, H9, MT2, MT4, and 293T.

**Host/vector system**

The system is based on retroviral vectors developed for gene therapy in humans, where safety is paramount, and physically separates the genetic elements of HIV over two or more expression vectors. This minimises homologous sequences and introduces gene inactivation mutations to decrease the chances for recombination. The pseudoviruses produced are replication incompetent and only capable of a single infectious event. Multiple recombination events between non-homologous regions and/or multiple mutation events would have to occur to create a replication competent virus which is considered to be impossible.
Co-transfection of two or three plasmids provides HIV-1 proteins in trans. The genomic packaging signal is present on RNA transcripts with a combination of a reporter gene and variable fractions of a deleted HIV-1 genome (often highly deleted). HIV-1 surface glycoprotein is not present in pseudovirus virion particles, due to replacement by that of vesicular stomatitis virus (VSV-G).

Plasmids used in this study are detailed below. The two-plasmid system uses plasmids 2 and 4, whereas the three-plasmid system uses plasmids 1-3:

1. p8.91 or p8.9NSX (and derivatives of) encoding HIV-1 Gag-POL, Tat and Rev but with virulence genes vif, vpu and nef deleted, as well as truncation of env (on ly the regions needed for the tat and rev genes are maintained).
2. pMDG encoding the vesicular stomatitis virus glycoprotein (VSV-G) as an envelope protein. For the study of HIV-1 entry and co-receptor usage, the HIV-1 env is expressed from an appropriate plasmid in place of VSV-G.
3. The HIV-1 packaging signal is provided on an RNA that also contains a reporter gene under the control of the SFFV promoter and HIV-1 Long Terminal Repeat regions. This RNA is transcribed from one of the following closely related plasmids: pHR-SIN-CSGW (encoding GFP), pCSGW-YFP (encoding YFP), or pCSFLW (encoding firefly luciferase).
4. pNluc or pHl(WT] and derivatives encoding all HIV-1 proteins except for the virulence factor Nef and receptorbinding Env. In the former, Nef has been replaced by the firefly luciferase reporter gene.

The plasmids are transfected into eukaryotic transformed human cell lines as listed above. Upon transfection, pseudovirus particles will be produced and secreted into the tissue culture medium.

**Origin & function**

Non-vector-derived genetic material will originate from HIV-1 isolates obtained from clinical samples and/or laboratory strains. These will be cloned into the appropriate vector for expression in one of the recombinant pseudovirus systems detailed above, with target genes replacing exactly their plasmid homologues. The genetic material under study may be further subjected to site-directed mutagenesis to investigate the functional and phenotypic effects of specific point mutations.

**Evaluation of foreseeable effects**

Final recombinant virus: Owing to multiple deletions in the packaged genetic material, the recombinant pseudoviruses produced are capable of only a single cycle of infection. This is sufficient for use in a phenotypic assay where reporter gene expression can be quantified or used as reference material for validation or quality assurance of next generation sequencing assays.

Exposure of a lab worker could lead to integration of the packaged genome and localised expression of the reporter gene. The hazards associated with retroviral vectors are through the risk from accidental infection causing insertional mutagenesis and/or over-expression of cellular genes by random integration. The main risk is to the laboratory personnel directly handling the retroviral vectors. However, the replication-defective nature of the HIV vectors ensures that even in the case of a breach of containment and accidental infection, no virus can spread within an individual or from individual to individual.

The final recombinant virus is not a risk to the environment as the replication-defective HIV vectors are extremely susceptible to desiccation and will only survive a few hours at room temperature.

The non-vector-derived material comprises wild-type HIV sequences or those from drug-resistant isolates and will be cloned from HIV molecular clones, near full-length clones, laboratory HIV strains or HIV infected patient material. Insertion of genes from drug-resistant HIV poses no more danger than the original retroviral vector since the drug resistance genes are not packaged into the vector and no viral replication can occur.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Although HIV is classified as an ACDP level 3 biological agent, it poses limited risk of infection to laboratory workers as it normally cannot be transmitted by the airborne route. Therefore the production of retroviral vectors and subsequent work with live recombinant virus (e.g. single cycle phenotypic assay work) is to be carried out at containment level 2 within a Class II microbiological safety cabinet to minimise both human and environmental contact. Disabling mutations and splitting of the HIV genome into 2 or more plasmid vectors that result in a recombinant pseudovirus capable of only a single round of replication means the viruses are not pathogenic when tested in mice and a minimum of 3 recombination events and/or mutations are necessary to produce replication competent, recombinant virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (g loves, plastic ware, etc.) are autoclaved on-site (100% kill). Autoclaves are monitored regularly for performance via thermocouples and records kept on site. Each autoclave discard run is monitored for satisfactory time/temperature levels. Soiled glassware and liquid waste is disinfected with chlorine at final concentration of 2,500ppm (prepared from sodium dichlorocyanurate tablets) and left for a minimum of 16 hours prior to disposal via drain. Work surfaces are decontaminated before and after use by using chlorine-based disinfectants at a minimum concentration of 1,000ppm.

Is an emergency plan required according to regulation 20? N

Construction and characterization of Bacterial Artificial Chromosomes (BACs) containing Herpes Simplex Virus (HSV) Full-length genomes

The bacterial artificial chromosome (BAC) vector system will be used for the cloning, manipulation and maintenance of full-length herpes simplex virus type-1 (HSV-1) and type-2 (HSV-2) genomes in E. Coli. The HSV BAC vectors will be used to generate recombinant HSV viruses for use in the characterization of genotype-to-phenotype correlates of viral genes or specific genetic changes from HSV clinical samples or molecular clones. We will use BAC vectors to clone, manipulate and maintain full-length HSV genomes that will then be expressed in eukaryotic cells to generate recombinant viruses. The recombinant viruses will be used to validate the phenotype associated with specific genetic changes identified in clinical isolates such as antiviral resistance. This information will be incorporated into a genotype-to-phenotype interpretation system for evaluation of HSV drug resistance from sequencing data.

HSV-1 and HSV-2, belong to the sub family Alphaherpesviridae in the family Herpesviridae. They are 120-300 nm in diameter and consist of a linear, double stranded DNA genome (152 Kb for HSV-1 and 155 Kb for HSV-2) enclosed within an icosahedral capsid, surrounded by a phospholipid rich envelope. HSV-1 and HSV-2 cause oralabial or anogenital infections with -70% and -20% seroprevalence in the UK population, respectively. Primary infection is selflimiting and is followed by latent infection in neural ganglia from where it can reactivate upon immunosuppression. HSV is classified as ACDP hazard group 2.
1. A BAC transfer plasmid vector will be constructed by introducing homology regions containing the HSV UL3 and UL4 genes into the commercially available BAC vector pBeloBAC11. Intergenic regions e.g. between HSV UL3 and UL4 genes are recommended for insertion of BAC genes which avoids interference of HSV promoter or polyadenylation sequences [Nagel, C.-H., Pohlmann, A. & Sodeik, B. in Herpes Simplex Virus Methods Protoc. (Diefenbach, R. & Fraefel, C.) (Humana Press, 2014)]. In addition, it has been demonstrated that insertion of foreign genes in the intergenic region between HSV UL3 and UL4 has no effect on virus growth in cell culture [Morimoto et al., 2009 Microbial ImmunolS3(3): 155-161].

2. HSV vectors generated by the introduction of a BAC origin of replication into an HSV full-length genome by homologous recombination in eukaryotic host cells. Circular viral genome intermediates which form as part of the HSV nuclear replication cycle will be harvested from the host cells by a modified Hirt method [Arad, U. Biotechniques 24, 760-2 (1998)] and used to transform E. coli.

The plasmid vectors will be maintained in OH10B E. coli cells. This strain is K-12-derived, and has multiple functional deletions which minimize recombination events (e.g. recA 1) and render the cells auxotrophic; and unable to survive in the environment (e.g. LeuB, ara-14, etc.).

The plasmid vectors will be transfected into African green monkey Vero cells or human fibroblast MRC-5 cells to generate recombinant vectors or virus particles.

Sequencing of full-length plasmid, vectors and recombinant viruses will be carried out after each cloning or mutagenesis procedure to confirm the presence of the introduced changes and absence of any undesired changes or foreign BAC genes.

### Origin & function

Specific frame-shift, point mutations or full-length HSV UL23 and UL30 genes or parts thereof derived from laboratory-adapted viruses, molecular clones or clinical samples will be introduced into wild-type molecular clones of HSV-1 and HSV-2 using site directed mutagenesis or by using different cloning techniques. These will then be assessed for their effect on antiviral drug resistance using a cell culture-based phenotypic drug susceptibility assay. The SACs origin of replication and associated genes will be introduced into the HSV genome to allow propagation of HSV vector as a single copy within E. coli cells, and facilitating cloning and stable maintenance of the large HSV genome.

### Evaluation of foreseeable effects

The recombinant HSV viruses that will be generated by the HSV SACs vector system will be constructed to contain no foreign genetic material and will only express genes from naturally occurring HSV viruses. The genetic changes introduced will be nucleotide substitutions that have been identified in clinical isolates to be associated with antiviral resistance. Only changes detected in a single clinical isolate will be introduced simultaneously, therefore it is highly unlikely that novel multi-drug resistance changes would be created by homologous recombination in the mammalian cells or E. coli. Thus, the main safety concerns with regards to using this system can be divided into two areas:

1. The potential for infection of laboratory worker with the recombinant HSV viruses
2. The potential for the insertion of foreign SACs sequences into the human genome

The potential for infection with recombinant HSV virus will be no greater than that for HSV isolates from clinical samples used for phenotypic drug resistance testing. The recombinant viruses will be expressing HSV genomes from laboratory strains or clinical samples and thus pose no greater risk. Appropriate risk assessments and safety measures are already in use for HSV phenotypic drug resistance testing.

The potential for insertion of foreign SACs sequences into the human genome will be eliminated by deleting the SACs sequences from the HSV vectors prior to the generation of recombinant viruses. Furthermore, the viral DNA produced by the HSV vectors persists inside the mammalian cell nucleus as an episomal element eliminating the
possibility of random integration into the host chromo.some.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be inactivated with chlorine diSanfectant followed by disposal through drain. All solid waste (gloves, plastic ware, etc) is sent for autoclaving on site (100% kill). Autoclaves are monitored regularly for performance via thermocouples and records kept on site. Each autoclave discard run is monitored for satisfactory time/temperature levels. Soiled glassware and liquid waste is disinfected with 0.5% hypochlorite or 5,000 ppm (prepared from sodium dichlorocyanurate tablets) and left for a minimum of 16 hours prior to disposal via drain. Work surfaces are decontaminated before and after use by using chlorine-based disinfectants at a minimum concentration of 5,000ppm followed by rinsing with water.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The committee had no objection to the risk assessment that had been undertaken for this GMSC proposal number R01017-538

The objective of our work with GMM influenza virus is to increase understanding of immune responses to influenza viruses and influenza vaccines, and of antiviral susceptibility. One way of doing this is to measure antibodies to the different viral proteins including viral surface haemagglutinin (HA) and Neuraminidase (NA) protein. We know that the immune system makes protective antibody to, both proteins, which can be measured in functional assays, such as neutralisation, and HA and NA inhibition assays. These assays require live or native virus so that only functional antibody is measured (making recombinant protein unsuitable for the purpose). This is potentially problematic when the virus under investigation is not a seasonal virus - i.e. the laboratory personnel and the population at large are naïve/not immune to this – and results in the need to create safe viruses through genetic engineering, which are highly attenuated (crippled for replication in humans).

In order to make sure that we are measuring only antibody to the protein target(s) of interest (and not other viral proteins), we need to work with constructs where we can be sure that there are no confounding antibody Interactions. As part of the design of these, we edit which viral proteins are expressed on the virus particle surface to give the best chance of a definitive result. The resulting viruses contain a seasonal virus backbone (internal proteins) (usually A1Puerto Rico/8f1934; = PR8) for safety, expressing the HA and/or NA proteins from the virus of interest. Because of the central role of these surface proteins for virus infectivity; spread and host immunity, they are also important targets for antiviral drugs. We frequently need to investigate how these work and whether viruses develop resistance, which can also be assessed using the aforementioned recombinant influenza viruses.

Recipient or parental organism

The primary organism for GM work within our laboratory is "PR8", a former influenza vaccine strain: A1Puerto Rico/8f1934; = PR8".
Rico/8f1934(H1N1). PR8 is a highly attenuated Influenza strain, which is no longer infectious in humans.

Reassortants derived from PR8 have been used routinely for production of inactivated influenza vaccines for the past 30 years. Use of PR8 as the backbone of GM influenza viruses provides the first line in biological contained use, since any virus generated using PR8 internal genes will be replication attenuated in humans and animals.

To achieve our research and public health objectives, we wish to make use of genetically modified influenza viruses generated in two ways:

1) GM influenza viruses generated by collaborating laboratories.

1.A) Candidate vaccine strains to mitigate potential pandemic influenza virus threats are frequently created and shared through the Global Influenza Surveillance and Response System (GISRS): a network of laboratories experienced in working with influenza viruses. Viruses are shared under the WHO pandemic influenza preparedness (=PIP) framework and recommended by WHO as candidate vaccine strains. These viruses are generated by one of the designated PIP laboratories, de-pathogenized by specific removal of pathogenic sequences, safety tested and distributed through this WHO Framework. GM viruses created for this purpose use a PR8 backbone (6 internal genes) with the HA and NA from the novel, potential pandemic influenza viruses.

We have attached a list of viruses of interest which are part of the pre-existing notification for work with H5N1 viruses designated as CL2. To these H5N1 viruses we wish to add H5NX viruses and H7NX viruses (Table 1). Further viruses will be obtained, always subject to the same biological adaptations for contained use described above, in addition to the physical and chemical containment used within our laboratory.

