### Project Additional Information

**Purposes of the contained use**

Previous studies, such as microarrays, have identified a number of candidate genes that may be critical regulators of normal haematopoietic cells development. This project seeks to evaluate the role of these genes in murine model systems using genetic knockdown of forced expression experiments. Briefly, murine cell populations will be transduced using lentiviral vector, retroviral vectors or transfected with normal plasmids containing shRNAs or the cDNA of the gene of interest. The cells will then be...
functionally evaluated using a combination of in vitro and in vivo techniques, the letter involving transplantation of cells in to mice.

**Recipient or parental organism**

Lentivirus parental organism- Human Immunodeficiency virus-1 (HIV-1 is classified as ACDP hazard group 3

Murine stem Cell Virus- derived from the Murine Embryonic Stem Cell Virus (MESV) and the LN retroviral vectors (first described in Hawley et al, (1992) Journal of experimental medicine 176:1149

**Host/vector system**

Recombinant lentiviral vectors pseudotyped with VSV-G envelopes, will be used with 293T cells

MSCV used with Phoenix A and Phoenix GP cells

**Origin & function**

Candidate regulator genes for normal haematopoietic cell development will be obtained in the form of cDNA originating from murine genomic or RNA libraries

**Evaluation of foreseeable effects**

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (details of the origins and deletions within the MSCV and lentiviral constructs are given in appendix 1 of the risk assessment)

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated residual risks.

The target genes do not encode viral specific protein, Nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon) work carried out in containment 2 laboratories or home office inspected animal facilities; work within class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.
Virkon is routinely used as per the manufacturer’s recommendations –

Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.
Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation)

**Project Additional Information**

**Purposes of the contained use**

Viruses have been explored as agents to target cancer either in a gene therapy setting (through the delivery of cytoxic gene payloads or alike) or as attenuated strains which replicate within tumour cells leading to the subsequent destruction of that cell. The replication competent virus approach is being explored in the clinical setting with a number of different viruses including reovirus and adenoviruses. Whilst attractive, there are a number of potential barriers which the viruses need to efficiently overcome in order to drive tumour destruction including efficient tumour cell targeting, infection and replication. This project seeks to use gene-modified replication competent viruses to investigate whether the approach can be improved in model systems.

**Recipient or parental organism**

Adenovirus type 5 (Replication Competent): ACDP Hazard Group 2
The actual genetic modification work will be carried out by colleagues in The Netherlands. In this project the already modified virus will be used for in vitro and in vivo (mouse) experiments.

The modification removes the ability for the modified virus to infect via the coxsackie B adenoviral receptor (CAR).
The modification enables the virus to infect cells via the Carcinoembryonic antigen (CEA), which is highly expressed in a number of solid tumours, but only in the luminal side of the gastro intestinal tract of a normal human adult. Thus the tropism of the virus has been affected. This characteristic of the virus targeting CEA is realised by the incorporation of a 58 aa affibody specific for the tumour antigen.
The immunogenicity of the affibody is currently unknown - as such, if immunogenic, it may further drive the immune response against the virus.

**Host/vector system**

Not applicable - the already modified virus will be supplied by collaborators based in the Netherlands

**Origin & function**

Gene-modified adenovirus targeted to CEA. The gene modification involves the deletion of amino-acids within the fibre domain which disrupts the normal infective route of the virus (through CAR) and incorporates an affibody for targeting. An affibody is effectively a very small antibody type domain that is small enough to permit efficient expression on the adenoviral fibre without significantly reducing viral titre. Viruses directed to the Her2/neu antigen have been described (Myhre S et al. (20090 Gene Therapy 16:252-261). In effect, these modifications of the virus re-direct the virus to target known tumour antigens thereby improving the specificity of targeting of the virus.

Origin of the affibody.
Affibodies have been generated using combinatorial protein approaches - effectively the antigen binding domain was generated from synthesised library cDNA's and tested using a screening approach to bind antigen. The cDNA of the affibody was then cloned into the H1 loop of the adenoviral fibre domain which contains mutations destroying
natural CAR binding and then introduced into the Ad5 genome by homologous recombination replacing the endogenous Ad5 wild-type fiber. The Ad5 genome is then used to generate functional viruses using standard methods.

**Evaluation of foreseeable effects**

The virus is essentially wild-type but with mutations of the fibre domain which prevents binding to the normal virus receptor (coxsackie adenovirus receptor - CAR) and incorporation of a 58 aa affybody specific for the tumor antigen. Initially, the target antigen used will be Carcinoembryonic antigen (CEA) which is highly expressed on a number of solid tumors but only within the luminal side of the gastro-intestinal tract of the normal human adult. The fibre attenuation prevents the normal route of viral infection and the CEA specificity will result in targeting to CEA expressing cells. These viruses have only recently been generated and part of this proposal is to test the level of specificity of infection driven by the affybody.

The affybody/fibre mutations will modify the range of cell the virus will be able to infect. Normal targeting should be severely reduced and targeting of target antigen cells increased; consequently, this will alter the tropism of the virus. The mutations will otherwise have no major effect upon the individuals except that the immunogenicity of the affybody is currently unknown - as such, if immunogenic, it may further drive the immune response against the virus.

Currently we do not have any information on the shedding of the modified virus during animal experiments. As the virus lacks CAR binding, it is possible that more virus could be shed since there isn't the extensive pool of cells to soak up the virus. However, all work using this virus will be performed in the class 2 containment room within BRU. Waste disposal procedures are stringently adhered to (see section 12).

Further viral modifications may be generated at a later date. But these will be submitted to the local GMSC for consideration.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Solid waste material (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Project Ref 141/09.2

Date Ackn'd: 25/05/2017

CU2 Project Title: RNAi knockdown of genes involved in stress responses using the BLOCK-iT Lentiviral miR RNAi Expression System from Invitrogen

Class: Class 2
Culture Volume: < 1 Litre
Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

We wish to study the role of the transcription factor ATF2 in tumour cells. By knocking down the expression of ATF2 in a variety of cell lines, we will assess the contribution of ATF2 to the transformed phenotype. Knockdown will be achieved using Lentiviral based gene transfer. Genetic modifications include the sub-cloning steps involved in the production of a Lentiviral expression plasmid, co-transfection of this expression vector together with packaging vectors into a host cell line to produce virus, and subsequently, use of Lentiviral stocks to infect target cell lines that will stably express the miRNAi of interest.

Recipient or parental organism

Lentiviral parental organism - Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system

Bacterial host - E.coli XL1-Blue
Plasmids - all have pUC origin of replication and all are mobilisation defective.

Lentiviral vector system- commercially available BLOCK-IT Lentiviral miR RNAi Expression System fro Invitrogen.
HEK 293 cells is packaging cell line.
The ‘Block-It Lentiviral miR RNAi expression system’ (Invitrogen cat no K4937-00) is a four plasmid virus production system and consists of:
pLenti6/V5 DEST - packaging vector into which the target sequence of interest is sub-cloned.
pLP1 - encodes Gag (viral structural protein) and Pol (viral replication protein).
pLP2 - encodes Rev (viral transcription factor)
pLP/VSVG - encodes the VSV-G glycoprotein for production of pseudotyped virus.
Target cells for viral vector are:- Ramos, Raji, Nmalwa, SudHL4, CRL 2261

Origin & function

ATF2 - Human - both tumour suppressing and tumour promoting phenotypes have been described for ATF2 gene. It functions as a transcription factor.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produce in packaging cell lines are replication incompetent. This whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target gene does not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class 2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animal work will be carried out by trained staff only. Intravenous injection of cell lines stably expressing miRNA of interest only. NO live virus will be injected in to mice, therefore shedding of virus is not an issue.

The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush fitting doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-pont thermocouple tests on an annual basis. Records are kept on site.

Please enter comments on the GM safety committee on the risk assessment

Since the project employs a lentiviral system with a gene that shows both tumour promoting and suppressor activities it was thought GM Class 2 was appropriate and this agreed with the applicants classification.

Project Containment

Project Ref 141/10.1
Human tumours are frequently found to contain activating mutations in the ras family of oncogenes. Expression of oncogenic ras in cells leads to aberrant signalling and acute activation of the AP-1 family of transcription factors. We wish to study the signalling events occurring downstream of oncogenic ras and subsequent changes in gene expression with a particular focus on ATF2-dependent gene expression. To do this we need to differentiate between events occurring early (within a few hours), after ras expression, and those occurring later (several days). This will be achieved by generating high-titre recombinant adenoviruses that express oncogenic ras. This allows the synchronous infection of all the cells in a sample followed by a rapid onset of ras gene expression (within 8 hours). Given the hazardous nature of the ras oncogene we are proposing to undertake and employ a range of control measures, as detailed in the risk assessment.

Recipient or parental organism

Adenovirus: ACDP Hazard Group 2

Origin & function

Human cDNA encoding HRasG12V, KRasG12V. These are oncogenes frequently found to be mutated in human cancers. Their expression causes constitutive activation of MAPK and PI3K signalling pathways and acute activation of the AP-1 family of transcription factors. We will carry out experiments intended to gain a better understanding of their role in tumourigenesis of interest and these cause aberrant expression and acute activation of the AP-1 family of transcription factors.
Flp recombinase. Required to initiate a recombination event to remove the STOP cassette and allow expression of ras in cells co-infected with recombinant ras-Adenovirus.

Evaluation of foreseeable effects

The recombinant Adenovirus lacks the E1 region and so is replication-incompetent. However, it is possible that an adverse recombination event occurring within the 293 packaging line, (or theoretically in human tissues, since adenovirus is ubiquitos in humans), could lead to generation of a recombination-competent virus (RCV). We plan to use a well characterised PCR-based assay to screen our virus stocks for RCV (indicated by the presence of the E1a gene). We will carry out this test each time we expand the virus. Furthermore we will check our stocks by infection of either HeLa or A549 cells which do not contain the E1 region. Only if RCV is present will this lead to cytopathic effects in the infected cells.

The recombinant Adenovirus possesses a STOP cassette located upstream of ras which essentially prevents its expression. Gene expression requires removal of the STOP cassette by a recombination event mediated by Flp recombinase. Flp will be expressed by means of a second recombinant adenovirus. Therefore, ras gene expression only occurs if both the ras-expressing virus and the Flp-expressing virus co-infect the same cell. This will significantly reduce the risk of workers accidentally expressing oncogenic ras in their own tissues. We will undertake not to handle open tubes of the ras-expressing and the Flp-expressing virus stocks at the same time.

Stringent disinfection regimes are applied in the laboratory along with autoclaving of all solid contaminated waste. The use of biosafe rotors and microbiological safety cabinets are also employed to protect human health and the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail " alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per the manufacturers recommendations:-
Solid surfaces are disinfected with 1% Virkon solution
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
Liquid waste (culture medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation by a third party. Records are kept on site.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form  
Tick to confirm that you have attached a risk assessment to this form
The committee asked for additional information on the STOP cassette and the possibility of read-through: the techniques employed to detect replication competent adenovirus; and whether both viruses are handled at the same time. This additional information is included in the Appendices 2 and 3 of the risk assessment.

**Historical Significant Changes**

- Transferred from GM141

**Project Additional Information**

02/03/2022
Purposes of the contained use

5T4 and related molecules will be introduced or knocked down in cell lines to investigate their biological functions. These goals will be achieved with the use of lentiviral vectors which are able to infect dividing and non-dividing cells and stably integrate into their genome. The vectors will encode the desired genes under constitutive or inducible promoters. Gene knock down will be achieved by the use of vectors encoding for shRNA against target genes. The system for lentiviral vector production is available from Invitrogen. The system utilises SIN (self inactivating) vectors which have had regulatory and accessory genes deleted to ensure that viral particles produced in packaging cell lines are replication incompetent.

Recipient or parental organism

Lentiviral parental organism- Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3.

Host/vector system

Bacterial: E.coli One Shot Stbl3’
Plasmids: pLP, pcDNA, pLenti, pENTR, pDONR, pMDLg/pRRE, pRSV-Rev and pMDg.2 plasmid vectors for packaging of lentiviral particles.

Origin & function

Human and mouse 5T4 coding sequence cloned from cDNA of respective species and is deposited in NCBI database. The sequences of other 5T4 related genes will be cloned from cDNA obtained from human or mouse cell lines. siRNA sequences targeting genes of interest will be designed and/or purchased from Invitrogen. Fluorescent protein genes are commercially available. High expression of 5T4 is very strongly expressed in normal placental trophoblast. We therefore believe 5T4 is "Oncogenic by ACGM definition" and this is highlighted in the risk. Assessment (section 7 (iv))

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular topism and confers greater stability and environmental survivability it is though that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.

The target gene does not encode viral specific protein, nor does it interfere with known activities of the virus and so is unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Contaime and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon Is routinely used as per the manufacturer’s recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to insineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowe prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation. Records are kept on site.

Please enter comments on the GM safety committee on the risk assessment

Committee agreed with the GM Class 2 classification of the work.

It asked if 5T4 was expressed in foetal cells. 5T4 is expressed in normal placental trophoblasts although the risk to any pregnant females is considered to be very low, due to the nature of the viral vector system used which generates replication competent viral particles. No pregnant females work on project. This will be kept under review.

**Project Additional Information**

**Purposes of the contained use**

We seek to investigate the role of normal and activated fibroblasts in tumour-stromal interactions upon knockdown or overexpression of genes of interest. Fibroblasts are known to exert tumour-promotive as well as tumour-suppressive functions depending on cell and expression level context. We intend to co-culture fibroblast cells with breast cancer cell lines and analyse proliferation, migration and molecular markers with Western blot, real-time PCR and Elisa.

**Recipient or parental organism**

- Lentivirus parental organism - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.
- Retroviral system parental organism - Moloney Murine Leukaemia virus (MMLV)

**Host/vector system**

- Bacterial host: E. coli DH5 alpha and Stbl3
- Viral vector/Host system - 3 plasmid based systems will be used
- Lentiviral system is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using HEK 293T packaging cell line.
- Retroviral system: pBABE system with packaging plasmids pCMV-VSVG and pUMVC3-gag-pol. Viral particles produced are replication incompetent. System is available from Adgene. (More detailed descriptions of vector system characteristics are given in Appendix 1 of risk assessment)
- Target cell lines for recombinant virus are Fibroblast cell lines 522 and 544 (see Appendix 4 of risk assessment) and breast cancer cell lines (MCF7, T47D, ZR75.1, MDA-MB -231!, MDA-MB-468). Other tumour, non-tumour epithelial and stromal cell may be investigated. Amendment and GMSC approval would be sought beforehand.

**Origin & function**

- Human genes TGF beta receptor2 has suspected tumour promoter and suppressor functions. See appendix 2 of risk assessment for more detail. (Obtained from colleagues in PLKO1 plasmid as a knockdown). Lentiviral vector system will be utilised to generate knockdown versions of this gene; whilst the MSCV retroviral system will be used to over express these genes in the target cells.
- Cyclin D1 is a tumour promoter gene (cDNA from Adgene) will be knocked down and over expressed with the same systems as above; within the breast cancer cell lines.
given in section 4 of the risk assessment.

**Evaluation of foreseeable effects**

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per manufacturer's recommendations:-

Solid surfaces are disinfected with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation by a third party company. Records are kept on site.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N

Please enter comments on the GM safety committee on the risk assessment

The committee agreed with the GM Class 2 classification.
### Project Additional Information

**Purposes of the contained use**

The work involves the study of Rho proteins (a family of GTPases involved in many cell signalling functions), their regulators and pathway-related genes along with their mutant forms. Frequently we use either overexpression or RNAi knockdown as a method of study. We have identified some important cell lines where lentiviral transduction may be required to get acceptable expression levels either transiently or to produce stable cell lines.

**Recipient or parental organism**

Lentivirus parental organism - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.
Bacterial host: E. coli NEB 10-beta (DH10B derivative) from New England Biolabs

Viral vector/Host system - 3 plasmid based systems will be used from sigma and/or Invitrogen (PLkO.1 and pLenti respectively).

Lentiviral system is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using HEK 293T packaging cell line.

Target Cells: Well established cell lines such as MDCK II (dog) and human cancer cell lines (e.g. breast cancer cell line MDA 231 and osteo-sarcoma cell line HOS and MG63).

Cloning will typically be subcloning of existing vectors (pcDNA) or if not available from a cDNA library. This will include versions of mammalian species including human, mouse and dog. Target siRNA sequences are designed from existing databases.

Cloning will typically be subcloning of existing vectors (pcDNA) or if not available from a cDNA library. This will include versions of mammalian species including human, mouse and dog. Target siRNA sequences are designed from existing databases.

Origin & function

Cloning will typically be subcloning of existing vectors (pcDNA) or if not available from a cDNA library. This will include versions of mammalian species including human, mouse and dog. Target siRNA sequences are designed from existing databases.

Evaluation of foreseeable effects

The recombinant Lentiviral viral vector systems consist of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The systems employed will be Self Inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and enironmental survivability, it is though there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation by a third party company. The performance test results generated during validation are kept on site.

Virkon is routinely used as per the manufactur's recommendations:-

Solid surfaces are disinfected with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer's recomendations).
The committee asked for additional information in the form of maps of the lentivector systems which are to be employed. These were supplied - see maps attached to risk assessment.
The committee agreed with the GM Class 2 classification

**Project Additional Information**

**Purposes of the contained use**

Novel molecular based therapeutics work by targeting enzymes, such as kinases or substrate transporters. However, these drugs frequently have off-target effects and it is important to know exactly what the mechanism of action of the drug is. To demonstrate that a drug is acting through its main target one can either knock-down the target by RNAi or overexpress a dominant negative version of the protein and show that this produces the same effect as the drug (both approaches are required for convincing proof of on target effects). This also allows for dissection of downstream pathways to ascertain the effectors responsible for drug related changes. The work needs to be carried out in a variety of cell lines and for a variety of targets due to the varied nature of Clinical and Experimental Pharmacology, which not only depends on the results obtained with different drugs but also the availability of drugs which depends on collaborations with pharmaceutical companies. Some of the cell lines we work with, mainly small cell lung cancer cell lines, are impossible to transfect with conventional transfection approaches (e.g. Lipofection or electroporation and therefore a lentiviral based approach has been chosen. As knocking-down/overexpressing some of the targets of interest may prove lethal to the cells ability to carry out inducible knock-down/overexpression is key to this proposal.

**Recipient or parental organism**

Lentivirus parental organism - Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

**Host/vector system**

Bacterial Hosts: E. coli DH5 alpha and ccdB survival 2 (genotypes are given in appendix 2 of the risk assessment).

Plasmid Vectors:
- pENTR/pSUPER+; pENTR/pTER+ (used for RNAi delivery into cell lines expressing target mRNA/protein via lipid based transient transfection).
- pENTR4; pENTR4-FLAG (used for protein expression studies).
- pLenti X1 GFP-Zeo; pLenti X2 Puro; pLenti CMV TetR Blast; pLenti X2 Puro; Lenti CMV TetR Blast; pLenti CMV Puro; pLenti CMV/TO Puro; pLenti CMV/TO GFP-Zeo; psPAX2; oMD2.G (used for lentiviral particle generation)

Viral vector system: HEK293 cells will be used to generate lentivirus particles

The lentivirus vector system is a Self-inactivating (SIN) vector system. Disablement characteristics of the system is given in Appendix 4 of the risk assessment.

**Origin & function**

Wild-type and mutated (activating or inactivating mutations) genes of the following proteins TDP2, MCT-1, MCT-4, c-Myc, p110alpha, p110beta, AKT1, AKT2, AKT3, PDPK1, K-Ras and other PIP3 interacting proteins. Also Bcl-2 family members including Mcl-1, Bcl-2, Bcl-xL, Bax, Bak, Bim, Bid, Bad, Puma and Noxa.

The genetic material is mainly human in origin, but some genes may be animal in origin (mainly murine). The genetic material will be in the form of cDNA.

The function or suspected functions of these genes are listed in Appendix 3 of the risk assessment. They are also listed below.

Biological function of proteins of interest.

TDP2 - Resolves DNA-topoisomerase adducts induced by topoisomerase poisons such as etoposide.

Overexpression may result in resistance to topoisomerase. Unlikely to be oncogenic.
MCT-1 and MCT-4 - Monocarboxylate transporters. Involved in the influx and efflux of molecules such as lactate from cells. Unlikely to be oncogenic.

C-Myc - Transcription factor involved in expression of numerous prosurvival and proliferation genes. Frequently activated in cancer and known to be oncogenic when overexpressed in presence of other mutations which promote cell survival.

K-Ras - GTPase known to activate the prosurvival and proliferation signalling pathways PI3K and MAPK. Frequently activated in cancer and oncogenic when activated.

P110 alpha and beta - PI3K catalytic subunits which generate secondary messenger PIP3. Frequently activated in cancer and oncogenic when activated.

AKT1, 2 and 3 - Main PI3K downstream effector which promotes survival, proliferation and migration. Frequently activated in cancer but not oncogenic by itself.

PDPK1 - Required for activation of AKT downstream of PI3K signalling. Frequently activated in cancer but not oncogenic by itself.

Other PI3K interacting proteins - Biological function not clear but likely to be activated in cancer and could potentially be oncogenic.

Mcl-1, Bcl-2 - Anti-apoptotic (pro-survival) Bcl-2 family members which inhibit Bax and Bak. Frequently upregulated in cancer but not oncogenic by themselves.

Bax and Bak - Pro-apoptotic proteins which cause release of cytochrome C from mitochondria. Frequently downregulated in cancer but require other mutations for their tumour suppressor function to be apparent.

Bim, Bid, Bad, Puma and Noxa - Pro-apoptotic BH3 only proteins which inhibit anti-apoptotic Bcl-2 family members and therefore activate Bax and Bak. Frequently downregulated in cancer but require other mutations for their tumour suppressor function to be apparent.

**Evaluation of foreseeable effects**

The recombinant Lentiviral viral vector system consists of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The system employed is a Self Inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Non-GMM Consent Granted

Project notified under transitional arrangements  N

Tick if notifying a connected programme of work  N
Over-expression or knockdown of kinases to study the role of various kinases in cell lines and patient samples. Genetic modifications include the sub-cloning steps involved in the production of a Lentiviral expression plasmid, co-transfection of this expression vector together with packaging vectors into a host cell line to produce virus, and subsequently, use of Lentiviral stocks to infect target cell lines that will stably express the protein of interest. Downstream analysis of stable cell lines will involve Western blotting, FCAS analysis and microscopy.

Lentivirus parental organism-Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3

Bacterial: E.coli Oneshot stbl3; E. coli ccdB survival 2; E.coli TOP10; E.coli Oneshot Omnimax. Bacterial hosts are disabled. Genotypes of bacterial host are given in Appendix 2 of the risk assessment.

Viral vector system: Lentivirus (VSV-G) with 293FT as host.
This system is a self-inactivating (SIN) vector system. The system is a 4-plasmid system. Details of the biosafety features of this system are given in appendix 4 of the risk assessment.

Target cells: ATCC catalogue lung cancer cell lines and patient B-cell lines or fibroblasts, HTCC116 DLD-1 colon cancer cell lines and additional catalogue colon and breast cancer cell lines.

The likelihood of the presence of adventitious agents in patient derived cells is considered in Appendix 7 of the risk assessment.

Biological Functions of Proteins of Interest are given below. They are all of human origin.

PKC - Protein kinase C (PKC) is a family of serine- and threonine-specific protein kinases. PKC family members phosphorylate a wide variety of protein targets and are known to be involved in diverse cellular signalling pathways PKC family members also serve as major receptors for phorbol esters, a class of tumor promoters.

MLK4 - MLK4 is a member of the mixed lineage family of kinases activated by environmental stress, cytokines and growth factors. This family of kinases lies upstream of
the kinase MKK4 and these kinases are critical regulators of the JNK pathway. In addition MLKs can activate the MKK3/6-p38 pathway and the Raf/Mek/Erk pathway.

FRK - The protein encoded by this gene belongs to the TYR family of protein kinases. This tyrosine kinase is a nuclear protein and may function during G1 and S phase of the cell cycle and suppress growth.

PAK3/7 - Both are Ser/Thr p21 activated kinases that have been described to regulate the Raf-Mek-Erk pathway and play a role in regulating the cell cycle.

Abl 1/2 - Is well studied tyrosine kinase that plays a role in CML and other cancers where the kinase is constitutively activated by a translocation to create a fusion protein BCR-ABL. Activated form can be oncogenic.

Cs1g2 - This is an undescribed kinase that is in the casein kinase family.

**Evaluation of foreseeable effects**

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whils the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, control measures utilised are appropriate to guard against the associated risks. These include the use of Class II safety cabinets, disinfection of liquid biological waste and autoclaving solid waste. The use of sharps is minimised in this project. Their use is not thought to be necessary. Any use will conform to the measures outlined in the Institute's Code of Practice.

The target genes do not encode viral specific protein nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site.

Trigene is routinely used as per the manufacturer's recommendations:
- Solid surfaces are disinfected with a 1 in 50 dilution of Trigene.
- Plastic ware that can be effectively disinfected is treated with a dilution of 1 in 50 dilution of Trigene overnight.
- Any contaminated glassware is treated with a 1 in 50 dilution of Trigene.
- The contact time is overnight.

Liquid waste (culture and medium) is disinfected by the addition of Trigene to give a working dilution of 1 in 50; and left overnight before disposal to sewers.
The committee thought that this risk assessment was comprehensive and supplied all the relevant information.

- **Historical Date of Additional Info**
- **Significant Change ID**
- **Date of Significant Change**
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to develop a vaccine for childhood Acute Lymphoblastic Leukemia (ALL). As BCG is safely used as a childhood vaccine against tuberculosis, a childhood ALL specific recombinant BCG vaccine will be developed and tested in a mouse model. BCG has been shown to be an effective vaccine vector due to its adjuvant properties and ability to cross-present antigens to the MHC class I processing pathway. The TEL/AML fusion protein occurs in 25% of cases of childhood ALL. T-cell peptide epitopes have been identified in this protein and will be cloned into wildtype BCG to make a recombinant vaccine.

**Recipient or parental organism**

*Mycobacterium Bovis BCG Pasteur strain (BCG) (attenuated with a long history of safe use)*. ATCC 35734.

Nucleotide sequence, AF095590

**Host/vector system**

Plasmid vectors:
- pCR3.1 (non-mobilisabe).

Bacterial hosts:
- *Echerichia coli DH5 alpha and TOP 10 series.*
- *Mycobacterium Bovis BCG Pasteur strain (BCG) (attenuated with a long history of safe use).* ATCC 35734

**Origin & function**

Genes of interest will be of human origin. Genes of interest will be junctional peptides from the TEL-AML1 and BCR-ABL. Either the whole gene, gene fragments or peptides will be used.

The TEL-AML1 fusion peptide is a small 30aa sequence taken from the TEL-AML1 fusion protein which is an oncogene fusion protein that is an initiating lesion in childhood ALL. However, this protein will not be used. The fusion peptide which will be cloned into the BCG and is not known to have any biological activity.

**Evaluation of foreseeable effects**

The BCG strain used in this project is a close relative of the commercially available BCG vaccine strain which has been used to vaccinate millions of patients. This strongly suggests that there would be minimal risk from the BCG strain used in this work.

The expressed tumour proteins should not be functional in the bacterial strain and given the nature of the vaccine approach, the bacterial vector with human proteins should be rapidly degraded by the innate immune system and used to prime an immune response. The risk to human health from the GMM is likely to be minimal.

The genetic insert would not alter the pathogenicity of the BCG but may impact upon deleteriously upon the growth of the bacteria since the expression of heterologous genes is commonly associated with reduced growth rates of the individual vector.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site.

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work.

Virkon is routinely used as per the manufacturer's recommendations:- 
Solid surfaces are disinfected with 1% Virkon solution. 
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. 
Any contaminated glassware is treated with 1% Virkon for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight. 
Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendations).

Project Ref 141/12.3

Date Ackn'd | CU2 Project Title | Class | CultureVolClass2 | CultureVolumeClass3-4
02/03/2022 | | | | |
Lentiviral transfection of fibroblast and epithelial cell lines using custom made lentiviral particles to over express or down regulate genes involved in the autophagic tumour/stromal model of cancer.

The aim of this project is to overexpress or knock-down genes of interest using lentiviral transduction in both fibroblast and epithelial cell lines to investigate the importance of these genes in both cancer cells and the associated stromal compartment in order to investigate effects on cancer cell growth, tumour-stoma interactions in co-cultures between stromal fibroblast cells and cancer cells, and in cancer cell metabolism.

For stable knock down experiments, lentiviral particles containing shRNA sequences targetting genes of interest will be custom made or purchased from Santa Cruz or Genocopia. The lentiviral particles are a pool of concentrated transduction ready viral particles containing target specific constructs encoding the specific shRNA under the control of a CMV promoter. Details of the viral vectors are provided in appendix 1 of the risk assessment.

For overexpression, pre-made or custom made lentiviral particles will be purchased from GeneCopoeia. The full coding sequences of the candidate genes will be inserted by the company into the viral vectors under the control of a CMV promoter and a puromycin resistance gene for selection purposes after transduction.

The viral particles are prepared by the company in the following manner. An OmicsLink™ ORF lentiviral expression plasmid (GeneCopoeia Cat. No EX-EGFP-Lv105) was constructed using GeneCopoeia proprietary RecJoin™ technology. This plasmid was co-transfected into 293Ta cells (GeneCopoeia Cat Np CLv-PK-01) with the Lenti-Pac HIV Packaging Mix (GeneCopoeia Cat. No HPK-LvTR-20). Lentivirus-containing supernatants were harvested 48 hours after transfection. Pre-made lentivirus titer ranges from 10^7 copies/ml for crude version to 10^9 copies/ml for purified lentivirus. Lentifact lentivirus production process involves stringent quality control processes including sequence verification of the insert, qRT-PCR based titer estimation, etc.

We intend to use these particles on a variety of cell lines in both monoculture and co-culture of fibroblast cells with breast cancer cell lines and look at cell metabolism, autophagy, mitophagy, proliferation, migration and molecular markers with Western blot, immunocytochemistry and flow cytometry, as well as biochemical assays of products of metabolism such as lactate and ketones.

Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus (HIV-2) is classified as ACDP hazard Group 3.

Host/vector system

Target Cells for Viral vector
Fibroblast cell lines BJ5TA, BJ1, 218, 522 and 544
Epithelial cancer cell lines MCF7, MCF10A, MDA-MB-231, SKBR3, T47D, BT20, BT474, MBA-MB-468 (all breast cancer cell lines) see appendix 2 in risk assessment for more details of the cell lines to be used. Other epithelial cell lines may be investigated, and amendment to the risk assessment would be obtained beforehand.

### Origin & function

**Genes of interest:**
- cDNA: Human Caveolin -1 and related genes
- cDNA: Human Autophagy/mitophagy related genes - including ATG16L, LAMP, TOM-20, LC3
- cDNA: Human Lactate transporter genes including MCT1 and MCT4
- cDNA: Human Transcriptional regulator genes - Including CAPER
- cDNA: Human genes associated with glycolysis and glucose transport - including GLUT-1
- cDNA: Human genes associated with senescence such as WNT5a, FBX032 and the CDK family of genes
- siRNA: to target Caveolin and related genes
- siRNA: to target MCT1, MCT4 and related genes
- siRNA: to target CAPER and associated transcriptional regulators.

As we will be studying a variety of similar and related genes within the above families, we will review the risk assessment when we look at other genes to ensure the assessment is still valid.

For knock-down experiments - Lentiviral particles containing shRNA sequences targetting genes of interest will be purchased from Santa Cruz or Genocopia.

For over-expression custom made particles will be purchased from Genocopia.

### Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of disinfectant); work carried out in containment 2 laboratories, work within Class 2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on...
an annual basis. Records are kept on site. Trigene is routinely used as per manufacturer’s recommendations:-
Solid surfaces are disinfected with Trigene trigger spray solution.
Plasticware that can be effectively disinfected is treated with final concentration of v/v 1% Trigene for a minimum of 1 hour prior to incineration.
Any contaminated glassware is treated with 1% Trigene solution for a minimum of 1 hour prior to cleaning.
Liquid waste (culture and medium) is disinfected by the addition of Trigene to give a 1% final working concentration.
A minimal contact time of 1 hour is allowed prior to disposal to sewers.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The committee agreed that this was a Class 2 project.
It was the committee’s view that the assessment was adequate for the risk profile of the work.

Date Ackn’d  25/05/2017

Date Project Ceased

CU2 Project Title

Lentiviral transfection of prostate epithelial cells

Class  Class 2

CultureVolClass  < 1 Litre

CultureVolumeClass  Consent Granted

Project notified under transitional arrangements  N
Previous studies have identified the attraction to, and the ability to cross the bone marrow endothelium as being pivotal in the metastatic process of prostate cancer. Previous studies have identified a number of candidate genes involved in targeting and crossing the endothelial membrane towards bone marrow stroma. This project seeks to evaluate these candidate genes in established cell line models of prostate epithelial metastasis. Cell lines used will be human bone metastatic cell line PC-3 and non-bone metastatic cell line LNCaP to assess action of these genes. Cell lines will be transduced with genes of interest or their corresponding siRNA pools using lentiviral vectors and analysed using a combination of human bone marrow stroma co-culture assays which model binding, transendothelial migration, colony formation and expansion.

Recipient or parental organism

Lentivirus parental organism - Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system

Bacterial host: E.coli JM109

Viral vector system: 3 generation system (ref: Dull & Zuerly et al (1998) J. Virology voi72# 11 p8463-8471) consisting of 3 packaging plasmids and a transfer vector containing the cassette of interest.

Host cell; HEK293

Target cells for viral vector:-
Human bone metastatic cell line PC-3
Non-bone metastatic cell line LNCaP

Origin & function

Ephrin receptors:-EphA1, EphA2, EphA4, EphB, 2EphB3, EphB4, EphB6
Eph receptors are a group of receptors activated by the ephrin and form the largest known subfamily of receptor tyrosine kinases (RTKs). Both Ephs and their corresponding ephrin ligands are membrane-bound proteins that require direct cell-cell interactions for Eph receptor activation. Subsequent downstream pathways have been shown to regulate motility, cell adhesion and cell polarity through the Rho family of GTPases.
Eph/ephrin signalling regulates a variety of biological processes including the guidance of axon growth cones, formation of tissues boundaries, cell migration, and contact inhibition of locomotion (CIL). Additionally, Eph/ephrin signalling has recently been identified to play a critical role in several processes including long-term potentiation, angiogenesis, and stem cell differentiation.
Genes listed are expressed in prostate epithelial cells.
Ephrin A1, A3, A4, A5; Ephrin B1, B2, B3:- The Ephrin family are a family of proteins that serve as the ligands of the Eph receptors, which compose the largest known subfamily of receptor protein-tyrosine kinases (RTKs). Both ephrins and Eph receptors are membrane-bound proteins binding and activation of Eph/ephrin intracellular signalling pathways only occur via direct cell-cell interaction. Subsequent downstream pathways have been shown to regulate motility, cell adhesion and cell polarity through the Rho family of GTPases.

Eph/ephrin signalling regulates a variety of biological processes including the guidance of axon growth cones, formation of tissue boundaries, cell migration, and contact inhibition of locomotion (CIL). Additionally, Eph/ephrin signalling has recently been identified to play a critical role in several processes including long-term potentiation, angiogenesis, and stem cell differentiation.

2 classes of ephrin:
- Ephrin A - GPI (glycosylphosphatidylinositol) linked ephrins
- Ephrin B - Transmembrane linked ephrins

Gene listed are expressed in prostate epithelial cells.

Caveolin: Cav-1 Cav-2:- Family of integral membrane proteins which are the principal components of caveolae essential for receptor-independent endocytosis. Caveolins act as scaffolding proteins within caveolins have also been shown to have lipid binding properties and mediate aspects of cholesterol and fatty acid metabolism.

The caveolin gene family has three members in vertebrates: CAV1, CAV2, and CAV3, coding for the proteins caveolin-1, caveolin-2, caveolin-3, respectively.

Evaluation of foreseeable effects

The recombinant Lentiviral vector system consists of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is though there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation by a third party company. The performance test results generated during validation are kept on site.

Virkon is routinely used as per the manufacturer's recommendations:
- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.
Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as manufacturer's recommendations).

The committee agreed with the classification. It asked the author for more information about the genes of interest and these were supplied and are listed in section 7 of this form and as a table appended to the risk assessment.

**Project Ref** 141/13.1

**Date Ackn'd** 25/05/2017

**CU2 Project Title**

Using fluorescent and luminescent reporters to monitor and isolate breast cancer (stem) cells in vitro and in vivo

**Date Project Ceased**

**Class**

Class 2

**Consent Granted**

Non-GMM

**CultureVolumeClass2**

< 1 Litre

**Project notified under transitional arrangements**

N
**Project Additional Information**

**Purposes of the contained use**

Primary aim: to monitor and isolate breast cancer (stem) cells in vitro and in vivo. Micrometastases are a major problem in breast cancer as they are resistant to standard therapies and have the potential to kill the host. It is known that breast cancer cells preferentially metastasise to the lungs, liver and bone, however the timing of this progression and the processes underpinning it are not clear. Understanding how and when breast cancer cells metastasise and how micrometastases are regulated in their environment will aid the development of new strategies to inhibit their formation or progression.

We plan to monitor cellular dissemination of breast cancer (stem) cells using in vivo imaging and isolation from mouse tissues. We have obtained bicistronic luciferase and green (GFP) and red (RFP) fluorescent cDNA vectors for lentiviral transduction from Standford University, USA (FULG and FULT vectors from (Liu et al., 2010)) for this purpose. We will transfect both breast cancer and cell lines and primary breast xenografts with the fluorescent vectors and inject them into mice. We will then monitor the spread of breast cancer (stem) cells to metastatic sites. The advantage of the bicistronic vector is that injection of luciferein can be used to detect as few as 10 cells in a metastatic site and the GFP/RFP+ cells can be localised in the excised tissues and sorted from host cells by FACS.

**Recipient or parental organism**

Lentivirus parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

**Host/vector system**

Bacterial: E. coli Stbl3 (from Invitrogen)

Viral vectors; pMDLg/pRRE, pRSV-Rev, pMD2.G, pCMVdelta8.91 lentiviral packaging plasmids

Lentiviral system: This is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using the HEK293T packaging cell line.

FLUG and FULT plasmids contain multifunctional reporter genes firefly luciferase and fluorescent proteins

Target cells: Continuous human breast cancer cell lines: MCF-7; T47D; MDA-MB-231; BT474 - All from ATCC Primary human tissue samples from Christie Hospital Biobank.

**Origin & function**
The FULG and FULT plasmids are described in Liu et al, 2010 (PNAS vol. 107 p18115-18120). They are multifunctional reporter genes used to analyse disease models by linking in vivo and ex vivo assays. They contain both firefly luciferase (Luc+) for whole body tracking of cells via bioluminescence imaging, and fluorescent proteins to allow intravitral imaging and ex vivo analyses. In FUKG and FULT Luc2 is fused to either enhanced GFP (eGFP) (FULG) or the red fluorescent protein tomato (FULG).

Evaluation of foreseeable effects

The recombinant Lentiviral vector systems consist of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The systems employed will be Self-inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The reporter genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The mice used in this study will not be GM animals. GM human tumour cells will be injected into mice. These will not have the ability to infect the animals cells.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site. It also undergoes a quarterly maintenance regime as recommended in BS2646.

Any plasticware that can be effectively disinfected is treated with 1% virkon and left overnight before entering the clinical waste route.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturers recommendations) but it is usual to leave overnight until disposal to drains.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
The Committee agreed with the classification of the work as GM Class 2. It is asked for confirmation that no sharps would be used during lentiviral particle generation. This was confirmed by the research group concerned.