1.B) We intend to utilise viruses generated at NIBSC specifically for experiments characterising the antibody response to the NA protein. This work requires a GM influenza virus expressing a non-human HA (to prevent anti-HA antibody interference in the assay). All of these reassortant viruses (6:1:1) obtained from NIBSC have been generated by reverse genetics with the HA gene derived from AJequine/Prague/56, the NA gene from different strains (Table 2) and the 6 Internal genes from AJPuerto Rico/8/34 (H1 N1) and are designated for use at CL2 by NIBSC. Their sequence will not be manipulated from the original aliquot.

2) GM influenza viruses generated in our laboratory not using the PR8 backbone.

2.A) The prototype influenza AJH1N1 2009 virus AJEngiand/195/2009 isolated during the first pandemic wave has been used to create a genetic backbone for reverse genetic studies. Since this virus (and therefore all gene segments) is in wide circulation in the community, there is widespread natural immunity. This strain is antigenically similar to the vaccine strain.

Modifications to the HA and NA expressed on the backbone of the AJEngiand/196/2009 strain will be to evaluate receptor binding properties, and the effect of antiviral resistance mutations on virus replication. The final GMMs will have the same pathogenicity and virulence as clinical Isolates of influenza A/JH1 N1 2009 virus. No HA or NA genes from non-seasonal viruses will be utilised on this backbone.

2.B) Cold adapted Ann Arbor backbone virus (either influenza AlAnn Arbour/B/60 or BIAnn Arbour/1/66) are the basis of the Live Attenuated Influenza Virus Vaccines (LAIV) in use in the UK since 2013. These cold adapted strains will contribute the internal influenza virus genes with the viral surface glycoproteins; the haemagglutinin and neuraminidase genes inserted from currently circulating strains, in accordance with the annual WHO recommendation. While Ann Arbor backbone-LAIV produced by AstraZeneca is licensed in North America and Europe respectively, Leningrad backbone-LAIV is produced In Russia (Ultravac®) and India (Nasovac-S®) and used primarily in those two countries. We may use those Leningrad backbone-LAIV strains if we can't get hold of the Ann Arbor backbones (i.e. in case of IP issues) or if we need to clarify differences in efficacy between products.
The host/vector system utilises E.coli as the host and the plasmid pRecBF-BsmBI as the vector. The host is disabled and the vector is non-mobilisable. There will be no attempt to maximise the expression of DNA, biologically active molecules may be expressed but are unlikely to have a deleterious effect. Containment level for working with host/vector will be containment level 2.

The host is a chemically competent E.coli strain TOP10F’ (F’lacIq, Tn10(TetR)) mcrA (mrr-hsdRMS-mcrBC) d40 lacZI(M15II,lacX74 deoR recA1 araD139 A(ara-leu)7687 galU galK rpsL(StrR) endA1 nupG) or similar. The vector (pRecBF-BsmBI) is based on the pUC18 plasmid, which is a non-mobilisable vector.

Origin & function

The inserted genes are those for the Haemagglutinin (HA) and/or Neuraminidase (NA), which are inserted into a backbone of seasonal influenza virus (current circulating, or with attenuating features). Haemagglutinin is a receptor binding protein, which attaches to cell surface receptors and mediates cell fusion. In high pathogenic viruses, this contains a polybasic cleavage site (=virulence determinant). Genetic engineering to remove this site renders the previously high pathogenic phenotype of the protein to low pathogenicity.

Source and type of HA we want to use:

We want to work with HA's from human influenza strains, found on viruses which circulate seasonally; for which vaccines are available and widely used and to which the population is generally immune (ie. H1 and H3). These HA's recognise and bind human upper airway epithelial cell receptors.

We also want to use avian and swine HA which are derived from viruses that could cause a pandemic, (because the population is not immune to these), as these get identified and suitable viruses get distributed by the PIP framework.

We want to use HA derived from NequineJPrague/56(H7N7) for use in NAI assays. While Human influenza viruses preferentially bind to a2,6-linked sialic acid receptors, found in the human respiratory tract, the HA from H7 equine influenza virus has been shown to have a preference for binding to a2,3-linked sialic acid, and differ from other viruses by binding to the N-glycolyl form of sialic acid (NeuSGc) which is the major sialic acid species found in the horse epithelium, but entirely absent from human tissue (and birds). This effectively results in a species barrier for the resulting GMM.

The Neuraminidase is a receptor destroying enzyme (also called sialidase) and cleaves glycan residues from cell surfaces to free budding virus particles which are trapped via their HA on the cell surface receptors as they emerge from the infected cell surface.

Source and type of NA we want to use:

The NAs are either from previous or current seasonal influenza strains of derived from avian and swine influenza; please see table 1 and 2.

Evaluation of foreseeable effects

All GMM covered in this proposal have similar hazard profiles and belong to ACDP2.

GMM with non human HA or NA

PRB is the only parent organisms that will be used as the generic back bone for insertion of any non human HA or NA. It is expected (and has also been shown for rgH5N1 and rg H7N7; rg=Reverse Genetic generated viruses) that these GM viruses are attenuated compared to the wildtype donor virus due to the presence of the internal genes from the laboratory strain PR8, either when grown in vi tro in eggs, or in vivo in infections of chickens or humans.

PRe belongs to previously circulating seasonal influenza A(H1 N1) and was isolated in 1934. It is highly attenuated (it...
is non-infectious in humans) and has been widely used in the field and is commonly used for vaccine reassortment -
the products of which are regularly part of commercial vaccine products with no indication of safety concern due to
this or parts of this strain.

Due to the circulation history of H1N1(s) strains during the periods 1917-1957, 1977-2009, and 2009 to the current
day (H1N1 pdm09), the majority of the population is not immunologically naive to H1N1 viruses.

Viruses are created by cloning the genes for the parent Haemagglutinin and/or Neuraminidase into the PR8
backbone, thereby removing any pathogenicity marker coded in internal genes (e.g. specific amino acid substitutions
in polymerase genes and NS1). No further manipulation of these internal genes is intended.

Pathogenicity in the context of influenza is categorised as high or low and refers to pathogenicity in poultry. It can be
predicted by looking for molecular markers which are mainly on the Haemagglutinin (and on proteins of the viral
backbone such as M1, M2, PA and PB1). The viruses described here carry the HA from seasonal, avian/swine and
equine influenza (Alequine/Prague/S6) on the virus surface. The function of the HA is receptor binding and fusion with
the host cell - this protein determines, which cell species a virus can infect. While the viral backbone determines
attenuation as explained above, the change in HA from H1 to an alternative HA, changes the host range and tissue
tropism from that of AIPuerto Rico/8/1934 (seasonal, with preference to bind a2,6-linked sialic acid receptors) to that
of the alternative HA (e.g. for Alequine/Prague/S6 virus => binding a2,3-linked sialic acid (N-glycolyl form of sialic acid
( Neu5Gc) *, which is not found on human tissue and is also not found in birds thus restricting the potential for spread
to species other than the horse).

The Neuramindases enzymatic function, should not lead to harm - Sialidases are currently trialed in human Phase II
trials as prophylactic treatment to prevent influenza infection (by removing cell surface receptors and thus blocking
virus entry). Both proteins, HA and NA are the main component of subunit vaccines, which make up the majority of
modern trivalent/quadrivalent influenza vaccines. Furthermore, DNA vaccines expressing these genes have been
trialed in animals - no adverse effect.

If handled within the code of practice and VRD H&S regulation, these gene products should not cause direct harm to
the staff, environment or wider public .

... A. S., G. C. Schild, and J. W. Craig. 1975. Trials in man with live recombinants made from AIPR8/34 (HO N1) and

There is a low but theoretical risk of recombination between the GMM and currently circulating strains (by means of
cross-contamination during work or dual infection of staff), potentially leading to viruses capable of infecting humans,
but not recognised by the immune system from being antigenically different to seasonal strains.

=> The main control measure being SEPARATION from other influenza strains and is achieved by exclusively
working in a specifically designated laboratory and a specified waste disposal route as described below.

Reassortment in a person (dual infection with wt virus and GM strain) is unlikely due the ‘design features’ of the GM
viruses (use of HAs that do not bind to human upper airway epithelial receptors; use of an attenuated backbone that
does not replicate in humans) and further reduced by vaccination policy (relative protection from infection with
seasonal influenza), the acquired immunity of healthy adults (from previous exposure to seasonal influenza viruses)
and exclusion of individuals who are Immunocompromised or pregnant from live virus work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None, containment at Level 2 with enhanced control of waste disposal.
SEPARATION: All work with GMM influenza virus is carried out in a designated laboratory (room) reserved for GM work only, within the Respiratory Virus Unit. Different GMM influenza viruses are not used at the same time in the laboratory, or are, separated further, by physical containment i.e. use of different microbiological safety cabinets.

Designated protective clothing
Laboratory coat and disposable gloves will be worn at all times in the lab. The lab coats to be worn by staff in this laboratory are green colour to differentiate the room purpose (white disposable lab coats are available for engineers and visitors). They will not be worn outside the specifically designated GMM laboratory. For disposal, used gloves will be put in yellow bags for incineration of clinical waste and the bag sealed and labelled with room number and date prior to transfer to wash-up for disposal. If gloves are known to be contaminated with influenza GM viruses, disposal is via a disposal jar for autoclave sterilisation. For cleaning, coats are autoclaved as enhanced CL2 waste before going to the laundry as for CL2 coats.

Waste disposal
Non-hazardous waste: Materials which have not been in contact with infective material are placed into black plastic bags, held in the waste bins in the Laboratory, which are removed when full and sealed before placing the bags in the appropriate trolley in the wash-up room and discard via contracted waste collector (offsite).

Uncontaminated plastic from the laboratory can also be recycled via the recycling bins provided in the lab.

Uncontaminated cardboard for recycling can be placed in the appropriate trolley in the wash-up room for collection by porters and discard via contracted recycling partner (off site);

Solid waste with infectious potential; e.g. bench and cabinet waste, and laboratory coats, must be autoclaved using specific sealable autoclave bins if those items had been used for work with reverse genetics constructs with nonseasonal HA and NA. For this, any item is enclosed in the specific autoclave-able bin liners, before being placed in the bin, the bin is labelled correctly and transported to the central autoclave facility by the lab staff, following Standard Operating Procedure (0-061) - the designated route for the waste trolley is stated in this document and has to be followed, while staff also witness the disposal and keep hard copies of the paperwork as evidence for correct waste disposal. Once autoclaved, the waste is discarded via contracted waste collector (offsite) by incineration.

Solid waste from work with all other RG viruses (e.g. constructs with seasonal HA and NA) is treated like wildtype seasonal Influenza as re-assortment with circulating strains is not a risk and is disposed via the route for clinical Category 2 waste. For this, any loose items not collected in a disposal jar (e.g. 96-well plates) are enclosed in the specific autoclave-able bin liners before being placed in the bin. Once autoclaved, the waste is discarded via contracted waste collector (offsite).

Green Lab coats are always autoclaved prior to washing - independent of type of work done.

Liquid waste with infectious potential: is either autoclaved (filled in Shott bottles) or treated with chlorine disinfectant at a concentration of 2500ppm (SOP V5708). Liquid waste is labelled with the date of discard and operator initials. Disinfected waste is transported in a sealed container to a room with a fume cupboard, where it is discarded in the sink (inside the fume cupboard). followed by flushing of the sink with copious water. A Chlorine Disinfection Validation Sheet (VWI33.01) is updated to allow tracking of the process.

Surface decontamination is achieved using chlorine disinfectant at 1000ppm. or Virkon ® for equipment sensitive to chlorine.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Ref 203/18.2

Date Ackn'd: 20/04/2018

CU2 Project Title: To Determine the Role of Key Genes in Antimicrobial Resistance in Neisseria gonorrhoeae

Class: Class 2

Culture Volume: < 1 L

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Antimicrobial resistance in Neisseria gonorrhoeae is an area of increasing concern with therapeutic options becoming limited. NCTC has a panel of WHO N. gonorrhoeae control strains which have closed genomic sequences and well defined phenotypic and genotypic antimicrobial resistance profiles (Unemo et al., 2016). Mass spectrometry-based quantitative proteomic analysis of this set of strains revealed that in addition to the previously described genotypic markers (23S rRNA mutations and. the mtrCDE efflux pump operon) the macB protein was reproducibly upregulated in WHOV which is a strain which exhibits high level resistance to Azithromycin. The macB gene, according to its E. coli homologue, is an efflux pump for macrolides. However, its role in macrolide resistance in N. gonorrhoeae has not yet been described and further work is required to differentiate association from cause and effect.

Other studies that have examined macrolide resistance isolates of N. gonorrhoeae have concluded that the mechanisms of resistance are unknown in - 30% of resistant isolates examined (Grad et al., 2016). It is currently accepted in the literature that all the mechanisms of macrolide resistance have not been fully described despite NGS data being available for many strains and therefore it is likely that differences in protein expression levels may play a role.

A method to inactivate macB in N. gonorrhoeae through gene homologous recombination is proposed. The method is intended to both (i) disrupt the macB gene and (ii) insert a spectinomycin resistance selective marker from which mutants can be selected for because the transformation efficiency in N. gonorrhoeae is very low (Duffin, 2010). This method has been previously been successfully applied to disrupt a related gene (macA) in drug resistant isolates of N. gonorrhoeae in other studies and therefore is the preferred selection method of choice as there is a precedent for this being a successful, ethical and scientifically acceptable manipulation technique (Rouquette-Loughlin et al., 2005; Golparian, 2014).

References

Recipient or parental organism

Neisseria gonorrhoeae WHOV (NCTC13B1 B).