### Project Additional Information

**Purposes of the contained use**

We seek to investigate the role of normal and cancer-activated fibroblasts in tumour-stromal interaction using knockdown or overexpression of genes of interest. Fibroblasts are known to exert tumour-promoting as well as tumour-suppressing functions dependent upon micro-environmental conditions and the metabolic state of the contributing cell types. We intend to co-culture fibroblast cells with breast cancer cell lines and analyse cell functionality (proliferation, migration, invasion, stem cell expansion) as well as biochemical states (molecular markers by western blot, real time PCR and Elisa).
Recipients or parental organism

Moloney Murine Leukemia Virus (MMLV)-based retroviral vectors pBabe, pWZL and pLNCX used to generate recombinant viral particles using a HEK293T based packaging cell line.

Host/vector system

Phoenix-amphotropic HEK293T packaging cell line. Provides the env gene and protein which determines the virus particle infectivity range. In this case- amphotropic.

Retroviral vectors pBabe; pWZL and pLNCX MMLV-based retroviral vectors

Details of the host vector system are given in Appendix 1 of the risk assessment

Origin & function

The host-vector system will produce recombinant virus particles which will then be used to infect a range of cell lines. These cell lines are human breast cancer cell lines and human and murine fibroblast cell lines.

The genes of interest comprise a wide range including those involved in proliferation, migration, invasion and stem cell expansion; as well as biochemical states. The known or suspected functions of these genes are listed in Appendix 2 of the risk assessment.

Evaluation of foreseeable effects

The recombinant virus has its structural genes deleted, which disables the virus and so prevent its growth in the absence of complementing cell lines or co-transfection of appropriate plasmids.

The amphoteric envelope, conferred by the packaging cell line, changes cellular tropism to most mammalian cells including human. It may be able to confer greater stability and environmental survivability of the virus. However, appropriate work practices will prevent the replication incompetent viruses from being released in to the environment.

The absence of the use of sharps in this work should help minimise risks to workers

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per the manufacturer's recommendations:-

Solid surfaces are disinfected with 1% Virkon solution

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to being placed in to the clinical waste route and then goes for incineration

Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).
The autoclave undergoes annual validation by a third party. Records are kept on site.

The committee asked to be informed of the genes that the project studies, as work progressed. This was agreed by the risk assessment author.

Historical Significant Changes

- transferred from GM141

Historical Date of Additional Info

02/03/2022
Purposes of the contained use

Microarray and single cells expression profiling experiments previously performed have identified a number of candidate genes that may be critical regulators of normal and tumorigenic prostate progenitor cells. Genes expressed in the stromal compartment of the prostate may also have a critically important function in the regulation of normal prostate and tumour-initiating cells. This project seeks to evaluate the role of these genes in these cell types in murine and human model systems using genetic knockdown experiments. Briefly, murine or human prostate cells will be transduced using lentiviral vectors containing shRNAs and cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells in to mice. One retroviral vector system will be used: pSHAG-MAGIC2, which provides constitutive expression of the shRNA from MSCV promoter. Two lentiviral vector systems will be used: (i) pLKO.1, which provides constitutive expression of shRNAs from a PolIII promoter, and (ii) pSicoR, which provides constitutive expression of shRNAs from a Pol III promoter with the option of irreversible Cre-mediated conditional inactivation of knockdown. In some cases, we would like to ensure that the genetic alteration is restricted to specific prostate lobe/area in vivo. For this, adenovirus or lentivirus will be injected intraprostatically to genetically modified mice and their control counterparts.

Recipient or parental organism

Bacterial hosts: Escherichia coli Stbl3 (for use with lentiviral vector system plamids)
   Escherichia coli Dh5 alpha (for general cloning purposes)
Bacterial recipients are none-infective strains and have multiple auxotrophic requirements. Growth and survivability is unlikely out of laboratory growth medium.
Transformation with plasmids used in this work will not alter this phenotype.

Target cell lines—Primary murine and human prostate cells (please see appendix 7 for cell use criteria)
Growth and survivability of modified and un-modified cells is unlikely outside of laboratory growth medium.

Host/vector system

Bacterial hosts: Escherichia coli Stbl3 (for use with lentiviral vector system plamids)
   Escherichia coli Dh5 alpha (for general cloning purposes)

Lentivirus pLKO.1 and pSicoR systems: parental organism is Human Immunodeficiency virus (HIV-1) and is classified as ACDP hazard group 3. Used with HEK 293 FT cells.
More details can be found in appendix 1 and 3 of the risk assessment.

The pSHAG-MAGIC2 retrovirus system: parental organism is Murine Stem Cell Virus. Used with Phoenix-E and Plat-E cells.
More details can be found in appendix 3 and 4 of the risk assessment.

Target cells: primary murine and human prostate cells

Origin & function

shRNAs expressed will target the genes listed in appendix 2 of the risk assessment, for knockdown. The function of these genes in leukaemia stem cells is not known formally, however, genes such as Pten, Brca1, and ATM are cell cycle/dna damage regulators/tumour suppressors so their knockdown may accentuate oncogenesis.
**Evaluation of foreseeable effects**

The recombinant viral vectors are highly disabled vectors based on the HIV or MSC virus. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

For the lentivirus, whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability it is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor does they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus or MSC retrovirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon is routinely used as per the manufacturer's recommendations:-

Solid surfaces are disinfected with 1% Virkon solution.

**Project Additional Information**

**Purposes of the contained use**

The proposal concerns the immortalisation of primary cells that can be readily expanded in a number for experimental investigations. Specifically, the primary cells of interest will be those that comprise the tumour microenvironment. This
is a broad set of cell types but the aim of the work is to attempt to generate mixed cultures of cells that re-capitulate key aspects of the tumour microenvironment including immune suppression. Consequently, cells that would be of interest include tumour and non-tumour stromal cells including fibroblasts and the diversity of immune cells. We have expertise in disaggregating tumours and expanding T cells for in vestion and also immortalising B cells employing EBV. We also have performed short-term tumour cell growth for co-culture assay. However, in the absence of immortalisation, cell number is usually a limiting factor for the breadth of potential experiments that can be performed. For this project, we propose to exploit the directed expression of single genes that have been shown to immortalise a range of primary cells.

Recipient or parental organism

Primary human tumour or peripheral blood cells

Host/vector system

Retroviral vectors.
Retroviral viral gene transfer vectors have been extensively engineered to eliminate all virus protein coding sequences within the vector itself. Vector particle are generated by co-expression of gag/pol and env genes with the retroviral vector within a packaging cell. The gag/pol and env genes are encoded on separate plasmids and engineered to reduce homologous sequences with the retroviral vector. This degree of engineering reduces the possibility of generating a replication-competent retrovirus to essentially zero based upon the extensive history of use of retroviral vector technology in the pre-clinical and clinical situation.

Lentiviral vectors.
Lentiviral vectors have been engineered as described below:
An enhancer deletion in the U3 region of 3'L1LTR ensures self-inactivation of the lentiviral vector following transduction and integration into the target cell’s genomic DNA.
• The number of lentiviral genes necessary for packaging, replication and transduction is limited to three (Gag/Pol/Rev), and their expression is derived from different plasmids, all lacking packaging signals. These plasmids share no significant homology to the expression vector, thus preventing the generation of replication-competent virus by recombination events.
• None of the Gag, Pol, or Rev genes will be incorporated into the packaged viral genome, thus making the mature virus replication-incompetent.

Origin & function

The genes to be used are sourced commercially with sequences as listed below.

Immortalising genes.

SV40 large and small T antigen sequences. Full sequence available here: http://www.abmgood.com/SV40-CellImmortalization.html
hTERT. Full sequence available here: http://www.abmgood.com/hTERT-Cell-Immortalization.html
siRNA targets to aid immortalisation:
pRB siRNA. Full sequence available here: http://www.abmgood.com/Myc-p53-Rb-Ras-Cell-Immortalization.html

Evaluation of foreseeable effects

Both retroviruses and lentiviruses are lack any potentially immune avoidance gene products that are encoding within the wild type viruses hence they are unlikely to have the same degree of immune protection as that afforded to the
wild type virus. The envelope glycoproteins lend to be derived from other viruses which possess different and, most
often, increased immunogenicity profiles compared to the retrovirus lentivirus envelope glycoproteins. Indeed, the
VSVg envelope commonly used to pseudotype lentiviral vectors is sensitive to complement mediated destruction in
human serum. Overall, the replication deficient virus vectors are most likely to possess an increased immunogenicity
profile as compared to the wild type vector suggesting that in the immune-competent individual, these vectors are
more likely to be subjected to immune-mediated clearance.

For the target cells ..

The genes to be expressed facilitate the modified cell 10 overcome cellular senescence and to allow the transduced
cell to become immortalised.

The modified cells require specific conditions to survive including maintenance at 37 degrees C and cultured in
incubators flushed with C02. Outside of this environment, the cells could survive in media for a period of time but
would be unlikely to expand in number. However, with evaporation, solute concentrations would build within the
remaining media and the cells would either die of that level of toxicity or die through drying out. Outside of the media
environment, cells would last only a short period of time (hours) before dying due to dehydration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a
validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes
for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is
displayed on the autoclave at the end of each cycle and this is monitored by the end-user.
The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company.
All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets
employed for this work.

Virkon is routinely used as per the manufacturer's recommendations: Solid
surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.
Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the
contact time is longer, typically overnight.

liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration.
2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to
disposal to sewers. (as per manufacturer's recommendations).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form
Then committee agreed with the classification and that the assessment was comprehensive and well written.

**Purposes of the contained use**

This project involves over expression of the PDGFRαIB in human lung cancer cells from the ATCe. The PDGFR gene is implicated in lung cancer and we wish to introduce and express these genes in a small range of cell lines. The
gene will be introduced into the cell by chemical means e.g. lipofectamine. Downstream analysis, involving cell sorting and various assays will be carried out. Other genes of interest involved in lung cancer may be used subsequently (e.g. AMPK, 81M, NKIRAS2) but the Biosafety Committee will be informed beforehand. We also intend to transfect a small range of cell lines with microRNAs. miRNAs will be introduced into the cell lines using premade Lentiviral particles resulting in integration into the cell genome. The modified cells will then be analysed using standard laboratory assays and techniques such as western blotting. Whilst we have identified the use of two miRNAs which we intend to use, other miRNAs may be used later in the project. The Biosafety Committee will be informed beforehand if this occurs. We also plan to stably silence important oncogene targets of the identified microRNAs using the shRNA lentiviral particles. We will purchase ready for use Lentiviral particles from Santa Cruz Biotechnology. Lentiviral particles are replication-incompetent and are designed to self-inactivate after transduction and integration of shRNA constructs into genomic DNA of target cells.

### Recipient or parental organism
Lentiviral systems: Lentivirus parental organism- Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

### Host/vector system
Bacterial Host Vector system: E.coli TOPO 101 pCMV expression vectors
Viral/Host systems: Custom made lentiviral particles from Santa Cruz Biotechnology for transduction of shRNA constructs into target cells
microRNA lentivector expression systems from System Bioscience (SBI), involving co-transfection of expression and packaging vectors in HEK.293 cells, resulting in pseudo-viral particles harbouring miRNA expression constructs for transduction in to target cells
Target Cells: A549 lung cells from ATCC,
H292 lung cells from ATCC

### Origin & function
Human PDGFR Gene eDNA Clone (full-length ORF Clone), expression ready, C-HA-tagged
Vector: pCMV3-C-HA
HA Tag Sequence: TATCCTTACGACGTGCCTGACGCC
Species: Human
Gene Synonym: PDGFR Bela and PDGFR-Alpha
Gene Bank ref 10: NM_002609.3 and NM_002609.4

### Health and Safety
PDGFR is implicated in lung cancer in humans. Other genes implicated in human lung cancer, such as AMPK, 81M and NKIRAS2 and genes of similar functional profile, may also be investigated.

### Evaluation of foreseeable effects
The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self-inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal. Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Lentiviral vector packaging systems will be used to transduce cells which are otherwise difficult to modify using retroviral or other methods of transfection. This will mostly be employed within a pancreatic cancer setting, focusing on the tumour cells and surrounding stromal cells.
Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

Host/vector system

Lentiviral vector systems:-
Lentiviral vector packaging systems have divided the essential functions amongst multiple plasmids to reduce the risk of generating replication-competent lentivirus (RCL). The split-genome packaging system is designed so that multiple recombination events between the components are required for autonomous replication. Clinical trials using a split-genome packaging system have shown that this strategy effectively eliminates the creation of RCLs (see Levine et. al. PNAS, 103: 17372-17377, 2006). Commercially available 3rd generation lentiviral vector systems separate the viral envelope, env (e.g. VSV-G) from the gag-pro-pol, which encodes structural and enzymatic functions. We will be using pLB, pSicoR and pSLiK which lack gag, pol, env,tat, rev and other accessory viral genes.
We will also be using GIPZ shRNA Lentiviral Particles which are produced using the Trans-Lentiviral Packaging System. The Trans-Lentiviral Packaging system provides an even higher level of safety over 3rd generation packaging systems by further splitting the viral pol (reverse transcriptase (RT) and integrase (IN) functions) from gagpro. Because the RT and IN enzymes are provided in trans to gag-pro, additional recombination events are necessary to produce RCLs

Target cells:-
Cells will be cultured from primary animal or human sources or through immortalised cell lines. Cell lines of human origin will be verified using the Institute's human cell line authentication service. The source tissue of the cells includes pancreas, kidney, spleen, liver, breast, pleural effusion, lymphocyte, brain, pericardial effusion, ascites, lymph node and endothelium. Human patient material will be acquired via the MCRC Biobank. The Institute prohibits the collection of human tissue known, or highly likely, to be infected with a human pathogen. Any deviation from this rule must be approved by the Institute Director and Biosafety Committee.

Origin & function

PKN2 (Protein Kinase N2) is a PKC-related serine/threonine-protein kinase and Rho/Rae effector protein that participates in specific signal transduction responses in the cell. Plays a role in the regulation of cell cycle progression, actin cytoskeleton assembly, cell migration, cell adhesion, tumour cell invasion and transcription activation signalling processes.
Other genes of similar function or implicated in the same cellular processes to that named may be investigated. But information as to their name and nature will be provided to the Biosafety Committee beforehand.
GFP (Green Fluorescent Protein) is a Energy-transfer acceptor. Its role is to transduce the blue chemiluminescence of the protein aequorin into green fluorescent light by energy transfer. Fluoresces in vivo upon receiving energy from the Ca2+-activated photoprotein aequorin.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV virus. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/ infection cycles. The probability of seroconversion is minimal.
For the lentivirus, whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environment metal survivability it is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.
The target genes do not encode viral specific protein, nor does they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Project Additional Information**

**Purposes of the contained use**

The project aims to investigate the immunomodulatory properties of factors derived from cancer cells on innate and adaptive immune cells typically found in the tumour microenvironment. Briefly, mouse cancer cell lines will be transduced using standard retro and lentiviral vector packaging systems such as pFB, pMSCV, pRevTRE or pLKO.1 to variably induce the upregulation or downregulation of candidate factors that might impact on the ability of the cancer cells to modulate inflammation and subvert immune surveillance. The factors will typically involve inflammatory and immune mediators but might also include known oncogenes or tumour-suppressors in order to examine how specific mutations impact the ability of the cancer cells to modulate the inflammatory and immunogenic properties of cancer cells.

**Recipient or parental organism**

Lentivirus parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

Moloney Murine Leukaemia Virus parental organism is classified as hazard group 1.

**Host/vector system**

Lentiviral vector systems:-

Lentiviral vector packaging systems have divided the essential functions amongst multiple plasmids to reduce the risk of generating replication-competent lentivirus (RCL). The split-genome packaging system is designed so that multiple
recombination events between the components are required for autonomous replication. Clinical trials using a split-genome packaging system have shown that this strategy effectively eliminates the creation of RCLs (see Levine et al. PNAS, 103:17372-17377, 2006). Commercially available 3rd generation lentiviral vector systems separate the viral envelope, env (e.g. VSV-G) from the gag-pro-pol, which encodes structural and enzymatic functions. We will employ systems such as pFB, pMSCV, pRevTRE and PLKO.1. These systems are designed as described above with the gag and pol elements provided in trans using GP-2 or Phoenix cells.

Retraviral vector systems:- GP2-293 (Clonetech@631458) is an HEK-derived cell line engineered to express the Moloney Murine leukemia Virus (MoMuLV) essential viral packaging components by stably integrating, gag and pol genes. The viral envelope must be supplied in trans. High titre recombinant retrovirus particles are produced by transient co-transfection of pFB or pMSCV-based retraviral expression vector and a plasmid that expresses a viral envelope, such as pVSV-G. These commercially available vectors with proven safety profile are in use over many years for producing infectious but defective retroviral particles. These replication deficient VI Ps will be used to transduce the target cancer cells to study the impact of the encoded transgene expression on its immunogenic properties.

The final genetically modified retroviral and lentiviral particles will be replication incompetent and therefore will not be able to propagate and establish a clinical infection. However, because they are infective they will be treated under containment level-2. Their properties are not expected to be altered by any of the inserts we will introduce into the vectors.

The potential route of transmission of the viral particles in the laboratory is mainly through skin contact that could arise from splashes, touching the objects or surfaces that are contaminated with culture media. Precautionary measures such as wearing laboratory coats and gloves and working in a laminar flow safety cabinet will prevent transmission through direct contact or inhalation of aerosol. Airborne transmissions are minimised since all cell culture work will be conducted in a class 2 microbiological safety cabinet and all centrifugation steps will be carried out in specialised sealed centrifuge buckets to prevent the generation of aerosols. Filter tips will be employed to prevent cross contamination of pipettes. No sharps or needles will be used so there is not risk of percutaneous transmissions. Accidental spillages will be dealt with by cleaning with appropriate disinfectant solutions (i.e. 1% Virkon). Any viral particle suspensions will be disposed of only after completely neutralising the virus using 1% Virkon for at least 24 hours. Contaminated consumables will be autoclaved prior to incineration.

Target Cells:- Well-characterised mouse cancer cell lines such as melanoma (8 16, 5555), colon-carcinoma (CT26) and breast-carcinoma (4T1), will be used in this project and are (or in the process to be) commercially available. B16 (ATCC® CRl6475™) and 5555 melanoma cells are a mixture of spindle-shaped and epithelial-like cells derived from C57BU6J mice. CT26 (ATCC® CRL-2638™) is an induced, undifferentiated colon carcinoma cell line derived from Balb/c mice. Product data sheets and certificate of analysis are available on the ATCC website.

Origin & function

The specific gene that we are using in this project is mouse Cycloxygenase-2 gene that was supplied commercially by SourceBioscience. COX-2 is an enzyme that is responsible for formation of prostanoids.

Other genes may be employed in this project encoding for molecules that may play a role in inflammation and immunity. In this event the Biosafety Committee will be notified beforehand.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication infection cycles. The probability of seroconversion is minimal.
For the lentivirus, whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability it is thought that there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks. The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets. etc) are rendered inactive by autoelaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon is routinely used as per the manufacturer's recommendations: Solid surfaces are disinfect with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.

Project Ref 168/18.2

Date Ackn'd: 01/10/2020

CU2 Project Title: Experimental evolution of bacterial pathogens and their mobile genetic elements

Class: Class 2

CultureVolClass2: < 1 Litre

CultureVolumeClass3-4: 

02/03/2022
In vitro experimental evolution is an experimental tool for studying the evolutionary dynamics of microbes, such as bacteria. Replicate experimental population of microbes are propagated under controlled laboratory conditions for several 100s or 1000s of generations and the evolution of their phenotypes observed over time. We are interested in how bacterial populations adapt to their abiotic and biotic environment. Genome sequencing is used to determine the mutations targeted by natural selection that underpin the observed evolutionary adaptation. These mutations are then introduced into the ancestral genotype to test their phenotypic effects. Labelled strains of the ancestral genotype allow these to be distinguished in mixed cultures, allowing for changes in Darwinian fitness to be measured by direct competition. We will use these approaches to understand how opportunistic bacterial pathogens, Escherichia coli and Pseudomonas aeruginosa, adapt to their biotic and abiotic environment. Specifically, we will test how bacterial pathogens adapt following acquisition of mobile genetic elements (e.g. plasmids), and how bacterial pathogens adapt to different microenvironments known to be present within hosts or natural environments.

Recipient or parental organism

- Pseudomonas aeruginosa
- Escherichia coli

Host/vector system

Origin & function

During this project we will generate the following GMMs:
1) Variants of bacterial strains carrying selectable markers. This allows us to:
   a) select for transconjugants (i.e. bacteria which are carrying the plasmid).
   b) identify differently marked strains when in co-culture, for example, during competition experiments.
2) Variants of bacterial strains in which we have deleted genes that were the target of natural selection during the experimental evolution.
3) Variants of plasmids labelled with derivatives of green fluorescent protein (GFP), enabling their identification using fluorescence.
4) Variants of bacterial strains carrying vectors allowing complementation, e.g. by reintroducing different alleles of a gene into a strain in which that gene has been deleted.
5) Generating these strains will also require us to use standard laboratory E. coli cloning strains such as DH5-alpha and constructs such as pUC18.

Inserted genes:
- aacC1 (encodes gentamicin acetyltransferase-3-1), confers resistance to the antibiotic gentamicin
- strpAB (encodes aminoglycoside 3-phosphotransferase), confers resistance to the antibiotic streptomycin
- aphA1 (encodes aminoglycoside 3-phosphotransferase II), confers resistance to the antibiotic kanamycin
- aadA (encodes aminoglycoside 3-adenyllyltransferase), confers resistance to the antibiotic spectinomycin
- gfp and derivatives (encodes green fluorescent protein)
- telAB (and similar), confers tellurite resistance
- lacZ (encodes beta-galactosidase), results in production of blue pigment when grown on X-gal

These inserts encode enzymes that modify antibiotics rendering them non-functional (aacC1, strpAB, aphA1, aadA), that detoxify tellurite (telAB), or that produce fluorescent or chromogenic markers (gfp, lacZ). None of them are likely to pose any direct risk to humans, animals, or plants. The insertion cassettes are designed to encode the gfp variants under the control of the lactose-inducible PA1/04/03 promoter followed by the resistance gene under its own native level promoter. Total expression of inserted proteins is unknown, however as the inserts are generally of low copy number, total amount of protein produced should be similarly low and unlikely to pose any additional risk.

Evaluation of foreseeable effects

P. aeruginosa and E. coli are designated as Class II organisms by ATCC and as Hazard Group 2 by the Advisory Committee on Dangerous Pathogens (ACDP).

E. coli is a commensal bacterium and part of a healthy mammalian gut flora but may also cause opportunistic infections. The project uses environmental and clinical isolates of E. coli. Healthy individuals are not typically at a high risk of infection. Infection may occur where the user is immuno-compromised (e.g. undergoing treatment for cancer or HIV) or via infection of existing wounds or burns. Certain strains of E. coli can cause diarrhoea, while others cause urinary tract infections, respiratory illness and pneumonia, and other illnesses (CDC). Infections of healthy people are readily treatable with antibiotics and most patients recover within 10 days.

P. aeruginosa is an environmental bacterium inhabiting freshwater and soil environments, but also causes opportunistic infections. Healthy individuals are not typically at risk of infection. Infection may occur where the user is immuno-compromised (e.g. undergoing treatment for cancer or HIV, cystic fibrosis patients) or has exposed burns. Infections of healthy people are readily treatable with antibiotics and most patients recover within 10 days.

The addition of resistance markers may increase the risk that infections are harder to treat with antibiotics. However, such risks will be mitigated by selecting resistance gene markers against antibacterials that are not used clinically (e.g. streptomycin, gentamycin).

The inserted genes will be introduced using a mini-Tn7 transposon system or homologous recombination system, both of which introduce the marker into a known location in the genome (confirmed using PCR). Labelling the bacterial chromosome poses little risk of horizontal gene transfer as the delivery vectors are unable to replicate and therefore are rapidly lost. The E. coli cloning strains are highly compromised laboratory strains and are uncompetitive outside of the lab environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection using Virkon or Distel: company testing shows effectively 100% killing of related strains of P. aeruginosa and E. coli.
Autoclaving using standard cycles effects 100% killing. Material contaminated with GMOs is autoclaved at 134 degrees C for 20 minutes. This cycle kills all plant materials and (soil) microorganisms, and has been validated by BMM Western (the autoclave manufacturer). In all autoclave runs, the temperature is monitored and recorded by a probe placed in the centre of one of the bags being autoclaved. The autoclave is checked and tested by BMM Western every 3 months. Autoclave conditions are automatically recorded and checked and archived for 3 years. The autoclave is regularly serviced and maintained.

Project transferred from GM207 on 11/05/2014
Project Additional Information

Purposes of the contained use
To image analyse and manipulate fungi expressing recombinant fluorescent and luminescent proteins in vitro

Recipient or parental organism
A range of containment level I and II fungi and disabled E. coli K12. Some of the fungi are pathogens of plants and humans.

Host/vector system
Standard host/vector systems used for yeast and filamentous fungi

Origin & function
Green fluorescent protein, other fluorescent proteins and the luminescent protein aequorin derived from Aequoria victoria and other marine organisms. These proteins will be used to label fungal proteins and organelles, and measure intracellular calcium, in fungal cells.

Evaluation of foreseeable effects
There is no possibility for increasing the pathogenicity of the pathogenic organisms with the experiments performed on them in the proposed work. The other non-pathogenic fungi to be used are model organisms that are considered generally safe to work with. The genetic material to be inserted into the recipient fungi and E. coli are not involved in pathogenesis and are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible but unlikely to be hazardous

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solids (e.g. plastic-ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (bloack bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for
treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

SPILLAGES

Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste stream.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

### Project Additional Information

#### Purposes of the contained use

The objectives of this programme are to construct and characterise mutants of *Mycobacterium bovis* BCG. These mutants will be used to analyse well-defined, non-toxic, mycobacterial cell wall components (proteins, lipids, etc) and genes that contribute to the basic physiology of mycobacteria. This project is of special interest because *Mycobacterium tuberculosis*, the causative agent of tuberculosis, is a major cause of death worldwide. The use of *M. bovis* BCG as a model organism to study *M. tuberculosis* coelomocyte genetics and physiology is well documented and will aid in the development of new classes of drugs against tuberculosis.

#### Host/vector system

DNA sequences will be introduced into *M. bovis* BCG using well characterised and harmless non-mobilisable shuttle vectors that can replicate in *E. coli* and mycobacteria (eg pJEM15, pMV261, pVV16, pPR27). These vectors contain both an *E. coli* and mycobacterial origin of replication (from the pUC cloning vector series and plasmid pAL5000, respectively) and antibiotic resistance markers (eg kanamycin and gentamycin). Only antibiotic resistances that are already present in very widely used bacterial cloning vectors will be exploited. Some of the vectors also contain the mycobacterial hsp60 promoter, the reporter genes lacZ (encoding B-galactosidase), phoA (encoding alkaline phosphatase) and gfp (encoding green fluorescent protein) or the counter-selective marker sacB (causing sucrose sensitivity to mycobacteria).

#### Origin & function

Only DNA sequences encoding non-toxic products of known function will be inserted into the vectors for introduction into *M. bovis* BCG. These products will be involved in the synthesis of cell wall components (eg. B-keto-acyl synthase and mycolyl transferase) and/or contribute to basic cellular physiology (eg essential metal ion homeostasis). The latter will include metal transporting P-type ATPases and SmtB-related metal-sensor proteins that occur in a wide range of bacteria, including non-pathogenic strains.

All sequences will be well characterised prior to introduction into *M. bovis* BCG and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced). The DNA sequences will include defined sequences, amplified by PCR, from *M. tuberculosis* (ACDP hazard group 3) DNA which has been provided by Colorado State University (USA) through the Tuberculosis Research Materials Contract of The National Institutes of Health and *M. smegmatis* (ACDP hazard group 1) DNA. The sequence of the *M. tuberculosis* genome is complete and contains no toxin-life genes.
Introduced DNA sequences will either (i) remain on self replicating plasmids to drive reporter gene expression or for expression from the mycobacterial hsp60 promoter, or (ii) be used to direct allelic replacement mutagenesis and hence generate gene deletion mutants of M. bovis BCG.

Evaluation of foreseeable effects

M. bovis BCG is a widely used live attenuated vaccine strain used to protect against tuberculosis. Staff working on this programme have previously been immunised with BCG. We will only introduce very short (<4kb) DNA sequences into M. bovis BCG using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode non-toxic cell wall components and that contribute to basic physiology (such as the sensing and transport of essential metal ions). It is therefore very unlikely that these sequences would restore virulence to M. bovis BCG which has numerous unlinked genetic alterations. Only non-mobilisable vectors will be used to introduce DNA sequences and hence it is highly unlikely that these sequences will be transferred to another organism. For reasons outlined above, the likelihood of harm in the event of exposure would be no greater than that with non-GM M. bovis BCG.

Environment

It is difficult to envisage how either the vectors or the inserts could confer a harmful phenotype or competitive advantage to M. bovis BCG. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM M. bovis BCG. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste materials (bacterial liquid cultures/Agar plates) will be completely inactivated (100% kill) by autoclaving: All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by Thermocouple testing. All solid waste will subsequently be incinerated.

Project Ref: 541/01.34

Date Ackn'd: 21/02/2001

CU2 Project Title: GENERATION OF RECOMBINANT ADENOVIRUSES EXPRESSING IMMUNE STIMULATORY MOLECULES (FU3, MDC) FOR USE IN AN IMMUNOTHERAPEUTIC APPROACH FOR THE TREATMENT OF SOLID TUMOURS

Class: Class 2

Consent Granted: not applicable

Project notified under transitional arrangements: Y

Withdrawn: N

Tick if notifying a connected programme of work: N

Project Additional Information:

Purposes of the contained use

Recipient or parental organism

Host/vector system

Origin & function
Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Significant Change ID: 541/01.58a

Date of Significant Change: 17/09/2007
**Project Additional Information**

**Purposes of the contained use**

Identified proteins enriched in particular stages of the trypanosome life cycle will be expressed or their genes manipulated in cultured insect or bloodstream forms of the parasite. This will allow investigation of the development of Trypanosoma brucei spp. through its life cycle at the cellular and molecular level. Our aim is to improve understanding of the function and regulation of these molecules, which it is expected will be clarified by these experiments. This may identify strategies to control the transmission of these parasites in Africa.

**Recipient or parental organism**

GMO: Cultured insect or bloodstream forms of the parasite. Insect forms are non-pathogenic, non-transmissible. Bloodstream forms require tsetse fly transmission. These are only indigenous in Africa. No tsetse fly colonies are maintained at the University of Manchester. Trypanosome do not produce toxins and we expect most genetic manipulation of the parasite to reduce fitness and therefore virulence.

**Host/vector system**

Parental organism: Trypanosoma brucei spp. blood and insect forms

Vector system: pGEM or pBluescript based bacterial shuttle vectors engineered to enable parasite gene expression or modulation in the parent organism using a tetracycline regulated inducible expression system. These are non mobilisable shuttle vectors. Specific vectors are pET series, pGem, pGemT-easy, pLew100, pZJM, pBluescript ll, p2T7, pH5D41 and pH430

**Origin & function**

1. T.brucei spp. genes or proteins displaying specificity, enrichment or implicated in the involvement in particular life cycle stages of the parasite. Their function is expected to be in progression of the parasite through its developmental cycle and, potentially, parasite metabolism.
2. Reporter gene expression to allow selection of transgenic parasites or detection of the expression pattern or location of those proteins described in (1). This will include genes for resistance to antibiotics used for parasite selection and green fluorescent protein gene fusions for protein localisation.

**Evaluation of foreseeable effects**

Where gene expression of particular molecules implicated in life cycle regulation are expressed we anticipate differentiation phenotypes to be observed. Specifically we will use markers for each life cycle stage to detect reduced ability to initiate differentiation, enhanced differentiation rates of failure in the programme of differentiation events at particular points. Transgenic parasites harbouring regulatory molecules with specific mutations to enable the isolation of interacting partner molecules (for example substrate-trapping mutants) or which generate altered differentiation phenotype will be used for protein isolation or examined for altered pattern of gene/protein expression. In each case transgenic bloodstream and insect form parasites will be used and differentiation between these stages examined. However, it is not possible to differentiate parasites from the insect form back to the bloodstream form in the absence of the tsetse fly vector. Therefore the life cycle cannot be completed in the laboratory. These genes will be expressed using a tetracycline inducible expression system. Therefore, in the absence of tetracycline the genes are effectively silenced.

Antibiotic resistance genes used for selection of transgenic parasites are not those used for clinical treatment of the parasite and will otherwise have no foreseeable effect. Reporter genes (e.g. green fluorescent protein) are for localisation and assay of expression pattern for particular parasite genes or sequences. There is no foreseeable consequence of this.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

T. brucei spp. does not produce spores. They are rapidly killed outside of the culture vessel or blood by desiccation osmotic shock (washing with water, detergents) and cannot penetrate unbroken skin. Parasite genes are expressed or perturbed using a tetracycline inducible system and will be effectively silenced outwith the culture vessel.
Tsetse flies are required for transmission and completion of the life cycle; these are indigenous only in sub Saharan Africa. Thus the parasites, whilst mammal infective as the bloodstream forms are effectively deficient in mobilisation capacity.

The wild type bloodstream form parasite is mammal infective and virulent. It is highly unlikely that genetic modification will enhance this; rather gene manipulation is likely to reduce virulence and transmissibility.

We request derogation from Containment class III to containment class II for specific containment measures.

CONTAINMENT MEASURE:
1. Isolation. The laboratory is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised lab personnel.
2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSHH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation.
3. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.
4. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSHH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.
5. Filtration of extract and input air. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms. These are opened only in a microbiological safety cabinet with HEPA filtration. We request derogation to level 2.
6. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms although purification of parasites from blood is not practical in a safety cabinet. However there is no generation of aerosols. The laboratory is self contained providing containment. We request derogation to level 2.
7. Autoclave in the laboratory suite. There is a central sterilisation facility in the Stopform building, but no autoclave facility within the laboratory. However, all parasites, and material that has come into contact with parasites is rendered non-infective by soaking in 2% Virkon for 12h prior to transport to the autoclave facility. Transport is in sealed containers. Therefore we request derogation to level 2.
11. Shower. Trypanosomes are only transmitted by blood-blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

REQUEST FOR DEROGATION OF ANIMAL FACILITIES
The School of Biological Sciences BSU operates as a first class animal containment facility. Laboratory rodents infected with Trypanosoma brucei spp. will be contained in accordance with the regulations defined for Containment level III. However we request derogation to containment level II for specific regulations:

1. Isolation. The BSU is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised BSU personnel.
2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSHH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation because trypanosomes do not produce spores, cannot be transmitted in an airborne form, or by aerosol. Blood-blood contact is required.
4. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.
5. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSHH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.
6. Filtration of air. Trypanosomes do not form spores and cannot undergo airborne transmission. Transmission can occur only by blood-blood contact or inoculation. Standard operating procedures minimise risk of aerosol. We request derogation to containment level II with respect to HEPA filtration of the animal enclosure.
7. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Operating procedures limit the possibility of aerosol. The
BSU is self contained providing containment. We request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood-blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

14. Control of disease vectors. Trypanosomes can only complete their life cycle in the tsetse fly. These are not indigenous in the UK, or outside sub Saharan Africa. There are no tsetse flies maintained at the University of Manchester.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A laboratory scale project employing good microbiological practice and good occupational safety and hygiene.

Disenfection with 2% aqueous Virkon solution according to University Policy and Guidance document. Material that has come into contact with parasites is inactivated by soaking in hypochlorite (1:500) for 24h.

Liquid waste and solid waste (other than sharps and animal waste) is sterilised in an autoclave maintained and validated by the manufacturer's service organisation for the destruction of clinical waste prior to transfer by a licensed operator to a commercial incinerator site authorised to treat GM waste. Sharps and animal waste are transferred directly to the incinerator for destruction.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GM committee, at a meeting held on 29.4.97, endorsed the decision of the local GM committee (dated 16.4.97) and the two outside experts from other local committees that this project requires Containment Level 2 facilities that are available in laboratories 2.681 and 2.682 of the Stopford Building. No special problems were identified that could not be contained by Good Microbiological Practice. It was noted that Group II organisms were involved and that HSE approval was required before work could start.

</table>
Genes encoding proteins likely to be important in controlling cell shape, motility, metabolism and nuclear organisation of the African trypanosome will be modified, expressed or manipulated in cultured insect or blood stream forms of the parasite. Our aim is to study fundamental aspects of parasite molecular cell biology - in particular, cell differentiation, cell motility, mitosis and control of antigenic variation. Overall, we believe that these experiments will assist in providing insight to basic parasite biology and to pathogenicity mechanisms. Given the emerging T.brucei spp. sequence information, these experiments may identify strategies and targets important for future control measures of these parasites.

GMO: Cultured insect or bloodstream forms of the parasite. Insect forms are non-pathogenic and non-transmissible. Bloodstream forms require tsetse fly transmission. These are only indigenous to Africa. There are no tsetse fly colonies maintained at the University of Manchester.

Trypanosomes do not produce toxins and we expect most genetic manipulation of the parasite to reduce fitness and therefore virulence.

Parental organism: T.brucei spp blood and insect forms.
Vector system: Non-mobilisable shuttle vectors engineered to enable parasite gene expression or modulation in the parent organisms using a tetracycline regulated inducible expression system.
Vectors used: pET series, pGem, pGem T-easy, pLew100, pZJM, pBluescript II.
1. T. brucei spp. genes or proteins displaying specificity, enrichment or implicated in the involvement in particular life-cycle stages of the parasite. Their function is expected to be in differentiation, motility, cytoskeleton, metabolism or nuclear organisation.

2. Reporter gene expression to allow selection of transgenic parasites or detection of the expression pattern or location of these proteins described in (1). This will include genes for resistance to antibiotics used for parasite selection and green fluorescent protein gene fusions for protein localisation.

**Evaluation of foreseeable effects**

We expect to see phenotypes dependent upon the specific situation. These will range from paralysis (flagellum motility); abnormal shape/division defects (mitotic and cytoskeletal proteins); antigenic coat abnormalities (nuclear regulatory proteins); general growth phenotypes (metabolic proteins). Often, the outcome will be a lethal phenotype particularly in initial gene experiments using RNA interference. In many cases, transgenic bloodstream and insect form parasites will be used and differentiation between these stages examined. However, it is not possible to differentiate parasites from the insect form back to the bloodstream form in the absence of the tsetse fly vector. Therefore, the lifecycle cannot be completed in the laboratory. These genes will be expressed using a tetracycline inducible expression system. Therefore, in the absence of tetracycline, the genes are effectively silenced.

Antibiotic resistance genes will be used for selection of transgenic parasites are not those used for clinical treatment of the parasite and will otherwise have no foreseeable effect.

Reporter genes (e.g., green fluorescent protein and epitope-tagged proteins) are for localisation and assay of expression pattern for particular parasite genes or sequences. There is no foreseeable consequence of this.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

T. brucei spp. does not produce spores. They are rapidly killed outside of the culture vessel or blood by desiccation osmotic shock (washing with water, detergents) and cannot penetrate unbroken skin. Parasite genes are expressed or perturbed using a tetracycline inducible system and will be effectively silenced outwith the culture vessel. Tsetse flies are required for transmission and completion of the life cycle; these are indigenous only in sub Saharan Africa. Thus the parasites, whilst mammal infective as the bloodstream forms are effectively deficient in mobilisation capacity.

The wild type bloodstream form parasite is mammal infective and virulent. It is highly unlikely that genetic modification will enhance this; rather gene manipulation is likely to reduce virulence and transmissibility.

We request derogation from Containment class III to containment class II for specific containment measures.

**CONTAINMENT MEASURE:**

1. Isolation. The laboratory is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised lab personnel.
2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation.
3. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.
4. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.
5. Filtration of extract and input air. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms. These are opened only in a microbiological safety cabinet with HEPA filtration. We request derogation to level 2.
6. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most
commonly as in vitro cultured forms although purification of parasites from blood is not practical in a safety cabinet. However there is no generation of aerosols. The laboratory is self contained providing containment. We request derogation to level 2.

8. Autoclave in the laboratory suite. There is an autoclave in the laboratory for sterilisation of small volume waste. Most sterilisation is carried out within the central sterilisation facility in the Stopford building. However, all parasites, and material that has come into contact with parasites is rendered non-infective by soaking in 2% Virkon for 12h prior to transport to the autoclave facility. Transport is in sealed containers. Therefore we request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood:blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

REQUEST FOR DEROGATION OF ANIMAL FACILITIES

The School of Biological Sciences BSU operates as a first class animal containment facility. Laboratory rodents infected with Trypanosoma brucei spp. will be contained in accordance with the regulations defined for Containment level III. However we request derogation to containment level II for specific regulations:

1. Isolation. The BSU is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised BSU personnel.

2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation because trypanosomes do not produce spores, cannot be transmitted in an airborne form, or by aerosol. Blood: blood contact is required.

4. Entry via airlock. Trypanosomes can only be transmitted by blood: blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.

5. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.

6. Filtration of air. Trypanosomes do not form spores and cannot undergo airborne transmission. Transmission can occur only by blood-blood contact or inoculation. Standard operating procedures minimise risk of aerosol. We request derogation to containment level II with respect to HEPA filtration of the animal enclosure.

7. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Operating procedures limit the possibility of aerosol. The BSU is self contained providing containment. We request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood-blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

14. Control of disease vectors. Trypanosomes can only complete their life cycle in the tsetse fly. These are not indigenous in the UK, or outside sub Saharan Africa. There are no tsetse flies maintained at the University of Manchester.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A laboratory scale project employing good microbiological practice and good occupational safety and hygiene.

Disinfection with 2% aqueous Virkon solution according to University Policy and Guidance document.

Liquid waste and solid waste (other than sharps and animal waste) is sterilised in an autoclave maintained and validated by the manufacturer's service organisation for the destruction of clinical waste prior to transfer by a licensed operator to a commercial incinerator site authorised to treat GM waste. Sharps and animal waste are transferred directly to the incinerator for destruction.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y
On 6.9.2000, the local GM committee considered a risk assessment submitted as a 5-yearly review of this project. The two outside experts from other local committees had questioned whether the two laboratory-attenuated strains (427 and 927) of Trypanosoma brucei brucei could be considered as specially disabled. However it was confirmed that the strains could not survive outside the culture medium and that their ‘procyclic’ forms, exclusively used in this work, were not infective to either mammals or rodents. Nevertheless, the fact that these organisms are categorised by ACDP as Hazard Group 2 requires that the experiments be performed under Containment Level 2 conditions. This decision was endorsed by the University GM committee at a meeting held on 11.10.2000.

Subsequently, in view of the fact that the range of properties of strains of organisms classified as Trypanosoma brucei brucei is not clearly differentiated from the range of properties of strains classified as Trypanosoma brucei rhodesiense, (a member of Hazard Group 3) it was decided to apply for approval of this work as a class 2 activity, with derogation as described in section 11.

02/03/2022
Adenoviral vectors expressing interferon alpha, endostatin, angiostatin or antisense CD105 mRNA will be developed by co-transfection of the shuttle vector and plasmid pJM17 into the embryonic kidney 293 cells. Transduction efficiency of the vectors will be first tested on endothelial, breast cancer and smooth muscle cells in vitro followed by their application in mouse models of angiogenesis and restenosis. Inhibition of CD105 in the endothelial cells by the antisense CD105 vector may lead to inhibition of angiogenesis and hence the regression of the tumour. Selective vascular expression of the interferon alpha, endostatin or angiostatin driven by the CD105 promoter will suppress angiogenesis and tumour growth. Application of these vectors in a mouse restenosis model may also inhibit the formation of neo-intima.

Recombinant adenoviruses with deletions in the E1 and E3 regions generated by homologous recombination between the shuttle vector pMV60 and plasmid pJM17 are replication deficient. The viruses will be used to infect cultured endothelial and smooth muscle cells and finally applied in mouse models of angiogenesis and restenosis. The viral vectors will be able to inhibit angiogenesis and tumour growth and reduce the formation of neo-intima in the mouse models.
Hosts: mouse vascular endothelial cells and smooth muscle cells; human vascular endothelial cells and smooth muscle cells; MCF-7 breast cancer cells; 293 embryonic kidney cells.

Vector: recombinant adenovirus type 5.

Origin & function

The vectors (Ad 5) will be generated by cotransfection of plasmid pJM17 and the shuttle vector pMV60 into 293 embryonic kidney cells. Plasmid pJM17 contains the genome of Ad 5 with deletions in the E1 and E3 regions. The antisense Ad 5 for CD105 may act as an inhibitor of CD105 gene expression in endothelial cells and smooth muscle cells. The Ad5/IFNalpha, Ad5/endostatin and Ad5/angiostatin may function as inhibitors of angiogenesis, tumour growth and enointima formation.

Evaluation of foreseeable effects

CD105 is a gene expressed in vascular endothelial cells and smooth muscle cells and regulates TGFB signalling. The antisense Ad 5 will be constructed to express a small fragment (< 1 kb) of CD105 antisense mRNA. The antisense Ad 5 may be able to down-regulate CD105 gene expression in the cultured endothelial and smooth muscle cells and the mouse models. Since CD105 is pro-angiogenic and correlated with tumour progression, down-regulation of CD105 expression is likely to suppress angiogenesis and tumour growth. Endostatin and angiostatin are natural peptides which are present in the body. The two peptides are known to inhibit tumour angiogenesis. The Ad5/endostatin and Ad5/angiostatin will exhibit antitumour effects when applied in the mouse tumour models. IFNalpha is used for tumour therapy, but it possesses various side-effects. The Ad5/IFNalpha driven by the CD105 promoter will restrict the expression of IFNalpha to the vasculature only, thus reduce its non-specific effects on other tissues. IFNa side-effects include fever, malaise and myalgia.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the culture media, washing solutions such as PBS, used plasticware, eg tissue culture flasks, pipettes and tips will be inactivated in a validated autoclave within the building. The mouse carcasses will be bagged in 800 gauge yellow bags, labelled and transported to a licensed incinerator. These processes of waste treatment will give 100% kill. The individuals who perform this project will receive regular medical check up.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GM Committee met on 13 September 2001 and agreed that this application would be satisfactory provided that certain changes (now incorporated into the application) were made. Reasons for arriving at conclusions were to be given, and particular alternative was to be given to assessing the risk of experiments employing the human interferon gene. Such changes have now been made to the satisfaction of the Chair of the committee.
The genes for a number of proteins involved in sulfonate and sulfate ester metabolism in Pseudomonas putida, Pseudomonas aeruginosa, and E. coli have been cloned and studied in the laboratory. The project involves molecular genetic, biochemical and physiological approaches to examine the role of these genes and their products in Pseudomonas species, with special emphasis on their relevance in the soil sulfur cycle.

The organisms to be transformed are Pseudomonas putida S-313 (Zurrer et al (87) Appl. Env. Microbiol. 53:1459-1463) and Pseudomonas aeruginosa PA01 (Holloway (55) J. Gen. Micro. 13:572-581). P. putida strains are non-pathogenic (ACGM, Annex II), whereas P. aeruginosa is an opportunistic pathogen that attacks...
Host systems used for the cloning experiments are E. coli K-12 derivatives (strains DH5α, JM109, XL1-Blue), which are disabled strains (ACGM, annex II). Expression experiments will be carried out in E. coli BL21(DE3) (Annex II), and gene transfer to pseudomonads will be done with strain S17-1 (hsdR thi recA mob+ pro) (Simon et al (83) Bio/Technology 1:784-791). Vector systems to be used include non mobilisable vectors of the pUC series and pBluescript (Annex II), expression vectors of the pET series (Novagen) and mobilisable vectors of the pUCP series (West et al (94) Gene 148:81-86) and the pBBR series (Kovach et al. (95) Gene 166:175-176). The mobilisable vectors used are not self-mobilisable, but rely on the presence of mob genes which have been integrated into the host chromosome to enable conjugative transfer. The host used in this case, strain S17-1, is auxotrophic for proline, and therefore unable to survive outside the laboratory. Other mobilisable vectors used include those the pKNOCK series (Alexayev, 1999, Biotechniques 26:824-828) and pUT series (De Lorenzo et al., 1994. Meth. Enzymol. 235:388-405), both of which contain the R6Kα replicon, and can only replicate in hosts containing the pir gene.

Origin & function

The genetic material involved in the study comprises genes involved in sulfur metabolism in soil pseudomonads (Pseudomonas putida, Pseudomonas aeruginosa). These genes encode enzymes for the desulfurisation of sulfonates and sulfate esters, and the transport systems required for uptake of the substrates into the cell. The presence of additional copies of the sulfonatase and sulfatase genes, or their deletion, is not expected to give a survival advantage to the strains used.

Evaluation of foreseeable effects

The presence of additional copies of the sulfonatase and sulfatase genes, or their deletion, is not expected to give a survival advantage either to the Pseudomonas strains used or to the disabled hosts used as intermediates in the cloning experiments.

Pseudomonas aeruginosa is a class 2 pathogen, and appropriate measures are required for its containment. The strain used (strain PA01) has been in laboratory cultivation for many years and is thought to display reduced virulence, but this is not experimentally proven or documented, and cannot be relied on.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be disposed of using a validated autoclave facility within the building. Solid waste will be disposed of using a licensed incinerator for genetically modified organisms. Small laboratory waste (pipette tips, Eppendorf tubes etc) will be immediately treated with disinfectant (Virkon) as required for Class 2 organisms, and subsequently incinerated in the GM-licensed incinerator.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

(a) E. coli BL21 is a problem strain. Its genotype does not indicate it is either auxotrophic or recombination-deficient. ACGM Compendium annex II para 12 indicates it is not a K12 or B strain derivative. Apparently this is in error, and it is known to be a B strain. It recommends an access factor of 10⁻³.

(b) E. coli S17-1 is clearly disabled, but what is the significance of mob+? This is normally part of a plasmid, does its presence in the host chromosome have significance for plasmid mobilisation?

(c) The overall risk assessment of 10-15 is correct and would normally warrant containment level 1 as proposed here. However, P. aeruginosa remains a Category 2 pathogen unless the proposer can provide convincing evidence that the incorporation of sulfonatases etc. render it otherwise. Therefore, this part of the proposal requires containment level 2 facilities to be consistent with its hazard group.

Date of Significant Change
Project Additional Information

Purposes of the contained use

The objectives of this project are to understand the biology of Salmonella, gain insights into the mechanism by which they cause disease, and develop more effective vaccines. This will involve cloning, expression and disrupting Salmonella genes. This research will be conducted using plasmids in disabled E. coli K12 hosts, and also re-introducing cloned DNA sequences back into strains of Salmonella.

Recipient or parental organism

E. Coli K12 strains (incl. DH5alpha, JM101, JM109, SURE & S17-1 lambda-pir), are disabled hosts, ACGM 2000 part 2A, annex II. Well characterised attenuated Salmonella hosts: Derivatives of WT S. typhimurium (SL3261), S. enteritidis (Se795aroA) & S. typhi (541Ty) attenuated by lesions in genes of the aromatic amino acid biosynthetic pathway, in the stress-response gene htrA, or both. They carry the same attenuations as disabled strains listed in ACGM 2000, part 2A, annex II. The S. typhi strains have been shown to be innocuous in humans and are considered disabled. The only WT hosts to be used are the well-studied S. typhimurium strains SL1344 and C5 (ACDP HG 2).

Host/vector system

Cloning & expression vectors: All derived from those listed in the ACGM 2000, part 2A, annex II as 'non mobilisable' (eg pUC series, pGEM series & derivatives) or 'mobilisation defective' (pBR322 & derivatives). Gene disruption vectors: Suicide vector pFUSE (Baumier et al., 1996) carries the mob region of RP4 allowing it to be mobilised by the transfer functions provided by an RP4 derivative integrated into the donor cell chromosome (E. coli S17-1 lambda-pir). It cannot to replicate in recipient cells lacking the essential pir gene, or be mobilised if the recipient cell provides RP4 transfer functions; hence is unable to replicate in/mobilised from the Salmonella strains.

Origin & function

Only DNA sequences constituting genes or parts of genes from Salmonella or E. coli that encode non-toxic products of known function will be inserted into the vectors for introduction into Salmonella. These products will contribute to basic cellular physiology such as essential metal ion homeostasis (including metal-transporting P-type ATPases and SmtB/MerR-related metal-sensing proteins). Introduced DNA will be expressed either individually as full-length proteins or sub-regions, and/or as fusions to other genes (within the vector) encoding non-toxic products, including the reporter genes lacZ (encoding beta-galactosidase) and gfp (encoding green fluorescent protein from jelly fish).

All sequences will be well characterised prior to introduction into Salmonella strains and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced).

Introduced DNA sequences will either i) remain on self-replicating plasmids to drive reporter gene expression or for expression of genes from their natural promoter or from vector promoters, or ii) be integrated into the genome to generate gene disruption mutants of Salmonella.

Evaluation of foreseeable effects

Human health:

The attenuated Salmonella strains employed are specifically designed to be given as oral vaccines. They can survive in and colonise the host gut sufficiently to induce an immune response however the ability to colonise the host is very dose dependent, and requires large numbers. There are no recorded instances of aro or htr mutants spreading between hosts. The wild-type S. typhimurium strains to be employed are of the type which could cause food poisoning if ingested in a large dose. These strains have been safely used for 20 years and the likelihood of hazard can therefore be considered low. We will only introduce very short (<4 kb) DNA sequences into Salmonella using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode non-toxic products that contribute to basic physiology (such as the sensing and transport of essential metal ions).
For reasons outlined above, the likelihood of harm in the event of exposure would be no greater than that with non-GM Salmonella and can be considered negligible.

Environment:
The disabled host strains will not replicate in the environment. Infections doses for man and animals are high and the probability of accidental infection low. The host strains are not known to be infectious for plants. The wild-type S. typhimurium strains may be able to replicate in the environment. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM Salmonella. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All contaminated waste materials (bacterial liquid cultures/agar plates) will be completely inactivated (100% kill) by autoclaving: All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by thermocouple testing. All solid waste will subsequently be incinerated.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee agreed that they represent realistic assessments of the risks involved, and that the facilities available and the experience of the proposers are adequate to control these risks. It was emphasised that the personnel involved must undergo Health Surveillance screening before work commences.

Project Title: Investigating gene function in the bacterium Campylobacter jejuni.

Purposes of the contained use:
The aims of the work are to determine the role of individual gene products in Campylobacter jejuni in order to understand how this organism colonises animals and causes disease in humans. Findings will facilitate design of strategies to reduce illness caused by the organism. The work will involve cloning, expression and disruption of C. jejuni genes.

Recipient or parental organism:
Escherichia coli BL21 and K12 strains and derivatives.
Campylobacter jejuni commonly used laboratory strains: NCTC 11168, NCTC 81128, 81176

Host/vector system:
Cloning and expression vectors: All derived from those listed in the ACGM 2000, part 2A, annex II as 'non mobilisable' (eg pUC series, pGEM series & derivatives) or 'mobilisation defective' (pET)
Gene disruption vectors: Suicide vectors unable to replicate in recipient campylobacter cells.

Origin & function:
Only specific Campylobacter genes or gene fragments will be inserted into vectors - no random sequences will be introduced.
Campylobacter genes or gene fragments will be cloned in Escherichia coli, disrupted through insertion of antibiotic resistance cassettes and reintroduced into Campylobacter strains whereupon through homologous recombination the disrupted non-functional gene will replace the chromosomal functional gene.
Full length functional Campylobacter genes will be cloned into Escherichia coli and reintroduced into Campylobacter strains constructed as immediately above to restore a functional gene. Again the full length functional Campylobacter gene will be recombined onto the Campylobacter chromosome.

Full length genes will be cloned into Escherichia coli and expressed as full-length proteins and as fusions to other genes (within the vector) encoding non-toxic products on plasmid vectors.

**Evaluation of foreseeable effects**

**Human health:**
Expression of Campylobacter genes in Escherichia coli is unlikely to render such disabled strains more harmful.

The wild type Campylobacter strains could potentially cause gastrointestinal illness if ingested. The strains employed are well characterised laboratory strains and have been used world wide for 20 years and therefore with good microbiological practice the likelihood of hazard is low. The gene knockouts constructed will only disable strains and complementation of gene knockouts can only restore potential hazards to wild type levels. Therefore the likelihood of harm in the event of exposure is no greater than with non-GM Campylobacter and can be considered negligible.

**Environment**
The disabled host strains will not replicate in the environment. Infections doses for man and animals are high and the probability of accidental infection low. The host strains are not known to be infectious for plants. The wild-type Campylobacter strains may be able to replicate in the environment. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM Campylobacter. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All contaminated waste materials (bacterial liquid cultures/agar plates) will be completely inactivated (100% kill) by autoclaving: All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by thermocouple testing. All solid waste will subsequently be incinerated.

**Is an emergency plan required according to regulation 20?** No

**If yes, tick to confirm that it is attached to this form** No

**Tick to confirm that you have attached a risk assessment to this form**

**Tick if you are claiming exemption from disclosure for section of the risk assessment** No
The committee agreed that they represent realistic assessments of the risks involved, and that the facilities available and the experience of the proposers are adequate to control these risks. It was emphasised that the personnel involved must undergo Health Surveillance screening before work commences.

**Project Ref** 541/06.3

- **Date Ackn’d**: 20/04/2006
- **CU2 Project Title**: The use of recombinant fungi to study allergen function.

**Project Additional Information**

**Purposes of the contained use**

The objectives of this project are to understand the biology of Aspergillus and to gain insights into how allergen proteins produced by this fungus work. In this instance allergenicity genes may also have a function in virulence. This will involve cloning and knockout of allergen and/or virulence genes from Aspergillus and expression of allergen proteins in small amounts in auxotrophic strains of Pichia pastoris. Gene knockout experiments involve cloning fungal genes in disabled E. coli K12 derivatives and reintroduction of DNA back into Aspergillus.
Recipient or parental organism

Escherichia coli K12 strains (incl DH5alpha, JM101, JM109, SURE & S17-1 lambda-pir), in the ACGM 2000 disabled hosts category, part 2A, annex II.
Well characterised Pichia pastoris His Arg auxotrophs
Laboratory strains of Aspergillus fumigatus (Af293, CEA10) (ACDP Hazard Group 2), A nidulans (Glasgow strains) and A. clavatus (NRRL1) (both ACDP Hazard group 1).

Host/vector system

Cloning and expression vectors: All derived from those listed in the ACGM 2000, part 2A, annex II as 'non-mobilisable' (eg pUC series, pGEM series & derivatives) or 'mobilisation defective' (pBR322 & derivatives). plCz alpha series plasmids for P. pastoris (Invitrogen) - non-mobilisable shuttle vector for E. coli and P. pastoris.
All vectors used for Aspergillus are integrative and based on E. coli vectors with no fungal origin of replication.

Origin & function

Only DNA sequences constituting genes or parts of genes from Aspergillus will be inserted into vectors. Allergen coding sequences (taken from the IUIS approved list of Aspergillus fumigatus allergens) will be cloned into Pichia expression vectors in E. coli before being transferred to Pichia. Flanking regions of allergen or selected known virulence genes with no coding sequence will be placed either side of a selectable marker (either Aspergillus pyrG or dominant selectable marker Hygromycin resistance from pCB1004) by PCR and transformed into Aspergillus. Avirulent and non-allergic strains of Aspergillus will be generated by gene knockout.

All sequences will be well characterised prior to introduction into Aspergillus or Pichia strains and will be generated by PCR from genomic DNA or total RNA using specific primers designed to amplify known DNA sequences (no random sequences will be introduced).

Introduced DNA sequences will either (I) remain on self-replicating plasmids to drive reporter gene expression or for expression of genes from their natural promoter or from vector promoters, or (ii) be integrated into the genome to generate gene disruption mutants of Aspergillus.

Evaluation of foreseeable effects

Human Health:
Aspergillus fumigatus is a known pathogen of immunocompromised individuals. It is also capable of being an allergen. However A. fumigatus spores are extremely common in the environment and respiratory exposure to this organisms is almost constant. These strains of A. fumigatus have been used safely in the laboratory for many years and there are no recorded instances of fungal infection resulting from this work during this time. The modifications to the organism proposed in this project would reduce allergenicity and/or virulence and thus the risk of harm due to exposure to organisms would be no greater than with non-GM Aspergillus and can be considered negligible. In the unlikely event that gene knockout causes increased virulence (as assessed by growth rate and sporulation in the first instance) live cultures will be destroyed, a small spore stock retained at -80 and HSE will be informed of the existence of the strain. GM strains produced in this project should pose no extra threat to immunocompromised individuals or women of childbearing age who are expecting a child or planning a pregnancy - exposure to wild-type Aspergillus is almost constant in the natural environment and strains produced in this project should be disabled with respect to virulence and pathogenicity.

Environment:
The disabled host strains will not replicate in the environment. Infection of immunocompetent individuals is extremely unlikely and the probability of accidental infection almost zero. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM Aspergillus. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by overnight treatment with Virkonp, autoclaving and incineration prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste materials (bacterial liquid cultures/agar plates) will be completely inactivated (100% kill) by autoclaving: All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by thermocouple testing. All liquid cultures are treated overnight with 2% Virkon prior to autoclaving. All solid waste will subsequently be incinerated.

All staff will be trained in handling sporulating fungi. GM Aspergillus will be treated with especial caution to reduce any airborne spore production - The GM strains will be handled exclusively as liquid cultures unless spore production is required for storage. Sporulation will be limited on solid media by limiting culture time to 24h at 37 degrees C and 48 h at 30 degrees C. Where sporulation is needed to produce stocks culture will be undertaken in narrow necked tissue culture flasks to limit spore escape. Flasks and other potentially sporulating cultures will be handled in a class 2 hood equipped with a UV light (in tissue culture room, ATR5) and the UV will be switched on for 1h after sporulating cultures have been opened. All work undertaken in type 2 safety cabinet according to the SOPs in Appendix 6. No culture larger than 200 ml used. All liquid waste sterilised using PreSept tablets prior to autoclaving at 121 degrees C for 30 mins. All solid waste autoclaved as above. Conveyance of culture sin double containment unbreakable sealed containers. All cultures specifically marked as “GM”. Spills to be mopped up with 10% bleach then 2% Virkon and waste autoclaved as GM waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee approved the application subject to provision of the following additional information.
1. Procedures to cover increased pathogenicity and methods for the control of spore formation.
2. Negative information, particularly where the project would have no known effect on pregnancy, childbirth and on immunocompromised individuals.

Project Ref 541/07.1
The project is to investigate the mechanisms by which regulatory proteins control the activities of stress-activated signalling pathways. cDNAs encoding mammalian protein kinases, regulatory proteins and transcription factors will be expressed in mammalian cells. Plasmids expressing siRNAi will also be used to knock down the expression of endogenous proteins in mammalian cells and to determine their function in order to obtain high transfection efficiencies we will use lentiviral and adenoviral vectors.

The recipient of the GMO’s will be established human, mouse, and rat cell lines (including HEK293, HeLa, N1E-115, NIH3T3, PC12 H1299, HepG2, INS1, U20S, Rin5F, C2C12) and primary cultures of rodent cells including neurones, myocytes, embryonic fibroblasts and embryonic stem cells.

Adenoviral expression vector pAdEasy will be used for protein expression in mammalian cells. Lentiviral Vectors (Pwpi, pLVTHM, pLKO.1) will be for protein and siRNA expression in mammalian cells. All vectors are replication incompetent. The HEK293 (human) cell line is used to generate the adenoviruses and lentiviruses.

The adenovirus features deletion of the complete E1 region and the majority of the E3 region that constitutes the early transcription portion of the genome. The E1 region allows the virus to replicate while the E3 region prevents proper function of the MHC class 1 proteins so that the hosts immune response to the virus is compromised. The virus is therefore replication incompetent and only grows in complementing cells such as HEK293 that contain the appropriate E1 sequences. The lentiviral vectors used contain deletions in their 3’ UTR which results in self-inactivation of the lentivirus after transduction of the target cells. The number of genes from HIV-1 that are used in the system has been reduced to four (gag, pol, rev, tat) and all viral auxiliary genes associated with virulence (e.g. vpr, vif, vpu and nef) have been deleted. The VSV-G gene from Vesicular Stomatis Virus is used in place of the HIV-1 envelope. The lentiviral particles produced in this system are replication-incompetent and only carry the gene
of interest. The genes encoding structural and other components required for packaging the viral genome are separated into three plasmids which have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. None of the HIV-1 structural genes are present in the packaged viral genome, and thus, are not expressed in the target cells.

The adenoviral and lentiviral vectors will be used to express protein under the control of a constitutive CMV and E1Flpha promoters (pAdEasy, pWPI, pLVTMMH). Human, mouse or rat cDNAs encoding protein kinases e.g. JNK, ERK, p38, PKA, CAMK, S6K, c-Abl, PKB, TOR, ULK1; regulatory proteins e.g. JIPs, Arrestin, Ser1, TRB, eIFs; and transcription factors e.g Jun, ATF2, p73, Elk-1, will be cloned into the vectors. Exceptions are bacterial Cre and beta-galactosidase and GFP from Aequoria Victoria. Beta-galactosidase and green-fluorescent protein (GFP) will be used as reporter genes. Cre recombinase will be used to excise segments of genes that have been flanked by loxP recombinase sites. Protein kinases transfer phosphate groups to substrates. Regulatory proteins bind to protein kinases and regulate their activities. Transcription factors bind gene promoters and regulate transcription. The c-Abl, JNK and p38 pathways are pro-apoptotic in response to stress stimuli but in some cell types can promote proliferation of differentiation. The ERK and mTOR pathways promote cell growth, while ERK, PKB and PKA can signal cell survival. Wild-type and mutant signalling proteins will be expressed to examine loss and gain of functions.

Lentiviral vectors (pLVTHM, pLKO.1) featuring RNA polymerase III promoters H1 and U6 will be used to express siRNAs in cells. siRNA is generated by the cellular machinery from a short hairpin RNA that is encoded by a small DNA insert in the vector. siRNA will be targeted to knock-down the expression of the signaling proteins described above.

Evaluation of foreseeable effects

Potential laboratory accidents would include ingestion and droplet exposure to mucous membranes (e.g. splashes in eye or mouth, direct injection). The viruses can transduce human cells but they are replication defective so will not colonise the host. The expressed proteins and siRNAs are biologically active and will affect signalling pathways involved in cell growth, differentiation and apoptosis. While not themselves oncogenic they may promote tumorigenesis. In addition some of the lentiviral vectors include the Woodchuck WPRE to enhance transgene expression. This is reported to promote tumorigenesis. All experimental procedures are carried out in a Class II laminar flow biological safety cabinet, therefore the chance of transmission in a Laboratory accident is low. In addition, tumorigenesis is a complex multifactor process that involves more than one oncogenic event.

The lentivirus includes the VSV-G protein that may potentially allow infection of the natural hosts of VSV, which include livestock. VSV-G may also stabilise the virus. However, the laboratory is in the city centre and there are no livestock nearby.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Good laboratory practice will be used including use of gloves and labcoats. All work will be performed in a Class II laminar flow biological safety cabinet in a tissue culture lab that is separated from the main lab. It will be communicated to all users of the tissue culture lab that Class 2 activity is taking place. Clearly labelled incubators will be used to culture the lentivirus infected cells. Liquid waste is soaked in 2% Virkon for at least 30 minutes prior to disposal down the sink. The viruses are rapidly inactivated after exposure to chemical germicides such as Virkon. Solid waste is removed daily from the laboratory and is incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This application has been fully discussed at two local GM safety committee meetings. The classification of the project as a Class II rather than Class I was fully discussed at the first meeting and due to the use of lentiviruses and the nature of the genes of interest it was decided that Class II classification was appropriate. The nature of the inserts, host vector systems, likelihood of harmful effects and potential stabilization of the virus were all fully explored. Amendments to the first draft recommended at the initial meeting were subsequently discussed at the second meeting when the committee approved the project and HSE notification.

Project Additional Information

Purposes of the contained use
To retrovirally transduce human, guinea pig, and rat cells with genes or shRNA oligonucleotides.

Recipient or parental organism
Human primary and established cell lines, such as mesenchymal stem cells (MSCs), smooth muscle cells (SMCs), human dermal fibroblasts (HDFs), and retinal pigmented epithelial cells (ARPE-19).
Rat established cell lines, such as rat foetal lung cells (RFL-6). Guinea pig primary cells, such as MSCs.
Retrovirus derived from Moloney murine leukaemia virus (MMLV) and murine stem cell virus (MSCV).

Host/vector system
Vectors: Commercially available retroviral and lentiviral self-inactivating vectore package into transducible viral particles by specific eukaryotic packaging cells. The lentiviral and retroviral expression vectors do not contain sequences required for virus packaging. Genes for packaging are provided by transient transfection of helper vectors or the packaging cell line.

Origin & function
Genetic material - subcloned from cDNA library, for example:
ERG (ets-related gene) and isoforms. From mouse kidney.
HDAC (histone deacetylase) family members. From human brain.
FGFR (fibroblast growth factor receptor) family members. From mouse brain.

Intended functions: to regulate differentiation of MSCs.

Genetic material - Human total RNA by RT-PCR, for example:
Elastin
Fibulin family members
Fibrillin family members

Intended functions: Recombinant expression for use in structural and functional assays.

Genetic material - Commercially synthesised oligonucleotides to form shRNA complexes to, for example:
Fibulin family members
Fibrillin family members

Intended functions: Downregulation of protein expression to monitor role of protein in ECM assembly and cell differentiation.

Evaluation of foreseeable effects
The majority of the gene products expressed have no known deleterious effects although some do have oncogenic properties. The split function of the viral vectors however greatly reduces the risk of recombination events occurring and the self-activating properties of the vectors themselves inhibit production of virus once the transgene becomes stably incorporated into the genome of the target cells, eliminating the risk of undesired infection. Therefore it is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Please enter comments on the GM safety committee on the risk assessment

All three risk assessments (GAW2, CMK2, CMK3) were initially considered at local GM safety committee meeting on 12/01/07. In addition to some minor amendments that were completed during the meeting, the committee requested clarification on the known or suspected physiological, pathological and/or pharmacological effects of the shRNA complexes from the fibulin and fibrillin families of proteins in the risk assessment CMK2.

This has now been answered fully in section 1.7, p47 of CMK2. All three risk assessments were approved in a supplementary meeting of the local GM committee meeting on 07/02/07.

Project Additional Information

Purposes of the contained use
The project will investigate methods to develop gene delivery strategies using self-inactivating HIV-1 based lentiviral vectors in mouse models of lysosomal storage disorders to a) improve stem cell engraftment, homing and enzyme delivery and b) reduce cellular substrate storage to improve phenotype.

Recipient or parental organism
Mice used in this study are wild type, heterozygous or mutant for mucopolysaccharide disease (MPS) type I, II, IIla and IIlb and metachromatic leukodystrophy MLD. Other mice for use in xenogenic transplantation studies of human stem cells will be immunodeficient NOD/SCID/gammaC chain (IL2R) -/- or SCID/Rag2 -/- /C3R -/- mouse strains, designed to be able to develop a partly functional human immune system. See 8. and A in additional comments.

Host/vector system
Hosts: Mammalian cells: human and mouse primary cells isolated from bone marrow (endothelial, mesenchymal and haematopoietic stem cells) and other cell types from eg. mouse skin, heart, and liver HeLa and HEK293 T, HUVECs, Jurkant, U937, HL60, microglial cells. Mice (see above)
Vector System: Disabled replication incompetent lentiviral vectors.

Origin & function
The inserted genes in the lentiviral vectors are either full length alpha-L-iduronidase, iduronate sulfatase, sulphamidase, alpha-N-acetylglucosaminidase, arylsulfatase (lysosomal enzymes) or factor VIII and factor IX. The lysosomal enzymes are deficient in different lysosomal storage diseases and are involved in the breakdown of the glycosaminoglycans dermatan sulphate and heparan sulphate. Factor VIII and factor IX are clotting factors which will
be used as markers. The transgenes used in this project occur naturally in mammalian cells and are not known to have any harmful physiological or pharmacological properties nor affect host or human defence mechanisms.

Lentiviral vectors containing short (23mer) antisense sequences of the genes encoding dermatan sulphate and heparan sulphate proteoglycans, CD26 and CXCR4 will also be used. Down-regulation of these genes would not have any harmful physiological or pharmacological properties nor affect host or human defence mechanisms.

eGFP (enhanced green fluorescent protein) or LacZ are used as markers to assess transduction efficiency of the lentiviral vectors. They are not known to have any harmful physiological or pharmacological properties nor affect host or human defence mechanisms.

2) Lentiviral vectors

A number of methods are employed to make lentiviral vectors non-mobilisable. The viral components are partitioned onto 3 (2nd generation) or 4 (3rd generation) plasmids with little or no shared homology to limit the risk of recombination. This ensures that there is no risk of replication competence beyond a single transfection. The HIV virulence genes are removed making the vector capable of a single infection but not of altering gene expression significantly as the wild-type virus does. The HIV specific envelope protein that targets CD4 T cells is exchanged for a ubiquitous envelope protein (VSV-G Vesicular stomatis virus G protein) which makes it more visible to the immune system and also expands the host range to mice, sheep and other mammals, although human cells remain the most permissive to transduction. Removal of the CD4 tropism removes the ability of lentiviral vectors to evade the immune system (normally achieved in wild-type virus by infecting and killing CD4 reactive T cells). Self inactivating long terminal repeats (LTR) are designed to minimise the risk of viral mobilisation from the chromosomal location once integrated and inactivates the viral LTR promoter at the same time.

**Evaluation of foreseeable effects**

Replication competent virus is a very small but potential risk. This is tested for by serial infections of HeLa cells with viral stocks, and two rounds of removal of supernatant and transfer to uninfected stocks after 48 hours. In addition other techniques can be employed such as Q-PCR.

The major risks of working with lentiviral vectors are associated with exposure to open wounds or by needle stick injury- A plaster should be placed over any open wound on the hands or lower arms even though all experiments are conducted with the appropriate PPE ie, gloves and a lab coat. Needle stick injury would only occur during animal inoculation. Any sharps or needles will not be used at any other stage in experiments involving lentiviral vectors — except when delivering vector to animals. Respiratory infection is effectively zero even when using high titre stocks. In addition, all experiments using lentiviral vectors will be conducted in a class II cabinet.

In the event of needle stick injury and the lentiviral vector was delivered into the hand then some cells in the skin would express the transgene. Some limited systemic spread is possible if delivered into a vein but large animal experiments have shown that even at the highest titres we intend to use, this will be relatively small. Also, the transgenes used in this project would not have harmful physiological or pharmacological properties nor affect host or human defence mechanisms. If skin cells express CFP for example (which is quite immunogenic) then it is likely that the host immune system will mount a T cell and humoral response which will slowly eradicate these cells to be replaced by others— as is seen in rodent and large animal experiments where vector is delivered to a few cells in a localised area. Insertional mutagenesis has been shown to be a small risk in retroviral vector systems, although lentiviral vectors appear to pose less of a risk to gene upregulation than retroviral vectors as they preferentially integrate into the 5' region of active genes and are thus most likely to abrogate gene expression.

Lentiviral vector half-life (the time taken for half of the lentiviral vector to become incapable of infection) at 37°C is less than 30 mins and less than 24h at 4°C

See A in additional comments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Viral vector transfected cells or animals receiving direct injections of viral vectors are not likely to pose a risk to users as the vectors are only capable of a single integration event and have been shown by RCR testing to be incapable of mobilisation from their site of integration. The main risk is from needle stick injury during injection. All staff will use appropriate PPE, animals will be anaesthetised during this procedure and staff appropriately trained in this procedure. Waste disposal will be carried out according to the SOP for waste disposal attached. In brief, needles will be disposed of in sharps bins, any directly contaminated material disposed of by autoclaving (on the central site) followed by the local clinical waste route (incineration) or sink in the case of liquid waste. Carcasses will be disposed of by incineration.

There is a small risk of mice receiving either transfected or untransfected human cells being able to harbour and transmit infections to humans. These models have been shown to be poor at propagating human pathogens in this manner. The major route if infection would be blood/blood contact as it is the blood system that is reconstituted with human cells. All these mice will be kept in SPF environments within IVC cage& They will only be handled by users with appropriate PPE, and workers will be notified of their increased pathogenic risk. Animals will be anaesthetised when withdrawing blood and staff appropriately trained in the procedure. In the event of transmission of
Infection to a human from a humanised mouse, this would be likely to be nothing more serious than the risk of working in a hospital. Hence workers may be at risk of contracting blood borne infections as mouse lung epithelia will not be humanised thus minimising risk of airborne infections such as cold or influenza viru&

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

[All class II waste on the production site will be treated with 2% virkon overnight prior to disposal via clinical waste route (incineration) or sink for liquid waste. This method is appropriate for 100% inactivation of viral vector and cell killing.

On the central site, GM contaminated solid waste will be autoclaved prior to incineration. Liquid waste will be treated with 2% virkon overnight prior to disposal via the sink. All GM animals will be bagged and incinerated according to local procedures for waste disposal. See SOP for waste disposal attached.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GM waste is to be autoclaved within the Stopford building following relocation of the project onto the main campus.

On the production site - Lentiviral vector waste (eg culture media, flasks, pipettes will be decontaminated in at least 2% virkon solution (final concentration) overnight (16hours) and then incinerated to give 100% kill at the site where viral vector production is undertaken.

The small amount of lentiviral vector waste generated by injections at the central site will be disposed of by autoclaving where appropriate prior to disposal via incineration to give 100% kill. GM animal carcasses and products will be disposed of by incineration. See SOP for waste disposal.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

The committee agreed with the GM classification of the project and Level I work was approved.

There were several points raised concerning various aspects of the Level 2 work detailed in the proposal. Namely;

• waste management
• needle-stick injury risk
• disablement characteristics
• health surveillance requirements

The principal applicant was requested to amend the proposal according to the suggestions made by the committee.

Project Additional Information

Purposes of the contained use

virally transduce human, mouse, and rat cells with genes, microRNAs or shRNA oligonucleotides.

Recipient or parental organism

Human primary and established cell lines, such as primary ductal carcinoma in situ derived breast epithelial cells, breast cancer cell lines (T 47D, SK BR 3, BT 474, Hs 578T, CAL51, MDA MB 468, BT 549, MDA MB 231, PMC 42). We will not be using any lymphocytic cell lines to minimise the risk of replication competent retrovirus being generated.

Mouse primary and established cell lines, such as mouse mammary epithelial cell lines (FSK7, HC1 1, C57MG) and mouse preaipocyte cell line (3T3;L1). Rat established cell lines, such as rat mammary epithelial cell line (RAC3I 1). Retrovirus derived from Moloney murine leukaemia virus (MMLV). Adenovirus (Ads). Lentivirus derived from HIV1.

Host/vector system

Vectors: Commercially available adenoviral, retroviral and lentiviral self-inactivating vectors, and well established retroviral vectors (pLNCX and pBABE) packaged into
transducible viral particles by specific eukaryotic packaging cells. The lentiviral, adenoviral and retroviral expression vectors do not encode proteins required for virus packaging. Proteins for packaging are provided by transient transfection of helper vectors or the packaging cell line.

**Origin & function**

Genetic material - subcloned from cDNA library, for example: Components of the Notch signalling pathway (Delta, Jagged, Notch, RBP-kappa, Numb, Hes, Hey, Deltex, Su(dx)) — human, mouse and rat. Components of the Wnt signalling pathway (Wnt, Frizzled, LRPS&6, Dishevelled, Axin, GSK3beta, beta-catenin, TCF, Lef1) — human, mouse, rat and Xenopus. Intended functions: to regulate proliferation, apoptosis and differentiation of human breast cancer cells.