Host/vector system

A linear synthetic sequence containing macB flanking regions with a spectinomycin resistance expression cassette (aadA gene with promoter). The aadA gene encodes for an enzyme which modifies the spectinomycin molecule rendering the GMO resistant to spectinomycin.
This project is designed to inactivate the macB gene in the N. gonorrhoeae WHOV strain by gene homologous recombination. A linear synthetic sequence containing macB flanking regions with a spectinomycin resistance expression cassette (aadA gene with promoter) will be introduced into WHOV. The linear DNA sequence will be made to order and purchased through DNA synthesis service. The spectinomycin resistant selective marker is the aadA gene which encodes for an enzyme which modifies the spectinomycin molecule rendering the GMO resistant to spectinomycin. The spectinomycin resistance cassette will be synthesised and flanked with macB fragments on both sides (Figure 1). The transformants will be selected by their resistance to spectinomycin.

This approach has been successfully applied to disrupt similar genes (macA gene) in other drug resistant strains of N. gonorrhoeae in previous studies so there is a precedent in place for this method being successfully applied to resistant gonococcal strains.

Evaluation of foreseeable effects

This work will result in a strain of N. gonorrhoeae WHOV with a (i) non-functional macB gene (which may or may not have an effect on the strain's susceptibility to azithromycin) and (ii) contains an additional resistance to spectinomycin. The manipulated strain of WHOV will remain fully sensitive to the first line recommended treatment for N. gonorrhoeae ceftriaxone.

N. gonorrhoeae is an obligate sexually transmitted human pathogen which is transmitted via close and prolonged contact with mucosal surfaces. N. gonorrhoeae does not live outside of its natural host for long periods of time and it is very difficult to contract within a laboratory setting. Laboratory acquired infections of N. gonorrhoeae remain extremely rare. However isolated cases have been reported and eyes are the main route of infection for laboratory acquired infections. The WHOV strain (including an additional spectinomycin resistance marker) will present a very negligible risk to human health within the laboratory setting when the routine lab control measures (described in risk assessment) are implemented.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable all work will be conducted at ACDP2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All infected waste will be placed into Dispo-jars or autoclave bags (agar plates) which are then placed into autoclave bins and transferred to the facilities management department (FMD) for autoclaving at 1210C for 15mins followed by off-site incineration (BRD0026/03-1S; 00870S-1 4). All waste will be managed and transported between labs and the autoclave facility using the service provided by the FMD in accordance with SOP (0060).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The PHE GMO Committee have requested staff performing the work make a declaration to the Occupational Health Department that they do not have a history of penicillin allergy. In addition it was requested that the GMO should be destroyed when all scientific investigations on the GMO have been completed.

Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste will be inactivated either by specified disinfection procedures or by autoclaving, prior to final disposal. Final disposal may be by various routes including to the non-hazardous waste stream (black bag/dustbin) or the clinical waste stream for microwaving or incineration. The clinical waste contractor has not made notifications to take waste containing genetically modified organisms, consequently all waste will be inactivated prior to consignment to the contractor.

Tick to confirm that you are attaching a summary of the risk assessment
All risk assessments will be reviewed by the local GM safety committees to confirm:
- proper and valid assessments have been made of the risks to human health and safety and to the environment;
- satisfactory decisions about the appropriate containment and control measures have been made; and
- the approach to risk assessment is in accordance with the guidance provided by ACGM taking into account the parameters detailed in the Regulations.
Origin & function

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20?

**Project Additional Information**

**Purposes of the contained use**

The Open Biosystems library contains over 70000 individual E. Coli glycerol stocks containin the pGIPZ lentiviral vector or pSM2 retroviral vector. Each stock contains a unique hairpin sequence within the vector designed to target and reduce the expression of the majority of genes within the human genomes via RNA interference (RNAi).

The project will involve lentiviral or retroviral knockdown vector maintenance, storage and use of Open Biosystems shRNA library, including lentiviral mammalian expression plasmids, as well as distribution of clones as bacterial stocks DNA plasmids and or lentivirus to members within University College London for use in various projects.

Specifically, these constructs will be used to identify the key functional regulators of normal and tumour-derived neural stem cell lines.

**Recipient or parental organism**

Cell lines: a panel of mouse and human cell lines derived from mouse or human foetal nervous system and/or adult tissues or tumour biopsies.

Primary cell cultures: derived from mouse or human foetal nervous system and/or adult brain tissues or tumour biopsies.

Established cell lines: 293T (for viral preparations)

Bacterial E.coli strains: HB101, XL1-blue, TOP10, Prime Plus, JM109, BL21, DH5alpha, SURE, KS1000, DE3

**Host/vector system**

Lentiviral vectors: commercial TZV vector from Tranzyme and derivatives (including pGIPZ).

Retroviral vectors: commercial retroviral hairpin pSM (pSHAG-MAGIC-2) vector from Open Biosystems.

The viral vectors are lentiviral vectors. The vectors contain the CMV (Pol ll) promoter to drive expression of the hairpin cassette or gene sequence. The lentiviral vector does not contain the appropriate accessory elements to form a functioning viral particle. Therefore it poses no threat to health or the environment. Packaging and envelope proteins are contained on two additional separate plasmids which are required in combination to produce viral particles. This separation of genetic elements essential for full viral functioning provides an addition safety measure. There shRNA cassettes are designed to target specific genes and will result in their knockdown.

**Origin & function**

The RNAi hairpins are sequences that have been derived de novo and are not from an organism. They have been designed as short sequences with both a sense and antisense and loop sequence. This results in formation of a RNA hairpin following transcription which in turn will trigger the appropriate RNA interference response (RNAi). The accessory protein derive from the HIV-1 virus.

**Evaluation of foreseeable effects**

The hairpin sequence will be transcribed following delivery into the host cells. This hairpin structure will trigger a normal cellular response pathway that results in the target sequence being suppressed in its translation or stability - this is known as the RNA interference pathway. The lentivirus and retrovirus can only infect mammalian cells. The target sequence of the shRNA is designed specifically for human sequences. There is a small risk that 'off target' sequences might be hit, including other mammalian species.

As the sequences are designed to target human genes there is the possibility that if the vector was delivered by accidental transfer to human cells it would result in gene...
knockdown. If the resulting downregulated gene was a gene such as tumour suppressor this might result in aberrant regulation of cell proliferation pathways. However, the virus is replication incompetent and therefore would not spread beyond the initial cell targeted. Genetically normal human cells which received this vector would undergo a process of programmed cell death. Physical insertion of the vector into the host genome might also disrupt critical gene functioning. However, the likelihood of this is extremely low, and similarly cells would trigger an endogenous cell death pathway. Thus, the ability of the virus to be accidentally transferred to human cells is extremely low, there is no possibility for the virus to spread and even if inserted the cells would be removed rapidly as part of their normal cellular response.

If virus is introduced into the body by injection, ingestion or through a wound the virus could potentially enter cells and integrate into the genome. Although the virus is replication incompetent (does not carry the packaging protein) its physical insertion into cellular DNA could result in an oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells would be affected. It would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection but not required for viral packaging have been removed. So the virus is attenuated and replication incompetent and will not make new viral progeny.

The most dangerous GMM is the lentiviral and retroviral preparations of viral particles. The most dangerous step is the collection, concentration and use of retrovirus/lentivirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All work will be carried out in level 2 containment facilities within Paul O’Gorman Building. Stably modified human cancer cell lines will ne maintained using level 2 containment facilities.

All staff involved in the project will be made aware of the associated risks described here and will be required to have appropriate safety training prior to beginning work on the project.

Workers will be required to wear lab coats as well as latex or nitrile gloves whilst working on all procedures. Any open wounds will be covered with a bandage also.

All solid waste and any spills will be treated with Virkon and/or trigene advance, both of which are certified to kill 100% of virus, bacteria and cells.

After treatment, all solid waste will be double-bagged, autoclaved, placed in yellow biohazard safety bags and furhter treated by UCL waste services.

All viral supernatant will be stored in double containment and transferred within the laboratory within doubly sealed containers.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

2-5% Trigene advance or Virkon (v/v) will be used to treat liquid waste (18 hrs) and also used to decontaminate an spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5% Trigene advance and 70% ethanol after use. Virkon and Trigene advance are certified by the PHLS to provide 100% viridal and GMO kill under these conditions be denaturing and inactivating viral and cellular proteins (Degree of kills: 100%). Trigene advance and Virkon will be used with its lifespan to ensure required kill is achieved.

Solid waste will be double-bagged in biological waste bags, sealed and autoclaved 132C for 15 min by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N
The project was approved by the GMSC, subject to minor changes, as an Activity Class 2 project.

Project notified under transitional arrangements

Historical Significant Changes

TRANSFERRED FROM GM 18.

Project Additional Information
Purposes of the contained use

Fundamental research aimed at understanding the molecular and cellular mechanisms of intracellular survival using bacterial models. Our principal model organisms are Listeria monocytogenes and Rhodococcus equi. Our experimental approach involves the inactivation of selected genes of these bacteria by standard laboratory protocols and the analysis of the effect of the gene-disabling mutations on the bacterial intracellular proliferation capacity in vitro, on virulence in vivo, and on the response of the whole bacterial genome as assessed by DNA chip and proteomic technologies. The ultimate goal of this research is to identify targets for new vaccines, antimicrobial therapies and diagnostic tools to combat infections due to intracellular parasites.

Recipient or parental organism

The research will involve the generation of four types of GMMs.

1. Derivatives of L. monocytogenes and R. equi in which selected genes have been "surgically" inactivated to deduce their function by phenotypic comparison with the wild-type parental strain. Gene inactivation will usually be carried out by in-frame deletion, a technique that does not leave any trace of foreign DNA in the bacterial genome. With this technique with GMMs only differ from their parental organism in that they lack a DNA fragment corresponding to the deleted gene(s).

2. Gene-inactivated derivatives of L. monocytogenes and R. equi in which a wild-type copy of the gene under study has been reintroduced to confirm that the observed phenotype is actually due to this gene(s) and not to a secondary, spontaneous mutation affecting other unrelated loci.

3. Non-pathogenic cloning hosts carrying sequences of our model organisms (L. monocytogenes or R. equi), required for the construction of the gene-deletion derivatives described in (1) or for gene function studies. As recipient organisms we will use the following non-pathogenic bacteria:
   * Escherichia coli K-12 or B disabled derivatives (strains DH5a, HB101, C600, HB101, XL1-Blue, etc)
   * Bacillus subtilis
   * Lactococcus lactis
   * Listeria innocua, a non-pathogenic Listeria sp which lacks all known listerial virulence genes
   * A well-characterised derivative of L. monocytogenes ( prfA, picA, hly, plcB, actA) which was irreversibly rendered totally non-pathogenic by deletion of multiple essential virulence genes

4. Miscellaneous GMMs. The following GM bacteria may be incorporated as controls in some of our experiments:
   * Salmonella typhimurium SL1344sifA, a derivative of the laboratory strain SL1344 lacking SifA, a protein required for the maintenance of the vacuole in which Salmonella replicates intracellularly
   * Shigella flexneri laboratory strain SC560, rendered non-pathogenic due to an icsA-disabling mutation which impedes host tissue colonisation
   * Yersinia enterocolitica WA-314 attenuated derivatives due to disabling mutations in the sodA (superoxide dismutase) and irp (invasion associated protein), virulence genes.

Host/vector system

For routine gene cloning we will use non-mobilisable or mobilisation-defective plasmid vectors, such as pUC series-based vectors, pBR322 or Bluescript II for E. coli, and pE194 derivatives for gram-positive bacteria (B. subtilis, L. lactis or Listeria spp). To produce gene-disabling mutations we will use thermosensitive derivatives of pE194 in Listeria and pUC derivatives in R. equi. For inactivation of the uhpT gene in Salmonella typhimurium SL1344sifA and Shigella flexneri SC560 (see below) we may use the "suicide" vector pGP704. This vector can only replicate in, and be mobilised from, strain SM10Lpir, a host E. coli C600 derivative engineered to contain the RP4 mobilisation and R6K replication functions integrated in the chromosome. Once conjugally transferred from this host strain, plasmid pGP704 cannot replicate and be mobilised further.

Origin & function

From Listeria monocytogenes.
In the context of a major EU-funded collaborative initiative in functional genomics of Listeria spp., our group will be allocated a number of L. monocytogenes genes to
inactivate them by in-frame deletion. A complete description of the 2,853 genes of the L. monocytogenes genome and their predicted products is publicly available at http://genolist.pasteur.fr/Listilist. All the gene-disabled derivatives contributed by the collaborating European partners will then be systematically analysed in the different laboratories by a number of approaches, including DNA chip technology and proteomics. Our research will particularly focus on the following Listeria genes.

- prfA, encoding a regulatory factory homologous to CAP/Crp from E. coli
- actA, encoding a surface protein involved in actin-based motility
- plcA, plcB and smcL, encoding phospholipases active on phosphatidylylcholine and sphingomyelin, respectively
- hpt, encoding a sugar phosphate transporter homologous to the E. coli Uhp T permease
- ptsH, encoding a putative glucose-specific enzyme II permease component of a phosphoenolpyruvate sugar phosphotransferase system (PTS)
- bvrABC, encoding a PTS permease system specific for beta-glucoside sugars
- agl, encoding a two-component regulatory system
- luxS, encoding a putative quorum-sensing signalling system.

From R. equi

Our work will focus on choE and choD genes, encoding cholesterol oxidases that are widespread among saprophyte soil dwelling actinomycetes (eg Streptomyces spp). We believe that these enzymes may contribute to the capacity of R. equi to survive within eukaryotic host cells, whether they are mammalian microphages or soil bacteriovorous protists.

From S. typhimurium and S. flexneri

Our work will focus on the uhpT gene, encoding a glucose phosphate transporter identical to that present in E. coli K-12 and widely distributed among bacteria. We believe that this transporter may play a role in the uptake of sugar phosphates in vivo when bacteria are within host cells.