Genetic material - Commercially synthesised oligonucleotides to express microRNAs to, for example: Components of the Notch pathway (Delta, Jagged, Notch, RBP-kappa, Numb, Hes, Hey, Deltex, Su(dx)). Components of the Wnt pathway (Wnt, Frizzled, LRPS&6, Dishevelled, Axin, GSK3beta, beta-catenin, TCF, Lef1). Intended functions: down regulation of protein expression to alter proliferation, apoptosis and differentiation in human breast cancer cells.

Genetic material - Commercially synthesised oligonucleotides to form shRNA complexes to, for example: Bcl-2 family members. Intended functions: downregulation of protein expression to monitor role of proteins in apoptosis. Genetic material - subcloned from complexes to, for example: IAP family members - human. Intended functions: to regulate apoptosis in human breast cancer cells. Genetic material - subcloned from cDNA library for example components of the spindle assembly checkpoint (BunM, BubR1, Mpsl, CenpF) and Histone H2B - human, mouse. Intended functions: to regulate cell division of human cell lines.

Genetic material - subcloned from cDNA library, for example: Genes within the adhesion signalling pathway regulating apoptosis, focal adhesion kinase and downstream components of the associated signalling cascade (PI3_Kinase, protein kinase b, the MAPKinases Jnk and p38) and apoptotic Bcl-2 proteins - human, mouse and bovine origin. Intended functions: to regulate apoptosis.

**Evaluation of foreseeable effects**

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion, polarity and fate. Also most have known or suspected oncogenic or tumour suppressor properties. The split function of the viral vectors however greatly reduces the risk of recombination events occurring and the self-inactivating properties of the vectors themselves inhibit production of virus once the transgene becomes stably incorporated into the genome of the target cells, eliminating the risk of undesired infection. Therefore it is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Spillages to be cleaned with 1% virkon.
All liquid waste to be soaked in 1% virkon overnight.
All solid waste to be autoclaved.
The area to be cleaned with 70% ethanol afterwards
It is anticipated that this will give 100% kill.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N
All five risk assessments (CHS4, CHS5, APG2, KRB I and SST1) were initially considered briefly at the local GM safety committee meeting on 22/06/2007 and in full at the meeting on 30/08/2007. At the second meeting the committee requested clarifications and amendments to all the assessments, in particular control measures, waste management and the biological activity of the inserted sequences were discussed at length. All five risk assessments were finally approved at a supplementary meeting of the local GM committee on 21/09/2007.

Project Additional Information

Purposes of the contained use

Gene transfer vectors will be used to deliver transgenic material (genes, siRNA and miRNA) to embryonic or adult stem cells in order to manipulate, analyse or promote phenotype, differentiation or immortalisation of such cells.

Recipient or parental organism

Human and mouse embryonic and adult stem cells (for example: mesenchymal stem cells, chondroprogenitors) and primary (for example: chondrocytes, fetal and adult fibroblasts) and established cell lines (for example; 293T, 3T3).

Human embryonic cells and tissues are obtained by donation after comprehensive pathogen screening at the clinic (HIV, Hepblc). Cell lines are also subjected to the same screening process once in the laboratory context. Human primary cells are donated from unscreened patients and are quaranteened pending the pathogen screening as described prior to genetic modification.

Retrovirus derived from Moloney murine leukaemia virus (MMLV) ACDP hazard group 2.

Adenovirus (Ad215) ACDP hazard group 2.

Adeno-associated Virus (AAV) ACDP hazard group 2.

Lentivirus derived from HIVISIV ACDP Hazard group I and EIAV IFIV ACDP hazard group I.

Host/vector system

Bacterial hosts derived from E.Coli strains DH5a, JM109, INVIO. Plasmid vectors derived from pcDNA3, pGL3, pENTRIA, etc.

Viral vectors- Recombinant lentiviral vectors based on HIV-I, EIAV, SIV, FIV pseudotyped with VSV-G, gp64, RRV, ENTV envelopes.

Retroviral vectors based on MLV, pseudotyped with MLVIVSV-G will be packaged by transient transfection in 293T cells.

Established adenoviral vectors (Ad215) will be produced by transient transfection of 293T (or derivative) cells.

AAV will be produced in an established transient 293T helper system.

Origin & function

Transgenic material - Human and mouse cDNAs of transcribed genes involved in aspects of transformation, self-renewal or differentiation will be expressed from pol II promoters. These genes would include transcription factors, signaling molecules, enzymes, growth factors and cytokines. Such genes would include: Transformation; hTERT, Bmi-I, Self-renewal; Oct4, Nanog, Sox2, Differentiation; FoxA2, Hnf4, GATA4, Sox9, FGF-2, FGF-1O, TGF-B. Only one potential oncogene will ever be expressed from a single cassette although reporter genes may also be expressed from bicistronic cassettes. These gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol 111111 promoters. Reporter genes include; Flourescent- e.g. GFP, YFP, CFP, dsRed, Luminescent- e.g. firefly and renilla Luciferase, biochemical e.g. CAT, AFP. Mammalian promoter/enhancer elements will be used to drive reporter genes as previously described.

Evaluation of foreseeable effects

The recombinant viral vectors are all highly disabled vectors based on Lentivirus/reovirus: These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Whilst they pose an infection risk they are unable to initiate further rounds of replication/ infection cycles. The probability of seroconversion is minimal. Whilst the envelope pseudotyping extends the cellular tropism and confers greater stability viral vector will always be contained within a class II safety cabinet thus user exposure to liquid aerosol is impossible.

The exposure of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.

Adenoviral vectors are deleted of essential replication/packaging genes that are supplemented by an established packaging cell line (293T).

Adeno-associated Virus is defective by nature and has a replication disabled genome and is incapable of replication without helper adenovirus. In this instance the vectors used would require the provision of cap and rep genes in trans in order to replicate and disseminate. There is no significant chance of reversion to the wild-type.

Furthermore, the AAV8 & 5 subtypes derived from humans are not able to replicate or cause disease in any animal species therefore it highly unlikely that such a virus, if released into the environment, would represent a significant risk.
The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion and fate. Also, most have known or suspected oncogenic or tumour suppressor properties. Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Viral vector expressing potential oncogenes are a potential environmental risk as host infection could elicit a transformation event. All work is carried out in a class II cabinet and all liquid waste inactivated by virkon treatment and solid waste autoclaved. Primary cells infected with viral vector containing potential oncogene would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals will be used in this project at this site.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. Virkon is routinely used as per the manufacturer's recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations). The autoclave undergoes annual validation. Records are kept on site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC assessed the project as GM Class 2. Some aspects of this work will be carried out in a clean room environment where there is a continual cascade of HEPA-filtered air under positive pressure. No aspect of viral production will be undertaken in the clean room only application of viral vectors to cells and as such there will be no possibility of generating a virus containing aerosol. All transfer of virus or virus transduced cells will be carried out using a secondary container from flow cabinet to incubator minimising the chances of spillage. Masks are worn at all times in the clean room which would avoid inhalation after spillage and any spill will be treated immediately with sterile biocide. This risk assessment was initially considered briefly at the local GM safety committee meeting on 22/01/2007 and in full at the meeting on 30/08/2007. At the second meeting the committee requested clarifications and amendments to all the assessments, in particular control measures, waste management and the biological activity of the inserted sequences were discussed at length. The risk assessment was finally approved at a supplementary meeting of the local GM committee on 21/09/2007.

Project Additional Information

Purposes of the contained use
To virally transduce human and rodent cells and tissues with genes, microRNAs or shRNA oligonucleotides, both in vitro and in vivo.

Recipient or parental organism

In vitro work (primary and established cell lines, ex vivo tissues)
Established cell lines (HEK293, COS, AT120, SH-SYSY)
Primary cells will be isolated from rats, mice, and hamsters (for example, mouse fibroblasts and primary cortical neuronals).
Tissue slices will be isolated from rats, mice, and hamsters (for example, coronal brain slices through the hypothalamus or hippocampus).
In vivo work:
Extremely small volumes (nL-qL) of viral gene delivery particles introduced into specific tissues of rats, mice or hamsters with recovery and behaviour monitoring. Mice used for these experiments will either be commonly used laboratory strains (eg C57B6) or established transgenic lines housed at the University of Manchester (eg GPR5O knockout mice, 3xTg transgenic mice).
We will not be using any lymphocytic cell lines or tissues to minimise the risk of replication competent retrovirus being generated.

Viral delivery systems:
Retrovirus derived from Moloney murine leukaemia virus (MMLV).
Adenovirus (Ads).
Lentivirus derived from HIVI (3 generation, self-inactivating).

Host/vector system

Vectors: Commercially available adenoviral, retroviral and lentiviral self-inactivating vectors, and well established retroviral vectors (pLNCX and pBABE) packaged into transducible viral particles by specific eukaryotic packaging cells. The lentiviral, adenoviral and retroviral expression vectors do not encode proteins required for virus packaging. Proteins for packaging are provided by transient transfection of helper vectors or the packaging cell line.

Origin & function

Genetic material - subcloned from cDNA library:
Components of the molecular clock (e.g. Clock, Period, Cryptochrome, Rev-erb, BMAL, VIP, CKIE, CK1O) — mouse, rat, hamster. Intended functions: to regulate circadian patterns of gene expression in cells and tissues.
G-coupled protein receptors (e.g. GPR5O, MTI, MT2, ChR2) — mouse, rat and hamster. Intended functions: to modulate specific signalling pathways within the nervous system.
Components of the thyroid hormone signalling pathway (e.g. TRH, D102, D103) — mouse, rat, hamster. Intended functions: To modify local (hypothalamic) thyroid hormone availability.
Genes involved in cellular trafficking (e.g. PSD95, GFP-based reporters: pIN-G and pIN-ER) — mouse, rat, hamster. Intended functions: To visualise intracellular trafficking using GFP-based reporters.
Ion channels (e.g. Kv4, Cav2.2 and auxiliary Ky and CaV) — mouse, rat, hamster. Intended functions: To discretely modify neuronal ion homeostasis.
Reporter genes (eGFP, mRFP, luciferase, organelle-targeted GFP-based reporters) — from jellyfish, coral and firefly respectively. Intended purpose to act as reporters of gene expression when driven under specific gene promoters, to allow intracellular localisation of fusion proteins, and visualisation of organelle dynamics.

Genetic material - Commercially synthesised oligonucleotides to form shRNA complexes to:
Components of the molecular clock (e.g Clock, Period, Cryptochrome, Rev-erb, BMAL, VIP, CK1&), CK1O) — mouse, rat, hamster. Intended functions: to regulate circadian patterns of gene expression in cells and tissues.
G-coupled protein receptors (e.g. GPR5O, MTI, MT2, ChR2) — mouse, rat, hamster. Intended functions: To modulate specific signalling pathways within the nervous system.
Components of the thyroid hormone signalling pathway (e.g. TRH, D102, D103) — mouse, rat, hamster. Intended functions: To locally (e.g. within the hypothalamus) modify thyroid hormone availability.
Genes involved in cellular trafficking (e.g. P6D95) — mouse, rat, hamster. Intended functions: To alter intracellular trafficking of PS D95-associated proteins.
Ion channels (e.g. Kv4, Cav22 and auxiliary Ky and CaV) — mouse, rat, hamster. Intended functions: To discretely modify neuronal ion homeostasis.

Genetic material - cloned from genomic DNA:
Promoter region of molecular clock genes (e.g. Clock, Period, Cryptochrome, Rev-erb, SMAL, VIP) — human, mouse and rat. Intended functions: to drive the expression of eGFP or Luc reporter genes.
Gene inserts: The majority of the gene products expressed are expected to affect cellular properties such as circadian gene expression, intracellular trafficking, neuronal communication, and ion homeostasis. None of the genes are known to have direct oncogenic properties. As the purpose of this research is to modify physiological processes within the cells/tissues/animals, the gene inserts are expected to have effects on the host. However, these effects will be highly localised within the animals, due to the targeting on very small quantities of virus to specific sites of the nervous system. For example, we aim to modify thyroid hormone (T3) availability within the hypothalamus using a lentiviral delivery system. Within this line of research we would expect to observe a number of potential effects in the transfected animals, such as altered metabolic rate and feeding behaviour. Because we are using a lentiviral system, we would expect these effects to be relatively long-lasting. However, the risk posed to the environment, general public, animals care staff, and researcher working with the animals can be considered very low. Exposure of an individual to live virus could allow the gene insert to be expressed, but since viral particle cannot replicate gene expression would be highly localised to the site of exposure. None of the genes of interest have foreseeable hazardous consequences if expressed at localised areas of the skin and lungs, the most likely sites of exposure. Risks of exposure will be minimised at all stages of the work by employment of good laboratory practice and adherence to Class 2 containment measures.

Viral vectors: All viral systems to be employed involve split function of the viral vectors, which greatly reduces the risk of recombination events occurring. Lentiviral systems are also self-inactivating, so that the vectors themselves inhibit production of virus once the transgene becomes stably incorporated into the genome of the target cells, eliminating the risk of undesired infection. Therefore it is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

Transfected animals: Although unlikely tranfected animals have the potential to pass skin or blood into their immediate environment, the risk from such contaminants is negligible. It is unlikely, but possible that viral particles could transfect skin cells or blood during injection of the virus. However, because the particles are non-replicable, shed skin/blood cells would not be able to pass on the viral vector. Animals will be housed in filter top cages to minimise the spread of bedding and shed skin, and all animal remains/waste will be autoclaved prior to incineration. The likelihood of escape of genetically manipulated animals into the environment is negligible due to the breeding and maintenance of these animals in dedicated facilities. However, even should an animal escape the risk to public health or the environment would be negligible. While it would be possible for these animals to breed with animals in the wild (although unlikely due to behavioural differences in lab-reared animals), the potential for GM animals to transfer transiently expressed genes is extremely low because these will not be targeted to reproductive organs (ie. do not enter the germline). Even should this occur, penetrance of the knockout or mutant loci into the wild population would be negligible because no (foreseeable) selective advantage would be passed on the offspring.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM animals will be held in a purpose-built facility (Biological Services Unit; BSU) at the University of Manchester. The BSU has restricted swipe-card access at all times. All areas have sealed floors, temperature and humidity control, and filtered ventilation. All animals which have been injected with viral vectors will be housed within individual filter cages, and all animal carcasses, waste and bedding will be autoclaved and incinerated. Cages will be autoclaved and washed.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In vitro:
Spillages to be cleaned with 1% virkon
All liquid waste to be soaked in 1% virkon overnight.
All solid waste to be autoclaved.
The area to be cleaned with 70% ethanol afterwards.
It is anticipated that this will give 100% kill.

In vivo:
Spillages to be cleaned with 1% yukon.
All liquid waste to be soaked in 1% virkon overnight.
All solid waste to be autoclaved. The area to be cleaned with 70% ethanol afterwards. All animal remains and bedding will be isolated, autoclaved and incineration. Used cages will be soaked in 1% virkon overnight, then washed and autoclaved. It is anticipated that this will give 100% kill.

The risk assessments submitted herein (ASL/01) were considered initially at the local GM safety committee meeting on 17/01/2008, where the committee commented on the containment level of the programme of work. Specific comments were made about by the committee regarding the nature of the lentiviral system being used & the activity of the proposed inserts to be examined. Further meetings were subsequently held between the researchers, the local BSO & the University Biological Safety Adviser to discuss the details of containment measures and waste management. The risk assessments underwent a final review & approval at a specially convened meeting of the local GM safety committee on 26/02/2008.

**Project Ref** 541/08.3

- **Date Ackn’d**: 21/11/2008
- **CU2 Project Title**: The use of intestinal pathogens to study mucosal immunity, regulation and initiation.
- **Class**: Class 2
- **Culture Volume Class 2**: 1-50 Litres
- **Non-GMM Consent Granted**: Not Applicable

Is an emergency plan required according to regulation 20? **N**

If yes, tick to confirm that it is attached to this form **N**

Tick to confirm that you have attached a risk assessment to this form **Y**

Tick if you are claiming exemption from disclosure for section of the risk assessment **N**
The objective of this project are to understand the biology of immune responses to intestinal pathogens, gain insights into the mechanism by which they cause disease and identify molecules and pathways involved in elimination of the pathogens. This will involve infection of genetically-modified mice with different intestinal pathogens (either wild type strains, or genetically modified strains). Cells isolated from genetically modified mice will also be infected with different gut pathogens and their characteristics studied in vitro.

**Recipient or parental organism**

Genetically modified mice (listed below) or primary cells isolated from these mice (T-cells, dendritic cells, epithelial cells).

- Genetically modified mice, for example:
  - knockout for the protein Nod2
  - Conditional knockout for intrgrin β specifically in leukocytes. T-cells or dendritic cells.
  - Conditional knockout for arginase
  - Tagged with yellow fluorescent protein in cells expressing CD11c

**Host/vector system**

Genetically modified intestinal pathogens, for example:

- Listeria monocytogenes bacterial strain (described by Wollert et al, 2007, cell v. 129, p 891-902): modified so that the E-cadherin receptor of the bacterium recognizes mouse E-cadherin, therefore facilitating oral infection of mice in vivo.

Non-genetically modified intestinal pathogens, for example:
- Trichuris muris parasite
- Toxoplasma gondii parasite
- Trichinella spiralis parasite
- Heligmosomoides polygyrus parasite
Salmonella typhimurium bacteria
Yersinia enterocolitica bacteria

**Origin & function**

For genetically modified mice:

All mice are genetically altered by disruption of gene function by targeted homologous recombination. For complete knockout mice, homologous recombination occurs to disrupt the gene of interest. For conditional knockout mice, loxp sites are inserted to flank important regions of the gene of interest. In the presence of Cre recombinase (which is under the control of a cell type-specific promoter), the gene region between the loxp sites is removed, therefore disrupting the gene of interest. None of the genetically modified mice to be used are any more dangerous to humans or the environment than non-genetically modified strains.

For genetically modified micro-organisms:

Genetic modifications in the gut pathogens involve tagging of the pathogen with a non-toxic fluorescent protein to aid visualisation during experimentation, or facilitating oral infection of mice for example the Listeria monocytogenes strain listed above. None of the genetically-modified strains to be used are any more dangerous to humans or the environment than non-genetically modified strains.

**Evaluation of foreseeable effects**

**Micro-organisms**

For all intestinal pathogens detailed in Part 7, there is potential risk of hand-mouth transmission. This risk is extremely low, as all work involving these pathogens will be carried out in a Class II biological safety cabinet, all workers will wear protective lab coats that are only kept in Class II areas, and all workers will wear gloves. Additionally, all workers will be specifically trained in working with Class II organisms. Hands will be washed with anti-bacterial cleaner before and immediately after any work has been carried out.

There is no risk of contamination with needles, as no work will involve the use of needles.

Upon infection of mice with the intestinal pathogens detailed in part 7 (except for Toxoplasma gondii) there is the potential for the organism to be shed through the animal's faeces. However, the risk to animal workers of contamination is extremely low. All the handling and mice and changing of bedding will be carried out in a Class II biological safety cabinet, protective equipment will be worn at all times (gloves, mask), and hands will be washed immediately after removal of gloves. All waste bedding from the mice is bagged, tagged and incinerated off site.

In the extremely unlikely event of infection of a worker, mild sickness may occur. However, this will be very short-lived and the organisms expelled by a normal immune response. For work with Listeria monocytogenes, an additional infection risk is posed to pregnant women. Therefore female staff will be informed of this risk and will not be asked to work with Listeria or Listeria-infected mice if they may be at risk.

For genetic modification of the Listeria, Salmonella and Toxoplasma strains detailed in the attached risk assessments, the genetic modification does not in any way increase the potential risk to humans or the environment versus the risk of using the unmodified strain.

**Mice**

For the use of genetically modified mice detailed in part 7 (and use of cells from these mice), no increased risk over the use of non-modified mice is apparent (i.e. negligible). The genetic modifications do not cause any changes in the mouse that will increase risk to humans, or increase survival in the environment. In the unlikely event of escape of the genetically-modified mice into the environment, the mice are extremely unlikely to survive in the wild and replace indigenous mouse populations.
Similarly, infection of genetically modified mice with the genetically modified/non-modified micro-organisms will have no greater detrimental effects than the infection of non-genetically modified mice with non-genetically modified micro-organisms. Potential outcomes of infection of the genetically modified mice are:

- the GM mice will expel infection more quickly than wild type mice.
- the GM mice will show identical infection clearance compared to wild type mice.
- the GM mice will be more prone to infection than wild type mice.

If GM mice are protected from infection, this will not provide any significant survival advantage over wild type mice in the environment, as such infections are extremely rare. If mice are more prone to infection, the mice will certainly not have any selective advantage over wild type mice in the environment. In terms of animal welfare, all infected animals will be monitored regularly during infection, and humanely sacrificed if significant weight loss occurs (as detailed in our Home Office Animal Licence).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All genetically modified mice will be housed in wire or isolator cages within secure, designated animal units within the University of Manchester. Infected mice will be kept in isolator cages. Bedding changes and mouse retrieval are carried out in closed rooms, and mouse transport between animal facilities is carried out in sealed filtered transport cages within linked buildings (i.e. not outside), making escape of mice very unlikely.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For genetically modified micro-organisms:
- Spillages to be cleaned with 1% virkon
- All liquid waste to be soaked in 1% virkon
- All solid waste to be autoclaved
- The area to be cleaned with 70% ethanol afterwards

- It is anticipated that this will give 100% kill.

For genetically modified mice:
- Animal carcasses are placed in thick walled body bags that cannot be pierced by body parts of the mouse.
- These bags are tagged and incinerated off site.
- Waste bedding is double bagged in clinical waste bags, tagged and incinerated off site.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
Risk assessments for projects MAT2 (encompassing MT1-3) and SMC1 (encompassing SC1-6) were discussed at the local GM sub committee working party meetings on 01/09/08. At both meetings the working party asked for amendments to be made to the risk assessments for both projects, these mainly concerned control measures, waste management, assessing the potential risk of infected animals to animal workers, assessing potential risk alteration in pathogenicity of GM pathogens infecting GM mice. After all amendments had been made, risk assessments were approved by the local GM committee on 10/11/08.

**Purposes of the contained use**

- **Therapeutic Aim (Clinical Trial - Beyond This Project)**
- **Vascular endothelial growth factor (VEGF)** is a paracrine and endocrine agent, naturally expressed in several tissues and commonly known for its part-role in blood and
Lymph vessel growth and development, but less known for its vasodilatory properties. Fetal growth restriction (FGR) is sometimes characterised by reduced blood flow from the uterus to the placenta, dangerously compromising the delivery of oxygen and nutrients to the fetus during its development.

Our long-term aim (Phase 2 Clinical Trial) is to exploit the vasodilatory property of VEGF, by transfecting the uterine artery of pregnant humans that exhibit poor uterine artery Doppler (a clinical measure of maternal blood flow efficacy to the placenta/fetus), to improve maternal blood flow to the placenta, in clinical cases where neonatal morbidity and mortality outcome is dire.

Research Objective (This project application)
The aim of this current Phase Zero clinical trial proposal is to test for potential toxicological effects of VEGF transfection on human placental tissue in vitro; a side-effect which is theoretically possible in future in vivo administration studies, since the placenta occurs downstream of uterine artery blood flow. The currently proposed Phase Zero Clinical Trial will provide valuable data from which to pitch a safe dose of the VEGF viral vector in a subsequent Phase 1 Clinical Trial (rabbit, in vivo, London based project, UCL collaborators to notify) and Phase 2 Clinical Trial (early onset human FGR cases with a poor fetal and neonatal prognosis).

Recipient or parental organism
Not applicable

Host/vector system

Viral Vector. The vector to be used will be a replication deficient adenovirus, carrying either the human recombinant VEGF gene (a growth hormone with vasodilatory properties), or lacZ beta-galactosidase (for viral localisation in ex vivo tissue).

Host (in vitro) human Tissue: There are two proposed stages of work, with in vitro human placental tissue as the host in both cases:
Stage A. Dose ranging experiments of the viral vector in the in vitro human placental explant (tissue fragment) model (host) to determine appropriate starting dose of viral vector - applicable to stage B (below). 3mm³ pieces of human placental villous tissue will be cultured in 12 well plates for 7 days. On day 4, they will be exposed to one of 4 doses of adenoviral vector with recombinant human VEGF, or a PBS control, or the adenoviral vector control. Culture medium will be harvested and assayed for measures of host cellular death, differentiation and function. Host tissue fragments will be harvested at day 7 and their protein content measured. In parallel treated 12-well plates of cultured tissue, fragments will be fixed in zinc fix solution and their morphology analysed. Stage B. 5-hour in vitro dual perfusion of the human placental lobule (host). A high dose of adenoviral vector, determined from stage A (above), containing recombinant human VEGF will be administered to the maternal-side circulation of the in vitro dual placental lobule. Samples will be taken from the host in vitro fetal venous circulation to enable measurements of transplacental viral transfer (courier transfer of samples to Finland for assay; Biological Sample Category B UN3373, IATA 650 compliant packaging used with thermal control unit for dry ice shipment - compliant with UN1845; we are a licensed dry ice shipper with DHL). Other host in vitro venous sampling will occur to assay for tissue cellular integrity, differentiation, function and changes in paracellular permeability.

Origin & function

Stock viral vectors will be supplied in a ready to use form Ark Therapeutics Inc, Huopio, Finland.

Evaluation of foreseeable effects

The recombinant virus is replication deficient due to the loss of the E1 gene. The loss of the E1 gene suppresses assembly of infectious viral particles in host cells. 20% of normal healthy adults have the E1 insert in their respiratory epithelium (SACGM Compendium of Guidance, part 2.7, paragraph 14), raising the possibility of the adenovirus becoming replication competent, whilst also carrying the VEGF gene. However, the insertion of the VEGF gene in place of the E1 cassette ensures that any homologous recombination that restores the E1 sequence to the vector also deletes the VEGF insert, so the genetically modified component would be lost if RCAs were inadvertently be generated.

Furthermore, part of the E3 gene has also been deleted, making the virus less likely to establish an infection and spread the community, being more susceptible to immune surveillance. This dual gene deletion makes self-replication capability extremely unlikely. The vector will not replicate in other in vivo, or in vitro cells. The replication deficient characteristic means that there is also a reduced capacity for colonisation and if there was any accidental exposure to the environment, there would be
compromised productive infection.

Increased immune surveillance through E3 gene deletion may cause a more severe immune response than would be the case for the wild type virus (SACGM Compendium of Guidance, Part 2, paragraph 50). The vector is produced in a cell line, which minimises potential for recombination to create replication competent adenovirus.

Recombinant adenoviral vectors infect a variety of human cell types. The virus may enter the human body via cuts and sharps injury. The virus could transmit via the lungs if the virus becomes airborne, should aerosol generation be permitted. If a worker becomes infected by the AdVEGF virus, the transgene may be expressed in any infected cells. In the unlikely event of inhalation of aerosol, a small degree of transfection will occur in the airways, predominantly in the upper respiratory tract. However, infection will be the host’s immune response and the infected cells should be rapidly cleared, such that expression is only transient and localised. The recombinant adenovirus is designed to be replication deficient; therefore, should the virus infect the worker, it should not replicate. This is verified in paragraph 25 of the SACGM Compendium of guidance, Part 2, where it is stated that these strains are disabled and incapable of establishing a productive, transmissible infection in humans. Adenovirus can provoke a strong immune response and non-productive infection symptoms could include fever, rhinitis, pharyngitis, cough and conjunctivitis. However, manufacture and testing of the viral seed stocks (see below) ensure that potential for contamination with infectious productive adenovirus is low, so any symptoms will be very transient. In practice, aerosol generation will not occur, and even if this did occur, any inhaled dose would be very low, so symptoms are unlikely to occur. Furthermore, whilst the naturally occurring adenovirus is associated with mild respiratory infections in children, it is thought that the majority of the population is likely to have antibodies to the wild type virus, inferring life-long immunity. The wild type virus is ubiquitous, causing only a mild respiratory disease in humans which is self-liming and does not require any specific treatment.

The viral vector will be supplied to us in a ready to use state, by Ark Therapeutics, Kuopio, Finland (EU). Its production is described as follows: “Recombinant adenovirus type 5 was rescued in human embryonic cells by co-transfection of a plasmid containing the VEGF gene and an adenovirus backbone sub360. The resulting E1-E3 deleted viral progeny was plaque purified and an appropriate clone was selected and used to produce a crude viral lysate.” (Source: GMO Information Form: Recombinant adenovirus containing the short, mature form of human vascular endothelial growth factor D, 24th February 2009, Ark Therapeutics Oy, Kuopio, Finland).

Although not every batch of virus produced for non-clinical use will be tested by Ark Therapeutics, their testing of the viral seeds stocks and the derived lots that are tested indicate that replication competent adenoviruses are not expected to be detectable in test samples. It may be judged that considering the amounts that will be handled in this work the chance of a laboratory worker being accidentally exposed to a single RCA virus, let alone sufficient to produce a clinically relevant infection, is effectively zero.

The gene product, VEGF, is under the control of the CMV promoter and so is constitutively produced. VEGF is a human gene, which promotes vasodilation, angiogenesis and lymphangiogenesis and is naturally expressed in several tissues. However, the upregulation of VEGF production alone is unlikely to promote successful vascularisation, which needs to be balanced out with other angiogenic factors (Carmeliet, 2000, Nat Med 6, 1102-3). Hence, it is unlikely that infection with adenovirus expressing VEGF will be more hazardous than infection with wild-type adenovirus. The inappropriate expression of VEGF, might theoretically worsen pre-existing conditions such as diabetic retinopathy, or cancer but it is unlikely to cause any de novo disease. Indeed any transgene expression from this limited infection will be limited both in amount and duration, so the exacerbation of any underlying conditions in the worker is unlikely. Furthermore, any potential impact of transgene expression away from the site of infection will be further limited by sequestration in local tissues, the dilution and degradation of the produced VEGF in body fluids. For these reasons, the likelihood of VEGF gene recombination with any host endogenous adenoviruses is low and any scope for VEGF hypotensive effects in the host’s systemic circulatory system is negligible.

We do not anticipate that the worker’s immune response would in any way be compromised by any transient over-expression of the transfected protein, should infection and transfection happen. In fact the deletion of the E3 region, which encodes proteins involved in the evasion of the host’s immunity, will offer extra immune surveillance against the virus. The complete vector sequence has been determined and no novel or truncated reading frames, which may have an adverse effect on the safety profile of the product, have been introduced during manufacture. Adenovirus does not integrate into the host cell genome and the vector has no additional features that promote integration.

Health Surveillance is required: initial pre-project appointments with University Occupational Health have been carried through for all scientists working on this project. Routine health surveillance will occur once every 3 months for this project.
The use of a Class 2 MSC for viral stock handling and at other points where possible is a prudent measure, although not considered necessary from the perspective of virulence for this E1 deleted adenoviral strain.

Potential routes of transmission are eyes, mouth (ingestion), skin (puncture wound and lungs. Any previous skin break injuries will be covered prior to experimentation. In the laboratory, care must be taken to avoid the spread of viral material by aerosol, direct contact, or accidental injection.

Self-inspection and risk assessment: Laboratories will be routinely self-inspected (at least annually) and results recorded. Defects found at any time will be amended before work recommences. Risk assessments for each laboratory are undertaken to account for all activities performed. Risk assessment will include details of secondary containment of materials during transport between laboratories.

Signage: The laboratory will be clearly signed (biohazard sign plus a sign explaining the pathogen containment level and the level of GM working on the laboratory doors). Local rules relating to this project will be drawn-up and displayed within the GM laboratories. A list of current GM inductees will also be displayed.

Controls and segregation of activities: The dispensing and diluting of viral vector stocks will be done in Class 2 MSC. On other occasions, the worker will be protected from eye and mouth contact by the glass screen of the MSC or perfusion cabinet. Sharps will be avoided at the stage of the viral experimental process, during tissue exposure periods to the virus and at any subsequent stage where residual virus might be present in culture medium, perfusates and assay solutions. Sharps (pointed forceps and sutures) will have been used during the tissue cannulation process in “Stage B”, prior to working with the viral vectors, but these will have been used at a separate workstation and will have been decontaminated and put out of use at the point of viral working. The GM laboratory doors have digi-locks fitted and their codes are known only to GM inducted personnel. The MSC and tissue incubator used for this project will be separate to those on other GM projects in this laboratory (room 330). For perfusion work, one whole bay of this laboratory will be reserved for this project and the perfusion cabinet will be located against a wall, away from the central bench, shared by bays.

GLP, hygiene and PPE: Good laboratory practice will be used throughout. PPE, including Howie type lab coats and gloves will be used. Before leaving the laboratory, used gloves will be discarded and hands will be washed thoroughly with soap and water.

Administration of the virus to tissue fragments in “Stage A” will be done in a Class 2 MSC, whereas viral handling with the perfused tissue model in “Stage B” will be otherwise controlled, when reasonably practicable to do so. Perfusion in “Stage B” will occur within containment trays within containment trays within the perfusion cabinet (not a Class 2 Containment apparatus). Aerosol generation risk will be zero and drip splashes minimised in “Stage B”, since we will: control viral stock handling (Class 2 MSC for aspirating into syringe, syringe with luer-locking cap for transit to perfusion cabinet), control pressurised viral administration (manual syringe plunging) to sealed perfusate tubing line (luer locking of syringe to a three way tap, so no needle involved) and control post-experimental transfected tissue dissection (Class 2 MSC). All viral work in “Stage A” will be performed in a Class 2 MSC. Aspirated wash solution will be collected into a secondary contained 2.5 litre sealed waste bottle, containing an appropriate quantity of Virkon to give a 2% solution following maximum experimental aspiration; bunged and held under negative pressure by an aspirator pump fitted with a 0.22µM syringe filter at the air inlet port, avoiding potential viral dissemination into the laboratory atmosphere. Spent culture media (sample) collection and aliquoting will occur into gasket sealed sample vials. Vials will be put into secondary containers for storage at -80ºC. At the end of tissue culture, tissue fragments will either be rendered non-infective by dissolving in 0.3M sodium hydroxide (for subsequent protein assay), or they will be zinc fixed (for imaging).

In “Stage B”, perfusion of exposed human placental tissue will be conducted in trays and all venous perfusate samples will be treated as potentially infectious. Samples will be collected into polypropylene tubes and capped in the perfusion cabinet before being centrifuged. Our SOP on centrifugation instructs the user to leave the centrifuge unopened for 30 minutes in the event of a tube break, so eliminating the risk of aerosol leak into the laboratory. This SOP also advises on spillage disinfection. All aliquoting of supernatants (virus containing) will occur in a Class 2 MSC. This control is a prudent measure, although not actually necessary, as aerosol generation is not anticipated. Storage of supernatants will occur at -80ºC in gasket sealed sample vials, within secondary sealed containers. All assays will be performed in a Class 2 MSC. 96-well plate reading of assayed samples will occur in another laboratory commissioned for GM working.
Generally, during placental perfusion, placental venous perfusate from the maternal-side and fetal-side will be aspirated into a secondarily contained and sealed waste bottle in a controlled manner. This will contain significant levels of virus, especially immediately after the transfection period. This non-pressurised venous perfusate will be channelled into a drip-point and collected into a secondary contained beaker within the perfusion cabinet (not a class II containment piece of apparatus). In reference to “System of Work – M10” for Containment Laboratory Level 2, Schedule 8, Part II of the GMO (CU) Regulations 2000, there is a negligible risk of aerosol generation at this point in the procedure, since the elution from the placenta is not pressurised and is without mechanical force (unlike examples given of mechanical process, including shaking, centrifugation and sonication). Nonetheless, splash risk from droplets has been evaluated (see end of this section). During viral tissue perfusion, the collection vessels will be continually aspirated into a secondary contained 2.5 litre sealed waste bottle, containing an appropriate quantity of Virkon to give a 2% solution following maximum experimental aspiration; bunged and held under negative pressure by an aspirator pump fitted with a syringe filter at the air inlet port, safely containing the waste and preventing viral release into the laboratory atmosphere. At the end of perfusion experimentation, using blunt ended scissors and blunt ended forceps, the perfused placental tissue (approximately 150g) will be transferred to the biological safety cabinet, cut up into small cubes, and either zinc fixed for imaging, or immersed in 2% Virkon overnight, drained and sent to clinical waste (supervised burn).

Viral-containing droplet production and decontamination evaluation during perfusion:

To ensure that droplet splashes were minimal and fully contained during perfusion, a simulation experiment was performed with a low hazard dye, bromophenol blue. The simulation perfusion was carried out, substituting the virus with the dye. An A3 sheet of white paper was taped to the inside of the perfusion cabinet sash, adjacent to the dripping perfusate (perfusate drips 15 cm into an aspirated beaker, placed in a secondary containment tray). We also took this opportunity to evaluate the syringe/three way-tap “luer locking system” that we thought would protect from viral spray risk during virus administration to the perfusion inflow line. We found that this was very effective at preventing any dye from leaking under the pressure generated from syringe plunging. Perfusion was performed for 30 minutes at normal flow rates. The A3 paper was inspected at the end of this period for contamination and was found to be clear of dye.

There was a minor risk of splashes from drips, beyond the inside wall of the glass collection beaker into the secondary containment tray. However, repositioning of the aspiration tube inside the beaker, to a vertical position, prevented splashing onto the white secondary containment tray. We evaluated that flooding the secondary containment tray with a 2% Virkon solution prior to controlled aspiration would be a reasonably practicable measure if splashes were found to occur during the course of an experiment and we would have plenty of Virkon solution at hand before each experiment. Also, we found that channeling the dripping perfusate, using parafilm, which had been trapped into the placental perfusion clamp assembly prior to experimentation, was very effective at ensuring all drips were controlled into the beaker, before dye administration occurred. We will use this method routinely.

2% Virkon treatment of the disassembled apparatus, beaker, aspirator, secondary containment trays and the inside of the perfusion cabinet (non-disposable parts of perfusate delivery system, clamp apparatus and non absorbent cabinet surfaces, i.e. all surfaces) would be an easily achievable SOP after experimentation. The perfusate dye (dye/virus) distributor, a disposable part associated with the luer-locking syringe mechanism, occurring just upstream of perfusate delivery to the placental tissue, would undergo 2% Virkon soaking, but would then need to be routinely subjected to autoclave treatment, to ensure penetrating decontamination.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon tablets (working concentration = 2% minimum of 2 hours) will be used to render waste culture media and perfusate disinfected. 2% Virkon will be used to wipe all trays, MSC, perfusion cabinet and equipment surfaces and will be used to soak smaller disposable consumables items. Following at least 2 hours of disinfection, the 2% Virkon solutions will be poured into the normal drainage system. Used culture plates and their ‘net-well’ inserts, used viral administration syringes, three way taps, perfusate line and cannulae will be autoclaved at 123°C held for 40 minutes, within the building, before being disposed of into normal clinical waste for incineration. All metal re-usable equipment (placental clamp apparatus, blunt forceps and scissors) will be soaked in 2% Virkon for 10 minutes and then autoclaved, as above.

Culture medium and perfusate spillage within trays, during experimentation, will be dealt with by aspirating the liquid into the controlled waste bottle, as normal liquid waste (see above). Trays will then be flooded with a 2% Virkon solution then aspirated to the controlled waste bottle, in the same way. Non-contained spillage will be dealt with according to our displayed SOP podter “Permitted Disinfectants”. Waste paper towing and Virkon powder scoping utensils, used to clear surfaces after spillage
disinfection, will be bagged, sealed, autoclaved (as above), before being disposed of into normal clinical waste for incineration.

It is expected that all solutions, materials and transfected tissue will be completely killed after the above measures have been undertaken. 2% Virkon disinfectant solutions will be made up weekly and will be discarded thereafter, or if the pink colouration fades. All autoclaving of waste will be logged following the checking of time, temperature and vent settings, prior to switch on. Arrangements will be made periodically to have the autoclave tested for functionality by a trained engineer. Records of function testing will be retained alongside the autoclave.

After reviewing the assessments the committee raised several points which required clarification:
1. Address the effects of possible homologous recombination with wild type E1 gene. Would this make the GM Adenovirus replication competent, whilst continuing to carrying genetic insert gene (VEGF)?
2. Should transfection occur in human, explain scope for hypotensive effects in the systemic vasculature.
3. Evaluate the potential for droplet splashes in phase B (perfusion of placental lobule) of the proposed wok.
4. Describe the likely replication competency of the supplied virus.
5. Describe segregation of projects sharing the GM lab (330).
6. For aspirated viral containing waste, explain how you might disinfect the solution that enters the waste bottle, to disable the infection hazard in the most immediate and controlled manner.

All these points have now been addressed to the satisfaction of Genetic Modification Safety Committee and are encompassed in the current version of the Risk Assessment.

Project Ref 541/09.2
Purposes of the contained use

A broadly cross-reactive meningococcal vaccine developed by Novartis Vaccines is currently undergoing phase 3 outer membrane proteins – factor H binding protein (fHBP) fused with a further protein GNA2091), GNA2132 (fused with a further protein GNA1030 and Neisserial adhesion A (NadA). The vaccine also has an outer membrane vesicle component. fHBP is a virulence factor that binds the human complement factor H thereby enhancing bacterial survival in the host. The function of GNA2132 is unknown though it has been implicated in heparin binding, which may also lead to enhanced survival within the host. NadA is avirulence factor involved in host cell adhesion and invasion.

In order to predict the efficacy of the vaccine in England and Wales it is necessary to characterise native case isolates for fHBP, GNA2132 and NadA in terms of a) genetic variation, b) surface expression levels and c) serum bactericidal antibody (SBA) susceptibility to pre and post-vaccination sera – the gold standard assay for predicting Men B vaccine efficacy (there is no reliable animal model for meningococcal disease). To enable the evaluation of surface expression, e.g. by Whole cell ELISA and Immunoblotting, it is necessary to compare wild type native isolates against negative control (gene-knockout) isolates such that e.g. non-specific antibody binding may be accounted for. Similarly, in order to evaluate SBA susceptibility, knockout isolates of a) each gene, b) different combinations of 2 genes and c) all of the genes, will be required to help elucidate the SBA activity against any single antigen.

Single and multiple knock out strains have been developed for these antigens, for the purpose outlined above, by Novartis vaccines (Sienna, Italy). It is our intention to obtain these isolates from Novartis for use in the present study.

Recipient or parental organism

The knockout strains will be required for comparison with the wild type strains used in the immunoassays and are therefore required to be wild-type in all respects other than that of the gene/s being disabled. The GMM constructs will therefore be treated as wild -type. A deficit of one or more of the antigens - fHBP, GNA2132 and NadA is likely to significantly reduce invasiveness and the ability in the host.

Host/vector system

fHbp, NadA and gna2132 knockout isolates and combination thereof were constructed at Novartis Vaccines, Siena, Italy. Briefly, In order to generate Neisseria meningitides mutant strains lacking the main antigens contained in the vaccine, three knockout plasmids were constructed for the deletion of all or part of the respective antigen-coding gene and replacement by allelic exchange with an antibiotic resistance cassette. Using standard cloning procedures, upstream and downstream flanking
regions of the gna2132 and fhbp genes were amplified by PCR from the MC58 genome and cloned on either side of an erythromycin resistance cassette into the pBluescript (Pharmacia) cloning vector, generating the knockout plasmids pBSUDgna2132:Erm and pBSUDfhbp:Erm, respectively. For the generation of the NadA knockout construct, the nmb1994 gene and surrounding upstream and downstream regions were amplified by PCR from the MC58 genome and cloned into the pBluescript cloning vector, and subsequently an internal HincII fragment at the 5’ end of the coding region was substituted with the erythromycin resistance cassette, generating pBS961:Erm. For generation of the single knockout mutants, the knockout plasmids were linearised and transformed into the wildtype strains. Erythromycin resistant colonies were selected and checked by PCR for correct insertion due to a double homologous recombination event and colonies with correct PCR profile were further analysed by Western Blot for the lack of expression of the respective antigen.

For generation of a single Nm derivative strain lacking the expression of two or three antigens, a stepwise deletion by allelic replacement strategy was used in which double-knockouts were constructed using Erythromycin and Kanamycin cassettes and triple-knockouts were constructed using Erythromycin, Kanamycin and Chloramphenicol cassettes.

**Origin & function**

The function of the genetic material, i.e. antibiotic resistance genes, is to enable the selection of isolates in which the genes of interest have been successfully removed.

The erythromycin (Erm) cassette contains a Streptococcus pneumoniae gene for rRna adenine N-6-methyltransferase. This protein produces a dimethylation of the adenine residue at position 2058 in 23S rRNA, resulting in reduced affinity between ribosomes and erythromycin resulting in erythromycin resistance.

The Kanamycin (Kan) cassette contains the Campylobacter coli aphA-3 gene. The gene product is an aminophosphotransferase (APH) that inactivates kanamycin by transferring the γ-phosphate of ATP to the hydroxyl group in the 3’ position of the pseudosaccharide.

The chloramphenicol (Cin) resistance cassette contains the Campylobacter coli chloramphenicol acetyltransferase (cat) gene. The enzyme chloramphenicol acetyltransferase covalently links acetyl groups to the chloramphenicol molecule. This in-turn prevents chloramphenicol from binding to the ribosome – its site of action.

The knockout isolates and their respective antibiotic cassettes are listed in the table below:

</tbody>
</table>
The pathogenic traits of these strains are likely to be lessened since isolates lacking nadA (that previously harboured the gene) are likely to be less invasive whilst fHbp deficient isolates are less likely to survive within the host due to the loss of a virulence factor shown to be important in this respect. Strains deficient in gna2132 may also be less likely to survive within the host since the GNA2132 antigen is has been shown to bind hepan - also proposed to enhance survival within the host.

The single gene knockout strains were all constructed using Erythromycin resistance cassettes. Double-knockouts were constructed using Erythromycin and Kanamycin cassettes and the triple-knockouts were constructed using erythromycin, kanamycin and chloramphenicol cassettes. These antibiotics do not constitute first line therapeutic/prophylactic antibiotics against meningococci (curent guidelines include penicillin, cefotaxime or ceftriaxone for therapy and rifampicin, ciprofloxacin or ceftriaxone to eradicate carriage in close contacts/exposed individuals). The presence of one or more exogenous antibiotic resistance genes may also place a disadvantageous burden on these strains.

Meningococci are obligate human pathogens and survive only within the human nasopharynx.
The local GMO committee reviewed the risk assessment and local application form at length and were generally happy with the contents. The committee asked for more detail of working with meningococci to be added; in particular the means of controlling aerosol production and ensuring worker safety training. This detail has been added to the risk assessment.

**Project Additional Information**

- **Purposes of the contained use**: To virally transduce human, mouse and rat cells with genes, microRNAs or shRNA oligonucleotides
**Recipient or parental organism**

- Human primary, established cell lines, and tissue explants, such as epithelial cells, fibroblasts, vascular smooth cells and organotypic cultures of lung, and synovium, and primary human peripheral blood derived cells.
- Mouse primary, and established cell lines, and tissue explants, such as mouse monocytes, macrophages, lymphocytes, vascular smooth muscle cells and organotypic cultures of lung.
- Rat primary, and established cell lines, and tissue explants, such as Rat1 cells.

**Host/vector system**

Vectors: Commercially available adenoviral, retroviral and lentiviral self-inactivating vectors, and well established retroviral vectors (pLNCX and pBABE) packaged into transducible viral particles by specific eukaryotic packaging cells. The lentiviral, adenoviral and retroviral expression vectors do not encode proteins required for virus packaging. Proteins for packaging are provided by transient transfection of helper vectors or the packaging cell line.

**Origin & function**

- Genetic material - subcloned from cDNA library, for example: expression vectors for glucocorticoid receptor, HIF1a, macrophage migration inhibitory factor, Notch receptors and their signalling network.
- Genetic material - Commercially synthesized oligonucleotides to express microRNAs to, for example: to modulate expression of glucocorticoid receptor, Notch receptors and their signalling network, HIF1a.
- Genetic material - Commercially synthesized oligonucleotides to form shRNA complexes to, for example: glucocorticoid receptor, and its signalling partners, Notch receptors and their signalling network, HIF1a.

**Evaluation of foreseeable effects**

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion, polarity and fate. The split function of the viral vectors however greatly reduces the risk of recombination events occurring and the self-inactivating properties of the vectors themselves inhibit production of virus once the transgene becomes stably incorporated into the genome of the target cells, eliminating the risk of undesired infection. Therefore it is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Spillages to be cleaned with 1% virkon.

All liquid waste to be soaked in 1% virkon overnight.
All solid waste to be autoclaved. The area to be cleaned with 70% ethanol afterwards. It is anticipated that this will give 100% kill.

Please enter comments on the GM safety committee on the risk assessment

All risk assessments were initially considered at local GM committee meetings for the Stopford and AV Hill Buildings in June and August 2009. The committee requested clarifications and amendments to all the assessments, in particular control measures, waste management and the biological activity of the inserted sequences were discussed at length. All the risk assessments were finally approved at meeting of the local GM committee on the following dates:

- DWR003 approved 1/9/09
- TWO001 approved 1/9/09
- AWO002 approved 4/8/09

Date Project 02/03/2022
The purpose of this research is to gain an insight into the growth and nutrition of filamentous fungi. The work will primarily involve Aspergillus and will involve knocking out, placing under conditional promoters, or tagging with N or C terminal fusion with green fluorescent protein or derivatives genes thought to play a role in the growth and nutrition of filamentous fungi. The work will also involve the expression of some of these proteins in auxotrophic strains of Pichia pastoris to enable these proteins to be purified and characterised. Gene knockout/conditional promoter constructs will involve cloning into disabled E. coli K12 derivatives and reintroduction back into host fungus. Auxotrophic and antibiotic resistance markers will be used for selecting recombinant strains. Strains may also be tested for changes in the ability to infect insect larvae such as the Wax Moth, an alternative system to using animal models.

**Recipient or parental organism**

Escherichia coli K12 strains (including DH5 alpha, JM101, JM109, SURE) are disabled.

Pichia pastoris His and Arg auxotrophs.

Aspergillus strains including Aspergillus fumigatus (ACDP Hazard group 2) and Aspergillus nidulans (ACDP) Hazard group 1) and ACDP Hazard group 1 soil/compost residing filamentous fungi.

**Host/vector system**

Cloning and expression vectors are all "non-mobilisable (e.g. pUC-based such as pGEM and pBluescript series and derivatives and the yeast pPIC series)."

**Origin & function**

For knockout vectors, promoter replacement vectors and for C or N terminal green fluorescent protein tagging, a selectable marker such as PyrG or hygromycin resistance will contain upstream and downstream sequence of the target gene of the host and will be cloned in E. coli before transforming into the host fungus.

For expression in Pichia pastoris, gene sequence compromised of the ORF will be cloned into E. coli before transforming into P. pastoris for methanol-induced gene expression.

All host sequences will be generated by PCR using specific primers from host genomic DNA or cDNA derived by reverse transcription of mRNA or synthesised synthetically by a commercial company following codon optimisation.

Cloned DNA will be verified by sequencing prior to introduction into the gene expression organism and introduced sequences will be integrated into the host genome. Proteins encoded by the cloned DNA will be overexpressed using an inducible promoter system.
Human health:

With the exception of Aspergillus fumigatus, all the fungi in this study are ACDP Hazard group 1 and do not pose a significant threat to human health. Aspergillus fumigatus (ACDP Hazard group 2) is an opportunistic pathogen that can cause a threat to immunocompromised individuals. In addition, it is also capable of being an allergen. However, A. fumigatus spores are extremely common in both indoor and outdoor environments and respiratory exposure is almost constant. The modifications proposed are in genes related to growth and nutrional capability of this organism and would either have negligible effect or would impair growth compared to the parental strain and thus recombinant strains would pose no increased risk to individuals. Recombinant strains may be tested for virulence in an invertebrate pathogenicity model (e.g. wax moth larvae) or animal model (e.g. mouse) and in the unlikely event that virulence is shown to be increased, the strain will be destroyed. Recombinant A. fumigatus strains generated should pose no greater threat to immunocompromised individuals or women of child-bearing age or who are expecting or planning a pregnancy. Respiratory exposures to wild-type A. fumigatus is constant in both indoor and outdoor environments.

Environment:

A. fumigatus as well as being extremely common in the air (spores) is also extremely common and ubiquitous in soil and decaying plant material. The recombinant strains will have no positive phenotypic effect that would make them advantageous in the environment compared to the wild-type strain and are likely to be less competitive. Pichia pastoris auxotrophic strains are unlikely to survive in the environment without supplementation and recombinant gene expression is methanol induced and unlikely to occur outside the laboratory. In addition, all manipulations are on a small laboratory scale and only small amounts of recombinant material will be generated. All work is carried out in a class II laboratory and all open manipulations where spores may escape are conducted in a Microbiological Class II safety cabinet that is routinely maintained under a service contract. In addition, biomass and materials are destroyed by contact with Trigene and autoclaving prior to disposal. In the unlikely event of release into the environment, no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Some of the work will involve studying the ability of genetically modified strains to infect insect larvae such as Wax moth larvae. The larvae themselves are not genetically modified. Infected larvae will be contained in sealed plastic boxes and destroyed by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste will be completely inactivated by autoclaving (121 degrees for 15 min). Autoclave runs are validated by monitoring on a chart recorder and autoclaves are maintained annually and checked by thermocouple testing. In addition, liquid wastes are treated overnight with 10% Trigene prior to autoclaving. All research members will be trained in the safe handling of sporulating fungi to minimise the release of spores into the air. For long term storage, small quantities of spores will be stored frozen in glycerol at -80 degrees C. In addition all cultures of genetically modified organism will be clearly labelled and disposed as soon as possible. All manipulation of organisms will be carried out in a Microbiological Class II safety cabinet which is routinely maintained and sterilised under a service contract. All containers (petri dishes, flasks etc) containing cultures are sealed with parafilm. Any spills will be immediately treated with 10% trigene and contaminated material autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The project was discussed at the local GM/Biohazard safety committee held on 10.02.11. Committee chair (BSO). It was commented commercially sensitive box has been ticked. However, notifications are on public register, GDR stated that work described on forms was not commercially sensitive. Noted that spores will not naturally infect wax moth larvae, hence need for injections this information needs to be added under environmental risk section. Suggested replacing animal from with description of the procedure used to inject, including the hazards, estimated risk and control measures. Under section 7 of the CU2 form, virulence genes need to be mentioned with a discussion of possible outcomes of oer expression. Other minor amendments were also noted.

**Project Additional Information**
**Purposes of the contained use**

We are involved in the systematic analysis of stem cell differentiation and oncogenic transformation of haemopoietic cell lines via proteomic and phosphoproteomic analysis. Protein profiles obtained by Mass Spec analysis of differentiating cells and the consequences of leukaemic oncogene expression on the proteome will allow potential targets to be identified. Lentiviral vectors will be employed to either express genes of interest or reduce their expression via delivery of shRNA whilst simultaneously expressing a mutated form of the protein of interest. The work will be undertaken in primary haemopoietic cells and murine and human cell lines. The genes will be assessed for their effects on the growth, survival, motility and differentiation capabilities of the cells.

**Recipient or parental organism**

Target cells will be either primary or well established immortalised murine or human haemopoietic cells. Cell lines include; Baf3, FDCP-Mix, NFS60- and K562.

**Host/vector system**

Replication disabled self inactivating lentiviral vectors will be used to transfect either primary or well established immortalised murine or human haemopoietic cells. The lentiviral expression system use a third-generation HIV derived lentiviral system. The system consists of three packaging plasmids and a transfer vector containing the gene of interest. The structural complexity of the lentiviral genome has been designed to minimize its relation to the wild-type, human HIV-1 virus to enhance biosafety. The key safety features are:

1. The expression vector contains a deletion in the 3’ LTR that is copied to the 5’ LTR upon integration leading to self-inactivation of the lentivirus. Once targeted into the transduced target cell, the lentiviral genome is no longer capable of producing packagable viral genome hence cannot be rescued by replication competent virus.

2. The number of genes from HIV-1 that are used in the system has been reduced to three. Rev is on a separate vector to gag, and pol. This means that 5 genes are absent including tat which is essential for viral replication.

3. Viral particles are packaged in Envelope proteins from vesicular stomatitis virus rather than HIV-1.

4. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gag, pol, rev, env) none of them contain LTRs or the \( \Psi \) packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus are never expressed in the transduced target cell. No new replication-competent virus can be produced.

**Origin & function**

The genes we will be experimenting with will be identified through our Mass spectrometry screening programme of stem cell differentiation and leukaemogenic transformation. This means we will be investigating Mutine and human cDNA of various genes which will include:

CD45, a haemopoietic specific phosphatase involved in the regulation of cytokine signalling; FMIP, a protein involved in RNA transport and M-CSF signalling.

**Evaluation of foreseeable effects**

The GMOs in this proposal will consist of replication defective lentiviral vectors and human and murine haemopoietic cells.

Although the inserts within the lentiviral vectors will be expressed at levels high enough to achieve biological activity and could feasibly have a deleterious effect if delivered to a target tissue the fact that the DNA has been introduced without the ability to infect other cells and that the cells would rapidly induce an immune response make it very unlikely that any harmful effects would be seen (VSV are inactivated by Complement and \( \alpha \)-galactosyl natural antibody mediated mechanisms in human serum). The modifications to the lentivirus should not have any affect on host defence mechanisms or the tropism or host range. On packaging into the VSV coat proteins the lentivirus will be capable of infecting a variety of mammals however the virus will be replication defective and will therefore not cause an infectious disease. The safety features mentioned above insure that integrated vector DNA cannot be rescued by replication competent virus hence is unlikely to become mobilized. Although the genes will be expressed, or reduced in the presence of the shRNA, we do not expect them to have a deleterious effect. For example, although CD45 is involved in signal transduction it is
expressed on all hematopoietic cells being a defining marker of the hematopoietic system. Thus increased expression should not modulate the mature hematopoietic cell function to any extent. Further, there is no evidence of involvement of CD45 in complement activation processes.

Retroviruses are fragile structures and do not survive for long periods in the environment. Eukaryotic haemopoietic cells and the established cell lines to be used are fragile requiring distinct conditions for survival not available in the environment (temperature, growth factors etc). The cell lines would therefore not survive in the environment. The most likely routes of transmission however will be by inoculation by sharps, contact with open wounds and exposure to aerosols. Local rules requiring the dressing of open wounds, the use of gloves and the avoidance of the use of sharps will minimise transmission by the first two routes. The use of a class II biological safety cabinet will provide adequate protection against aerosols.

The conceivable routes of transmission to the environment would occur during waste disposal, accidental spillage or via aerosol production. The use of a class II biological safety cabinet will prevent the danger posed by aerosols. Standard laboratory practices of disinfecting liquid waste with Virkon (Antec International) and autoclaving solid waste will adequately control the risk during waste disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| Not Applicable |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| No application for derogation from full containment measures |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The waste material within this project includes the following GMMs E. coli K12, replication incompetent lentiviruses, murine cell lines. Further waste includes plasticware and other disposables used during experimental protocols. All waste material is treated with Virkon (Antec International) as per manufacturers instructions. A 1% solution gives effectively 100% kill of all the GMMs in this project within 30 minutes. (Manufacturers and independent testing). Liquid waste will be treated with a solution of 1% Virkon for a minimum of 2 hours before disposal down the sink. Solid waste treated with a solution of 1% Virkon for a minimum of 2 hours before disposal via autoclaving. Autoclaves are routinely run on a 30 minute cycle at 121°C. This ensures effectively 100% kill. The autoclaves have a data logging system. The autoclaves are serviced annually by LTE Scientific, Oldham which includes a UKAS calibraton and load validation.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

**Purposes of the contained use**

To virally transduce mouse peritoneum in vivo with replication deficient adenovirus expressing TGF-B1 transgene. Insertion of the transgene is in the E1 site which prevents a rescue of replication potential after possible subsequent recombination. The transgene is under the control of a mouse cytomegalovirus (CMV) immediate early promoter and terminated by the SV40 polyadenylation signal. The mouse CMV promoter is functional in a number of mammalian cells including human.

**Recipient or parental organism**

Mouse peritoneum

**Host/vector system**

The adenovirus was constructed by intracellular homologous recombination of a recombinant plasmid (comprising the cDNA of TGFβ inserted into the multiple cloning site of shuttle plasmid pACCMV using BgIII) and an adenovirus derivative (PJM17) in 293 cells. The shuttle plasmid contains a partial adenovirus type 5 genome with a human CMV promoter, a multiple cloning region and the SV40 polyadenylation signal inserted into the E1 region. Adenovirus derivative PMJ17 carries the entire Ad5 genome with a deletion/substitution in E3 and insertion of pBR322 in E1. Each of these will limit the risk of production of wild-type virus after recombination.
The adenovirus leads to expression of porcine transforming growth factor - beta 1 (TGF-β1) which is involved in fibrosis (scarring), and angiogenesis (blood vessel growth). AdTGF-β1 was created with TGF-β1 cDNA mutated at residues 223 and 225 so that the transgene product does not bind to latency-associated protein (LAP) and is therefore synthesized as in a biologically active form. The gene is under the control of the mouse cytomegalovirus (CMV) immediate early promoter and terminated by the SV40 polyadenylation signal.

TGF-β1 is a multifunctional cytokine that is central to increased collagen production and has been used topically to aid wound healing. When delivered to an organ or tissue, it may induce scarring/fibrosis. TGF-β1 has pro- and anti-wound inflammatory actions and can induce epithelial to mesenchymal transdifferentiation in certain epithelial-like cells. In a mouse model, intraperitoneal administration of both AdTGF-β1 or control adenovirus results in a transient, mild peritonitis that had resolved by day 4. Transient peritoneal expression of the ADTGF-β1 will induce fibrotic changes in the peritoneum. Expression of the transgene will peak around day 7 and then will return to baseline around day 14.

**Evaluation of foreseeable effects**

The gene product expressed is expected to affect cellular properties such as proliferation, apoptosis, migration, fate and protein synthesis. There would be no transfer of genetic material with other organisms and there would be no harmful products of gene expression. Peritoneal cells will be transiently transfected with replication-deficient adenovirus and will show no phenotypic or genetic instability or any other harmful effect. It is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

This adenovirus will be used at level 2 biohazard containment. All bench and animal work will be carried out in a level 2 biological safety cabinet. Spillages to be cleaned with Trigene. All liquid waste will be soaked in Trigene overnight. All solid waste to be contained separately and autoclaved. Animal waste is autoclaved prior to incineration via the clinical waste route. The area to be cleaned with Trigene afterwards. It is anticipated that this will give 100% kill.

Mice will be kept in appropriate cages in a separate category 2 area of the animal unit. Appropriate measures are in place to prevent animals escaping with barriers in place. Any escaped animal can be detected and recaptured. All experimental procedures will be carried out to minimise the chances of escape.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Y

02/03/2022
Q: Does the virus affect inflammation
A: The people who developed the model have not seen any signs of TGF-beta1 down regulating inflammation.

Q: As adenovirus is shed in the urine how would bedding be treated.
A: Bedding and cage are autoclaved in a containment class 2 autoclave and then the bedding is disposed of as clinical waste and the cage is washed as normal.

Q: How is stock of concentrated virus diluted.
A: The concentrated virus is transported to the BSF in a double boxed container and diluted in a class 2 cabinet in the BSF.

Q: Where is the gene inserted in the adenovirus
A: SaH will check this and amend the form

Q: The gene is under control of a mouse promoter. Can this work in humans
A: SaH will check this and amend the form

The appropriate changes were made and the committee are happy with the form and a

The main objective of this project is to generate human adult cardiomyocytes from skin fibroblasts to translate our findings in animal models to a human relevant model using human induced pluripotent stem cell (iPS) and iPS-derived cardiomyocytes (iPS-CM) technologies.

We will first reprogram skin fibroblasts to form inducible pluripotent stem cells (iPS) by expressing a cocktail of transcription factors: Oct4, ASox2, Mef2c, Klf4 (Takahashi et al., Cell. 2007;131(5):861-72). Then cardiomyocytes will be generated from the iPS using spontaneous differentiation protocol (Guan et al., Circ Res. 2007;100(11):1615-25). iPS formation will only be achieved if a highly efficient gene transfer system is used (Guan er al., Nat Protoc. 2009;4(2):143-54.) Lentiviral vector constructs have proven to be very productive in terms of transduction due to their ability to infect both replicating and non-replicating cells, including stem cells. It has been reported that lentiviral system is a method of choice for gene delivery system for generating iPS from fibroblasts because it integrates into the genome which make the gene transfer highly efficient and stable compared to the adenovirus system (Narsinh et al., Circ. Res. 2011, 108:1146-1156). Therefore we will use this method in this project.

Recipient or parental organism
Human and mouse

Host/vector system
Host cells will be: HEK293 cells, primary human/mouse skin fibroblasts, E.coli DH5a, JM109, TOP10, BJ5183, XL10-Gold, XL1 Blue.
Vectors will be: pHAGE-mSTEMCCA, pHAGE-hSTEMCCA, oHDM-Hgpm2, pHDM-tat1b, pRC/CCMV-rev1B, pHDM- VSV-G

Origin & function
Oct 4 (human and mouse): This gene encodes a transcription factor containing a POU homeodomain. This transcription factor plays a role in embryonic development, especially during early embryogenesis, and it is necessary for embryonic stem cell pluripotency. Stem cells maintain expression of Oct4, consistent with the stem cell hypothesis of carcinogenesis.

Sox 2 (human and mouse): This gene encodes a member of the SRY-related HMG-box (SOX) family of transcription facotrs involved in the regulation of embryonic development and in the determination of cell fate. The product of this gene is required for stem-cell maintenance in the central nervous system, and also regulates gene expression in the stomach. Stem cells maintain expression of Sox2, consistent with the stem cell hypothesis of carcinogenesis.

Mef2c (human and mouse): This locus encodes a member of the MADS box transcription enhancer factor 2 (MEF2) family of proteins, which play a role in myogenesis. The
encoded protein, MEF2 polypeptide C, has both trans-activating and DNA binding activities. This protein may play a role in maintaining the differentiated state of muscle cells. Mef2c is not expressed in cancer cells.

Klf4 (human and mouse): Krueppel-like factor 4 is a protein that in humans is encoded by the KLF4 gene. In embryonic stem cells (ESCs), KLF4 has been demonstrated to be a good indicator of stem-like capacity. It is suggested that the same is true in mesenchymal stem cells (MSCs). KLF4 was not detected in proliferating or cancer cells, indicating a non-cell autonomous effect of KLF4 on proliferation and carcinogenesis (Tetreault et al., Gastroenterology. 2010;139(6):2124-2134).

Lentivirus packaging genes (HIV-gag, HIV-env, HIV-tat, HIV-rev and VSV-G): The HIV lentivirus RNA genome consists of at least seven structural landmarks (LTR, TAR, RRE, PE, SLIP, CRS, and INS), and nine genes (gag, pol, and env, tat, rev, nef, vif, vpr, vpu, and sometimes a tenth vpr, which is a fusion of tat env and rev), encoding 19 proteins. Three of these genes, gag, pol, and env, contain information needed to make the structural proteins for new virus particles. During viral replication, the integrated DNA provirus is transcribed into mRNA, which is then spliced into smaller pieces. These small pieces are exported from the nucleus into the cytoplasm, where the are translated into the regulatory proteins Tat (which encourages new virus production) and Rev. As the newly produced Rev protein accumulates in the nucleus, it binds to viral mRNAs and allows unspliced RNAs to leave the nucleus, where they are otherwise retained until spliced. At his stage, the structural proteins Gag and Env are produced from the full-length mRNA. The full-length RNA is actually the virus genome; it binds to the Gag protein and is packaged into new virus particles (Pollard et al., Annu. Rev. Microbiol. 52: 491-532).

**Evaluation of foreseeable effects**

The viral vector is replication defective and the insertion of the genes listed above will not alter the properties of the final GM virus. Possible hazards associated with this vector may be caused by stable expression of the transgenes, insertional mutagenesis and potential for generation of replication competent virus. Lentiviral stocks may be contaminated with replication-competent viruses (RCV), generated by rare spontaneous recombination events in the propagating cell lines. However, the use of third generation vector using 5 plasmids approach as described above will significantly minimize the likelihood of RCV generation. Nonetheless, each preparation is screened for the presence of wild type contamination. Batches in which replication competent viruses are found at this level will be discarded by autoclaving and decontamination using 1% Virkon solution.

The viral vector has the potential to deliver its genetic material into humans. However, the expression vector is replication-incompetent in any mammalian cells since the part of the viral genome critical for viral replication has been deleted. Therefore, the potential hazard will be mainly due to the activity of the inserted genes.

The most likely route of accidental infection with a retrovirus will be via inadvertent percutaneous inoculation due to spilled reagent during pipetting, skin contact and ingestion. To minimise the risk workers must use suitable lab coats. Gloves must be worn at all times. Upon leaving the lab both gloves and lab coats must be removed and hands washed in the wash hand basin provided. Lab coats should not be worn or taken outside the laboratory except for autoclaving and cleaning and the safety procedures in place for this must be followed. All work will be performed in a Class 2 lab using Class 2 microbiological safety cabinet. Sharp material, i.e. glass pipette will be used to isolate stem cell colonies. To minimise inadvertent exposure due to the use of sharp materials the following procedures must be followed:

* Sharp materials should be used with extreme care and only when necessary.
* Ensure that sharp materials are not left exposed, but always removed promptly in the sharp bin
* Avoid injuries during preparation of Pasteur pipette
* Consider double gloving with a larger pair of gloves innermost for optimum comfort. Double gloving does not prevent sharps injury but has been shown to effect up to a six-fold decrease in inner glove puncture.
* Sharp materials must be discarded into a yellow sharps container which is clearly marked with the British safety number 7320 and UN3291. When the sharps container is 2/3 full the lid must be closed securely. The identification label must be completed to identify user, date and department. The closed bin must immediately be moved to the decontamination facility in room 1.402 stopford building which is located very close to our laboratory (1.302 stopford building).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste material will be packaged into biohazard clear autoclave bags and then decontaminated by autoclave before being discarded as clinical waste. Liquid waste will be soaked in 1% virkon for at least 1 hour before being discarded into general laboratory sink. Sharp materials will be discarded into a yellow sharps container which is clearly marked with the British safety number 7320 and UN3291. When the sharps container is 2/3 full the lid must be closed securely. The identification label must be completed to identify user, date and department. The closed bin must immediately be moved to the decontamination facility in room 1.402 stopford building which is located very close to our laboratory (1.302 stopford building).

Please enter comments on the GM safety committee on the risk assessment

The nature of the inserted genes and the VSV-G surface protein used in the virus packaging system have been discussed. It’s agreed that due to the activity of inserted genes in regulating cell growth and development all the work using these lentiviral vectors is classified as class 2 activities. The committee has suggested to precisely defined the safety measure in particular in the use of sharp materials Standard operating procedure (SOP) will be generated by the investigator.

The containment is required for the cultivation of erythrocytic stages of Plasmodium parasites. Parasites are maintained in in-vitro cell cultures by providing human red blood cells to support their growth. Erythrocytic stages are maintained in in-vitro cell cultures by providing human red blood cells to support their growth. Erythrocytic stages are used in the presented research project to study the biology of Plasmodium strains competent to infect humans. This project aims to discover and validate targets useful for malaria therapeutic interventions by applying genetic biochemical and cellular techniques presented.

Plasmodium is an apicomplexa parasite that completes its life cycle infecting alternatively mosquitoes (genus Anopheles) and vertebrates. In vertebrates it causes malaria. Human malaria is a deadly disease that affects about a half of the world population. The present project aims to study essential and critical genes for parasite asexual development and sexual differentiation. The strains under study are P. falciparum, vivax and knowlesi.

In mosquitoes and humans Plasmodium respectively accomplishes sexual and asexual development. Plasmocium developmental stages used in this project are the erythrocytic stages and the initial phases of sexual development in absence of the vector. These stages are cultivated in vitro by providing human red blood cells (RBC), essential to support parasite growth. In fact Plasmodium is an obligate intracelular parasite.

Fragments of DNA that encode for fluorescent proteins such as GFP, yFP and RFP derivates will be used as probes for transfected parasites, for promoter functions, for protein tagging and for trafficking detection. These fragments originate from jellyfish and corals. They enable detection and visualization of parasites using fluorescence microscopy or flow cytometry.

Fragments of DNA that encode for SB100x transposase, TALEN, endonucleases, recombinases, recombinase will be used in this project. SB100X derives from Sleeping Beauty transposases and was produced and characterized by the Izsvak's laboratory (Nat Genet. 2009 June ; 41(6): 753-76L1). SB100X enables the insertion of a DNA fragment flanked by specific inverted repeats into the genome. TALEN is a chimera of TALE (Transcription activator -like effectors from gene product recognizes specific
DNA sequences and digests in the proximity of them. Homing endonucleases, such as Scel, specifically recognize and digest long stretches of DNA sequence (Gimble & Thorner, Nature, 1992, vol 35: hybridized short RNA molecule (Mali P. et al., Science, 2013, vol339, pp823-826). Cre recombinase is a tyrosine recombinase enzyme derived from the P1 Bacteriophage (Abremski & Hoess Journal of Biological Chemistry 1984, 259: 1509-1514) and Flp is a recombinase enzyme derived from Saccharomyces cerevisiae (Broach & Hicks, Cell 1980, vol 21: pp. 501-508). These recombinases excise and insert DNA fragments flanked by specific DNA sequences called Lox and Frt, respectively. All these gene products enable genome editing and recombination. These molecules will be used to generate parasites that are defective in metabolic functions.

Other fragments of DNA included in our plasmids encodes for specific drug resistance, such as human dyhydrofolate reductase (hDHFR), yeast dihydroorotate dehydrogenase (yDHODH) and blasticidin-S deaminase (BSD); Tetracycline transactivator proteins, and specific Plasmodium proteins or protein fragments under biochemical characterization. Accessory DNA fragments are used for optimal plasmid segregation and Plasmodium expression, as minimal centromer, Rep20, Promoters and 3’ untranslated regions.

Evaluation of foreseeable effects

There is no risk in the genetic modifications included in this project for multiple reasons (1) The modifications will not cause a gain of function, or increase the wildtype danger, infectivity, virulence and environment or disinfectant resistance. In fact, used approaches aim to disable parasites in any of their vital functions and virulence, in order to gain access to unknown gene functions. (2) drug resistance genes (above listed), used to select transfected parasite, will be the only gain of functions. Nevertheless, despite the introduction of drug resistance genes, strains used in the present project will remain pharmacologically treatable, if therapeutic intervention is needed for accidental events. (3) There is no possibility to spread the modified parasite, wild type or mutant can survive in the environment. In fact, minimum changes is salts concentration of the media or air exposure will result in hemolyzed or dried RBC with consequent death of parasites (i.e. tap water kills parasites by RBC lysis). In order to reduce the risk of accidental injuries (like cuts or punctured wounds) that may expose to infection, glassware will be avoided as much as possible (details in the code of practice), and sharps (blades or needles) must not be used during Plasmodium culturing.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request some derogations to CL3 containment level in accordance to the fact that cultivated stages cannot cause airborne transmission and the vector is absent from the natural environment in the United Kingdom. In particular, the requested derogations regard the following CL3 requirements: sealable laboratory for fumigation (M2), entry to laboratory via airlock (M4), negative pressure relative to the pressure in the immediate surroundings (M5) and HEPA filtered air from the laboratory (M6)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment of contaminated items.
- Pippette tips and Graduated Pipettes: Place into polypropylene jars containing 2% Virkon. Incubate for 24 hours and then Virkon solution will be poured down the sink and solid waste disposed into autoclavable 'clini' bags.
- Microfuge tubes, Disposable cuvettes, Electroporation cuvettes, flasks and plates: they should be placed in a separate autoclavable 'clini' bag within the microbiological safety cabinet.
- 'Clini' autoclavable bages: When 3/4 full the neck of the autoclavable bag is loosely tied and moved into the autoclave tins and autoclaved within the suite. After autoclaving it is sent off site for incineration.
- Glass slides used in preparing blood smears of Plasmodium-infected red blood cells: they should be placed in a sharps bin. Plasmodium in blood smears on glass slides is inactivated by means of the fixative used to fix the blood film to the slide prior to staining. Because of this inactivation the glass slides can be disposed of by placing in a sharps bin and entering the clinical waste route.
- Liquid Waste: Cuvettes, glasks and universal/falcon tubes containing liquid waste are to be emptied or aspirated into jars containing 2% Virkon and after 24 hours incubation disposed down into the sink.

Disinfection procedures.
- Surface sterilisation; Hard surfaces such as the work surface of the safety cabinet or benches must be disinfected with 70% Ethanol.
- Equipments and their parts must be disinfected with 1% Distel.
- Spillages: Suspected contamination on hands, gloves or work surfaces must be disinfected immediately with 70% Ethanol. Minor spillages (up to ~10 ml) should be treated with 70% Ethanol and wiped with towels. Large spillages (>10 ml) must be treated with Virkon powder and then wiped with 70% Ethanol soaked towels.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This project was first presented to the FLS GM/Biohazard local committee on 28/06/2013 and discussed fully at a sub-committee meeting on 28/08/2013. It was decided that the work will take place in a separate Containment level 2 laboratory with restricted access (swipecard and PIN) and a limited number of registered users. It is in fact the suite used for the schedule 5 pathogens and toxins. The room cannot be fumigated and although it is under negative pressure, this is not currently monitored.

IR was asked to list the derogations from containment level 3 that are being requested - essentially fumigation monitored negative pressure.

As there is no vector present, the only route of infection is for the red blood cells containing the plasmodium (at a certain stage in their life cycle) to enter the blood stream via a cut or wound. IR was asked to consider the possibility of avoiding the use of glassware as much as possible. Although slides and cover slips would be used, the latter can be handled with forceps. No needles or blades will be used.

The need to use live Plasmodium - containing RBCs in experiments was discussed at length. They will need to be viewed under a fluorescent microscope and IR (and LG) to look into the access arrangements in the lab that will house the new CL2 flow cytometer that will be in the MCCIR labs.

The HSE notification form and code of practice will also need to be updated after the GM forms had been amended. IR was asked to revise the forms according to all the suggestions made and the group would look at them again before sending the project to the University advisory group.

The sub-committee met again on 11.10.2013 and 23.10.2013 to consider the amendments and the forms were approved locally prior to the University GM/Biohazard Advisory Group meeting in 08.11.2013.

The Advisory group noted that:
(a) the project was to creat mutant of Plasmodium spp, the causative agent of malaria, that are defective in growth and metabolic processes using a transposase based system to generate random mutants;
(b) the agent is a HG3, however, specific derogations for some of the control measures for working at ful CL3 are being sought from HSE;
(c) the culturing would be undertaken in a highly restricted dedicated laboratory also used for home office restricted biological agents;
(d) analysis will also be undertaken in restricted access, dedicated communal cell sorter facility, however, when cell sorting using live plasmodium work is being undertaken, no other user will be using the dedicated area other than the lab manager and the PI;
(e) there were a number of precautions in place to prevent needle stick injuries.

Agreed:
(i) blood from the blood transfusion center should be used for culturing malaria;
(ii) the final version of the occupational health guidance should be incorporated into the Appendix 2 of the Code of Practice

02/03/2022
This project aims to characterize staphylococcal genes encoding enzymes that are involved in the biosynthesis of wall teichoic acids (WTA) by recombinant, knock-out as well as complementation strategy. This project will involve cloning, expressing and genetically disrupting these genes. This research will be conducted using plasmids in disabled E. coli K12 hosts, and also re-introducing cloned DNA sequences back into strains of Staphylococcus aureus.