Evaluation of foreseeable effects

Hazard to human health

L. monocytogenes and R. equi, in which we are going to produce gene-disabling mutations, live as saprophotes in the soil and are widespread in nature. Occasionally, they can cause opportunistic infections in humans and animals and are thus classified in hazard group 2 in the Approved List of Biological Agents. Clinical infections occur only rarely, require a predisposing underlying condition and, presumably also, a high exposure. Both L. monocytogenes and R. equi are considered to have low infectivity and virulence. Under the designation L. monocytogenes we also include the closely related species L. ivanovii (formerly known as L. monocytogenes serovar 5), which is less virulent and has a narrower host spectrum than L. monocytogenes (L. ivanovii is not recognised as human pathogen). The gene *knock-out* derivatives of these bacteria will have the same low virulence as the parent strain if the deleted loci do not play a role in infection, or a lower virulence if the deleted genes play a role in infection. The *reconstituted* mutants, in which the deleted gene is reintroduced back for confirmation that the target gene is responsible for the observed phenotype, will have at most the same virulence as the parent strain. All these GMMs will therefore be handled under containment level 2.

The heterologous bacterial hosts that will be used as recipients of intermediate constructs for deletion mutant construction or to study gene function by complementation (E. coli K-12 or B disabled derivatives, B subtilis, L. lactis or L. innocua) are not considered pathogenic for humans or animals (hazard group 1). The attenuated L. monocytogenes (prfA, plcA, hly, plcB, actA) derivative lacks several critical virulence genes and consequently is entirely avirulent and non-pathogenic. The multiple gene deletions in this L. monocytogenes derivate guarantee that it is stably attenuated, there is no real possibility of reversion, and thus is a totally safe host strain.

Thanks to our participation in the Listeria sequencing projects we have precise information on the putative activities of the products encoded by L. monocytogenes. None of the L. monocytogenes genes code for known dangerous toxins, highly aggressive virulence factors or harmful products which can act directly to cause damage, allergy, oncogenesis or growth modulation. In the case where they do contribute to virulence, their role in infection is always subtle and they need to act alongside a number of other virulence and regulatory factors with which they have co-evolved in the source organisms. Therefore, the risk for one of the above heterologous non-pathogenic host organisms gaining virulence by introduction of L. monocytogenes sequences is negligible. Although in principle they might be handled under containment level 1, as a precaution and because they will be handled in parallel with the other bacteria, they will effectively be worked under containment level 2.
The miscellaneous bacteria that we may incorporate in our experiments all have disabling mutations that attenuate their virulence. S. typhimurium SL1344sifA, lacking the protein SifA required for the maintenance of the vacuole in which Salmonella replicates intracellularly, shows impaired replication in macrophages. The S. flexneri icsA derivative SC560 is virtually non-pathogenic (in fact one of its derivatives, strain SC602, is used at the institut Pasteur as the basis for the development of a vaccine against Shigella infection in humans). Yersinia enterocolitica WA-314, with disabling mutations in the virulence-associated sodA and irp genes, has impaired capacity to survive in vivo in animal tissues and is also used as the basis for a live oral vaccine. Nevertheless, these bacteria can have some residual virulence and therefore will be handled under the containment level required by their corresponding wild-type parental strains, which are classified in hazard group 2 (ie level 2).

The cholesterol oxidase genes choE and choD from R. equi, which are widespread among non-pathogenic actinomycetes (eg Streptomyces spp., Brevibacterium sterolicum), and the uhpT gene from S. typhimurium, encoding a sugar phosphate transporter also widely distributed among bacteria, are not expected to confer any virulence property to a non-pathogenic heterologous host.

The resistance genes used as selection markers in the cloning vectors have been approved for use at containment level 1 and confer resistance to "old" antibiotics for which resistance in clinical isolates is already widespread (and therefore are no longer used in clinical practice).

Hazards to the environment
None of the bacteria we will work with are exotic to the UK, are pathogenic to plants, or cause notifiable diseases under specific surveillance by DEFRA. They are already ubiquitous in the environment and are frequently carried by healthy animals. In some cases they may cause opportunistic infections in these animals.

The gene-disabling mutations introduced in the bacteria (in most cases by in-frame deletion, which does not leave any trace of foreign DNA) should normally lead to attenuation in vivo. Although these mutants may retain some of the original virulence of the parent strains, they will complete less well within an animal host and will be cleared from the infected tissues sooner than the wild type. The risk of pathogenicity is therefore reduced and less important than with the corresponding parent strain. The loss of a trait or genetic sequence that has been selected for through evolution is likely to reduce the fitness of the gene-deleted derivative to establish and survive in nature. Consequently, the gene-disabled derivatives, if accidentally released to the environment, are not expected to displace any indigenous population.

Listeria or R. equi bacteria in which the original phenotype has been restored by introduction of the wild-type allele in a plasmid vector always tend to lose these constructs because the vector is not naturally adapted to these host bacteria and represents a physiological burden (being thus rapidly lost in the absence of selective marker pressure). The non-pathogenic cloning hosts containing sequences from Listeria or R. equi are not expected to become established or be hazardous to the environment because the plasmid vectors will not be mobilised and the foreign genes, which are derived from ubiquitous soil dwelling bacteria, are already present in nature as a result of natural decay processes.

The likelihood of accidental environmental release of the GMMs is very low or negligible given the measures that will be applied to control any risk to human health and safety (level 2 containment). If release was to occur, the consequences can also be graded as very low or negligible. Therefore, the environmental risk can be judged as effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The GMM-contaminated waste will consist of broth/agar cultures, plastic labware and glassware. All this material will be inactivated in the building by autoclaving at 121 degrees C for 20 min (100% kill) prior to disposal or recycling. Carcasses of experimentally contaminated animals will be incinerated on site (100% kill). Non-contaminated general waste generated in the containment level 2 facilities and thus potentially exposed to the GMMs will be incinerated.
Discussed at Committee meeting of 19 February 2003 - extra information required re target genes and comment re pregnant workers suggested.

INVESTIGATION OF THE PATHOGENESIS OF THE HUMAN ALPHAHERPESVIRUS.

Project Additional Information

Purposes of the contained use
Biomedical research

Recipient or parental organism
Herpes simplex virus; Varicella zoster virus.

Host/vector system
Recombinant herpesviruses (Herpes simplex virus and varicella zoster virus) and replication defective derivatives.

Origin & function
The recombinant viruses will be based on established laboratory strains of HSV and VZV. Deleted viruses may contain marker genes derived from bacteria or the jelly fish green fluorescent protein. Viruses derived from the use of Bacterial artificial chromosome (BAC) technology may contain a bacterial origin of replication in addition to any marker genes or deletions. The HSV-DISC virus contains murine GMCSF that is only 43% similar to Human GMCSF.
The recombinant viruses would be expected to be of less or unaltered pathogenicity as the parental wild type viruses which are ACDP category 2 pathogens.

Use of HerpesBAc to generate modified HSV/VZV virus in tissue culture. In order to generate infectious virus the construct containing the herpesvirus genome as a bacterial artificial chromosome will be transfected into eukaryotic tissue culture cells. This will give rise to a genetically modified thymidine kinase minus (TK) virus. By comparison with other herpesviruses TK strains are normally attenuated HSV and VSZ are both ACDP category 2 pathogens therefore this portion of the work will be carried out in a Class II safety cabinet under Category 2 containment. All subsequent growth of modified virus will also be carried out under category 2 containment.

Generation of recombinant HSV by homologous recombination. Recombinant HSV can be generated following homologous recombination in eukaryotic cells between HSV sequences contained in an appropriate plasmid and superinfecting virus. This is the classical method by which recombinant HSV has been constructed. To select for recombinant virus a selectable marker under the control of an appropriate promoter will be used. Cells will be transfected with these constructs and subsequently infected with HSV. Mutant virus that arises by homologous recombination will be selected for by plaque purification in the presence of appropriate selection. Alternatively genes of interest will be inserted into the virus thymidine kinase gene so allowing selection using antiviral drugs such as Acyclovir.

As this work will generate mutated HSV, an ACDP Category 2 pathogen work based on manipulation of wild type HSV will be carried out under Containment level 2.

It is proposed however to primarily base these recombinants on a glycoprotein H deleted (gH) DISC (defective, infectious single cycle) virus which is replication defective and will only produce infectious virions when cultured on helper cell lines expressing gH. Similar studies to those outlined above will be carried out.

We will obtain from other workers a DISC virus that expresses murine GMCSF.

The DISC virus is replication defective and so cannot be transmitted from host to host. As these constructs are non-replicating the likelihood of infection of humans is low and the likelihood of transmission is effectively zero. The virus will cause a lytic infection at the site of injection and so some localised damage will occur. The insertion of genes (especially immunomodulatory genes) into the DISC virus may slightly increase the likelihood of adverse effects following infection. Therefore this work should be carried out under Containment level 2.

VZV cosmid. We will obtain from colleagues a series of 4 overlapping cosmids that span the entire VZV genome. These are non-mobilisable plasmids and no VZV genes are expressed in bacteria. The risk to humans of these cosmids is low/effectively zero. Mutation of virus sequences contained within these cosmids can be achieved following homologous recombination in bacteria using constructs outlined in section 1. No virus genes will be expressed in bacteria. Growth and manipulation of these cosmids can be carried out under Containment level 1.

To generate infectious VZV the complete set of cosmids are transfected into eukaryotic cells where low efficiency homologous recombination occurs resulting in the formation of full length infectious VZV genomes. The aim is to produce VZV deleted in specific genes for phenotypic analysis. Since these mutated viruses will be replication competent this work will be carried out under Containment level 2.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All spent culture media or other liquids, contaminated glassware, gloves microcentrifuge tubes, micro-pipette tips and tissue culture plastics are rendered safe by autoclaving prior to disposal as general waste. Pipettes (including Pasteurs) are completely immersed for a least 18 hours in Haztabs (Guest Medical) solution (Haztabs)
Solution = 1 tablet/litre of water = 2,500 ppm Chlorine) and then disposed of as clinical waste.

The autoclave is fitted with a thermocouple linked to a chart recorder to monitor the effective completion of the sterilization cycle. SOPs stipulate that no material should be removed from the autoclave without first checking that the cycle was completed. The degree of kill for autoclavng is effectively 100%.

Several studies have reported reductions in viral titre in excess of 99% following short (maximum 2hrs minimum 2mins) exposure to 2,500ppm Chlorine. These studies were carried out on both enveloped and non-enveloped viruses, on dried material, blood and virus solutions. The exposure of contaminated material for in excess 18hrs would be expected to exceed these levels.

Narang and Codd (1983) Action of commonly used disinfectants against enteroviruses J. Hospital Infection 4, 209-212 (100% kill).

This RA covers an extended project aimed at investigating herpesvirus pathogenesis. The initial bacterial cloning work and growth of the cosmid clones was considered straightforward and Containment Level 1. The manipulations of the BACs containing herpesvirus sequences was discussed and it was decided that the arguments laid out in the RA were acceptable and that the possibility of infection arising from ingestion of bacteria carrying these BACs was effectively zero: Containment Level 1. The work with recombinant virus was clearly Containment Level 2. The work with the amplicon was discussed and as the vector is non-replicating and will contain no HSV structural genes the risk to type operator and the environment is low/effectively zero: Containment Level 1. The work with the DISC virus was discussed. It was decided that although these vectors only undergo a single round of replication with no production of infectious virus the fact that they have the potential to establish a latent infection and are expressing an immunomodulatory gene should mean that they are handled at Containment Level 2.

The appropriate notifications to HSE must be completed.

Project Ref 207/02.1

GENOTYPIC AND PHENOTYPIC VARIATION IN HUMAN IMMUNODEFICIENCY VIRUS: RELEVANCE TO TROPISM IN VIVO

Purposes of the contained use

Entry of human immunodeficiency virus (HIV) into human cells usually requires the presence of both CD4 and a member of the seven transmembrane G-protein coupled receptor (GPCR) superfamily on the target cell. Chemokine receptors are the most common GPCRs to be used for viral entry, with CCR5 and CXCR5 appearing to be most significant in vivo. Several other chemokine receptors can however also be used as entry cofactors but their role during the course of natural infection has yet to be fully defined. HIV displays a high rate of mutation and evolution and after primary infection this genetic variation allows the virus to expand its cellular tropism to infect new cell and tissue types. Mutations in the envelope (env) gene of the virus allowing utilisation of different receptors for cellular entry appears to be a key step in this adaptive process and as such can compound the severity of the disease process.

It would therefore be useful to investigate at a molecular level the genetic and phenotypic viral determinants that confer differential tropism. To this end we propose to amplify by polymerase chain reaction (PCR) and clone HIV-1 env genes derived from a range of cell and tissue types into a eukaryotic expression vector or into a HIV proviral backbone. For pseudotype construction, these clones will then be co-transfected into eukaryotic cells in culture, with a vector containing a standard HIV proviral backbone with a non-functional env gene and green fluorescent protein (GFP) replacing the nef gene. Alternatively, a recombinant, replication competent virus will be expressed from a recombinant proviral sequence into which the PCR-derived env sequences has been inserted. Pseudotyped or infectious virus secreted in the culture medium can then be used to attempt infection of either primary cell types or cells stably expressing CD4 and/or one of the chemokine receptors. If infection is successful then both structural proteins and GFP in the viral backbone will be expressed thus allowing relative entry efficiency to be determined either by direct visualisation under fluorescence or by indirect detection of viral antigens.

Recipient or parental organism
Host/vector system

Bacteria (E. coli K12 derivatives: JM 109 (promega) and Top 10F’ (Invitrogen) will be used solely for plasmid DNA amplification, not for protein expression. Vectors used will be pGEMT easy (Promega), pGL3 (Promega), pEGFP-C1 (Clonetech), pCR3.1 (Invitrogen), and pSVIII.