Recipient or parental organism

Escherichia coli K12 strains (incl. DH5alpha, JM109, SURE & S17-1 lambda-pir, well characterised attenuated S. aureus hosts: strain RN4220. (Nair D, Memmi G, et al. Whole-genome sequencing of Staphylococcus aureus strain RN4220, a key laboratory strain used in virulence research, identifies mutations that affect not only virulence factors but also the fitness of the strain. J Bacteriol. 2011). The only wild-type hosts to be used are the well studied S. aureus strains USA300 and Newmann (ACDP haxzard group 2).

Host/vector system

Expression vectors: pET-28a carries the N-terminal His Tag sequence followed by thrombin site and three cloning sites (see The pET-28a-c(+) vectors carry an N-terminal His Tag®/thrombin/T7.Tag® (annex 1).
Gene disruption vectors: Suicide vector pKO-R1 (annex II) will be used to create knockout mutant by allelic exchange.

Plasmid pRB474, a vector is used for cloning and expression of staphylococcal genes in S aureus.

Origin & function

Only DNA sequences constituting genes or part of genes from Staphylococcus aureus that encode wall teichoic acids biogenesis genes will be inserted into the vectors for introduction into S. aureus. Introduced DNA will be expressed either individually as full-length proteins or sub-regions, and/or as fusions to other genes (within the vector) encoding non-toxic products.

All sequences will be well characterised prior to introduction into Staphylococcus strains and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced).

Introduced DNA sequences will either (i) remain on self-replicating plasmids for expression of genes or (ii) be integrated into the genome to generate gene disruption mutants of Staphylococcus aureus.

Evaluation of foreseeable effects

Human health:

The S. aureus lab strain RN4220 were recently sequenced and found to carry many mutation leads to decreased virulence. The wild-type S. aureus strains to be employed are of the type which could cause infection if exposed in a large dose. These strains have been safely used for many years and the likelihood of hazard can therefore be considered low. We will only introduce very short (<4 kb) DNA sequences into Staphylococcus using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode genes involved in the biogenesis of wall teichoic acid biogenesis. Since it was found that the deletion mutant deficient in wall teichoic acids (WTA) or WTA glycoepitopes are less virulent and more susceptible to antibiotics (ref 1,2), we expect that new mutants deficient in other WTA biogenesis genes will have similar phenotype: decreased virulence and more susceptible to antibiotics.

For reasons outlined above, the likelihood of harm in the event of exposure would be no greater than that with non-GM Staphylococcus and can be considered negligible.

Environment:
The disabled host strains will not replicate in the environment. Infections doses for man and animals are high and the probability of accidental infection low. The host strains are not known to be infectious for plants. The wild-type S. aureus strains may be able to replicate in the environment. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM Staphylococcus aureus. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste materials (bacterial liquid cultures/agar plates) will be completely inactivated (100% kill) by autoclaving. All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by thermocouple testing. All solid waste will subsequently be incinerated.
The risk assessment GM-GX001: Characterization of genes involved in biosynthesis of wall teichoic acids from Staphylococcus aureus, was reviewed by the Medicine (Stopford, AV Hill and CTF) Local GM/Biohazard Committee on the 10th April 2014. Minor corrections were recommended and the amended risk assessment was reviewed at the following meeting on the 8th May 2014. The committee were satisfied that the risk assessment covered all the relevant points and was signed by the chair.

### Purposes of the contained use

To virally transduce primary human lymphocytes with genes, microRNAs or shRNA oligonucleotides

### Recipient or parental organism

Human primary lymphocytes including natural killer (NK) and T lymphocytes isolated from PBMCs

### Host/vector system

**Lentiviral structural vectors:** pMDLg/pRRE (gag-pol packaging plasmid), pMD2.g (VSV-G envelope plasmid), pRSV-Rev (post-transcriptional regulatory plasmid)

**Lentiviral transfer vector** pLenti-PGK-Neo-DEST Transfer plasmid (PGK promoter) or pLenti-CMV-Neo-DEST Transfer plasmid (CMV promoter)

Host: HEK293T/17 cells (Human embryonic Kidney 293, large T Antigen, clone 17)

Retroviral vectors: The pQCXIN vector contains a CMV/MSV hybrid promoter in the 5' LTR to drive high titers during the packaging step. They also contain a self-inactivating 3' LTR to reduce promoter interference and drive high expression of your transgene from the internal CMV promoter. Expression of an antibiotic resistance genes is achieved through ribosome binding to an internal ribosome entry site (IRES).

Host: Using AmphoPack293 as the host system, TNA from the vector is packaged into infectious, replication-incompetent retroviral particles since pQCXIN lacks structural genes (gag, pol and env) necessary for particle formation and replication; however, these genes are stably integrated as part of the packaging cell genome. Once a high titer clone is selected, these retroviral particles can infect target cells and transmit the gene of interest but cannot replicate within these cells due to the absence of viral structural genes. The separate introduction and integration of the structural genes into the packaging cell line minimizes the chances of producing replication-competent virus due to recombination events during cell proliferation.

### Origin & function

Genetic material: subcloned from cDNA library, for example: Components of the NK cell inhibitory and activatory pathways, such as MICA, KIR2DL1, ICAM, and HLA-Cw4, and immuno-signalling and cytoskeletal proteins, such as LAT, TCRζ, tubulin and myosin.

Intended functions: to inhibit or activate NK cells and to regulate immuno-signalling and cytoskeletal pathways in NK and T cells.

### Evaluation of foreseeable effects

These gene products expressed can affect many cellular signalling pathways, including those involved in cell proliferation, differentiation, adhesion, migration and apoptosis. The exact effects of expression of these proteins will be dependent on the cell type. However, expression would be very limited due to the replication-incompetence and self-inactivation features engineered into the lentiviral transduction system. Furthermore, the extreme vulnerability of lentiviral vectors to environmental conditions and cellular immunity makes any risk to human health extremely small. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

In the retroviral system, expression would be very limited due to the replication-incompetence and self-inactivation features engineered into the retroviral transduction system. Furthermore, the extreme vulnerability of retroviral vectors to environmental conditions and cellular immunity makes any risk to human health extremely small. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus.

Project Ref  541/14.4

Date Ackn'd  CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4

02/03/2022  Page 8502 of 15326
The aim of this project is to use the commercially available Sendai Virus kit to reprogramme human primary cells into iPSCs that can then be used for any further studies. The Sendai Virus, SeV, (mouse parainfluenza virus type 1, hemagglutinating virus of Japan (HVJ)) is a nonsegmented negative-strand RNA virus belonging to the Paramyxovirus family. CytoTune™-iPS Reprogramming System, that we will be using, uses vectors based on replication incompetent Sendai virus (SeV) to safely and effectively deliver and express key genetic factors necessary for reprogramming somatic cells into iPSCs.

Human primary cell (embryonic and adult skin fibroblasts, peripheral blood cells) will be used. Tissues or BioBanks, and patient biopsies via collaborations are all sources that will be used to obtain the cell line.

The Sendai Virus, SeV, (mouse parainfluenza virus type 1, hemagglutinating virus of Japan (HVJ)) is a nonsegmented negative-strand RNA virus belonging to the Paramyxovirus family. SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeVfTS6F, SeVrrS12t:.F, and SeVFt515t:.F) renders the vectors easily removable from transduced cells.

SeV vector can express the reprogramming genes without chromosomal integration. The Sendai virus vectors commercially bought contain RNA sequence that will express factors hOct3/4, hSox2, hKlf4, and hc-Myc. After
transduction, the viral vectors will cause the cells to express these four gene proteins. ALL the four transcription factors, Oct4, Sox2, cMyc, and Klf4 are both necessary and sufficient to induce pluripotent gene expression and therefore reprogramme somatic cells into a stem cell like state (iPSCs). ALL 4 vectors are required for reprogramming and the frequency of all 4 vectors getting into the same cell, executing reprogramming and generating a sustained colony in OPTIMISED culture conditions in vitro is only 0.01-<1%. There is no evidence that Sox-2 alone could reprogramme skin cells to neural especially as any skin cells infected would be terminally differentiated transient or dieing. The likelihood of any of these individual factors having effects on skin cells is negligible even in the unlikely event of skin contact since the RNA virus does not insert so is not propagated. No evidence that this has occurred during reprogramming is available even for integrating viruses (e.g.lenti).

Outside the generation of iPSC cells these factors have other functions. c-myc is a well recognised oncogene, Krueppel-like factor 1 is a transcription factor that is necessary for the proper maturation of erythroid (red blood) cells. SOX2, is a transcription factor that is essential for maintaining self-renewal, or pluripotency, of undifferentiated embryonic stem cells. Sox2 has a critical role in maintenance of embryonic and neural stem cells. Sox2 binds to DNA cooperatively with Oct4 at non-palindromic sequences to activate transcription of key pluripotency factors. Oct 4 is critically involved in the self-renewal of undifferentiated embryonic stem cells. All 4 are needed for reprogramming making this a low frequency event ( see later).

The virus is replication incompetent and the genes are only expressed in a transient manner so expression will not be constant enough to cause any significant changes via infection. PPE will always be worn (gloves and lab coat) as per University guild lines and regulations, so no skin will actually be exposed. In the extreme situation that an infection occurs to the skin should not cause any significant damage. Infection will occur only in the upper dead or terminally differentiated layers of the skin. Therefore, if infection occurs, it will be transitory as the cells are sloughed naturally.

The SeV vectors used in this kit are non-integrative, non-transmissable and not pathogen to humans and so the risk is very low. The viral vectors maintain full infectivity to a wide range of cells, including human cells, however they are no longer capable of producing infectious particles from infected cells because the viral genome lacks the F gene. Fusion PROTEIN (F) fuses the viral envelope with cell membrane when the virus enters the cell but the virus can't make any more. The gene encoding the F protein is deleted from the CytoTune™reprogramming vectors, rendering them incapable of shedding infectious particles from infected cells, and therefore it is replication incompetent. Therefore although c-myc is an oncogene the likelihood of shedding c-myc containing particles is negligible.

PPE will always be worn (gloves and lab coat) as per University guild lines and regulations, so no skin will actually be exposed. In the extreme situation that an infection occurs to the skin should not cause any significant damage, as the virus is replication incompetent as well as a non-integrative vector with transient expression only. This means that this system is much safer than most lentiviral vector system even with the presence of c-myc. The risk of teratomas is negligible. It is actually quite hard to generate these using >1 million cells injected in vivo, (~50% success). ALL 4 vectors are required for reprogramming and the frequency of all 4 vectors getting into the same cell, executing reprogramming and generating a sustained colony in optimised culture conditions in vitro is only 0.01-<1%.

Evaluation of foreseeable effects

Spillages to be cleaned with 1% virkon.
All liquid waste to be soaked in 1% virkon overnight
All solid waste to be autoclaved.
The area to be cleaned with 70% ethanol afterwards.
It is anticipated that this will give 100% kill.

13.
The project SJK-1 (risk assessment submitted with this notification) was initially presented to the FLS GM/Biohazard local committee held on 08.07.2014. The committee made the following comments:
How is the virus disabled? The committee felt that "F-protein deletion" was not sufficient explanation, and asked for more details and further information on why this would prevent new virus being formed.
To address concerns about local infection of the operator, if it splashes/spills onto broken skin.
Origin of the human cells to be used in the study, and screening status of the samples.
Details as to why a class II microbiological safety cabinet is being used in the project.
Details required as to how the samples are manipulated - e.g. use of sharps, etc.
The committee was unable at this stage to determine whether the project was GM class 1 or 2.
The committee chair (Dr. G) subsequently met with the project PI (Professor K) in order to address these concerns. The project was amended and resubmitted as GM class 2. Dr. G finally signed the project off on 10.10.2014.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 541/16.1
The main objective of the project is to generate gene knock-out cells appropriate for cardiovascular research using the Crispr-Cas9 lentiviral system. Crispr-Cas9 is a technique that can enable us to precisely define the functional aspect of genes. Lentiviral vector constructs have proven to be very productive in terms of transduction due to their ability to infect both replicating and non-replicating cells, including stem cells. We will study the functional mechanistic aspects of genetic variants associated with cardiovascular development and functions. In these stem cell models, the genotypes of embryonic stem or induced pluripotent stem cells (iPSC) will be edited with the Crispr-Cas9 lentiviral system. Alternatively, genotypes of fibroblast cells will be edited prior to iPSC generation. We will generate embryonic stem, iPSCs or fibroblast cell lines with stably integrated plasmids containing Cas9 nuclease gene and specific guide RNA (gRNA) sequence against target genes. Through transduction with lentiviral particles, the transduced cells will be selected by media containing puromycin/reporter gene products for obtaining a population of cells with the plasmid successfully integrated/high expression of Cas9 nuclease and gRNA. The stem or iPSC cells with edited genotypes will be differentiated into cell types that are related to cardiovascular development and functions. For efficiency testing, cell lines that can be easier maintained and transduced/transfected will be transduced/genome edited/assayed first (eg HEK293, HepG2 etc). For negative controls, Crispr-Cas9 plasmids without or with scrambled gRNA sequence may be used.

Recipient or parental organism

Parental organism is a 2nd generation lentivirus vector derived from HIV-1.

Host/vector system

Host cells will be human/mouse ESC, iPSC or fibroblasts, HEK293, HepG2, E.coli DH5a. TOP10 Vectors will be: pLentiCRISPRV2 (modified), pCMV-VSV-G, pMD2G, psPAX2,
CRISPR-Cas9 gene and guide RNA CRISPR consists of two components. a "guide" RNA (gRNA) and a non-specific CRISPR-associated endonuclease (Cas9) The gRNA is a short synthetic RNA composed of a "scaffold" sequence necessary for Cas9-binding and a user-defined -20 nucleotide spacer" or "targeting" sequence which defines the genomic target to be modified. Therefore, one can change the genomic target of Cas9 by simply changing the targeting sequence present in the gRNA CRISPR was originally used to "knock-out target genes in various cell types and organisms, but modifications to the Cas9 enzyme have extended the application of CRISPR to selectively activate or repress target genes, purify specific regions of DNA and even image DNA in live cells using fluorescence microscopy. Furthermore the ease of generating gRNAs makes CRISPR one of the most scalable genome editing technologies and has been recently utilized for genome-wide screens (https://www.addgene.org/CRISPR/guide/)

Lentivirus packaging genes (Gag, Pol, tat, rev and VSV-G/Env). The HIV lentivirus RNA genome consists of at least seven structural land marks (LTR, TAR RRE, PE, SLIP, CRS, and INS), and nine genes (gag, pol env, tat, rev, nef, vif, vpr, vpu, and sometimes a tenth ev, which is a fusion of tat env and rev) encoding 19 proteins. Three of these genes gag pol, and env. contain information needed to make the structural proteins for new virus particles. During viral replication the integrated DNA provirus is transcribed into mRNA, which is then spliced into smaller pieces

These small pieces are exported from the nucleus into the cytoplasm. where they are translated into the regulatory proteins Tat (which encourages new virus production) and Rev as the newly produced Rev protein accumulates in the nucleus. It binds to viral mRNAs and allows unspliced RNAs to leave the nucleus, where they are otherwise retained until spliced. At this stage the structural proteins Gag and Env are produced from the full-length mRNA. The full-length RNA is actually the virus genome. It binds to the Gag protein and is packaged into new virus particles (Pollard et al, Annu Rev. Microbial 52 491-532)

Evaluation of foreseeable effects

The viral vector is replication defective and the insertion of the genes listed above will not alter the properties of the final GM virus. Possible hazards associated with this vector may be caused by stable expression of the transgenes, insertional mutagenesis and potential for generation of replication competent virus. Lentiviral stocks may be contaminated with replication-competent viruses (RCV), generated by rare spontaneous recombination events In the propagating cell lines. However, the use of second generation vector using 3 plasmids approach will significantly minimize the likelihood of RCV generation. Nonetheless, each preparation is screened for the presence of wild type contamination. Batches in which replication competent viruses are found at this level will be discarded by autoclaving and decontamination using 1% Virkon solution. The viral vector has the potential to deliver its genetic material into humans. However, the expression vector is replication-incompetent in any mammalian cells since part of the viral genome critical for viral replication has been deleted. Therefore the potential hazard will be mainly due to the activity of the inserted genes or insertional mutagenesis.

The genes (including annotated/unannotated genes non-coding RNA genes and transcribed/untranscribed non-genic genomic regions) of interest (targeted by the gRNA) are those related to cardiovascular development and functions selected/discovered from genetic studies. Most of the candidate genes In this study are of unknown functions while some genes are known as regulators of cell growth differentiation/development or physiological functions in the cardiovascular system. We will target both human and mouse genes whenever appropriate if a candidate gene is later known to be involved in oncogenesis. we will review the risk assessment.

The most likely route of accidental infection with a retrovirus will be via inadvertent percutaneous inoculation due to spilled reagent during pipetting, skin contact and ingestion. To minimise the risk workers must use suitable lab coats.
Gloves must be worn at all times upon leaving the lab both gloves and lab coats must be removed and hands washed in the wash-hand basin provided. Lab coats should not be worn or taken outside the laboratory except for autoclaving and cleaning and the safety procedures in place for this must be followed. All work will be performed in a Containment level 2 lab using Class II microbiological safety cabinet.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste material will be packaged into biohazard clear autoclave bags and then decontaminated by autoclave before being discarded as clinical waste liquid waste will be soaked in 1% Virkon for at least 1 hour before being discarded into general laboratory sink sharp materials will be discarded into a yellow sharps container which is clearly marked with the British safety number 7320 and UN 3291. When the sharps container is 2/3 full the lid must be closed securely. The identification label must be completed to identify user, date and department. The closed bin must be immediately moved to the larger clinical waste collection bins in room 3 44 CTF building (for 3 23b CTF) or room 5 018 AV Hill BUilding (for 5 019m-n AV Hill)

Is an emergency plan required according to regulation 20? No

If yes, tick to confirm that it is attached to this form No

Tick to confirm that you have attached a risk assessment to this form Yes

Tick if you are claiming exemption from disclosure for section of the risk assessment No

Please enter comments on the GM safety committee on the risk assessment
It was agreed that due to the nature of the vector being used (ie, the gRNA and Cas9 genes are located in the same plasmid) and the activity of the inserted genes in targeting genes encoding products involved in cell growth and development, all the work using these lentiviral vectors is classified as class 2 activities.

Animal Units Large Scale Activities Human Clinical Applications
The aim of this project is to generate a recombinant vaccinia virus expressing a bacterial enzyme, for use in gene-directed enzyme prodrug therapy (GDEPT). GDEPT is a two-step gene therapy approach where the gene for a non-endogenous enzyme is directed to target tissues. The enzyme is expressed intracellularly where it is able to activate a subsequently administered prodrug. In this instance, a GDEPT strategy will be employed with the aim of improving the therapeutic ratio of cancer chemotherapy. This involves delivery a non-secreted form of the carboxypeptidase G2 (CPG2) gene of Pseudomonas spp. strain RS16 specifically to solid tumours where it can be used to activate nitrogen mustard prodrugs to release an active drug producing DNA-DNA interstrand cross-links and cell death.

Specific delivery of CPG2 to tumour cells will be achieved through the use of the Copenhagen strain of vaccinia virus. The CPG2 gene will be inserted into the vaccinia virus genome such that it disrupts the viral thymidine kinase (TK) gene. The virally encoded TK is utilised for the synthesis of the thymidine nucleotide, required for viral DNA synthesis and ultimately viral replication in quiescent cells. Dividing cells transiently express TK in order to produce the components required for division during the synthesis phase of the cell cycle. As such the majority of rapidly dividing cancer cells constitutively express TK and the pool of nucleotides is consistently high. Therefore deletion of viral TK forces the virus to rely on cellular TK, most highly expressed in cancer cells thereby contributing to a restriction of tissue tropism of the virus for productive replication.

To generate the TK deleted recombinant virus, the open reading frame for a non-secreted form of the CPG2 will be cloned into a recombination transfer vector so that it will be control of a synthetic vaccinia virus promoter. This transfer vector will be transfected into vaccinia virus strain Copenhagen infected cells to permit specific insertion of the vaccinia promoter-CPG2 cassette at the TK locus of the viral genome, mediated by homologous recombination. Successful recombinant virus will be recovered through plaque purification in conjunction with selection utilising marker genes included alongside the inserted CPG2 cassette. Marker genes will be those for a yellow fluorescent protein-guanine phosphoribosyltransferase fusion protein (YFP-gpt) and red fluorescent protein (RFP). Following recombinant purification, the virus will be passaged in cells transiently expressing the Cre recombinase gene of the P1 bacteriophage for Cre/LoxP recombination based excision of the marker genes from the viral genome, leaving only the VACV promoter-CPG2 cassette. The resultant virus will be amplified and used to produce virus stocks. The recombinant virus will then be tested in vitro for...
confirmation of transgene expression and activity.

Recipient or parental organism

Vaccinia virus strain Copenhagen. The Copenhagen strain is an attenuated vaccinia virus strain which was utilised as the smallpox vaccination strain during the 1950’s and 60’s in Northern European countries.

Host/vector system

VACV recombination transfer vector containing synthetic VACV promoter used to drive hologous recombination in infected cells

Origin & function

Carboxypeptidase G2 (CPG2) is a zinc-dependent metalloenzyme from Pseudomonas spp. strain RS16 that cleaves the glutamic acid moiety from folic acid and its analogues

Evaluation of foreseeable effects

The insertion of the CPG2 gene into the vaccinia virus genome will further attenuate the vaccinia virus resulting from a restriction of tropism. The recombinant virus will be used for cancer tissue specific expression of the CPG2 enzyme, where it can be used to activate nitrogen mustard prodrugs to release an active drug producing DNA-DNA interstrand cross-links and cell death.

The inserted transgene, CPG2, does not interfere with any known activities or modulate the immunogenicity of vaccinia virus. Additionally, CPG2 will be inserted into the vaccinia virus genome such that it specifically disrupts the viral thymidine kinase (TK) gene. TK deleted vaccinia virus is highly attenuated in normal cell lines, and permits only limited replication at the site of inoculation in immunocompetent individuals. Thus, the final TK deleted vaccinia virus vector will have a highly restricted tropism, limiting the potential effects of both viral pathology associated with systemic disease and the side effects of transgene expression.

The complete host range of wild-type vaccinia virus includes many vertebrate species. A similar host range is potentially possible for the recombinant virus. However, owing to the viral TK deletion during transgene insertion there would be a limited viral replication especially with regards to the dissemination of the virus in the host and replication in internal organs required for vaccinia virus pathology and transmission.

To minimise risks to the environment and human health control measures will be employed. These control measures include rendering all solid and liquid waste inactive within the building (either by autoclaving or use of disinfectant); routine disinfection of work surfaces; all work to be performed in a containment level 2 facility, including use of a class II microbiological safety cabinet for all virology work; all staff are suitably trained in GMO work and employing the necessary risk control measures; workers will inspect hands and exposed skin for abrasions or wounds, and cover them with appropriate dressings, prior to putting on PPE.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (e.g. gloves, plastic ware, etc.) will be rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste will enter the yellow bag clinical waste stream and go for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Liquid waste will be decontaminated via chemical disinfection with 1% sodium hypochlorite or 5% Virkon (50% potassium peroxomonosulfate 5% sulfamic acid and 15% sodium alkylbenzene sulfonate) for a contact time of at least 2 hours prior to disposal to drain.

Disinfection of surfaces will also be performed with either of the chemical disinfectants listed above, followed by wiping with 70% ethanol.

Clothing or fabric material that may have come into direct contact with the virus should be autoclaved prior to being collected for washing.
The committee agreed that this was a class 2 project. It was the committee's view that the assessment was adequate for the risk profile of the work.

### Purposes of the contained use

To virally transduce mammalian cells with genes, microRNAs, shRNA oligonucleotides or CRISPR/Cas9 constructs.

### Recipient or parental organism

| Human primary and established cell lines, such as MCF7, T470, BT474, SKBR3, MCF10AHEK293 |
| Other mammalian primary and established cell lines, such as primary murine myeloid cells, murine RAW 264.7, c17.2, BV-2 and C3H/1 OT112 cell lines |
| Retrovirus derived from Moloney murine leukaemia virus (MML V). Adenovirus (Ad5). Lentivirus derived from HIV1 |
| Adeno Associated Virus |

We will not use primary lymphocytes to minimise the risk of generating replication competent retrovirus or lentivirus.

### Host/vector system

Vectors: Commercially available defective viral vectors, which may include adenoviral, adenovirus associated viral, retroviral and lentiviral self-inactivating vectors, and well established retroviral vectors with a history of safe use (such as pLNCX and pBABE) packaged into transducible viral particles by specific eukaryotic packaging cells. The lentiviral, adenoviral, adenovirus associated viral and retroviral expression vectors do not encode proteins required for virus packaging. Proteins for packaging are provided by transient transfection of helper vectors or the packaging cell line.

### Origin & function

| Genetic material - subcloned from cDNA library, for example: cDNAs from genes or gene transcripts involved in stem cell potency or differentiation e.g. Oct3/4 and Nanog |
| Genetic material - commercially synthesised oligonucleotides to express microRNAs to, for example: miRNA from genes or gene transcripts involved in ocular physiology e.g. bestrophin 1 |
| Genetic material - commercially synthesised oligonucleotides to form shRNA complexes to, for example: CBFb/RUNX transcription factors which will cause decreased migration of cancer cells; shRNA against H2A.Z is predicted to reduce chromatin accessibility, leading to decreased transcription factor and activator binding at key developmental genes; shRNA against murine Pu.1, Cebpa, Runx1, or Spi1 transcription factors to knock them down. These factors promote haematopoietic cell differentiation. |
| Genetic material - commercially synthesised oligonucleotides to form gRNA complexes to guide CasSo Intended functions: to generate null mutations at the targeted genetic locus or to introduce specific mutations by homologous recombination |

We will not include genetic material into the defective viral vectors that changes the tropism of the virus or encodes a toxic protein, such as diptheria toxin.

### Evaluation of foreseeable effects

The majority of the gene products expressed are expected to affect gene transcription and thus will have an effect on cellular properties such as proliferation, apoptosis, migration, adhesion, polarity and fate. Also many have known or suspected oncogenic or tumour suppressor properties.

The split function of the viral vectors however greatly reduces the risk of recombination events occurring and the self-inactivating properties of the vectors themselves inhibit production of virus once the transgene becomes stably

02/03/2022
incorporated into the genome of the target cells, eliminating the risk of undesired infection. Therefore it is highly unlikely that replication competent virus will be produced. Good laboratory practice in accordance with the risk assessment of the experimental procedure will ensure that the worker or others within the laboratory will not be exposed to the virus. This will include:
- viral production within a Class 2 Safety Cabinet;
- the wearing of gloves and a howie-style labcoat;
- the use of sealed containers when centrifuging the virus to concentrate it;
- the opening of sealed containers within a Class 2 Safety Cabinet;
- not using sharps during viral production;
- not vortexing solutions that contain viral particles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
This project aims to functionally characterize the genomic alterations found in prostate cancer. The target cells for this project will be either well-characterized prostate cell lines, or primary material collected from patients via the MCRC Biobank. Lentiviral, retroviral and Adenoviral expression vectors will be used to introduce point mutations, deletions, and reporter gene fusions and to over-express or knockdown genes that are found to be altered in cancer. Non-viral and lentiviral CRISPR platforms will be used to edit target cell genomes.

Well characterised prostate cell lines and/or primary human prostate cells obtained from patients via the MCRC Biobank.

Lentiviral vector systems: 3rd generation (4-plasmid) systems will be employed for this work. More specifically, they are pMDLg/RRE, pRSV-Rev, pMD2.G used together with a transfer vector e.g. pLJM, pLKO, pLenti-puro, pLenti-CRISPRV2.

Virus replication and production requires co-transfection of all 3/4 vectors into a suitable producer cell line (HEK293). This means the risk of producing...
replication-competent virus is negligible because it is very unlikely that all the necessary components will be re-combined into a single viral genome. These systems have a good track record with regard to safety, and production of replication-competent virus is very unlikely. These systems have the usual deletions associated with their development (e.g. U3 deletion)

2nd generation (3-plasmid) lentiviral vector systems will only be used if it is unavoidable for technical reasons.

Retroviruses will be produced by transfecting the transfer vector along with an envelope vector into the packaging cell line, GP2 (Clontech). This leads to the production of a disabled virus since the components for replication are supplied in trans during packaging. The transfer vectors employed will be pBabe series, pQCX series (Clontech), pMSCV series, pRetroX series (Clontech).

Adenoviruses expressing either Cre recombinase or markers eg GFP with be purchased from the University of Iowa. For in-house production we will use the Adenovirus Dual Expression kit (TaKaRa #6170) which generates replication incompetent virus lacking the E1 region. These essential gene products are supplied in trans during packaging by HEK293 cells, but the E1 genes are not transferred to progeny virus

**Origin & function**

We are attempting to model the genetic changes that occur in cancer. Therefore our genes of interest are either over- or under-expressed in human cancers. This project aims to characterise known/novel oncogenes (e.g. c-myc, n-myc, med12, mutant TP53, kras, hras, GSK3B, MTOR) or tumour suppressors (e.g. PTEN, wt TP53, BRCA2, Rb1, ATF2).

Changes in expression of these classes of gene alter the proliferation and survival of cells to promote the development of tumours in humans.

Cas9 is a nuclease that can be directed to specific regions in the target genome by a guide RNA. The researcher designs the guide RNA sequence such that Cas9 molecule will target to a particular locus and delete the gene of interest. Modification of this system also allows a gene of interest to be over-expressed or epitope tagged. Risks to human health depend on the gene being targeted, but since most of our genes of interest are cancer-associated, the CRISPR systems we will use may have the potential to be oncogenic. The control measures employed in our laboratory make accidental transfer of the CRISPR machinery to lab workers highly unlikely.

Cre and Flp are recombinases which promote recombination of DNA in a sequence-specific manner. Accidental transfer of these genes to lab workers would not be anticipated to have any serious or lasting effects, since the recognition elements for these enzymes occur only infrequently in the human genome.

Marker genes GFP, RFP, Puro, Neo, Hygro express non-toxic gene products - either fluorescent proteins or antibiotic resistance genes used to identify and track genetic modification events

**Evaluation of foreseeable effects**

GM virus:-

The Lenti and Retrovirus produced will be replication-defective and this will limit the extent of any accidental infection of lab workers. Nevertheless, since the recombinant virus has the potential to deliver cancer-associated genes to humans, it should be considered hazardous and potentially oncogenic. However the working practices employed in department (principally the use of PPE, Class 2 MSCs and no sharps policy) effectively reduce this risk to zero.

Furthermore both retroviruses and lentiviruses are lacking any potentially immune avoidance gene products that are encoded within the wild type viruses hence they are unlikely to have the same degree of immune protection as that afforded to the wild type virus. The envelope glycoproteins tend to be derived from other viruses which possess different and, most often, increased immunogenicity profiles compared to the retrovirus / lentivirus envelope glycoproteins. Indeed, the VSVg envelope commonly used to pseudotype lentiviral vectors is sensitive to complement mediated destruction in human serum. Overall, the replication deficient virus vectors are most likely to possess an increased immunogenicity profile as compared to the wild type vector suggesting that in the immune-competent individual, these vectors are more likely to be subjected to immune-mediated clearance.

The Adenovirus system used lacks the E1 region and is replication incompetent. This will limit the extent of any accidental infection of lab workers. Nevertheless, since the recombinant virus has the potential to deliver cancer- associated genes to humans; it should be considered hazardous and potentially oncogenic. However the working practices employed in department (principally the use of PPE, Class 2 MSCs and no sharps policy) effectively reduce this risk to zero.

Target cells:-

The genetic modifications will not alter the ability of our mammalian cell cultures to survive in the general environment. The modified cells require specific conditions to survive. They are maintained at 37 degrees C and cultured in a humidified atmosphere containing 5%CO2. Outside of this environment, the cells could survive in media for a period of time but would not expand in number. In non-sterile conditions the culture would be rapidly killed by contaminating micro-organisms. The GM cells cannot tolerate evaporation of the medium. Solute concentrations would build within the remaining media and the cells would either die of that level of toxicity or die through drying out. Outside of the media environment, cells would last only a short period of time (hours) before dying due to dehydration.
The GM cells have no ability to colonize a human host. During accidental transfer of the cells to a lab worker (e.g. needle stick), the cells would be rapidly eliminated by an immune response. Lab workers are never permitted to culture their own cells.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

In relation to waste processing we request the following derogation Schedule 8 Part 2 Table 1a: Autoclave required in the building

Although an Autoclave is present, all plastic ware that has been used with live GMMs we wish to treat it with an appropriate volume and concentration of disinfectant (1% Virkon) for at least one hour (typically overnight), prior to it being sent directly for incineration. In this way any residual GMMs that may be present are killed at the point of use, rather than transporting them alive to an autoclave within the same building.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work. Virkon is routinely used as per the manufacturer’s recommendations (99.99% kill):- Solid surfaces are disinfected with 1% Virkon solution. Plastic ware is disinfected with 1% Virkon for a minimum of 1 hour (typically overnight) after which it is removed from the tissue culture laboratory and sent for incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour (typically overnight) prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer’s recommendations).

### Purposes of the contained use

This project aims to functionally characterize genes and genomic alterations in breast cancer and associated stromal cells. The target cells for this project will be either well characterized breast or stromal cell lines, or primary samples collected from patients via the MCRC or similar biobanks. Non-viral and lentiviral CRISPR platforms will be used to introduce point mutations, deletions, fusions or copy number changes. Lentiviral expression vectors will be used to over-express of knock-down genes that are found to be altered in breast cancer or associated stromal cells.

### Recipient or parental organism

The recipient cells will be either well characterized breast or stromal cell lines and/or primary human breast cancer or stromal cells obtained via the MCRC Biobank or other biobanks.
- Well characterised cell lines will present a low risk to workers; as they are free of human pathogens and are tested for authenticity and mycoplasma by on-site testing. They will have a history of safe use.
- Primary human cells: obtained from patients whose clinical history will be known. As such this will prohibit collection from patients who present an increased risk through infectious disease e.g. BBVs.

More precisely patient samples will be collected only from those where the information available asserts that the only disease they have is cancer.

We will employ pseudotyped envelope systems such as VSVg to produce lenti- or retroviral particles and to ensure transduction of established cell lines and primary human breast and stromal cells.

The lentiviral vectors employed will be e.g. pCCL, pBABE, pTRIZ, pLV-Puro, pLenti-CRISPRV2.

Other lentiviral vector systems will be added as the technologies evolve.
3rd generation (4-plasmid) lentiviral vector systems will be preferentially employed for this work. If it is unavoidable for technical reasons, 2nd generation (3-plasmid) lentiviral vector systems will be used. The risk of producing replication-competent recombinants is negligible because viral production requires cotransfection of 3/4 vectors into a suitable producer cell line (e.g. HEK293T). Moreover, these systems have deletions and modifications in specific regions associated with activating viral transcription (e.g. U3 deletion, truncated 5'LTR). Therefore it is very unlikely that all the necessary components will be re-combined into a single viral genome. These systems have a good track record with regard to biosafety. The lentiviral vectors employed will be e.g. pCCL, pBABE, pTRIZ, pLV-Puro, pLenti-CRISPRV2. Other lentiviral vector systems will be added as the technologies evolve.

We are attempting to understand the role of cancer-associated genes during tumour development and progression. Therefore our genes of interest are either over-, or under-expressed, down regulated or mutated in human cancers. Or its oncogenic potential is unknown. The genes of interest are:

1) NOTCH related genes (including NOTCH1-4, DLL1/3/4, JAG1/2, DTX1-4).
   NOTCH activation and deregulation of NOTCH signalling is observed in many cancers and their progression. Also mutations within and upstream of the PEST domains of NOTCH1-4 receptors have been observed. Mutations and amplifications of NOTCH signalling often increases the expression of target genes, resulting in the progression of cancer.

2) Other breast cancer related genes such as PIK3CA, STAT3, IL1B, IL1R, ILRA, ESR1, PGR, HER2, GATA3, ALDH1A1-3.

3) Recombinant and fusion proteins (e.g. NOTCH1-IgG Fc decoys).

The lentiviruses produced will be replication-defective and this will limit the extent of any accidental infection of lab workers. Nevertheless, since the recombinant virus has the potential to deliver cancer-associated genes to humans, it should be considered hazardous and potentially oncogenic. However, the working practices employed in department (principally the use of PPE, Class 2 MSCs and no sharps policy) effectively minimises the risks to workers. Furthermore lentiviruses are lacking any potential immune avoidance gene products that are encoded within the wild type viruses; hence they are unlikely to have the same degree of immune protection as that afforded to the wild type virus. The envelope glycoproteins tend to be derived from other viruses (e.g. VSV) which possess different and, most often, increased immunogenicity profiles compared to the lentivirus envelope glycoproteins. Although VSVg has a broader host range, VSVg envelope is indeed commonly used to pseudotype lenti- and retroviral vectors because it is sensitive to complement-mediated destruction in human serum. Overall, the replication-deficient viral vectors are most likely to possess an increased immunogenicity profile as compared to the wild type vector suggesting that in immune-competent individuals, these vectors are more likely to be subjected to immune-mediated clearance.

The genetic modifications will not alter the ability of our cell cultures to survive in the general environment. The modified cells require specific conditions to survive. They are maintained at 37 degrees C and cultured in a humidified atmosphere containing 5%CO2. Outside of this environment, the cells could survive in media for a period of time but would not expand in number. In non-sterile conditions the culture would be rapidly killed by contaminating microorganisms.
The GM cells cannot tolerate evaporation of the medium. Solute concentrations would build within the remaining media and the cells would either die of that level of toxicity or die through drying out. Outside of the media environment, cells would last only a short period of time (hours) before dying due to dehydration. The GM cells have no ability to colonize a human host. If accidental transfer of the cells to a lab worker occurred (e.g. through an open wound), the cells would be rapidly eliminated by an immune response. Lab workers are never allowed to culture their own cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Although an autoclave is present, any plasticware (e.g. plastic pipettes) that has been in contact with live GMMs and can be effectively disinfected will be immersed in disinfectant for a minimum of 1 hour. (typically overnight); prior to it being sent for incineration. In this way any residual GMMs that may be present are killed at the point of use rather than being transported to an autoclave.

Any plastic ware that can not be disinfected as described above will be sent for autoclaving.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work.

Virkon is routinely used as per the manufacturer's recommendations (99.99% kill):- Solid surfaces are disinfected with 1% Virkon solution.

Plastic ware is disinfected with 1% Virkon for a minimum of 1 hour (typically overnight) after which it is removed from the tissue culture laboratory and sent for incineration.

Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour (typically overnight) prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The Committee agreed that this was a GM Class 2 project and that the risk assessment was suitable and sufficient for the work described.

**Project Containment**

02/03/2022
The main objective of this project is to explore/establish an experimental/computational framework to study epigenetic inheritance in cancer relevant settings. In particular, we will generate from a single non-transformed 'parental' cell line a battery of cellular models where the introduction of oncogenic factors (H-RAS(G12V), SRAF(V600E), MYC, etc) will drive cellular transformation. To do so, we will use a variety of well characterized cell lines (HA1 E, HA1 ER, HeLA, among others) that will be transduced with lentiviral vectors carrying the oncogenes under study. Moreover, we plan to use lentiviral delivery systems to over-express or knockdown genes altered in cancer whether we obtain results that support us doing so using CRISPR/CAS9 technologies. Finally, we will use non-viral and lentiviral CRISPR/CAS9 platforms to edit target genomes. All the cell lines generated throughout our research program will be used to analyse the generation and
propagation of innate/acquired resistant phenotype to a given drug at a single-cell level. In particular, we will explore dynamic changes in the expression, intracellular localisation and segregation of non-coding RNAs and its link with epigenetic events supporting drug resistance.