Origin & function

pEGFP-C1 and pGL3 will be amplified in E. coli then transfected, unmodified, using CaPO4 or electroporation into eukaryotic cells (293 T or C8166) as controls for transformation efficiency. Various viral genes and gene fragments will be amplified from clinical specimens and cloned into pGEMT easy or pCR3.1 for DNA sequencing and in the case of pCR3.1 also for transfection into eukaryotic cells (293T, C8166). The pSVIII constructs contain either one of a variety of HIV-1 envelope genes. Env sequences will be directionally ligated into the proviral backbone pNL43 2KpnI as previously described (Dittmar et al. Virus Genes 23: 281-290; 2001), and directly transfected into 293T cells for recombinant virus expression. Alternatively, amplified env sequences will be ligated into the expression vectors pSVIII or pCR3.1, and co-transfected with pNL43 envGFP to generate pseudotypes (He at al., Nature 385: 645-649; 1997). Replication competent or pseudotyped virus will tested against a range of CD4 and co-receptor expressing cell types (U87, NP2, GHOST) or primary cells.

Evaluation of foreseeable effects

The clones will be used both for direct DNA sequencing of inserts and expression in eukaryotic cells to produce virus capable of in vitro replication. The proposed experiment can be separated into two basic sections:

(1) Amplification of DNA in bacteria. Constructs are non-mobilisable plasmids in a disabled host. After bacterial transformation the genetically modified host is unlikely to survive outside the culture conditions. Maintenance of plasmids within bacteria requires specific concentrations of ampicillin the culture media and other conditions unlikely to be replicated in nature. Additionally the presence of the large NL4.3 envGFP plasmid results in a severe reduction in bacterial fitness even when compared to the standard disabled strains, further reducing the likelihood of bacterial spread outside of the culture conditions. The individual plasmid DNA extracted from these bacteria does not contain all the relevant sequences to produce functional virus. The expression of virus requires the mixing of two plasmids in appropriate proportions before careful eukaryotic transfection and can only produce low levels of viral particles capable of a single cell infection and no virus spread. The genetically modified bacteria and extracted DNA therefore represents low/no risk to human health.

(2) Transfection into Eukaryotic cells. The DNA will be transfected into 293 T cells using either calcium phosphate or electroporation. All steps associated with transfection and subsequent infectivity assays with pseudotyped and replication competent HIV-1 will be carried out at containment level III. In the event that DNA will be electroporated into 293T or other mammalian cells, this will be done in an adjacent laboratory which houses the apparatus, but immediately transferred to the containment level III laboratory following transfection. The relatively long replication cycle of HIV-1 between infection and generation of infectious virus (>18 hours) makes the electroporation procedure non-biohazardous; transfer to the containment level III laboratory will in all cases be carried out within 15 minutes of electroporation. Generation of infectious virus will in all cases, produce HIV that is identical to its native configuration; no attempt will be made to modify transcription, envelope proteins etc. We can therefore predict that containment level III facilities designed for handling natural isolates of HIV-1 will be suitable for HIV-1 generation by the above procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All spent culute media or other liquids, contaminated glassware, gloves microcentrifuge tubes, micro-pipette tips and tissue culture plastics are rendered safe by autoclaving prior to disposal as general waste. Pipettes (including Pasteurs) are completely immersed for at least 18 hours in Haztabs (Guest Medical) solution (Haztabs
Solution = 1 tablet/litre of water = 2,500 ppm Chlorine) and then disposed of as clinical waste.

The autoclave is fitted with a thermocouple linked to a chart recorder to monitor the effective completion of the sterilisation cycle. SOPs stipulate that no material should be removed from the autoclave without first checking that the cycle was completed. The degree of kill for autoclaving is effectively 100%.

Several studies have reported reductions in viral titre in excess of 99% following short (maximum 2 hrs minimum 2 mins) exposure to 2,500ppm Chlorine. These studies were carried out on both enveloped and non-enveloped viruses, on dried material, blood and virus solutions. The exposure of contaminated material for in excess 18 hrs would be expected to exceed these levels.

Narang and Codd (1983) Action of commonly used disinfectants against enteroviruses J Hospital Infection 4, 209-212 (100% kill)

This is straightforward project that aims to investigate the co-receptor usage of different strains/isolates of HIV. The approach taken is to use PCR to amplify the envelope gene from clinical isolates of HIV and to either 1) generate defective pseudotype HIV strains carrying the expressed env protein gene on the surface of the virus, but without the env gene being carried in the encapsidated genome. Or 2) to generate replication competent HIV carrying the cloned env gene. In the first case the virus generated will be replication defective and so should pose little or no risk to the population or environment. In the second case the virus being recreated is derived from and so similar to those existing in nature and so poses no additional risk above that of wild type HIV. In both cases the use of Category III containment is appropriate. The use of Category 1 containment for the initial cloning steps in bacterial is also appropriate.

INVESTIGATING THE PATHOGENESIS AND IMMUNE CONTROL OF EPSTEIN BARR VIRUS (EBV) RELATED TUMOURS. TO INVESTIGATE THE INTERACTION BETWEEN LYMPHOCYTE SUBCLASS (CD4/CD8/NK) AND EBV INFECTED CELL LINES.

Biomedical research.

The recombinant viruses will be based on established laboratory strains of vaccinia, (thymidine kinase gene deletion) (western reserve strain) and synthesised by Alan Rickinson at the Institute of Cancer Research, Birmingham University. The EBV sequences were positioned downstream of the vaccinia P7.5 early late promoter.

Recombinant modified vaccinia virus with individual Epstein Barr Virus genes expressed.

EBNA 3A
EBNA 3B
EBNA 3C
EBNA 1
MA 9210
Plasmids containing EBV-LMP 1 and 2 genes
The induced genes are to be expressed to (1) act as antigens to stimulate the proliferation of EBV specific lymphocytes, and (2) to allow recognition by lymphocyte effector cells. All EBV coding sequences used to generate the vaccinia virus recombinants were made of B95.8 virus.

**Evaluation of foreseeable effects**

The recombinant viruses would be expected to be of less or unaltered pathogenicity as the parental wild type viruses which are ACDP category 2 pathogens.

Culture of modified Vaccinia virus with Epstein Barr Virus (EBV) constructs.
The recombinant modified vaccinia virus with Epstein Barr Virus inserts were obtained from colleagues at Birmingham University. The vaccinia virus has a deleted thymidine kinase gene and is therefore attenuated compared to wild-type virus. The recombinant virus being approximately tenfold less virulent in mice than wild type virus (Buller et al 1985). Small stocks of vaccinia virus containing EBV constructs will be grown up and stored in the John Hughes Bennett Laboratory at the Western General Hospital where health and safety procedures are in place. Both the Vaccinia Virus and EBV are category 2 pathogens and therefore this portion of the work will be carried out in a Class II safety cabinet under Category 2 containment.

**INFECTION OF HUMAN CELL LINES WITH MODIFIED VACCINIA VIRUS WITH EBV CONSTRUCTS**

EBV negative cell lines will be infected with recombinant vaccinia in a small volume of PBS (0.5ml) in a 10 cm petri dish, the maximum number of cells to be infected with be approximately 10 x 10 (to the power of 6), at a multiplicity of infection 10:1. The cells will be incubated overnight and will normally be used in a chromium 51 release cytotoxicity assay. Both the Vaccinia Virus and EBV are category 2 pathogens and therefore this portion of the work will be carried out in a Class II safety cabinet under Category 2 containment.

**CHROMIUM RELEASE ASSAY**
The chromium release assay is in routine use and all radiological health and safety procedures are in place. In order to carry out this assay we will need to transfer small aliquots of infected cells (less than 10 x 10 (to the power of 6)) into the designated radioactive room and associated tissue culture room routinely used for this work. All cells will be placed in sealed plastic tubes in a sealed plastic box to transfer between rooms. Radioactive waste will be soaked in 1% virkon for at least 30 minutes, monitored for radioactivity and disposed of either down the sink designated for radioactive waste (liquid) or in the appropriate radioactive bins (solid). As the final stage of the experiment requires measurement in the gamma counter, 1% Virkon will be added to the tubes, prior to disposal in the radioactive waste.

**PROLIFERATION ASSAY**
If we require to do proliferation assays, we will decontaminate the cells with 1% virkon for at least 30 minutes prior to use of the Tomtec for counting tritiated thymidine release.

**Reference**
Buller RM, Smith GL, Cremer K, Notkins AL, Moss B

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All spent culture media or other liquids, contaminated glassware, microcentrifuge tubes, micro-pipette tips and tissue culture plastics are rendered safe by soaking in 1% virkon for at least 30 minutes prior to autoclaving to as general waste. All gloves and tissues used will be autoclaved.
The autoclave is fitted with a thermocouple linked to a chart recorder to monitor the effective completion of the sterilization cycle. SOPs stipulate that no material should be removed from the autoclave without first checking that the cycle was completed. The degree of kill for autoclaving is effectively 100%.

Radioactive waste will be soaked in 1% virkon for at least 30 minutes, monitored for radioactivity and disposed of either down the sink designated for radioactive waste (liquid) or in the appropriate radioactive bins (solid). As the final stage of the experiment requires measurement in the gamma counter, 1% Virkon will be added to the tubes, prior to disposal in the radioactive waste.

---

The expression of potentially transforming genes was discussed and it was agreed that the lytic nature of the Vaccinia infection made the risk of transformation following infection negligible. The committee requested a comment re any immunomodulatory function of the expressed genes be made. This was done. The use of 30 minutes incubation in a 1% (final concentration) solution of Virkon as a means of disinfection of the small volumes of infected and radioactive samples was deemed satisfactory. (see www.antechh.com)

It was accepted that it was appropriate to carry out the work under category 2 containment.

### Project Additional Information

**Purpose of the contained use**
Biomedical research.

**Recipient or parental organism**
Murine (MCMV) and human (HCMV) cytomegalovirus, adenovirus, vaccinia virus, herpes simplex type 1.

**Host/vector system**
Recombinant herpesviruses (murine and human cytomegalovirus, herpes simplex type I) and replication defective derivatives.

Adenovirus
Vaccinia virus.

**Origin & function**
The recombinant viruses will be based on established laboratory strains of MCMV, HCMV, HSV I adenovirus and vaccinia. Deleted viruses may contain marker genes derived from bacteria, the jellyfish green fluorescent protein (GFP) or the bacterial lacZ gene. Viruses derived from the use of Bacterial Artificial Chromosome (BAC) technology may contain a bacterial origin of replication in addition to any marker genes or deletions.

**Evaluation of foreseeable effects**
The recombinant viruses would be expected to be of less or unaltered pathogenicity as the parental wild type viruses which are ACDP category 2 pathogens in the case of HCMV, HSV I, adenovirus or vaccinia, or category 1 in the case of MCMV.

Generation of recombinant CMV by homologous recombination. Recombinant CMV is generated following homologous recombination in bacterial cells between CMV sequences contained in an appropriate plasmid and the entire CMV genome contained in a BAC. The CMVBAC DNA is predicted to be infectious and therefore could theoretically be taken up by and infect a host cell if released intact from a killed bacterium in the gut. However, the efficiency by which virus DNA produces an infection following electroporation into permissive eukaryotic cells is low, and the likelihood of BAC DNA being released intact and then being taken up by a cell to produce virus is therefore low/effectively zero. HCMV (but not MCMV) to infect human cells and therefore any infection that did arise could be theoretically give rise to infectious virions. The consequence of infection via this route is however likely to be low as there is little evidence that HCMV is an enteric pathogen and it is unlikely that any released virus would survive. Therefore this portion of the work will be carried out under Category 1 containment.

Use of CMVBAC to generate modified HCMV/MCMV virus in tissue culture. In order to generate infectious virus the construct containing the HCMV or MCMV genome is a
bacterial artificial chromosome (BAC) will be transfected into eukaryotic tissue culture cells. This will give rise to genetically modified viruses. With the exception of MCMV, all viruses are ACDP category 2 pathogens; therefore this portion of the work will be carried out in a Class II safety cabinet under Category 2 containment. All subsequent growth of modified virus will also be carried out under category 2 containment.

Recombinant herpes simplex virus I. The recombinant HSV I strains containing the lac Z or GFP fusion products were obtained from the University of California, Irvine, USA. All work done with the infectious virus will be under Category 2 containment while work on viral nucleic acids will be done under Containment level 1.

Recombinant adenovirus. CMV regulatory sequences of interest are first cloned into the pShuttle-GFP vector. These are then co-transfected with the adenoviral backbone plasmid pAdEasy-1 (deleted for the oncogenic proteins E1 and E3) into bacteria to generate recombinants. Since no virus genes will be expressed in bacteria, these manipulations will be done under Category I containment. Thereafter the Adenovirus/CMV.reporter gene recombinant plasmids are transfected into the adenovirus packaging cell line 293, and the resulting recombinant adenoviruses are used for in vivo and in vitro studies in order to determine the tissue tropism of the wild-type or modified CMV regulatory sequences by measuring reporter gene activity. All this work will be carried out under Containment level 2.

Vaccinia virus. The mutant vaccinia virus contains the bacterial lacZ gene which is unlikely to enhance viral virulence or pathogenicity compared to its wild type counterpart.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture plastics and all contaminated liquid waste such as spent culture media or blood products will be autoclaved prior to disposal as general waste. Individual waste bags will be tagged and detailed records will be kept as to their origin and time of sterilization. The autoclave is fitted with a thermocouple linked to a chart recorder to monitor the effective completion of the sterilisation cycle. SOPs stipulate that no material should be removed from the autoclave without first checking that the cycle was completed. The degree of kill for autoclaving is effectively 100%. Dry waste such as pipette tips and eppendorf tubes will be bagged for incineration as clinical waste. Similar tagging for identification of the bag contents will apply.