Recipient or parental organism

Well characterized cell lines and eventually primary human material sourced from the MCRC biobank.

Host/vector system

We will use a 3rd generation Lentiviral packaging systems in which the packaging components are split across 4 different plasmids. Viral replication required to generate infective particles is only achieved by the concomitant cotransfection of the 4 plasmids into a single cell from a suitable lentiviral producer cell line (293T). The immediate consequence of the use of such a system is that the risk of producing replication competent viral particles is negligible due to the low probability that the 4 vectors recombine into a replication competent viral genome. These systems are widely used and have a good record regarding safety as the production of replicative competent viruses is highly unlikely. In particular we will use the following system:

- pMDLgplRRE (Addgene) expresses HIV-1 Gag-Pol
- pRSV-REV (Addgene) expresses HIV-1 REV
- pMD2.G (Addgene) expresses VSV-G
- pLEX_307 (Addgene) modified to express H2B-GFP instead of puromycin and carrying the mutant/wild-type ORF

Origin & function

The Target Accelerator Pan·Cancer mutant collection is a library of cancer associated ORFs. Although the library will be obtained from Addgene, it has been created in the Broad Institute and it is showcased in several publications (For details regarding each library component please refer to https://www.addgene.org/kits/boehm-target-accelerator-cancer-collection/). Our project aims to characterize the effect of cancer related oncogenes (BRAF, k-RAS, etc) or tumor suppressors (PTEN, BRCA2, etc) in the acquisition of epigenetic mechanisms of drug tolerance/resistance. A large body of evidence suggests that the overexpression or silencing of the aforementioned genes may cause changes in proliferation and survival of cells promoting the potential development of tumors. Although most of the genes that will be used are oncogenic, the accidental transfer and propagation of these genes to operators is highly unlikely.

The Crispr/Cas9 system enables the modification of the genome in a site-directed manner. Based on the research needs the Cas9 nuclease can be programmed to operate on a sequence dependent basis as a guide RNA dictates their targeting to alter/mutate a gene of interest. Modifications of the system includes epitope-tagging and expression control (over-expression and knock-down). We believe that risk to human health are highly associated to the genes to be modified. The security measures employed in our lab make accidental transfer highly unlikely. In addition, selection markers will be used in most of our systems such as GFP, RFP. Puromycin resistance, G418 resistance, etc to track efficiency of transduction. Those markers express non-toxic gene products therefore they cannot be considered a hazard to human health.

Evaluation of foreseeable effects

The potential for generation of replication-competent lentivirus is addressed by the design of the vectors and by safe laboratory practice. In terms of vector design. 3rd generation lentiviral systems provided by Addgene separate transfer, envelope, and packaging components of the virus onto 4 different vectors. The transfer vector encodes the gene of interest and contains the sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors. Unless recombination
occurs between the packaging, envelope, and transfer vectors, and the resulting construct is packaged into a viral particle, it is not possible for viruses normally produced from these systems to replicate and produce more virus after the initial infection.

As we are going to generate a pooled ORF library and use it as such to transduce cells, we do not believe that there is a risk associated to the ORF expressed from the lentivirus as its contribution to the global pool will be minimal. Furthermore, we will screen transduced cell lines using a life/death approach thus reducing the complexity of the final output. In the eventuality that transduced cells get in direct contact with the operator, we anticipate that those cells will be recognized as non-self by the operator immune system and will be rapidly cleared.

Nevertheless, as little recombinant viruses has the potential to deliver cancer-associated genes to humans, they should be considered potentially oncogenic. In the unlikely event of accidental infection with a single or pooled lentivirus, infected cells can be readily identified and monitored by tracking GFP expression. As stated above, the lentivirus will not be able to replicate unless a highly unlikely recombination event takes place involving all 4 plasmids. Therefore, from a health and safety perspective, only a multi-hit transformation event (highly unlikely) could be potentially unsafe to the operator. At this point, it is important to stress that the working practices in place in our lab reduces the risk to accidental contamination to a minimum. Furthermore, any exposure of a worker is expected to result in a normal immune response, thus the non-self material will be cleared by the immune system.

All manipulation will be performed in a Class II biological safety cabinet and a specific cell culture incubator will be designated for working with lentivirus. All members of staff involved in this project will be trained in the safe handling of viral stocks. Controls will be in place to minimize accidental infection via skin contact or injection. The use of aspirators, scalpels and needles will be entirely banned whilst working with viral stocks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All members of staff involved in lentiviral production and experimentation will be trained thus minimizing the risks. Virucidal disinfectant will be permanently available for decontamination (spills, waste fluids, plasticware).

Any solid material which cannot be effectively disinfected will be autoclaved on site and then sent for incineration via an approved hazardous waste contractor.

All liquid laboratory waste will be inactivated prior to removal from the Class II MSC employed for this work. Viriton is routinely used as per the manufacturer's recommendations (99.99% kill); Solid surfaces are disinfected with 1% Viriton solution.

Plasticware is disinfected with 1% Viriton for a minimum of 1 hour (typically overnight) after which it is removed from the tissue culture laboratory and sent for incineration.

Any contaminated glassware is treated with 1% Viriton solution for a minimum of 1 hour (typically overnight) prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Viriton to give a 1% final working concentration. 2% or 3% solutions of Viriton are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).
The GM Safety committee discussed the risk assessment, agreed that this was GM class 2 work and suggested some minor amendments to aid clarity.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The overall purpose of the work is to investigate the effect of changes of the glycoprotein genotype of human cytomegalovirus (HCMV) on the phenotypic characteristics of the laboratory strain Merlin of HCMV in order to better understand the pathogenesis of congenital HCMV infection.

In this work the genome of HCMV strain Merlin held within a bacterial artificial chromosome (BacMid) will be used to exchange the glycoprotein sequence of the parental strain with alternate genotypes of individual HCMV glycoproteins. GM HCMV strains will be propagated in cell culture and the resulting virus will be characterized by growth kinetics, cytopathogenic effect, enzyme linked lectin assay, and cytokine production in a discrete cell culture model, to characterize the effect of change of virus glycoprotein sub-type on glycosylation of surface glycoprotein, viral replication kinetics and induction of innate immune responses.

Recipient or parental organism

It is important to state that the GMM will not create new strains of virus as the glycoprotein alterations will only produce strains of virus that are already represented in the normal, circulating, populations of wild-type virus. The worst case scenario is, therefore, a strain of HCMV equivalent to a wild-type clinical strain in virulence. As such, the recombinant virus would not infect immunocompetent, HCMV seropositive individuals. If immunocompetent, HCMV seronegative individuals were exposed they may develop silent infection (approximately 95% of cases) or a self-limiting infectious mononucleosis syndrome. HCMV seronegative individuals who contract infection in pregnancy would be at risk of transmission of the virus to their fetus.

However, HCMV strain Merlin contains disabling mutations in genes RL13 and UL128, which were repaired first singly and then in combination to produce BACs containing a complete wild type (WT) gene complement. Growth of the wild type virus in cell culture necessarily induces changes in the RL13 and UL128 loci thereby reducing the virulence and capability of causing infection of humans. The potential for causation of human disease is thus significantly reduced and as infectious virus is only produced on transduction of cells by the BacMid DNA, attenuated virus will be generated during ongoing culture.

Host/vector system

The genome of human cytomegalovirus strain Merlin inserted into a bacterial artificial chromosome will be propagated in disabled E.coli strain SW102 and mutated in that background using homologous recombination with a maker cassette amplified from plasmid pEP-Kan using polymerase chain reaction (PCR). To reconstitute virus, BacMid DNA will be purified from E.coli and used to transfect human embryo lung fibroblast cells (HEL). The BacMid can only give rise to infectious virus when propagated in permissive human cells. HCMV strains will be propagated in HEL (MRC-5 cells).

Origin & function

Only glycoproteins present in HCMV strains that exist in nature will be used and will result in altered genotype that already exists in nature. Altered virus is anticipated to pose no more risk of infection and disease than any existing wild type HCMV isolate. No or only subtle change in pathogenicity of the laboratory adapted strain is anticipated. In immunocompetent (and non-pregnant) individuals the altered virus is anticipated to pose no more risk of infection or of disease than any of the currently circulating HCMV strains.

Evaluation of foreseeable effects

Change of genotype of a single glycoprotein is highly unlikely to significantly change the transmissibility or virulence of the recombinant virus as glycoproteins require interaction with a cluster of other glycoproteins to exert their effects. One such complex, (glycoprotein complex II) is known to be involved in virus entry into host cells and changes in the action of this complex are anticipated to be in the efficiency of infection of cells and more subtle change in the interaction with the innate immune system. It is possible that recombinant viruses may have altered tissue tropism in vivo. This would allow the recombinant virus to enter and replicate in alternate cell types to the HEL cells used for propagation in vitro. The altered cell tropism could potentially result in the cell tropism observed with existing wild-type strains of HCMV. Immunocompetent (and non-pregnant) individuals this pose no more risk than the risks of infection with existing circulating strains of HCMV and would likely be of lower risk than wild type strains because of the attenuation of the virus by growth in cell culture.

The DNA sequence corresponding to the modified glycoprotein gene is unlikely to present a hazard if they were to recombine into a wild type HCMV as the recombinant...
would only acquire genes that would already exist within currently circulating HCMV genes. Inadvertent recombination would generate a virus that would represent a similar hazard to the intended GMM. Therefore, it is unlikely that specific containment measures (over and above those inherent in biohazard category 2 containment) will be required to prevent cross-contamination.

The HCMV genome was derived from a wild type strain of HCMV and has the characteristics of wild type virus save for known mutations that allow growth of the virus in culture. The mutations serve to attenuate the virus relative to the parental wildtype strain of virus. Return of the recombinant virus to full wild type virulence would require reversion and this is not achievable within cell culture, and is extremely unlikely to be achieved by re-combination within a human host.

The HCMV strains produced will be transmissible by aerosol/droplet as per normal person-to-person contact. For this reason, viruses will be handled exclusively within a class II microbiological safety cabinet inside a containment level 2 laboratory. Workers will wear labcoats and disposable gloves.

The cell lines containing virus are unlikely to survive in the environment as they require specific laboratory growth media and conditions in order to survive. HCMV is unlikely to survive for more than a few minutes in the external environment. The virion lipid envelope is essential for virus infectivity and is readily disrupted on drying in the external environment. More prolonged environmental survival (several hours) has been reported when the virus is contained within bodily fluid.

If the recombinant virus did survive in the environment, it would join similar wild type virus which only circulate in the environment by direct person: person transmission. It is important to emphasize that the alteration in glycoprotein types in the recombinant virus will only generate glycoprotein types which are already circulating glycoprotein types.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To prevent environmental release, anticipated 100% kill of viral particles will be contained through appropriate decontamination and disposal procedures. The disinfection, decontamination and discard policy of the virology unit (Local Policy 02) will be followed. Briefly, small plastic disposables such as pipette tips, Eppendorf tubes and plastic pastettes will be discarded into dry, screwtop, disposal jars. The dry discard jars will be removed for autoclaving, after one week or when full, whichever is the soonest.

For contaminated material which is not suitable for disposal in the single use dry jar, such as larger volumes of liquid or known “high titre” material, then a liquid disinfectant will be employed (Distel 5%, Tristel Solutions Ltd., Snailwell, Cambridgeshire). Virkon powder (Day Impex Ltd., Colchester, Essex) will be used as a dry powder for containment and decontamination of fluid spills.

All other material for decontamination by autoclaving will be placed in the appropriate discard bin provided in each laboratory. When full, bins will be lidded and transported to the decontamination suite for autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The committee agreed that this was GM class 2 and directed that even though the work will generate recombinant forms of virus representative of the glycoprotein types already found within the circulating wild-type HCMV virus strains, the fact that the viruses were being produced using recombinant techniques meant that notification was required, even though the Department already hold internal authorisation for handling wild type strains of HCMV in teaching and research.
**Project Additional Information**

**Purposes of the contained use**

In broad terms the aim of the work is to enhance the understanding of cancer and its development in humans which may lead to better treatment of the disease and better outcomes for patients. In this context Lentiviral vectors will be produced for use in basic research and be applied to human primary and established cell lines and/or murine or other mammalian primary or established cell line basic research and pre-clinical studies. Transduced cells and lentiviral particles may also form the inoculum for in vivo work.

**Recipient or parental organism**
lentiviral vectors derived from HIV-1 which are commercially available will be used.
The strategy will be to employ a hierarchy of choice to encourage the use of the most bio-safe systems first. Thus
researchers are expected to utilise self-inactivating vectors (SIN) where possible; and 3rd generation systems rather
than 2nd generation systems.
The use of systems in the lower parts of the hierarchy (eg 2nd generation systems) must be justified on technical
grounds (e.g. higher ranked systems do not provide a high enough titre). The choice of systems will be scrutinised by
the Biosafety Committee.
Genetic material - Virus genome components sourced as cloned inserts on plasmid backbones or engineered
inpackaging cell lines in which the viral genes are integrated. These materials will be well characterised and sourced
from commercial suppliers or may be shared between researchers.

Host/vector system

Vectors Will be used to transduce:
Well characterised human and murine cell lines. These present a low risk to workers: as they are free of human
pathogens and are tested for authenticity and mycoplasma by on-site testing. They will have a history of safe use.
Primary human cells: obtained from patients (where their clinical history will be known): usually via the MCRC Biobank
(although other Biobanks may be used) . As such this will mostly prohibit collection from patients who present an
increased risk through infectious disease e.g. BBVs. In what we anticipate to be rare or exceptional circumstances
there may be a need to obtain material from patients whose cancer has some sort of clinical association with another
disease. For example hepatocellular carcinoma has a clinical association with Hepatitis: cervical cancer with Herpes
infection). In such cases the work, having been suitably risk assessed, will need to be authorised by the Director of
the Institute.
Primary human cells may also be obtained from "healthy volunteers." (lab workers are not allowed to culture their
own cells and use it in their own research).

Live mice - The majority of in vivo work carried out will involve the use of lenti-transfected cell lines where the
expectation is that there to be no Lentivirus carry over due to the number of passages and time that has elapsed to
prepare the cellular inoculum. This part of the work. may involve the use of sharps (needle and syringe, blades).
Accordingly appropriately trained staff (usually BRU trained animal technicians) carry out this part of the work.
Some aspects of the work the inoculum may be the viral vector particles themselves. Where possible the use of
sharps will be avoided. For example by delivering the inoculum by inhalation via a pipette. If direct injection of viral
particles is required, as above, this part of the work will be carried out by experienced workers ( usually BRU trained
animal technicians) employing anaesthetics, restraining devices or scruffing to minimise the mobility of the mice and
so reduce the likelihood of a sharps injury and needle safe devices if appropriate.

Origin & function

The employment of lentiviral based genetic modification systems in vitro and in vivo will enable us to study a number
and range of genes involved in cancer. In this respect almost all of the genes of interest will be oncogenes or
potential oncogenes, tumour suppressors or involved in cell cycle and/or cell signalling pathways. Use of lentiviral
vector and CRISPR sytems will be used to
- Introduce, knockdown, over express, silence or otherwise edit genes that we study to further our understanding of
the role they play in cancer development and/or treatment
- Study genes involved in the immune systems response to cancer
- Generate receptors targeting cancer cells e.g Chimeric antigen receptor; T-cell receptor
Lentiviral systems may be used in conjunction with other gene modification systems ( e.g siRNA knockdown or
CRISPR applications) either in parallel or to deliver components of such systems ( e.g stable expression of shRNA or
Genetic material from a variety of sources will be used:
- Subcloned from cDNA libraries (e.g., cDNAs from genes or gene transcripts involved in signaling pathways)
- Commercially synthesized oligonucleotides to express micro-RNAs and/or shRNA complexes
- Commercially synthesized oligonucleotides to form gRNA complexes to guide Cas9 in Lenti viral based CRISPR
- Commercially synthesized oligonucleotides that encode a construct (e.g., chimeric antigen receptor etc.)
- Human and/or murine or other mammalian DNA isolated from samples, or supplied by research colleagues or those that are commercially available
- Marker genes (e.g., GFP and luciferase which may originate from a range of organisms (e.g., bacteria, yeast, jellyfish etc.)

Similarly, Lenti-based CRISPR systems will be used which are commercially available.

Only genetic material known to be involved in the development and progression of cancer or its treatment using CAR-T cells will be studied. Using lentiviral vectors to express toxins or other biologically active molecules will not be included in this programme.

Evaluation of foreseeable effects

GM virus: The lentiviruses produced will be replication-defective and this will limit the extent of any accidental infection of lab workers. Nevertheless, since the recombinant virus has the potential to deliver cancer-associated genes to humans, it should be considered hazardous and potentially oncogenic. However, the working practices employed in the Institute (principally the use of PPE, Class 2 MSCs and minimisation of the use of sharps policy) effectively minimises the risks to workers.

Furthermore, lentiviruses are lacking any potential immune avoidance gene products that are encoded within the wild type virus; hence they are unlikely to have the same degree of immune protection as that afforded to the wild type virus. The envelope glycoproteins tend to be derived from other viruses (e.g., VSV) which possess different and, most often, increased immunogenicity profiles compared to the lentivirus envelope glycoproteins. Although VSVg has a broader host range, VSVg envelope is indeed commonly used to pseudotype lentivirus because it is sensitive to complement-mediated destruction in human serum.

Overall, the replication-defective viral vectors are most likely to possess an increased immunogenicity profile as compared to the wild type vector suggesting that in immune-competent individuals, these vectors are more likely to be subjected to immune-mediated clearance.

Target cells:

The genetic modifications will not alter the ability of our cell cultures to survive in the general environment. The modified cells require specific conditions to survive. They are maintained at 37 degrees C and cultured in a humidified atmosphere containing 5% CO2. Outside of this environment, the cells could survive in media for a period of time but would not expand in number. In non-sterile conditions, the culture would be rapidly killed by contaminating microorganisms. The GM cells cannot tolerate evaporation of the medium. Solute concentrations would build within the remaining media, and the cells would either die of that level of toxicity or die through drying out. Outside of the media environment, cells would last only a short period of time (hours) before dying due to dehydration.

The GM cells have no ability to colonize a human host. If accidental transfer of the cells to a lab worker occurred (e.g., through an open wound), the cells would be rapidly eliminated by an immune response. Lab workers are never allowed to culture their own cells.

Only work with lentiviral vectors with oncogenic/transformatory potential, or constructed for the use programming autologous T-cells to target cancer cells where a GM class 2 classification is indicated will be covered by this connected programme. Lentiviral vectors pre-presentation different risks to workers will not be considered in this programme and will be notified separately.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NIA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Any plasticware (e.g. plastic pipettes) that has been in contact with live GMMs and can be effectively disinfected will be immersed in disinfectant for a minimum of 1 hour. (typically overnight); prior to it being sent for incineration. In this way any residual GMMs that may be present are killed at the point of use rather than being transported to an autoclave.

Any plasticware that cannot be disinfected as described above will be sent for autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets and/or laboratory employed for this work.

Virkon and Distel is routinely used as per the manufacturer's recommendations (99.99% kill):- Solid surfaces are disinfected with 1% Virkon solution. Plastic ware is disinfected with 1% Virkon for a minimum of 1 hour (typically overnight), after which it is removed from the tissue culture laboratory and sent for incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour (typically overnight) prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

Solid or other waste that cannot be effectively disinfected (as per section 11) and thus requires sterilisation, is collected in an autoclave bag, sealed with tape or cable-tie and sent for autoclaving. The autoclave is located on the same site and is transported to it via leak proof containers. The autoclave is validated annually and undergoes regular maintenance.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed that the classification of these assessments were GM Class 2 (it was agreed that other elements, e.g. the use of adenovirus vectors, were class 1)

### Project Additional Information

**Purposes of the contained use**

To generate retroviral particles containing DNA sequences of molecules involved with cell fate decisions. To use these retroviruses to transfect mammalian primary or immortalised cells.

**Recipient or parental organism**

1. Primary cells of mammalian origin.
2. Immortalised cell lines.

Not genetically modified and no foreseeable adverse effects.

**Host/vector system**

1. Retroviral vectors such as PMX and pMSCV (see attached risk assessment)
2. Packaging cell lines such as phoenix

Expression of retroviral vectors in packaging cell lines will generate replication - defective viruses. Once these viral particles have been used to transfect recipient cells, supernatants from these cells will be screened for the presence of infectious virus.

**Origin & function**

cDNA of mammalian origin coding for molecules involved with cell fate decisions

Including: notch molecules 1-4

- notch ligands jagged 1/2, delta
- notch signalling molecules delta, csl
- notch modulatory molecules - the fringe family
- mutant forms of the above molecules

Notch molecules are thought to be involved with cell fate decisions in the presence of certain cytokines, notch delays differentiation and promotes the proliferation of primitive cell types. Notch 1 is a known oncogene and truncated, constitutively active forms of notch 1 have been found in T lymphoblastic neoplasms. Molecules which potentiate notch signalling may be expected to delay differentiation also.
Following retroviral transfection, cells will be monitored for the presence of infectious retroviral particles on a regular basis. Once it has been established that no infectious particles are generated by host (or recipient) cells, then transfected cells will be used for experimentation. Primary cells are routinely screened for the presence of infectious agents to reduce the risk of co-infection with more than one retrovirus. Primary cells will not be used from lab workers or their family members to the risk of engraftment of transfected cells likely routes of transmission of replication - deficient virus include aerosols and sharps injuries. See attached risk assessment. Accidental inoculation with replication - deficient virus is likely to result in the destruction of virus by the host immune system and therefore long-term injury is unlikely. Experimental waste containing virus particles and transfected cells will be autoclaved to minimise any foreseeable environmental effects.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

See section 7. Analysis of transfected cells will be performed under category 1 conditions only when the absence of infectious viral particles has been established.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Packaging cell lines, cell culture supernatants containing retroviral particles and transfected target cells will be treated with 1% virkon solution which will destroy any retrovirus or retroviral containing cells. (A 0.05% virkon solution is sufficient for retroviral destruction according to the manufacturer). Solid waste is also treated with 1% virkon solution for a minimum of 1 hour. Both liquid and solid waste is autoclaved in order to ensure a 100% kill of GM material. Departmental autoclaves are serviced annually using a thermocouple. Refer to attached virkon data sheet for further information.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The local GMSC considered that the work using retroviral vectors required containment level 2 because of the potential oncogenic properties of the inserts. Other aspects of the project e.g. construction of plasmids in disabled Ecoli K12 strains have been assessed separately by the GMSC.

02/03/2022
The folate pathway is an essential but complex metabolic pathway in malaria parasites that is involved in DNA synthesis and amino-acid conversion. We have identified and characterised most of the genes involved in this pathway and now aim to investigate the individual roles of these genes by transformation experiments. This will encompass experiments where individual genes are disabled, to assess whether their activities are mandatory for survival, and experiments where certain of these genes are modified, to assess the role of naturally occurring polymorphisms in a controlled genetic background. We have evidence that different parasite lines differ in their ability to make use of preformed folate from the host, and transformation provides a powerful route to investigate such a difference. This has been demonstrated in other laboratories where transformation is now routinely used to investigate basic questions about the biology of the parasite.

Laboratory strains of Plasmodium falciparum that have been in vitro culture for many years, both in this and numerous other laboratories will be used. The genetic modification introduced by transformation will render them more resistant to the drugs pyrimethamine, neomycin or blasticidin (used as the plasmid markers), but will have no effect on their susceptibility to a range of antimalarial drugs currently in clinical use. The risk of laboratory infection is extremely low, but such drugs will be able to clear infection rapidly. The targeted gene modifications in the folate pathway are likely to reduce their general viability relative to the untransformed host, or leave it unaffected. The modifications will not alter host specificity.

Recipient or parental organism
Laboratory strains of Plasmodium falciparum that have been in vitro culture for many years, both in this and numerous other laboratories will be used. The genetic modification introduced by transformation will render them more resistant to the drugs pyrimethamine, neomycin or blasticidin (used as the plasmid markers), but will have no effect on their susceptibility to a range of antimalarial drugs currently in clinical use. The risk of laboratory infection is extremely low, but such drugs will be able to clear infection rapidly. The targeted gene modifications in the folate pathway are likely to reduce their general viability relative to the untransformed host, or leave it unaffected. The modifications will not alter host specificity.

Host/vector system
The plasmid vectors to be used are derived from the commercially available pBluescript and pGEM series of E. coli vectors. These vectors are modified to include the necessary elements for targeting the genes of interest and introduced via electroporation. They are maintained by selection using the drugs mentioned above. If such selection is removed, plasmids are lost, unless integration has occurred at the target gene locus.
1. Plasmid sequences plus partial sequences of target P. falciparum folate pathway genes designed to disrupt the corresponding gene of the recipient cell.
2. Plasmid sequences plus sequences of target P. falciparum genes designed to alter the target gene at known polymorphic loci.
3. Plasmid sequences plus putative promoter regions of P. falciparum designed to test the effect of possible varying levels of expression on folate gene products.
4. Plasmid sequences that carry reporter activities such as Green Fluorescent Protein (GFP) or Chloramphenicol Acetyltransferase (CAT) to rapidly test for successful transformation.

All plasmids are constructed via cloning in standard disabled E.coli hosts (principally XL1-Blue, Stratagene).

**Evaluation of foreseeable effects**

No new potential hazards are identified as a result of the genetic modification. As with untransformed P. falciparum, the only route for transmission to humans will remain as direct inoculation into the bloodstream of the operator. The natural route of infection, via the bite of the Anopheles mosquito, is excluded by the complete absence of the latter from the working environment (mosquitoes are not bred in this Institute). Even if such a mosquito were present, it could not feed from culture flasks. Moreover, it would be unable to ingest sexual forms of the parasite for onward reproduction and transmission of the parasite, as only asexual forms will be cultured. Airborne contamination, e.g. by aerosol spread from cultures, is also not a risk with this organism, and there is no possible person to person transmission. Viability of these organisms for experimental purposes is totally dependent upon careful maintenance of stringent laboratory culture conditions and there is no known or foreseeable risk to the environment, as the parasite cannot survive in any environment outside of the tissue culture medium and the narrowly confined parameters of temperature, pH, and gas atmosphere (5% CO/5% O/90% N).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from full Class 3 containment because the Risk Assessment indicates that the following features of level 3 containment are not required, given the absence of an airborne contamination risk when working with this organism - see section 2 (Growth and propagation of the parasite); 3 (Assessment of risks to human health), and 4 (Assessment of risk to the environment), of the Risk Assessment.

1. Fumigation, and thus a sealable laboratory.
2. Airlock entry to the laboratory.
3. Negative pressure relative to the surrounding laboratories, and HEPA filtered air extract.
4. Autoclave in the culture facility. Biological material is completely killed by verified disinfection procedures before removal from the facility in sealed plastic boxes. These are transported directly to the nearby Departmental Autoclaving suite and the material sterilised in situ.
5. Specific measures to control aerosol dissemination.
6. Shower within the culture facility.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

1) Parasite microscope slides are treated with methanol + flaming before staining with dye (also in methanol) and viewing, rendering material on the slide harmless. After use, the slide are routinely treated with bleach (Chloros, in appropriate dilution) before disposal and areas such as the microscope stage are wiped with 70% ethanol after use.
2) Disposal of solid culture materials (plastic pipettes/tips/tubes/tissue culture flasks) is by placing the items in a separate labelled double biohazard bag kept in the tissue culture room which is subsequently directly removed from autoclaving. In the case of liquid waste (culture supernatants and residual cells), treatment is for 16-24hrs in a solution of bleach (Chloros) dilute to a final volume containing 10% free chlorine (1:3 v/v) before disposal. The container is then placed for autoclaving. Spills for infected material must be attended to immediately. The volume is reduced by use of dry paper towels (which must be placed for autoclaving) followed by treatment of the affected area with diluted (1:3 v/v) Chloros bleach followed by a wipe with paper towel soaked in 70% ethanol. The latter is important, as bleach is detrimental to many surfaces including stainless steel; for such surfaces, Virkon disinfectant can be used in place of the bleach, either as a solution or as powder.
3) Degree of kill: the parasite is an extremely fastidious organism entirely dependent for viability upon careful maintenance within host red blood cells in a stringent tissue culture medium under the atmosphere of a special gas mix. Lysis of the red cells, removal of the medium, exposure to normal air (as opposed to the 5% CO/5% O mix
needed for culture), increase in temperature above approx. 39°C, small changes in pH away from physiological, all lead to parasite death within a very short time. As established in microscopy, Chloros lyses all host cell within a short period, penetrating the parasites and killing them 100%. It is not possible to restore a viable culture from infected red cells treated in this way. Autoclaving also kills the parasite 100%. Autoclaving is carried out in our central sterilising facility in equipment employing data logging of all autoclaving cycles. The autoclaves are also checked regularly by internal indicator tablets included in the items for disposal that confirm the proper length and temperature of the cycle. In addition, thermocouple tests of appropriate loads are carried out as part of the annual autoclave service that is carried out by the manufacturer.

Please enter comments on the GM safety committee on the risk assessment

This project has been considered by the UMIST GMSC. The Committee believes that the containment measures and working practices described in the Risk Assessment are appropriate for this work on Plasmodium falciparum.

The application covers a range of specific projects with the overall goal to study the regulation and mechanisms of cell wall biosynthesis and its role in yeast-hypha morphogenesis of Candida albicans. More specific goals:
1/ Role of glycosylation
2/ Role of the Ras/cAMP-dependent pathway
3/ Role of specific O- and N-glycosylation enzymes in cell wall structure and adhesion

Recipient organisms include:
1/ E. coli - many multiply disabled K12 derivatives
2/ S. cerevisiae - many multiply disabled, non-pathogenic S288C derivatives
3/ C. albicans (CA14, ura3; CA18, ura3 ade2 abd derivatives of these strains with further disabling markers
(eg. glycosylation enzymes, components of the Ras/cAMP-dependent pathway).

Host/vector system

Vectors include:
1/ Many non-mobilisable E. coli vectors (including pUC 18/19, p8LUESCRIPT, lac-based expression plasmids such as pET vectors)
2/ Many non-mobilisable S. cerevisiae vectors (including YEps, YCps, Y1ps and single-copy GAL-based expression vectors)
3/ Specific non-mobilisable C. albicans vectors (single-copy integrating vectors PMB7, pDDB57, integrating expression vectors regulated by methionine pEXPa)The genetic materials in the modifications are all derived from naturally occurring organisms of E. coli, S. cerevisiae and C. albicans. More specific Candida genes include:
1/ Glycosylation genes (eg. CaSRB1, PMT1, PMT2, MNN1, 2, 3, and 4)
2/ Regulated promoters (MET3, MAL2)
3/ Auxotrophic markers (URA3, ADE2, LYS2)
4/ Components of the Ras/cAMP-dependent pathway (PDE1, PDE2, TPK1, 2, 3, BCY1)
5/ Candida genomic and cDNA libraries

Origin & function

The genetic materials in the modifications are all derived from naturally occurring organisms of E. coli, S. cerevisiae and C. albicans. More specific Candida genes include:
1/ Glycosylation genes (eg. CaSRB1, PMT1, PMT2, MNN1, 2, 3, and 4)
Candida albicans is a human pathogen in hazard group 2. Can dida albicans causes superficial infections of mucosal epithelia (thrush). However, at no time in the last 20 years since work with Candida began, has a member of any lab had a thrush infection caused by a lab strain. C. albicans also causes infections in severely immunocompromised patients and these can be fatal. However, it is important to remember that C. albicans is widely distributed, being carried by over half of the population. It rarely affects healthy individuals. IOt only becomes a potential medical problem when the immune system of an individual is impaired. Furthermore, as with most pathogenic microorganisms, the virulence of Candida albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culturing.

The strain Candida albicans CA1-4 (ura3) is the standard host for DNA transformation worldwide. Its uridine auxotrophy makes it avirulent (Leberer et al. 1996, PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CA1-4, but the restoration is not complete because the genes neighbouring URA3 remain inactivated. The URA3 marker is recycled for subsequent rounds of transformation (Fonzi and Irwin, 1993, Genetics, 134, 717). Therefore by necessity, some of the transformants we create are not genetically disabled, although their virulence is lower than the wild-type strains of C. albicans carried by most individuals.

C. albicans CA1-8 (ura3, ade2) is transformed with ADE2 or URA3 containing plasmids, leaving one remaining disabling mutation in the transformants. This is sufficient to render all of the transformants completely avirulent.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We follow all safety guidelines for operation at containment level 2. Briefly:

All waste materials will be inactivated before disposal:

* liquid waste - autoclaving at 121 degrees C for 15 minutes (proven to effectively 100% kill fungal cells). The Department of Biomolecular sciences has two large autoclaves, one of which is to be replaced in January 2001. The next thermocouple tests will be carried out on both autoclaves when the engineers are in the department to install the new autoclave. The autoclaves have always been serviced annually by BMM Weston/Drayton Castle, thermocouple testing of various loads of waste is to be included in the annual service contract. The new autoclave will have a data logging system, the old autoclave has a chart recorder to monitor the conditions. Autoclave indicating rubes are placed in bins of contaminated materials each week.

* glass ware - soaked with Virkon (see attached information provided by the manufacturer) proven to effectively 100% kill fungal cells)

* plasticware - autoclaved under the conditions shown above. Before inactivation, plastics will be double-bagged for transport to autoclaves

* sharps will be minimised, but any contaminated sharps will be placed in separate CinBins, bagged and incinerated.

Once GMMs have been inactivated, normal routes of disposal will be used. These measures will reduce the likelihood of all hazards to negligible. The overall risk is therefore effectively zero with the proposed containment and control measures.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N
The UMIST GM safety committee has considered this project. The work with E. coli K12 and Saccharomyces cerevisiae is Class 1 but the Committee thought that the Candida albicans experiments required containment level 2 and were thus Class 2 activities.

**Project Additional Information**
### Purposes of the contained use

The application covers various specific projects which all have the overall aim of understanding the relationship between cellular proliferation and protein synthesis. More specific goals include an investigation of the control of translation initiation in response to stress as well as an analysis of downstream effect such as flocculence and colony morphology.

### Recipient or parental organism

Recipient organisms include:

- C. albicans - strains such as CA1-4 (ura3) and CA1-8 (ura3 ade2). These strains are standard lab strains with auxotrophic phenotypes and highly attenuated virulence. These strains cannot survive without media containing high concentrations adenine and uracil, and given the stringent practises for autoclaving liquid and solid media prior to disposal in our institute, there is no possibility that these strains could escape into the environment.

### Host/vector system

Vectors include:

Specific non-mobilisable C. albicans (single integrating vectors and integrating expression vectors regulated by methionine).

### Origin & function

The genetic materials are all derived from naturally occurring organisms of E. coli, S. cerevisiae, and C. albicans. More specific Candida genes include:

1. Protein synthetic genes (e.g. GCD1, GCD6, CDC33)
2. mRNA decay genes (e.g. DCP1, CCR4)
3. Auxotrophic markers (e.g. URA3, ADE2, LYS2)
4. Candida genomic and cDNA libraries

These genes have homologues in all eukaryotic organisms. As a result there could be absolutely no effect of a gene transfer because the DNA sequences included in our constructs are part of the genomes of all known eukaryotic organisms.

### Evaluation of foreseeable effects

Candida albicans is a human fungal pathogen in Hazard Group 2. It is a micro-organism of a very low pathogenic potential that very rarely effects healthy individuals. It becomes infectious, however, in severely immunocompromised patients like HIV positive individuals or organ transplant patients. Candida albicans can cause superficial infections of mucosal epithelia (thrush). However, in the 20 or more years that C. albicans has been studied in labs, there has never been a thrush infection caused by a laboratory derived strain.

In fact the lab strain CA1-4 which is the standard lab strain worldwide is auxotrophic for uracil. This strain cannot therefore survive in the absence of high concentrations uracil and this makes the strain avirulent. It might be anticipated that transformation of this strain with plasmids bearing the URA3 gene restores the virulence of CA1-4, but the strain is still severely disabled (e.g. Chen et al., 2004. Mol Microbiol. 51:551-65). The lab strain CA1-8 is auxotrophic for both uracil and adenine. Transformation of this strain therefore would only ever complement one of these auxotrophies, thus this is sufficient to render all transformed strains avirulent. Even though these strains are avirulent, the stringent practises for autoclaving liquid and solid cultures prior to disposal eliminates the possibility of strains escaping into the environment alive.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **N/A**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- **N/A**
We follow all safety guidelines for operation at containment level 2. Briefly:

All waste materials will be inactivated prior to disposal. Liquid - autoclaving at 121 degrees centigrade for 15 minutes which has been proven to effectively kill 100% of fungal cells. The Department of Biomolecular Sciences has a large autoclave which replaced two autoclaves in January 2001. The autoclave is serviced annually by BMM Weston/Drayton Castle and thermocouple testing of various loads of waste is included in the annual service contract. The autoclave has a data logging system and autoclave indicator tubes are placed in bins of contaminated waste on a weekly basis.

Glassware - soaked with 1% Virkon (see information provided by the manufacturer - proven to effectively kill fungal cells)

Project Additional Information

Purposes of the contained use

To generate retroviral particles containing DNA sequences of molecules involved with cell fate decisions. To use these retroviruses to transfect mammalian primary or immortalised cells.

Recipient or parental organism

1) Primary cells of mammalian origin.
2) Immortalised cell lines.

Not genetically modified and no foreseeable adverse effects.

Host/vector system

1) Retroviral vectors such as PMX and pMSCV (see attached risk assessment)
2) Packaging cell lines such as phoenix

Expression of retroviral vectors in packaging cell lines will generate replication - defective viruses. Once these viral particles have been used to transfect recipient cells, supernatants from these cells will be screened for the presence of infectious virus.

Origin & function

cDNA of mammalian origin coding for molecules involved with cell fate decisions including: notch molecules 1-4
notch ligands jagged 1/2, delta
notch signalling molecules delta, csl
notch modulatory molecules - the fringe family
mutant forms of the above molecules

Notch molecules are thought to be involved with cell fate decisions in the presence of certain cytokines, notch delays differentiation and promotes the proliferation of primitive cell types. Notch 1 is a known oncogene and truncated, constitutively active forms of notch 1 have been found in T lymphoblastic neoplasms. Molecules which potentiate notch signalling may be expected to delay differentiation also.

Evaluation of foreseeable effects

Following retroviral transfection, cells will be monitored for the presence of infectious retroviral particles on a regular basis. Once it has been established that no infectious particles are generated by host (or recipient) cells, then transfected cells will be used for experimentation. Primary cells are routinely screened for the presence of infectious agents to reduce the risk of co-infection with more than one retrovirus. Primary cells will not be used from lab workers or their family members to the risk of engraftment of transfected cells likely routes of transmission of replication - deficient virus include aerosols and sharps injuries. See attached risk assessment. Accidental inoculation with replication - deficient virus is likely to result in the destruction of virus by the host immune system and therefore long-term injury is unlikely. Experimental waste containing virus particles and transfected cells will be autoclaved to minimise any foreseeable environmental effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

See section 7. Analysis of transfected cells will be performed under category 1 conditions only when the absence of infectious viral particles has been established.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Packaging cell lines, cell culture supernatants containing retroviral particles and transfected target cells will be treated with 1% virkon solution which will destroy any retrovirus or retroviral containing cells. (A 0.05% virkon solution is sufficient for retroviral destruction according to the manufacturer). Solid waste is also treated with 1% virkon solution for a minimum of 1 hour. Both liquid and solid waste is autoclaved in order to ensure a 100% kill of GM material. Departmental autoclaves are serviced annually using a thermocouple. Refer to attached virkon data sheet for further information.