Recyclable dry waste such as glassware or contaminated equipment will also be rendered safe prior to washing Depending on the material, methods of decontamination may include autoclaving or soaking in a commercial detergent such as Virkon for at least 18 hrs. Disposable dry waste such as gloves, microcentrifuge tubes, micro-pipette tips, agarose gels and tissue towels are incinerated as clinical waste. Pipettes (including Pasteurs) are completely immersed for at least 18 hours in Haztabs (Guest Medical) solution (Haztabs Solution = 1 tablet/litre of water = 2,500 ppm Chlorine) and then disposed of as clinical waste.

Several studies have reported reductions in viral titre in excess of 99% following short (maximum 2 hrs minimum 2 mins) exposure to 2,500ppm Chlorine. These studies were carried out on both enveloped and non-enveloped viruses, on dried material, blood and virus solutions. The exposure of contaminated material for in excess 18 hrs would be expected to exceed these levels.

Narang and Codd (1983) Action of commonly used disinfectants against enteroviruses J. Hospital Infection 4, 209-212 (100% kill)
Tyler et al (1990) Virucidal activity of disinfectants; studies with poliovirus, J Hospital Infection 15, 339-345 (100% kill at 5 mins).

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form
This proposal is concerned with the use of recombinant human and murine cytomegalovirus and also the use of Adenovirus vectors. The proposal was well presented and had considered the relevant points. The work proposed is straightforward and none of the proposed constructs are likely to increase the pathogenicity of the GMOs. It was agreed that the proposal be approved by the GMSC at containment level 2. The PI will be informed that the HSE must be informed via a CU2 prior to initiating this work.

### Project Additional Information

#### Purposes of the contained use

The objective of this project is to enhance fundamental understanding of the neuropathogenesis of RNA viruses by determining genetic loci in viral genomes which determine phenotypic properties of neurotropic viruses.

#### Recipient or parental organism

Semliki Forest Virus, Bunyamwera Virus and Theiler's Virus.

#### Host/vector system

cDNA derived, Semliki Forest Virus, Bunyamwera Virus, Theiler's Virus.

#### Origin & function

Specific gene loci will be targeted in Semliki Forest Virus, Bunyamwera Virus, Theiler's Virus. These sequences may be swapped between different natural isolates that have varying phenotypes or may be mutated or deleted. Any transfer of genetic material will only be between different strains of each virus, there will be no gene transfer between the different species.

Also standard marker and reporter genes such as bacteriophage cre recombinase, fluorescent proteins (eg EGFP) and luciferase.

#### Evaluation of foreseeable effects

Most of the genetic changes that will be introduced into the viruses can be expected to attenuate fitness. However in some cases changes in the sequences of avirulence virus cDNAs which change the sequence to that of a virulent virus cDNA would be expected to increase virulence but the changes are such that it would be only to a level seen in wild type isolates. These engineered recombinant viruses would only have sequences found in natural virus isolates, they are therefore considered highly unlikely to have increased virulence compared to that of wild type isolates.

The viral envelope glycoproteins and capsid proteins which are the major determinants of host range and cell tropism will not be changed in these studies; host range and cell tropism are therefore unlikely to be altered. The changes are not expected to significantly alter susceptibility to host defence mechanisms. There are no vaccines or treatments available for these viruses and so effects of the modifications on these aspects are not applicable.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes...
or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), dispose via clinical waste stream for incineration or microwave treatment.

Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), dispose via clinical waste stream for microwaving or via the industrial (black bag) waste stream for landfill.

Degree of kill:

Autoclaving - effectively 100% kill (annual validation)
Incineration and microwaving - not applicable, all waste is autoclaved prior to disposal by incineration or microwaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.

</table>
The study of the physiology and properties of bacteria of the genera Campylobacter and Arcobacter in order to study their ability to survive in the environment and their responses to physical and chemical stresses. The role of specific cell envelope proteins and their conservation in different strains is also under study. These studies are aimed at improving food hygiene measures and developing new detection methods.

Various strains of Campylobacter jejuni, Campylobacter coli, other Campylobacter spp., Arcobacter butzleri and non-pathogenic Arcobacter species.

Plasmids for transposon mutagenesis, shuttle vector plasmids.

Mutants will be made (knockout, complementation and targeted) mainly to study genes involved in lipopolysaccharide or capsular polysaccharide biosynthesis, cell envelope proteins stress responses and housekeeping genes. Any inserted genes are indigenous to Campylobacter and Arcobacter species.

Standard marker genes like GFP and lacZ and antibiotic resistance (e.g. kanamycin and chloramphenicol) genes will be used.

No adverse effects compared to wild-type bacteria - gene function for the target gene will be eliminated in knockout and transposon mutants and either impaired or wild-type in SDM mutants. Harmful changes leading to either increased infectivity in humans or disease in animals is extremely unlikely.

No applicable

None

Except where implicitly stated otherwise in the risk assessment, all materials (culture vessels, media plates, glassware etc.) are disposed of by autoclaving before disposal. Solids (e.g. plasticware such as pipettes, flasks, tubes etc. and agar plates) - autoclaving using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125)
degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge of any excess liquids to drains, disposal of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclaving using a make safe cycle as specified in BS 2646, Part 3, 1993 (eigher 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclaving using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for microwave treatment.

Spillages - treatment with 1% (v/v) hypochlorite for small spills for 10 min. Paper towels used to absorb liquid are autoclaved before disposal. Hypochlorite is an extremely strong disinfectant for bacteria achieving a 5-log kill at 0.0005% (AISE).

Degree of kill:
Autoclaving - effectively 100% kill (annual validation)
Microwaving or Incineration - not applicable, all waste is autoclaved prior to disposal by microwaving or incineration.

**Project Ref** 207/04.4

**Date Ackn'd** 04/06/2004  
**CU2 Project Title** Role of the tumour suppressor APC (Adenomatous polyposis coli) in medulloblastoma  
**Class** Class 2  
**CultureVolClass2** < 1 Litre
Medulloblastoma is the most common type of brain tumour in children. It is thought that the tumour suppressor gene Adenomatous polyposis coli (APC, a component of the Wnt signalling pathway) can contribute to the development of medulloblastoma. The hypothesis that loss of the tumour suppressor gene APC in mice leads to the development of medulloblastoma (a tumour of the cerebellum) will be tested.

Recipient or parental organism

Mice genetically modified to confer susceptibility to Avian Leukosis Virus (ALV) will be infected with ALV vectors.

Host/vector system

ALV vectors will be propagated in chick embryo fibroblasts then used to deliver genetic material to mice. The work poses no foreseeable risk to human health and safety and appropriate containment procedures will be put in place to prevent environmental release. ALV is a retrovirus that causes leukosis in susceptible chickens. It is not able to infect mammalian cells.

Origin & function

Virus vector expresses cre recombinase from bacteriophage P1, this catalyses recombination between short inverted repeat sequences place in the mouse genome, thereby mediating gene deletion. The experimental mice have been genetically modified not only to express the ALV receptor in the developing cerebellum so enabling tissue specific infection by the vector, but also the APC gene has been floxed so that it is deleted by the cre recombinase on infection by the vector. The vector also expresses green fluorescent protein as an inert marker.

Evaluation of foreseeable effects

No risks to human health and safety have been identified and risks to the environment are comparable to those of the wild type virus with no additional risks arising from the genetic modification. The ALV vector is only able to infect the experimental mice because these have been genetically modified to express tv-a, the ALV receptor, in neural precursor cells in the developing CNS. Similarly, in the experimental mice the APC gene is only deleted because it has been floxed by genetically modifying the mice. Were the ALV vectors to infect a chicken there would be no action by the cre recombinase on genes such as APC. The recombinant virus is therefore considered unlikely to pose any additional risks to the environment when compared to the wildtype parent.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

## Project Additional Information

### Purposes of the contained use
To investigate the mechanisms by which different bacteria cause damage to the lungs alveolar wall. The role of potential virulence factors, such as bacterial adhesive proteins and toxins, will be investigated using mutant strains in which specific genes are deleted or over-expressed on plasmids.

### Recipient or parental organism
Staphylococcus aureus, Streptococcus pneumoniae, and Pseudomonas aeruginosa.

### Host/vector system
Bacteria with plasmid vector.

### Origin & function
Potential virulence genes deleted from bacteria genome and complemented mutant carrying deleted gene on single or multi-copy plasmid.

### Evaluation of foreseeable effects
Deleted mutants are likely to be less harmful than wild-type strains. Complemented mutants carrying deleted gene on single or multi-copy plasmid are likely to be no more harmful than the wild-type strains.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 1226-130 degrees for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excell liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 1226-130 degrees for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg neeedles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 1226-130 degrees for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for microwave treatment.

Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 1226-130 degrees for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for incineration or bedding may also be disposed via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Project Additional Information

The aim of this project is to express protein-coding genes from helminth parasites such as Brugia malayi, Schistoma mansoni and Toxocara canis in the protozoal organisms Leishmania major and L. mexicana. The purpose of the work is to investigate genes that modulate or interfere with host immune responses to parasites.

Helminths are multicellular worm parasites which infect more than 1,000 million people worldwide. Their extraordinary prevalence reflects relatively low morbidity and the ability to accommodate to the host immune system. Pathology is generally due to over-zealous reactivity of the immune response to parasite products, and the prevailing paradigm is that helminths release a spectrum of active counter-inflammatory agents which dampen both immunity and immunopathology.

The helminth genes of interest are those thought to be responsible in altering the host immune response, allowing the nematode parasites to establish a chronic infection, and/or blocking the inflammatory process which cause pathology. The project will also include genes from model parasites which are not themselves infective to humans. Some of the genes are homologues of normal mammalian proteins (such as cytokines, which are soluble messagers of the immune system), while others come from gene families which are associated with the infectivity process but for which a defined function is not yet known.

In the proposed work, helminth genes will be engineered into Leishmania. These are well-characterised intracellular protozoal parasites of macrophages, which can be cultivated in vitro, and which provide a well-documented model for immunity to infection.

Recipient or parental organism

Protozoal parasites Leishmania major and Leishmania mexicana.
Host/vector system

Leishmania major, Leishmania mexicana and the shuttle plasmid pSSU.

Origin & function

The criterion for selecting a helminth gene for study under this project will be if it appears possible that the gene in question functions within the host, rather than within the parasite, by interacting with the mammalian immune system or related physiological networks such as inflammation. In addition, control proteins, including marker/reporter products from a range of species (such as jellyfish Green fluorescent proteins and derivatives, or avian ovalbumin), housekeeping proteins from parasites (as negative controls), and inserts from related but non-parasitic species such as Caenorhabditis elegans (which are unlikely to have evolved immune modulatory function) will be tested. Finally, some inserts will be truncated forms (domain-deletions) or site-directed mutants (in which active sites have been annulled).

Evaluation of foreseeable effects

The purpose of this work is to investigate genes that modulate or interfere with host immune responses to parasites. Whilst some genes may result in either no change or an improved or more effective immune response in clearing any infections, it is expected that one or more of the test genes will depress the host immune response to Leishmania, and thereby delay lesion healing. Tropism of different species has not been attributed to differential responses of the host immune system. Thus, immune suppression is likely to prolong survival in vivo, but not to alter the preferred site of infection or host range.

As with the wild-type organism, in the event of accidental infection, onward transmission to other individuals or spread in the environment cannot occur without the sandfly vector, which is absent from the UK. Infection can be treated with antimonial therapy, and the proposed genetic manipulation will not alter susceptibility of the parasite to such therapy.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge via clinical waste stream for microwave treatment.

Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Degree of kill:

Autoclaving - effectively 100% kill (annual validation)

Microwaving or Incineration - not applicable, all waste is autoclaved prior to disposal by microwaving or incineration.
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.

**CU2 Project Title** Environmental responses of bacterial pathogens of animals and man.

**Class** Class 2

**CultureVolClass2** < 1 Litre

**Consent Granted** Not Applicable

**Non-GMM**

**Project notified under transitional arrangements** No

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**
Purposes of the contained use

To explore mechanisms by which a number of defined pathogens of animals and man respond to and adapt to changes in their environment. The principal processes which will be examined will be microbial responses to incubation at low temperature (refrigeration), to oxidising agents (e.g., hydrogen peroxide which is found in sanitizers), interaction with surfaces (e.g., biofilm formation and exopolysaccharide (slime) production, as occurs during colonisation of artificial joints and implants). Fuller understanding of these adaptive processes may result in improved abilities to reduce infection or to enhance animal or human health. The study will focus on Salmonella (non-typhoidal), Campylobacter jejuni, Staphylococcus and Pseudomonas aeruginosa and will use these as comparative model organisms for exploring the similarities and differences in adaptive stress responses.

Recipient or parental organism

The programme is centred on a strategy of gene disruption, restoration and characterisation of function, therefore the recipients are normally the natural bacterial hosts or genetic derivatives of them. Highly related genes or gene fragments from other organisms may also be examined to allow study of how the gene differences convey subtle differences in function.

Salmonella (non-typhoidal), Campylobacter jejuni, Staphylococcus and Pseudomonas aeruginosa. Where cloning DNA fragments is undertaken as the principle purpose, this will use well-studied, debilitated or non-pathogenic hosts, such as E. coli or B. subtilis or attenuated strains of Salmonella.

Host/vector system

Bacterial hosts with standard, well-described, and commonly, commercially available plasmids. Where mobilisable plasmids are used, they will lack the ability for conjugal plasmid synthesis and self-transmission.

Origin & function

Most of the work involves complementation by returning normal bacterial genes or their fragments or specific recombinant derivatives (homologous genes) to the organism from which it was derived although homologues or gene fragments may also be transferred from other organisms where subtle differences in function are of interest. Genes which allow bacteria to recognise and respond to changes in their chemical and physical environments will be studied. The main responses which will be examined are adaptation to low temperature, oxidative stress and the influence of changes in growth phases where biofilm formation and exopolysaccharide production may occur.

Standard antibiotic resistance markers for ampicillin, chloramphenicol, kanamycin and erythromycin and well-characterised, non-harmful markers such as gfp, lux, luc, lacZ and xylE.

Evaluation of foreseeable effects

The general strategy for analysis will be one of gene disruption (disruption of function) and complementation (restoration of function). It is therefore not anticipated that the genetic manipulations of the organisms being studied will substantially enhance their pathogenicity, tissue tropism or host range, or introduce significant additional hazards when compared with those of the parental organisms or those occurring in the natural environment.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Additional Information

Purposes of the contained use

Bacteroides spp. Are bacteria found in large numbers of the normal healthy human intestine. These bacteria are important for the correct development of the immune system and also for liberating many of the nutrients we consume. The methods by which Bacteroides survives and competes with other bacteria in the gut are not fully understood, but production of variable components on the bacterial cell surface are likely to help, perhaps by allowing it to avoid host immunity. If Bacteroides escapes from the gut into areas of the body in which bacteria are not normally found, for example following bowel surgery, they can cause infection. By studying virulence mechanisms and genes of unknown function further, we hope it will be possible to understand how these unusual bacteria provide benefits to the human host and will also identify potential targets against which new antibiotics can be developed for the times when these bacteria cause infection.

Recipient or parental organism

Bacteroides fragilis; Bacteroides thetaiotaomicron; Bacteroides vulgatus and other Bacteroides spp. Bacteroides spp. Are members of the normal resident microbiota of the human and opportunist rather than aggressive pathogens. Infections caused by Bacteroides spp. Generally occur following abdominal surgery or events that cause perforation of the bowel, eg ruptured appendix.

Host/vector system

Bacterial hosts with plasmid suicide and shuttle vectors.

Origin & function

Genes of interest are those involved in virulence, particularly the regulation of polysaccharide biosynthesis, DNA recombination and associated processes. Insertion and deletion mutants will be made. Antibiotic resistance markers eg, erythromycin resistance, inserted into the genome of any Bacteroides spp. Will not be a threat to human health because these antibiotics are not used therapeutically to treat Bacteroides infections. Transposon mutagenesis is a naturally occurring process and all the species
that we are interested in harbour transposable elements. Any disruption or alteration of gene function as a result of a transposon insertion is therefore already likely to have occurred in the natural environment. Mutations will be complemented, DNA for complementing mutations will be derived from Bacteroides spp.

**Evaluation of foreseeable effects**

The genetic modifications that will be carried out are limited to gene deletion and complementation. This is expected to result in GMOs that are likely to be either less fit or comparable to the wild type equivalent. It is considered unlikely that the changes would increase pathogenicity, alter tissue tropism or host range, or alter susceptibility to human defence mechanisms. Bacteroides spp. Are killed by oxygen at atmospheric levels and therefore will not survive in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for microwave treatment.

**Degree of kill:**

Autoclaving - effectively 100% (annual validation)

Microwaving or incineration - not applicable, all waste is autoclaved prior to disposal by microwaving or incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.

**Project Containment**
Attaching and effacing (AE) bacteria are a group of naturally occurring non-invasive mammalian intestinal flora, including Citrobacter rodentium and some strains of Escherichia coli, that carry and express a set of genes that together comprise the Locus for Enteric Effacement (LEE). Normal activities of these genes produce proteins allowing the bacteria to attach tightly to gut epithelium after an initial superficial adherence, causing changes to the host cell structure.

The biological processes of AE bacteria during acute infection of hosts are currently being studied in many labs around the world and much has already been elucidated, using in vitro models of infecting cell lines and some studies with human volunteers. Most of the information gained relates to the immediate cellular consequences of AE lesions of host cells, or the incidence of acute diarrhoea, and little is known about any longer term, sub-clinical interaction of the bacteria and host epithelia.

Enteropathogenic (EPEC) strains of E. coli are an example of the AE group of bacteria and are the primary focus of this project. On the basis of strongly suggestive data of the long-term tumourigenic consequences of AE lesions from bacterial attachment to gut epithelia, and the incidence of detectable EPEC in the general population as a risk factor, we are interested in the cellular processes that may link EPEC infection to tumour formation.
Recipient or parental organism

Well characterised strains of enteropathogenic (EPEC) strains of Escherichia coli. Citrobacter rodentium.

Host/vector system

Bacterial host with various standard plasmid cloning vectors.

Origin & function

All strains have been designed and made to delete or inactivate one or more specific genes of the Locus for Enteric Effacement (LEE), important for the attachment and effacement process. Genes are inactivated as a result of insertion of recombinant gene segments with antibiotic-selectable markers.

Evaluation of foreseeable effects

The mutant strains are each defective in one of the proteins encoded by genes of the LEE pathogenicity island and are to be used as specific negative controls to dissect out of the genes/proteins of interest. Inactivation of each of these proteins has been reported to partially (greatly or minimally) reduce the virulence/pathogenicity of the strain. Since these deletion mutants are bacteria that lack proteins allowing fully effective attachment capability to their natural human host, it is not expected that any gain of tissue or species tropism could occur, nor has any such effect been documented so far.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g., plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g., samples, culture supernatants, tissue culture media) - treat with Presept tablet, autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Project Ref 207/06.2

Date Ackn’d 13/03/2006
Date Project Ceased 16/12/2015

The contribution of RNA secondary structure to the replication of mammalian positive-stranded RNA viruses

Class 3 CultureVolClass2 up to 100ml CultureVolumeClass3-4

Non-GMM Consent Granted Yes

Project notified under transitional arrangements N

Historical Significant Changes
Transferred to GM553 17/12/2015

Significant Change ID

02/03/2022
### Project Additional Information

#### Purposes of the contained use

To carry out functional investigations of predicted RNA secondary structures in positive-stranded RNA viruses. For the investigations planned, infectious clones from hepatitis C virus (HCV), Theiler's murine encephalitis virus (TMEV), human enterovirus (Coxsackie A21 CVA21) and other non-polio human enteroviruses will be manipulated to investigate a range of potential replication elements and other larger scale RNA structures associated with virus persistence. All manipulations are designed to modify RNA structure without altering the coding capacity of the region altered. All changes will therefore be made at synonymous sites in codons so that the proteins produced by the modified viruses are unchanged. The replication ability of viruses with modified RNA structure will be investigated in cell culture, and where appropriate, in a mouse model (TMEV).

#### Recipient or parental organism

**Bacterial**

Disabled E. coli K12-derived strains for cloning mutated DNA copies of the viruses used for RNA structure investigations. All bacterial strains are unlikely to be harmful to man or the environment.

**Mammalian**

A variety of standard continuous and primary cell lines will be used for virus expression. (3TC, Huh7 and a range of other human hepatoma-derived cell lines, Vero cells and other continuous or primary fibroblast cell lines).

#### Host/vector system

Infectious clones of TMEV, human enteroviruses and HCV.

#### Origin & function

Transfection of in vitro-generated RNA into mammalian cells allows the full replicative cycle of TMEV, other non-poliovirus enteroviruses and HCV to be initiated. These cell lines will therefore produce infectious virus, whose replication abilities can be compared to those of wild-type viruses.

#### Evaluation of foreseeable effects

All bacterial strains are disabled and therefore unlikely to be harmful to man or the environment. All mammalian cell lines for virus expression are in standard use and are known to be non-harmful for human health or safety.

RNA transcribed from clones generates potentially infectious virus particles when transfected into the appropriate mammalian cell line, which are capable of being further propagated in cell culture and on passage into animals. However, none of the mutations introduced to investigate the role of RNA structure on virus replication allow protein coding of the viruses, and no steps lead to the production of chimaeric viruses, the insertion of foreign genes in the viral genomes. Furthermore, none of the mutants are likely to alter virus tropism or host range, nor increase infectivity, virulence or transmissibility. Since all mammalian expression uses transfected viral RNA sequences, no antibiotic resistance genes or gene products will be introduced into mammalian cells. We therefore anticipate that the mutant viruses will generally show impaired replication ability or at most, restored fitness to wild type levels.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc). All solids exposed to potentially infectious TMEV, CVA21 and other non-polio enteroviruses at containment level 2 will be immersed in 3% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then disposed of via the clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill. Used agar plates will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Any excess liquids will be discharged to drains, and solid then disposed of via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill. All HCV-exposed solid materials in the containment level 3 laboratory will be autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Any excess liquids will be discharged to drains, and solid then disposed of via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - All culture fluids and other liquids containing potentially infectious TMEV, CVA21 and other non-polio enteroviruses at containment level 2 will be mixed with 3% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then disposed of through the drain. HCV culture fluids, and other liquid waste originating from work on HCV at containment level 3 will be mixed with 5% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS2646 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then discharged to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - These will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), disposed via clinical waste stream for microwave treatment.

Animal bedding and carcasses - These will be autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Carcases will be disposed of via clinical waste stream for incineration and bedding via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving - effectively 100% kill of HCV.
Disinfectant - Trigene is used for disinfection and has proven efficacy (> 5 log reduction in infectivity) against highly resistant non-enveloped viruses such as enteroviruses, and also flaviviruses (Sources: MediChem, Abbott Analytical)
Microwaving or Incineration - not applicable, all waste is autoclaved or chemically disinfected prior to disposal by microwaving or incineration.

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.
A complex molecular and biochemical interplay exists between virus and host during infection, involving extensive interaction of viral and cellular proteins. Understanding the nature of these virus-host interactions is important for deeper understanding of the establishment and pathogenesis of viral disease.

A key feature of herpesviruses is their ability to produce persistent and latent infection, a mechanism for evading the host immune response. The main aim of this research is to better understand and define how herpesviruses interact with the host cell of the molecular and immunological level during the establishment of acute infection. Our primary interest is definition of the interactions between virus and host which follow infection with cytomegalovirus (CMV), a betaherpesvirus. We will make extensive use of genetically modified forms of human and mouse CMV to examine establishment of infection, replication and host response to the virus. We are particularly interested
In the role of the macrophage as a primary host cell for the virus since it operates as a key regulator of the immune response.

**Recipient or parental organism**

Human and mouse cytomegaloviruses (betaherpes viruses).  
Other viruses to be used for control purposes - typically herpes simplex, vaccinia and adenovirus.

**Host/vector system**

N/A

**Origin & function**

The HCMV and MCMV genomes will be modified by large scale deletions and defined point mutations to target genes involved in the viral replication cycle, particularly regulators of infection, and those which interact with the cellular immune response.

Viruses will contain various standard reporter genes for tracking and assay purposes - green fluorescent protein (GFP) from jellyfish, LacZ from E. coli, UPRT from T. gondii.

**Evaluation of foreseeable effects**

Human and mouse cytomegaloviruses

It is expected that the majority of viral mutations under study would generate a negative effect on virus replication since they are expected to lead to loss of function in the genes targeted. Therefore such alterations are unlikely to generate viruses with increased infectivity, virulence or pathogenicity and will most likely result in decreased infectivity and virulence. In the event of accidental inoculation of these viruses, they would therefore be expected to have either a wild type or attenuated level of infectivity and pathogenesis. It is unlikely that any of the CMV genetic modifications proposed in this project will lead to changes in tropism or the possibility of crossing the species barrier. A group of drugs (ganciclovir and related compounds) are used to control human CMV. The viruses used in this study would be expected to show wild type levels of sensitivity to these compounds. The commonly used genetic markers would not be expected to increase the infection capabilities of the viruses in any way.

Other control viruses

To provide more specific controls for certain techniques, certain wild type viruses carrying standard non-harmful marker and reporter genes markers such as GFP will be used. These modifications will not lead to enhanced replication or pathogenesis of these viruses, any changes in tissue tropism or host specificity, alteration in susceptibility to human defence mechanisms or any adverse effects resulting from inability to treat disease or offer effective prophylaxis where this might be available.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solids (eg plasticware such as pipettes, flasks, tubes etc) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes, or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - liquids will be treated with 1% Virkon for 2 hrs. to inactivate virus prior to autoclaving. Autoclaving will be carried out using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes, or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.
Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes, or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for incineration or microwave treatment.

Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes, or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for incineration or animal bedding may after autoclaving also be disposed of via the clinical waste stream for microwaving or via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation)
Incineration and microwaving - not applicable, all waste is autoclaved prior to disposal by incineration or microwaving.

</tr>
</tbody>
</table>
The development of systems for the verification, identification and understanding of cellular and subcellular mechanisms involved in viral replication and viral:host interactions by studying transient expression in Nicotiana species of foreign cDNAs from tobacco mosaic virus (TMV) and potato virus X (PVX) based vectors.

Recipient or parental organism
Tobacco Mosaic Virus (TMV) hybrid U1/U5 vectors.
Potato virus X (PVX) genome (strain UK3) and PVX deletion mutants altered in movement functions.

Host/vector system
Host species.
Nicotiana tabacum (tobacco), Nicotiana benthamiana (closely related to cultivated tabacco and an important model host to study plant disease interactions) and other Nicotiana species.

Vector system
The methodology for expression of the TMV or PVX viral vectors in this project is either via agroinoculation (in which case standard cloning and plasmid construction will be employed using well-characterised methods with a history of safe use) or by direct inoculation of virion-like particles into the plant.

Origin & function
Arabidopsis thaliana cDNAs, Nicotiana tabacum cDNAs, N benthamiana cDNAs, Celery (Apium graveolens) cDNAs,
Standard well characterised fluorescent reporter genes such as GFP, dsRed and similar,
Plant viral movement proteins such as eg cauliflower mosaic virus 3a movement protein, patato mop-top virus triple gene block protein 2 and 3 genes, tobacco mosaic virus gene-shuffled movement protein.
The genetic material listed above is to be used for the microscopic identification in plants of the subcellular targeting address or expressed cDNA-GFP (green fluorescent protein) fusions, the identification of proteins that have the ability to move cell-to-cell or enable other proteins to do so and the identification of protein-protein and protein-RNA interactions in vivo. Additionally, this genetic material will be employed in confocal microscopy studies on viral RNA movement in and between plant cells.

**Evaluation of foreseeable effects**

TMV forms very stable rod-shaped particles in infection tissues. It is not seed or pollen transmissible, or transmitted by arthropods, nematodes or fungi-and is readily mechanically transmissible. In comparison to wild-type, virus-hybrid U1/U5 vectors and the recombinants that arise in planta from them are attenuated and restricted in host range and thus, due to the absence of suitable hosts or transmission means in the UK environment, are highly unlikely to have any adverse effects on plants, animals, humans or environment.

PVX is only transmissible by direct contact between infected plants or indirectly through mechanical transmission. PVX is not transmitted by aphids, and its host range is limited to solanaceous plants. It is proposed to use genome (strain UK3) and PVX deletion mutants altered in movement functions and thus less fit than those already in the environment. In comparison to wild-type, virus-hybrid vectors and the recombinants that arise in plants from them are attenuated and any escape in this form due to the mechanisms of transmission that would need to be involved, would pose a negligible risk to plants, animals, humans or environment.

The fluorescent proteins have been expressed in a wide range of experimental systems and there is no known toxicity or allergenicity risk associated with them. The plant cDNAs and viral movement proteins that will be expressed from the plant viral vectors occur in nature, thus novel toxicological effects are predicted. There is no known risk from the Plant viruses to humans and in all previous studies with TMV-based vectors the pathogenicity of these has been reduced in comparison to the progenitor virus.

The effect of over-expression of known and unknown plant cDNAs on vector accumulation cannot be predicted, however, in all previous studies with TMV-based vectors the pathogenicity of these has been reduced in comparison to the progenitor virus. The inclusion of plant derived sequences in a plant virus-based vector gives rise to the possibility of gene silencing. Depending on the source of the cDNA inserts silencing rates of between 1% and 10% have been observed on N. benthamiana, (which is not indigenous to the UK), based on novel phenotypic symptoms. Induction of solencing with endogenous gene sequences or transgene sequences results in reduced viral titre and infections are attenuated in comparison to wild-type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

* All experimental solutions, material or consumables used to grow or manipulate bacteria/vectors will be autoclaved before disposal.
* All modified plant material is to be kept within the containment area, after which it is disposed of by autoclaving.
* All compost used within the glasshouse/growth rooms will be autoclaved before disposal, andy wash-off from plants will be collected and treated with appropriate chemicals before disposal.

Autoclave procedure - use a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration of microwave treatment or via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads) microwaving or Incineration - not applicable, ass waste is autoclaved prior to disposal by microwaving or incineration.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**
Leishmania spp. affect 12 million people worldwide causing a spectrum of diseases from cutaneous to visceral disease. The infections can be cured with drugs such as pentavalent antimonials, miltefosine, amphotericin B but the treatment is often not available or prohibitively expensive for people in developing countries. Therefore, there is a need for novel, cheap intervention strategies, e.g. new drugs or a vaccine. The protozoan parasites are transmitted by a blood sucking insect vector and the geographic distribution of the disease reflects the vector species distribution. The parasites replicate within phagocytes such as macrophages. We study the proteins expressed by the intracellular form of different species, as these potentially lead the way for the development of novel therapies or a vaccine. Our approach is based on the biochemical analysis of the parasite proteome whereby we have already identified nearly 500 proteins, of these a fraction is specifically or predominantly expressed in phagocytes and these include enzymes that may be potential targets for novel drugs and abundant parasite-specific proteins that are likely vaccine candidates. Thus, our strategy is to determine the relevance of the aforementioned candidate enzymes or vaccine candidates for the parasite’s fitness in vitro and in vivo by creating and characterizing parasites where the respective genes were knocked out, in order to select the most promising drug or vaccine targets.
ACDP guidance detailed above, various control measures specified at Containment level 3 are not considered necessary for this work and are proposed to be omitted. Consent is also sought for derogation of some additional measures, notably the laboratory to contain all its own equipment and inactivation of GMMs within the laboratory suite. Justification for not applying full containment level 3 measures is as follows:- Leishmania spp. including L. donovani are unable to form cryptic forms and are very sensitive to dehydration. In addition they depend on nucleic acid precursors for growth that are added to the rich media in which they are grown or provided to these intracellular parasites by host cells. As a consequence they cannot survive in normal media. They are also sensitive to hypoosmolarity and for example easily lyse in water.

- All Leishmania spp. are not per se invasive and require their bloodsucking sandfly vector for transmission and percutaneous penetration as a condition for successful infection.
- The parasites do not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes, under the laboratory conditions of constant air flow and room temperature. Once dehydrated, parasites or parasite-infected host cells would not be viable. In relation to the individual control measures to be omitted from both laboratory and animal facilities: 1. Isolation: A dedicated room will be used for the laboratory work, however this will be used for all the work with parasites detailed in this risk assessment (i.e. in classes 2 & 3) and also for other similar parasite work (e.g. with P. falciparum). The room will at all times be operated to containment level 3 working practices and have a documented Code of Practice. The animal facility is separate from the other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised personnel. 2. Laboratory sealable for fumigation: There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The affected area would be treated with appropriate concentrations of a suitable disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.
- 3. Negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination: The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures. 4. Autoclave and some other equipment not within the laboratory: Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment will be used, any equipment used cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities will be undertaken outside the dedicated laboratory: (i) Fluorescence microscopy: a fluorescent microscope is located within the same building. (ii) Fluorescence activated cell sorting and analyses (FACS): a laboratory holding all FACS equipment is located within the building and operated according to a documented code of practice to accommodate this work. (ii) Storage: transfected parasite stocks are frozen and stored at -80°C or in liquid nitrogen within the same building. The freezers are locked and accessed only by authorised personnel. (iii) Autoclaving: autoclaves validated for disposal of waste are present in the same building and within the animal facility.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill. Liquids (e.g. in waste fluid containers) For the disposal of liquid waste in waste fluid containers, Presept is used at the concentration of 2500 ppm (1 x 2.5g tablet in 560 ml) in accordance with the manufacturers instructions for waste fluid jars. The disinfected liquid waste containers should stand for at least 6 hours to allow adequate exposure of all liquid waste to the Presept before discharge to drains. Alternatively, autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), then discharge liquids to drains. Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge via clinical waste stream for microwave treatment. Animal bedding and carcasses – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via clinical waste stream for incineration or bedding may also be disposed via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill. Degree of kill: Chemical disinfection (Precept = Dichloroisocyanurate) – Precept has been validated for laboratory use against vegetative bacteria, fungi, viruses and bacterial spores by the manufacturer. Especially the latter are extremely resistant and difficult to kill. Leishmania are eukaryotic cells and do not possess equivalents of protective coats such as fungal cell wall that constitutes a diffusion barrier for chemical disinfectants and cannot form resistant structures such as spores. Dichloroisocyanurates, such as Precept, damage and inactivate organic molecules, e.g. proteins, by halogenation in an indiscriminate way. Thus, their effectiveness is dictated by the amount of organic material present in a solution. The medium in which parasites are grown contains less than 10% of the organic material present in whole blood for which a concentration of 10,000 ppm of Precept has been validated by the manufacturer and found to effectively kill spores as well as very difficult to inactivate viruses. A dosage of 2,500 ppm will be used for disinfection of waste fluids to
halogenate and inactivate the organic material present. Autoclaving - effectively 100% kill (annual validation) Microwaving or Incineration – not applicable, all waste is autoclaved prior to disposal by microwaving or incineration.

### Project Additional Information

**Purposes of the contained use**

Herpes viruses are large double-stranded DNA viruses that are present in a wide variety of organisms, including both vertebrates and invertebrates. More than 130 herpes viruses infecting a range of species (only eight found in humans) have been identified to date, and these are classified into three subgroups, α-, β- and γ-herpesvirinae, based upon their genome sequence and biological characteristics. Individual human herpesviruses (HHVs) are highly prevalent with incidence ranging from one third to >95% of all tested being seropositive in the human population. At least one of the two herpes simplex viruses (HSV-1 and 2) infects up to 90% of the human population, typically causing mucocutaneous ulcers at multiple sites including recurrent oral-labial infections. In its atypical infections HSV is the leading cause of sporadic viral encephalitis and viral-induced blindness in developed countries. Despite the availability of several antiviral agents, herpesvirus infections (such as HSV-1, 2, and HHV-8) remain a serious problem. Although much is known about most stages of the viral life cycle and the HSV genome was sequenced in 1988 (even the latest herpesvirus identified to infect humans, HHV-8 discovered in 1994, was sequenced in 1996), because of the large genome size (~200 Kb) encoding bidirectionally from both strands not all genes are fully characterised. Some of the less detailed characterized stages of the viral life cycle are the interaction of viral proteins with the nuclear transport machinery and transport of viral mRNA and proteins across the nucleus, regulation of gene expression of various kinetic classes of viral genes, and the interaction of viral proteins with the nuclear membrane prior to and during assembly of virions in the nucleus. Genetically modified strains of herpesviruses along with the wild type virus will be used to investigate regulation of gene expression by herpesviral proteins and to study herpesvirus interactions with the host cell, mainly with cellular nuclear pore complex proteins and nuclear envelope proteins. The modified viruses used for this studies may include HSV-1, HSV-2, HHV-3, 4, 5, 6, -7 and -8 as many reagents are available for these viruses and they provide members of the all alpha, beta and gamma-type herpesvirinae as examples for investigation.

**Recipient or parental organism**

Human herpes viruses - herpes simplex virus types 1 and 2 and human herpesviruses- 3, 4, 5, 6, 7 and 8.

**Host/vector system**

N/A

**Origin & function**

The two major categories of human herpesviral genes of interest are - A) viral regulatory genes such as genes from the immediate early class for e.g. ICP27 of HSV or ORF57 of HHV-8 and their homologues; and B) viral tegument and capsid genes for e.g. UL31 and UL34 tegument genes of HSV and their homologues. Viral genes of interest will be either: (a) deleted (i.e. complete null mutant or partial deletion of the genes) to characterize the importance and function of the gene under study, or(b) deleted and provided either as wild-type or mutant in trans (ie by infection in complementary cell lines that express the gene of interest) so as to help in studying its function.

02/03/2022
and kinetics of regulation (its expression can be more exquisitely controlled in trans), (c) mutated (point or substitution or temperature sensitive mutations of the genes) to
dissect the function or functional interactions of the gene under study, or (d) replaced in the virus with their wild-type homologues from other HHVs. If the gene of interest is
essential then the ability of the homologues to provide wild type function would indicate a high degree of conservation, or (e) replaced in the virus with a mutated (point or
substitution or revertant mutations) or chimeric HHV homologue under its endogenous promoter to dissect its functional regions and the complimentary nature and
conserved function of the homologue gene, or (f) fused with epitope tagged versions (e.g. spectral variants of fluorescent proteins such as GFP, RFP, YFP, CFP, or the
recent FLASH tags) for direct live analysis of their localization and interactions within infected cells, or (g) fused with epitope tags (e.g. HA-tag, Histidine tag, TAP tag,
streptavidin tag) for convenient purification of viral proteins and their partners during stages of infection. We could also utilize a herpesvirus mutant that fuses i and ii, having
a non-essential herpesvirus gene deletion (such as a tk- strain) replaced with a marker/reporter gene that is also deleted or mutated in a gene of interest (e.g. ICP27) in
order to accurately quantify the effect of mutating the gene of interest on viral growth. Cellular nuclear envelope proteins that exhibit aberrant localization or accumulation
during wild-type herpesvirus infection will subsequently be tested for interaction with human herpesviral capsid proteins. In order to achieve easy i) localisation and ii)
purification, [eg to monitor gene expression and assess the efficiency of transfection] marker/reporter genes will be introduced in viral genome as inserts- in form of fusions,
and various epitope tags, with the gene of interest. Commonly used marker/reporter gene examples used in this proposal are well characterized and non-harmful.

Evaluation of foreseeable effects

The genetically modified viruses produced in this work are not expected to have increased virulence, pathogenicity, extended tissue tropism or host range or altered
susceptibility to host defence mechanisms when compared to wild type strains and in many cases viruses will be attenuated. Insertion of foreign genes at the thymidine
kinase locus results in viruses that are resistant to the antiviral agent acyclovir, but inactivation of the thymidine kinase also prevents replication in neurons and thus strongly
attenuates the virus progeny. However, in the event of infection with a thymidine kinase negative virus, foscarnet can be used therapeutically.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc) - disinfect with either 10,000 ppm sodium hypochlorite (eg Clorox) or 1% Virkon for at least 12 hours, or autoclave
using a make safe cycle. Liquids (eg samples, culture supernatants, tissue culture media) – disinfect with either 10,000 ppm sodium hypochlorite (eg Clorox) or 1% Virkon
for at least 12 hours, or autoclave using a make safe cycle. Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle. Autoclave
procedure: Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or
134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids as appropriate either via clinical waste stream for incineration or heat treatment
or via the industrial (black bag) waste stream for landfill. Degree of kill: Disinfection – the concentrations and contact times used for disinfection have been shown to result in
> 5 log reduction in virus titres (sodium hypochlorite - Croughan and Behbehani 1988 J. Clinical Microbiol 26, 213-215, Virkon - manufacturers data). Autoclaving -
effectively 100% kill (annual validation) Heat treatment or Incineration via clinical waste stream – not applicable, all waste is disinfected or autoclaved prior to disposal by
heat treatment or incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