Please enter comments on the GM safety committee on the risk assessment

The local GMSC considered that the work using retroviral vectors required containment level 2 because of the potential oncogenic properties of the inserts. Other aspects of the project e.g. construction of plasmids in disabled Ecoli K12 strains have been assessed separately by the GMSC.

### Purposes of the contained use

The specific aim of this work is to identify, sequence, disrupt and analyse the expression of fungal genes involved in virulence. To achieve this genes will be isolated from genomic DNA by PCR, heterologous hybridisation, mutant complementation and related techniques. This will require construction of Aspergillus and Candida libraries in Saccharomyces cerevisiae/Escherichia coli shuttle vectors e.g. YEp24. Genes of interest will be sequenced and characterised further. As part of this further analysis gene disruption and replacement experiments will be performed. In addition these lesions will be complemented using the homologous gene. This will be done by DNA mediated transformation of viable fungal cells using non-mobilisable vectors carrying appropriate nutritional (for complementation of auxotrophy) or antibiotic (e.g. hygromycin and phleomycin) markers. Immuno compromised mice will be infected with GM Aspergillus and Candida spp by nasal droplet, or intravenous injection, and after sacrifice tissues excised and analysed for fungal gene expression.

### Recipient or parental organism

**Escherichia coli:** Strains in common laboratory use eg DH5alpha, XL-10 will be used as cloning tools. These strains, which are generally derivatives of the K12 strain, have a widespread and long history of safe laboratory use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment. ACDP HG1

Aspergillus nidulans: there are a huge number of classically produced mutant strains of A. nidulans. These have been constructed in many strain backgrounds and often have been crossed many, many times. These strains have a long history of safe laboratory use and usually contain auxotrophic mutations eg argB that would prevent survival outside the laboratory. ACDP HG1

Aspergillus fumigatus: AF237, D141 and ATCC46645, 293, CEA10 and auxotrophic derivatives thereof eg pyrG will be used to construct knock-out, regulatable and reconstituted strains. These backgrounds have a long and safe history of use worldwide. Additionally the pyrG auxotrophies would prevent survivial outside the host. ACDP HG2

Candida albicans: SC5314, CAI4 and CAI10 and auxotrophic derivatives thereof eg his3/his3, ura3/ura3 will be used to construct knock-out, regulatable and reconstituted strains. ACDP HG2

Candida glabrata: ATCC2001 and auxotrophic derivatives thereof eg his3, ura3, trp1 will be used to construct knock-out, regulatable and reconstituted strains. ACDP HG2

Pichia pastoris: A methylotrophic yeast used as a protein expression system, commercially sourced. GS115 and SMD1163 and auxotrophic derivatives thereof eg his4 will be used to express selected fungal proteins. These strains have a long and safe history of laboratory use worldwide. ACDP HG1

Saccharomyces cerevisiae: the majority of laboratory strains are derived from three major wild type lineages S288C,

We also seek permission to use other strains of the spp described above that have essentially the same characteristics as those described.

### Host/vector system

- E. coli and S. cerevisiae vectors including pUC, pBluescript, YE, Y1 and YC series and similar
- We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996)
- Mobilisable Aspergillus vectors will not be used.
We will construct Aspergillus and Candida libraries in Saccharomyces cerevisiae/Escherichia coli shuttle vectors e.g. YEp24. Genes of interest will be sequenced and characterised further. As part of this further analysis gene disruption and replacement experiments will be performed. In addition these lesions will be complemented using the homologous gene. It is not possible to list all of the genes that will be inactivated as we are attempting to characterise complex processes required to maintain fitness en vivo, e.g. nutrient sensing, adherence, metabolic plasticity etc. Disruption of these genes is by definition likely to result in a reduced ability to survive in vivo and therefore to cause disease. Inserted genes will either be from the same species, e.g. used to complement a null allele to create a reconstituted strain, tags added to selected genes e.g. GFP, TAP, HA, etc. Or heterologous antibiotic genes eg ampR, bleR, hygR as markers of transformation.

Evaluation of foreseeable effects

The most hazardous GMM will be a reconstituted Hazard group 2 Fungal pathogen from the list of hosts e.g. Aspergillus fumigatus. This will occur where gene disruption and replacement experiments have been performed and lesions complemented using the homologous gene and where DNA mediated transformation of non-mobilisable vectors is used carrying appropriate nutritional genes for complementation of auxotrophy. Any antibiotic or antifungal selection markers will not be the same as those used for frontline therapy.

The worst case GMO constructed is not anticipated to be any more hazardous than the wild type organisms. It is unlikely that an accidental release would harm the environment. Although classified as Hazard group 2, GM Class 2 the Aspergillus and Candida spp used are opportunistic pathogens that cause disease principally in immuno compromised individuals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste - Treated with virkon at a minimum of 1% concentration after dilution with the waste for a minimum of 30 minutes. Disposal after treatment will be to drains. This has been independently validated as an effective method of inactivation of the fungal pathogens in use and Aspergillus spores. http://www.therapeuticresource.ca/sporicidal.html

Solid waste - Plastic pipette tips will be disposed of into a 1% virkon solution after use for a minimum of 30 minutes before being drained and subject to autoclave treatment detailed below.

Solid Waste - Solid waste will be placed into autoclave bags and taken in lidded containers to the autoclave for treatment at 134 degrees for up to 30 minutes holding time. This waste will then be placed in orange clinical waste bags for disposal as clinical waste by the authorised Imperial College waste contractor. The Autoclave is serviced quarterly.

Annually a worst case scenario mock load is prepared and placed in the autoclave. An engineer using a 12pt thermocouple load temperature NAMAS test apparatus ensures that every test point within the load achieves a temperature known to be effective at inactivating pathogenic microorganisms. At the same time the autoclaves load and chamber sensors are calibrated against the test rig. In all cases a minimum of a 10^5 reduction in microbiological burden is expected.

Is an emergency plan required according to regulation 20? N

**Historical Significant Changes**

Transferred from GM141

**Project Additional Information**

*Purposes of the contained use*

The aim of the project is to assess the effect of blocking the expression of B-Raf and related signalling proteins on the growth of melanoma cell lines in a 3-dimensional model which more closely replicates the tumour.
microenvironment. We have previously shown that 5iRNA-mediated gene knockdown of B-Raf inhibits melanoma cell growth. However, this culture model is not compatible with siRNA oligonucleotides. Therefore, we wish to create melanoma cell lines which stably integrate 5hRNA sequences into their genome for long-term gene knockdown.

Recipient or parental organism

The recipient cell lines will be primary human melanocytes or immortalized human melanoma cell lines. Each of these cell lines are commercially available, have been maintained in cell culture for many years, are not known sources of human pathogens, and are unlikely to survive outside the laboratory environment.

Host/vector system

The vector to be used is a lentivirus derived from HIV-1. However the vector has been modified in several ways to ensure that the virus is replication-defective, and will not form active viral particles unless it is co-transfected into a packaging cell line with helper plasmids.

Origin & function

The genetic material that will be cloned into the lentiviral vector will be DNA that encodes a short hairpin RNA molecule directed against B-Raf or related genes which support melanoma progression. Expression of the shRNA molecule will result in gene-specific knockdown, most likely promoting growth inhibition or cell death in the transfected cells. We also propose to use a lentiviral vector encoding the bacterial Tet-repressor protein, so we can achieve inducible expression of 5hRNA in the cell lines under study. Once Tet-repressor and shRNA constructs have been stably introduced into cells, shRNA expression and subsequent gene knockdown will only occur if tetracycline is added to the culture medium.

Evaluation of foreseeable effects

The lentiviral vectors which we propose to use do have the potential for infecting any human cell. Through good lab ‘1’ practise (GLP) the risk of these vectors affecting the user or others in the laboratory is extremely low. In the unlikely event of infection, the viral particles will not replicate, as discussed above, The expression of these shRNA molecules is hypothesized to target the growth of melanoma cells, and would likely induce cell death. In the case of infection with a lentivirus encoding the Tet-repressor, expression of this protein would have little effect on human cells, as Tet-repressor promoter elements are not present in human genes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We are not requesting derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and infections of cells will be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 1% Virkon after use. Virkon is a chemical disinfectant that kills 99.999% of organisms in less than 10 minutes. The cabinet will prevent unwanted infection of the cell cultures as well as release of the viruses into the environment. Infected cells will be grown in a designated incubator. Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 1% Virkon before disposal. Cells and growth medium will be treated with 1% Virkon before disposal according to the Institute’s Waste Index and Disinfection protocols. HIV-1 is transmitted through blood and a limited number of bodily fluids, none of which will be encountered in the course of this work. Further, sharps will not be used. To date, no one has been identified as infected with HIV due to contact with an environmental surface (see http://www.cdc.gov/hiv/resources/qa/qa35.htm). No living material infected with HIV-1 derived lentivirus will be transported other than between cabinet, microscope and incubator in the tissue culture room 5C10.1 (ACGM2), but cell extracts will be transported between room 5C10.1, laboratories 4N19-21 (ACGM1) and the equipment room on the 4th floor (ACGM1). Viral preparations will be double-contained and transported between room 5C10.1 and the —80oC freezer (room 4S4, ACGM1) for storage. In the event of a spillage, chlorine-releasing disinfectant granules (HAZ-TAB) or 1% Virkon will be used for immediate disinfection.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

Membership
1. A Chairman to be appointed by the Executive.
2. Representatives appointed by management (such as the Group Leader of a laboratory, Floor or Quadrant manager or senior members of staff) with responsibility for or use biological agents activities and/or the use of radiation.
3. Representatives, chosen by the Staff Forum from all persons having access to the biological agent facilities, or who might otherwise be exposed to work with biological agents, such as research workers, administrative, technical and ancillary staff, students or visiting workers.
4. The Biological Safety Officer.
5. The Deputy Biological Safety Officer.
6. An Occupational Health representative will be a member of the Committee. The representative will automatically receive agendas and minutes, although attendance only needs to be as appropriate.
7. Where appropriate, at least one Committee member is to liaise between the BRSC and the Crick Health and Safety committee.
8. The Radiation Protection Officer and/or the Radiation Protection Advisor and the Laser Safety Officer.
9. Co-opted members to supplement internal expertise may be needed to assess particular proposals.

02/03/2022
Studies on biological clocks and sleep

Circadian (circa- approximately, -diem day) rhythms are a fundamental property of the life of a cell. When held in temporal isolation, organisms from unicells to humans exhibit behavioural and physiological rhythms that persist with a period of approximately 24 hours. These rhythms are driven by cell-autonomous molecular circadian clocks. They confer selective advantages to organisms by facilitating anticipation, and thereby adaptation to, the alternating day/night cycle. The competitive value of circadian clocks has been demonstrated in prokaryotes and higher plants, whilst disturbance of circadian timing in humans, as seen in rotational shift workers for example, carries significant long-term health costs.

We have developed novel tools, based on variants of fluorescent proteins and the luciferase enzyme, that allow us to probe the inner workings of the clockwork in more detail than previously possible. Since we now want to study the clockwork in neuronal systems and in primary cells, lentiviral systems are necessary to introduce relevant transgenes into the host cell genome for stable expression, especially in intact organotypic tissue slice cultures. Moreover, we also wish to perturb the clockwork by knocking down the expression of various ‘clock genes’ (and their modifiers such as peroxiredoxin proteins), and lentiviral systems allow this in neuronal and ‘difficult-to-transfect’ cell lines, including primary cells.

HIV1-based lentiviruses, modified for safety, have emerged as powerful tools for effecting changes in gene expression in terminally-differentiated cultured cells such as neurons and organotypic tissue slices. Therefore, we seek authorization to use such vectors to attain our goals in relation to clock research.
The lentivirus is produced by co-transfecting the packaging plasmid mix and the transfer vector into human HEK293FT cells. The recipient cells will be various murine and human cells in culture, including primary cells. Both the recipient cells and the producing cells require specific cell culture conditions to grow and are not harmful. They cannot colonise the environment nor cause disease by colonizing human or animal hosts and thus are classified as ACDP Group 1. Cells from human volunteers, which may be used in this project are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at Containment Level 2 within the host laboratory.

Host/vector system

The ViraPower™ Lentiviral Expression System (Invitrogen), facilitates highly efficient, in vitro or in vivo delivery of a target gene to dividing and non-dividing mammalian cells using a replication-incompetent lentivirus. Similar systems have been developed by multiple companies and use very similar (if not identical) components, e.g. Sigma Mission shRNA pLKO based system. This new generation of lentiviral systems has been used extensively throughout the World and includes important features designed to enhance its biosafety:

• The pLenti expression vector contains a deletion in the 3′ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
• The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
• The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).
• Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
• Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
• The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
• Expression of the gag and pol genes from pLP1 has been rendered Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
• A constitutive promoter (RSV promoter) has been placed upstream of the 5′ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

References

activate components of the circadian clock we will use cloned cDNA that will be over-expressed. The genes in question are neither oncogenes nor tumour suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an empty virus. We will also express bioluminescent and fluorescent proteins as 'reporters' of the clock within cells, which are derived from firefly and jelly fish sequences respectively. These have a long history of safe use in various non-replicative lentiviral systems.

A theoretical exception to this principle is a retrovirus encoding a prion-forming protein, which could theoretically set up a prion infection in the host. Therefore, proteins with a potential to undergo prion formation (e.g. mutant PrPsc) will not be used.

The short hairpin RNA (shRNA) sequences used to inactivate genes in the host are derived from the host cell genome and tested in conventional (non-lentiviral) vectors before use to test their function in cell lines. They will be directed to genes that function in the circadian clockwork, usually as transcription factors that switch oscillating genes on/off over the 24 hour day. These genes are neither oncogenes nor tumor suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an empty virus.

List of genes / fusions encoding 'reporter' proteins that will be expressed from lentiviral vectors:

- Basic fluorescent proteins: GFP, RFP, dsRED, CFP, YFP
- Redox-sensitive fluorescent proteins: roGFP1/2, roGFP1/2-Grx1, roGFP1/2-Trx, roGFP1/2-Prx1, roGFP1/2-Prx2, roGFP1/2-GAPDH
- NAD/NADH-sensitive fluorescent proteins: SuperFrex
- H2O2-sensitive fluorescent proteins: Hyper, Hyper-2, Hyper2-Grx1, Hyper2-Trx, Hyper2-Prx1, Hyper2-Prx2, Hyper2-GAPDH
- Bioluminescent proteins: Luciferase (Luc2), OxyLUC
- Light-sensitive ion channels: Channelrhodopsin, Halorhodopsin (and variants)
- Light-sensitive expression systems: Lite-On
- Voltage/Calcium sensing fluorescent proteins: Cameleon, Case12, GCAMPS, Arch3, PROPS, VFSP3
- pH-sensitive fluorescent proteins: pHluorin, synapto-pHluorin, pHred

List of genes encoding proteins that function in the circadian clockwork. The expression of these genes will be inhibited by shRNA-containing lentiviral vectors, or the genes will be over-expressed by lentiviral vectors:

- Mouse or human Clock, Bmal1/2. Encode clock-relevant transcription factors.
- Mouse or human peroxiredoxins (Prx1, 2, 3, 4, 5, 6). Encode clock-relevant antioxidant response proteins.
- Mouse or human catalase. Encode clock-relevant antioxidant response proteins.
- Mouse or human superoxide dismutase. Encode clock-relevant antioxidant response proteins.
- Mouse or human thioredoxins (Trx1, 2). Encode clock-relevant antioxidant response proteins.
• Mouse of human glutaredoxin (Grx). Encode clock-relevant antioxidant response proteins.
• Mouse of human glutathione reductases. Encode clock-relevant antioxidant response proteins.
• Mouse or human GAPDH, Enolase. Encode clock-relevant metabolic enzymes.

Evaluation of foreseeable effects

Inactivation of most genes involved in circadian clock function by RNA interference (RNAi) will have no significant effect on the cell, and if anything, make them more susceptible to undergo apoptosis. The genes that will be disabled are not known oncogenes. Thus, the risk associated with viruses encoding such genetic elements is predicted to be less than that or empty lentiviruses.

Gain-of-function of clock components by overexpression is unlikely to translate to a survival benefit for accidentally-transduced cells, let alone serve as an oncogenic event. The same is true for bioluminescent and fluorescent reporter proteins; these have no other recognised function than to produce light. Thus, the risk posed by gain-of-function vectors is likewise less than that of empty viruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture materials and labware will be autoclaved and incinerated which eliminates 100% of the infectious material. All solid waste will be collected in double autoclave bags, sealed with autoclave tape, labelled with the users name and the room number and will be autoclaved and incinerated. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) and disposed to drains. Alternatively, disinfected liquid waste will be gelled with Vernagel in sealed containers labelled with autoclave tape, and taken to the autoclave room for transfer to the incinerator. Spills will be sprinkled with Virkon powder/Trigene and Vernagel reagent to solidify. Recyclable labware will be soaked in 1% Virkon for 16 hours (which eliminates 100% of infectious material). Bench/cabinet surfaces will be wiped down with 10% Trigene and 70% ethanol (which eliminates 100% of infectious material).

**Purposes of the contained use**

Herpesviruses are ubiquitous pathogens of man and all vertebrates. In humans, herpes simplex virus (HSV) causes oral and genital lesions and occasionally more serious diseases such as keratitis and encephalitis. Following primary infection latent virus resides in sensory neurones and can reactivate from these cells to facilitate recurrent disease/
transmission. Murine gammaherpesvirus 68 is a gamma-2 herpesvirus, originally isolated from small free-living rodents in Slovakia. It behaves as a natural pathogen in conventional laboratory mice and has been used extensively as a model for the study of gammaherpesvirus pathogenesis. MHV-68 causes an infectious mononucleosis-like illness but is otherwise avirulent in adult, immunocompromised mice. Spread between mice is rare, even when housed in the same cage; intimate contact is probably required for virus transmission. Infection of humans has not been documented. In mice the virus productively infects epithelial cells and establishes a latent infection in B lymphocytes. The object of this research is to identify metabolic processes that influence the kinetics of virus replication in vitro and viral dissemination in vivo using reporter gene expressing HSV and MHV-68. This will be achieved by infecting mammalian cell lines and both wild type and genetically altered mice. The contribution of individual virus encoded gene products to such interactions will be assessed using viral mutants with specific gene truncations or deletions. In addition, viral gene products cloned into replication defective retroviral and/or Adenovirus vectors to facilitate the transduction of mammalian cells will be used to probe such interactions further.

Recipient or parental organism

Parental viruses: HSV 1/2 (HG2 pathogens), MHV68 (HG1 pathogen)
The biological functions of HSV-1, HSV-2 and MHV-68 genes are largely undefined however HSV and MHV-68 do not encode known toxins or proven oncogenes. In common with other well studied and genetically related herpesviruses it is expected that both HSV and MHV-68 will encode gene products including miRNAs that affect multiple cellular pathways/processes.

HSV encodes some 80 different gene products and at least 15 miRNAs involved in various aspects of virus replication, cell modification and immune evasion. The detailed mode of action of these virus encoded products is in many cases poorly understood. A number of gene products are known to be toxic in the expressing cell, for example the HSV-1 UL41 gene shuts off host protein synthesis and overexpression of a number of immediate early gene products prevent cell division (e.g. ICP0).

MHV-68 encodes some 70 different gene products and at least 8 miRNAs involved in various aspects of virus replication, cell modification and immune evasion. The detailed mode of action of these virus encoded products is in many cases poorly understood. A number of gene products are know to be toxic in the expressing cell, for example MHV-68 shuts off host protein synthesis and the virus can induce cell division and proliferation of B cells. In addition, specific gene products are involved in immune evasion, such as the K3 gene product that specifically degrades mouse (but not human) MHC class I, and M3, which is a pan chemokine binding protein.

Standard mammalian cell lines such as NIH 3T3, HEK (human embryonic kidney) 293, MEF (murine embryonic fibroblasts), HeLa and BHK (baby hamster kidney) cells. All mammalian cell lines used have a history of safe use and it is unlikely that they will carry adventitious pathogens.

Host/vector system

Bacterial artificial chromosomes (BAC): The use of full-length infectious herpesvirus genomes cloned as BAC has significantly improved the process of genetic manipulation of the genomes and is an approach widely used throughout the herpesvirus research community. The risks posed by working with either naked viral DNA or genomes cloned as BACs are low since the specific infectivity of DNA is many orders of magnitude lower than that of fully formed virus particles. Herpesvirus genomic DNA is however capable of infecting human cell lines in culture if introduced in certain ways (e.g. by transfection procedures) and therefore there is a potential risk of infection when working with or handling virus genomes cloned as BACs. The risk is very low because a route of direct delivery of the BAC DNA into cells is necessary for infection and would be highly unlikely during normal laboratory handling. Non mobilizable bacterial genomic vectors to be used: pUC series, HSV cloned as bacterial artificial chromosome in a derivative of pBAC108L (disabled F plasmid), MHV-68 cloned as bacterial artificial chromosome in a derivative of pBAC108L.
Bacterial hosts will be multiply disabled E.coli K12 derivatives eg DH5 alpha, DH10B, JC8679 for all bacterial cloning. These derivatives (HG1 pathogens) are disabled and do not compete with normal gut flora.

Adenovirus vectors: The parent vector is an Ad-5 recombinant in which the E1 region is replaced by a lacZ coding cassette. This virus grows only in helper cells (eg 293 cells) that provide the E1 gene product in trans, and is an ACDP hazard group 1 organism. All insertions will be in the E1 region, replacing the lacZ cassette. This effectively eliminates the possibility of generating a replication competent virus carrying the foreign insert by recombination with a wild type virus. Adenoviruses are spread via the respiratory aerosol route and this route represents the major risk of infection.

Retrovirus vectors: Third generation lentivirus vectors lack pol, tat, env, rev and gag genes and can only be packaged following complementation with helper plasmids expressing RT, IN, tat, rev together with the VSV G protein. These are expressed from different plasmids so reconstitution of wild type virus is not possible. In addition, the vector genome has a self inactivation LTR to reduce the risk associated with insertional mutagenesis. Host range and virus stability is expanded by incorporation of the VSV G protein.

Herpesvirus vectors: Herpes simplex virus deleted for the gH gene is replication defective and cannot complete a full round of replication. Such vectors can be propagated on gH expressing complementing cell lines that do not result in the generation of detectable levels of replication competent virus since there is no homology between the virus and the gH expression cassette in the CR1 cell line. Following infection of noncomplementing cell lines the virus can only go through a single round of replication and produces non infectious virus progeny. This vector is classified as a class I GMO by the HSE.

Technique used to introduce insert or vector into host:
Infection of mammalian cell lines and mice with recombinant HSV or recombinant MHV-68 containing gene disruptions and/or expressing reporter genes.
Cloned genomic fragments of HSV or MHV-68 will be cloned directly into pUC-based vectors and transformed into E.coli K12 derivatives. HSV or MHV-68 cloned as a bacterial artificial chromosome will be transformed into E.coli K12 derivatives and purified plasmid DNA used to reconstitute virus following transfection of mammalian cell lines.

Retroviral and Adenovirus vector mediated transduction of mammalian cell lines with HSV or MHV-68 encoded gene products.

Origin & function

Investigation into the interaction between viral replication and cellular metabolic processes may involve:
1. Genomic cloning of HSV1/2 or MHV68 sequences into plasmid and replication defective viral vectors.
2. Inactivation/modification of virus encoded genes and non-coding RNAs, including alteration of their regulation of expression, using full-length infectious herpesvirus genomes cloned as bacterial artificial chromosomes (BAC).
3. Cloning of reporter genes (e.g. GFP, betagalactosidase, Cre recombinase, luciferase) under latent or lytic cycle promoter control. Each of these proteins has no known biological effects in eukaryotes.
4. The expression of virus and/or cellular gene products in a glycoprotein H (gH) deleted HSV-1 (Class I GMO as agreed with Dr Mark Bale at the HSE) vector. This gH deleted vector is severely disabled and can only be propagated in a gH complementing cell line. The severely disabled nature of such a gH deleted vector makes it very unlikely that it will pose a risk greater than wild type HSV-1 since any cell entering a productive replication cycle will be killed and no infectious progeny will be produced.

Evaluation of foreseeable effects

HSV-1/2 (HG2): Recombinant viruses containing mutations of individual gene products or encoding reporter gene cassettes are most likely to be less virulent than wild type parental virus.
MHV-68 (HG1): recombinant viruses containing mutations of individual gene products or encoding reporter gene...
Retrovirus vectors: There is a low risk of aerosol transmission and efficient transduction would require breach of mucosal membrane or the skin surface. This would result in transduction of a small number of cells as the virus is defective and cannot spread.

Adenovirus vectors: Deliberate attempts to deliver foreign genes in vivo using adenovirus vectors (in gene therapy experiments) establish that this is an inefficient process. In the event of accidental infection:

1. A small number of cells would express the foreign gene. This might result in death of those particular cells if the gene product was cytotoxic.

2. There is a very small risk that a pre-existing adenovirus infection might result in complementation of a recombinant vector by wild type virus. Transient growth of the recombinant might then occur. Infected cells would be killed by virus growth or by immune response to infection. There is no expectation that a herpesvirus gene product would exacerbate an adenovirus infection or modify tissue tropism (note the receptor binding proteins of herpesviruses are integral membrane proteins which cannot assemble into an adenovirus virion). Given these factors, the proposed recombinants are of no greater risk than the parental adenovirus vector but given the uncertainty about the functions of herpesvirus gene products, category 2 containment is appropriate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All disposable culture materials and labware will be autoclaved and incinerated which eliminates 100% of the infectious material. All solid waste will be collected in double autoclave bags, sealed with autoclave tape, labelled with the users name and the room number and will be autoclaved and incinerated. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) and disposed to drains. Alternatively, disinfected liquid waste will be gelled with Vernagel in sealed containers labelled with autoclave tape, and taken to the autoclave room for transfer to the incinerator. Spills will be sprinkled with Virkon powder/Trigene and Vernagel reagent to solidify. Recyclable labware will be soaked in 1% Virkon for 16 hours (which eliminates 100% of infectious material). Bench/cabinet surfaces will be wiped down with 10% Trigene and 70% ethanol (which eliminates 100% of infectious material).

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
The project has been reviewed by the Institute of Metabolic Science's biological and genetic modification safety committee, and we are satisfied that the risk assessment is accurate and that the work will be carried out under the appropriate conditions.

Significant Change ID: 542/04.3

Date of Significant Change: 21/10/2004

**Project Additional Information**

Purposes of the contained use:

CL3: Expression of recombinant prion protein sequences (r-Prp) in bacterial and yeast hosts; protein isolation and purification using conventional protein chemistry techniques of cell lysis and centrifugation to produce samples of non-viable prion protein. Further handling of all protein samples will be at CL3, except for wt sheep r-Prp and its natural variants, which will be handled at CL2.
Recipient or parental organism

a) E.coli  b) P.pastoris

Host/vector system

Ecoli B and K12 strains, plus pTrcHis vector (IPTG induced): (for sheep and mouse Prp)
P.past. SMD1163 strain (Invitrogen) (methanol induced): (for human Prp).

Origin & function

The DNA material comes from a) (sheep and mouse r-Prp) Dr J hope, Institute of Animal Health, Compton, UK and b) (human r-Prp) Prof Stephan Weiss, Genecentre, Ludwig-Maximillian University, Munich, Germany.

Sequences of cDNA for sheep and mouse r-Prp will be expressed in E.coli to produce purified recombinant prion protein r-Prp lacking glycosylation and GPI anchor. This material has beh conformation of the non-transmissible cellular Prpc protein. The sequence will be modified to include FLAG, and/or hexaHis tags to aid purification. Single point mutations will be made of individual residues in sheep r-Prp, which are candidates for specific structural roles eg V115M to give the 3F4 monoclonal antibody epitope, as occurs naturally in hamster and mouse Prp. Truncation and deletions of large fragments, and concatenation of sequences will be performed for X-ray structural and spectroscopic studies of the conformational properties of the sheep r-Prp molecule as a model for the self-association of the non-transmissible prion protein in its wild-type cellular form.

The yeast expression system has been used (LMU, Munich) to express the monomeric and covalent dimeric form of the human prion protein r-Prp(Hu), with similar purification tags. This glycosylated material will be used for structural studies by X-ray diffraction.

Evaluation of foreseeable effects

Purpose of work:

1. To crystallise recombinant prion protein (recPrp) in its natural, cellular non-transmissible form, alone and as a complex with an existing monoclonal antibody.

2. To express and purify the recPrp in its wild type and various related forms for structural studies.

3. The aim is to use the structural information from the Xray analysis to interpret the known properties of the prion protein in solution. This will entail repeating some of the published biophysical and spectroscopic experiments using sheep r-Prp. In no case has any of these studies generated material with transmissible or infective properties.

Foreseeable effects:

A GMO expression or prion protein is classified as a potential hazard. Extensive published literature indicates that the proposed in vitro experimental conditions for handling the recombinant Prp are unable to bring about conversion of the natural form of Prp-c to an infective or transmissible form, Prp-sc. The genetic manipulation in E.coli will be performed using the sequence of sheep Prp, since this form is without known hazard; also there is no evidence for transmissibility of sheep scrapie in the human system. The recPrp(hu) dimer (expressed in yeast), and the rec-Prp(mouse) dimer (expressed in E.coli) have been shown to be non-toxic in neuronal cell culture. The recombinant prion protein materials will be used in vitro only. No scrapie protein material from any infected animal source will be involved, hence no hazards are foreseen. All expression and purification work will be performed at CL3. Wild-type sheep r-Prp and its natural variants (eg C151) will be handled at CL2. Other species, dimers and sheep r-Prp including mutations will be handled at CL3.

Also see Risk Assessment, attached.
Not-applicable.

For Class 2

Containment Measure 8 - Autoclave required in building.

An autoclave is an out-building serving the containment 4 laboratory has been adapted to take prion waste and we would wish to use this machine rather than adapt one in the main building. Waste will be decontaminated as far as possible and transported to the autoclave in robust sealed containers.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from the CL3 activities in the expression of recombinant prion protein will be pooled and autoclaved at 137 deg C in the special NIMR facility attached to the CL3/CL4 laboratory where all the contained work will be performed. These are standard conditions for the complete killing of bacteria and yeast. No toxic or transmissible material from animal sources is involved.

## Project Additional Information

### Purposes of the contained use

Generation of virus vectors; administration of vectors to tissue cultures and to intact tissue in situ.

### Recipient or parental organism

GMO: Replication-defective Sindbis virus. No adverse effects foreseen.

Recipient: rodent cells in culture; laboratory rats and mice.

### Host/vector system

Sindbis virus, replication defective.

### Origin & function

Reporter genes and probes derived from Aequoria and coral fluorescent proteins and firefly luciferase, and fusion proteins including various neurotransmitter receptors and signalling proteins of rat and mouse. These will serve as probes to determine activity-dependant activation and/or redistribution of proteins of interest, to monitor levels of intracellular messengers, and to ascertain the function of genes and gene products implicated in synaptic transmission and plasticity.

### Evaluation of foreseeable effects

None likely. The virus system to be used generates only replication-defective virus, not functional virus. Even normal virus can only be spread to humans via mosquitoes, and there is no obvious way for mosquitoes to take up our reagents.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Waste material will be managed according to the attached code of practice.

Historical Significant Changes
### Project Additional Information

**Purposes of the contained use**

We plan to study a series of genes from non human primates that are capable of blocking lentivirus replication at a post-penetration, preintegration step in the viral life cycle. For this purpose we intend to set up a series of assays allowing us to monitor HIV-1, SIV, FIV and EIAV replication in a one-step assay.

**Recipient or parental organism**

Viral vectors will be derived from HIV-1, SIV, FIV and EIAV.

**Host/vector system**

Viral vectors will be prepared by co-transfecting three plasmids into 293T cells. The first plasmid encodes the viral genome, and includes cis-acting sequences required for viral transcription, packaging, reverse transcription and integration and carries one or more reporter genes. It does not encode viral genes required for replication such as gag, pol or env. The second plasmid provides (in trans) the products of gag and pol but lacks an RNA packaging signal. The third plasmid provides (also in trans) env function via the VSV-G protein. Two days after transfection virus is harvested from the cell supernatant.

**Origin & function**

Recovered virus will be used to infect a variety of cell types. These will be cultured for 2-4 days, fixed in formaldehyde and scored for virus integration either by FACS analysis or by LacZ staining. This assay will form the basis of our attempts to probe the interaction between the restriction gene and its viral target.

**Evaluation of foreseeable effects**

Lentiviruses are associated with a number of pathological effects in humans and other animals. By comparison, the lentiviral vectors we are proposing to employ will be relatively harmless. Lentiviral pathogenicity required high level virus replication; the vectors we will be using are incapable of productive infection, giving rise to only one round of replication. They have been designed in such a fashion as to reduce the chances of recombination to yield infectious virus to effectively zero. However it is still theoretically possible that they might cause injury by a mechanism of insertional activation of cellular oncogenes. This remote risk applies equally to humans as well as other animals. This risk aside no other adverse effects are foreseen.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Ref 542/03.4

Date Ackn'd 12/11/2003

CU2 Project Title PRODUCTION OF HIV-ENV/INFLUENZA HA RECOMBINANT GENES FOR THE EXPRESSION OF RECOMBINANT GLYCOPROTEINS (RGPS) FOR STRUCTURAL (X-RAY CRYSTALLOGRAPHY) STUDIES AND INCORPORATION INTO INFLUENZA

Class CultureVolClass2 CultureVolumeClass3-4

Class 3 up to 2 litres

Non-GMM Consent Granted yes

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Vaccinia recombinants containing the envHA genes (VACeH) will be made and used to assess the feasibility of expressing proteins from such constructs. Experiments will be performed on protein expressed in VACeH-infected cells to assess the receptor-binding and fusion properties of the expressed proteins as indicators of their correct folding. If the expressed proteins function as predicted (based on what is known of the functions of the parent env and HA), cells will be cultured in bulk, infected with VACeH and used as a source of glycoprotein for purification for structural analyses. Additionally, mammalian cell clones will be established that constitutively express the envHA glycoprotein (based on the vector system pEE14tpa). The latter work can be conducted at containment level 1. Attempts to produce recombinant influenza viruses for therapeutic use in HIV-infected humans and studies of any viruses produced will initially be carried out at containment level 3 (see risk assessment). When (if) such studies establish the safety of the viruses permission will be sought to use them at lower containment levels.

**Recipient or parental organism**

Escherichia coli strain DH5a (for growth of plasmids).
Vaccinia strain vRB12 (to allow selection of VACeH recombinants).
A variety of transformed-mammalian cells (eg CV-1, BHK, CHO, NSO, 293TY, MDCK).
The plasmid-based reverse genetics system developed for the human H1N1 influenza virus, WSN.
The organisms indicated are those in use currently (in relation to other approved activities involving genetic modification) - we may wish to change specific reagents if better ones become available.

**Host/vector system**

pRB21 - vector used to allow production of vaccinia recombinants.
pEE14tpa - vector used to transform mammalian cells for constitutive expression of envHA.
pHH21-vector, a series of plasmids used to produce recombinant influenza viruses.

**Origin & function**

Influenza HA and HIV env-genes cloned into a variety of vectors (under approved activities involving genetic modification) already exist at NIMR. They are used for protein expression, functional and structural studies. In addition, the elements to construct the "conditionally lethal gene" (the HIV-2 LTR and the Thymidine kinase gene from Herpes Simplex 1) for inclusion in recombinant influenza viruses have already been cloned at NIMR.

The env-HA gene recombinants will be produced by PCR amplification of the relevant gene segments of pre-existing HA- (X31 in the first instance) and HIV env-gene (NL43 and JRFL in the first instance) clones. The fragments will then be stitched together using PCR-SOE (Splice Overlap Extension) and cloned into a vaccinia shuttle vector (pRB21 in the first instance) and mammalian expression vector (pEE14tpa in the first instance) for amplification in a disabled E. coli strain (DH5a in the first instance).

CV-1 cells will be infected with an attenuated strain of vaccinia (vRB12 in the first instance) and then the pRB21 constructs will be transfected in to allow production of vaccinia recombinants. The recombinants will then be used to infect CV-1 cells in bulk culture to produce rgps for purification.

The pEE14tpa constructs will be used to transfect mammalian cells (CHO in the first instance) which will then be treated with the drug Methyl-sulphoximine (MSX) to allow
selection of clones which express the rgps of interest constitutively. The rgps will be purified for functional and structural studies. envHA genes known to express in the recombinant vaccinia system will be modified by using specific primers in PCR to allow incorporation of the genes into the pHH21 vector system and propagation of these vector constructs in E. coli for subsequent generation of influenza virus recombinants. By replacing the influenza HA gene with that of envHA, recombinant influenza should infect cells expressing CD4 and certain chemokine receptors (rather than epithelial cells of the respiratory tract that express suitable sialic acid receptors). When the influenza NA gene is also replaced with the “conditionally lethal gene” and ganciclovir is administered (in culture or in whole body systems) only CD4 expressing cells that are infected with HIV should be killed. Such recombinant viruses may ultimately play a role in the treatment of HIV-infected humans.

See attached papers:
Blasco & Moss (pRB21/vRBV12) - 1995, Gene, 158, 157-162
Neumann et al (influenza reverse genetics) - 1999, Proc Natl Acad Sci USA 96, 9345-50

Evaluation of foreseeable effects

The disabled E. coli hosts will be transformed to ampicillin resistance by all vectors used and all genes to be used in the study have been shown to be stable when cloned. In particular, neither HIV-env nor influenza-HA genes are harmful in bacteria and both proteins (when produced in bacteria) are functionally inactive. It is therefore unlikely that the rgps (envHAs) will be active.

Vaccinia-envHA recombinants (VACeH) will express rgps in infected cells. Such cells will not express constitutively as vaccinia induces a lytic infection. Within the Division of Virology HSE approval has been given for the expression of HIV-env and influenza-HA using vaccinia-recombinant systems. This means that vaccinia has already been given the receptor binding (CD4 and chemokine receptors for HIV and sialic acid for influenza) and fusogenic properties of the other viruses without increasing vaccinia's virulence. The vaccinia recombinants to be produced here should have the receptor binding properties of HIV and, to some extent (to be assessed), the fusogenic properties of influenza.

Mammalian cells transfected with the pEE14tpa constructs will be resistant to MSX and will express rgps constitutively in a soluble condition.

The recombinant influenza viruses should show the receptor binding characteristics of HIV (human CD and chemokine coreceptors) and fusion characteristics of influenza. This will result in altered host cell tropism and may prevent influenza from being an aerosol-transmitted (respiratory) virus. The overall pathogenesis of the recombinant influenza viruses (ability to grow to high titre and spread to a wide range of cell types) are likely to be reduced compared to the parental virus WSN.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable at this stage, but would need to be able to use in a clinical setting when (if) the project goes to a human trial stage.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For work carried out at containment level 1 the relevant Codes of Practice will be used. Liquid waste (to include culture supernatant following removal of expressed rgps) to be treated with Chloros prior to disposal, solid waste to be bagged, autoclaved and incinerated.

For work carried out at containment level 2 the relevant Codes of Practice will be used. All work with vaccinia will be carried out in class II microbiological safety cabinets (laboratories 268b/202 - containment 2) or, exceptionally, in class 1 cabinets (RV2 - containment 3).

For work carried out at containment level 3 the relevant Code of Practice will be used. All work relating to the generation of the recombinant influenza viruses and their purification from bulk cultures will be carried out in class i microbiological safety cabinets (RV2).
The Secretary emphasised prior to the discussion that this project should be treated as Commercial - in - Confidence.

Dr Kioussis asked, on behalf of the committee, whether the virulence of the vaccinia and the env/HA influenza recombinant viruses would be changed by the presence of the fusion protein.

Dr Daniels answered that both parental proteins (influenza HA/gp160) have been expressed in the vaccinia system and used for vaccination purposes. The virulence of the vaccine strains has not been increased above that seen for the parental vaccinia vaccine strain.

Dr Kioussis also asked that since the ENV/HA influenza virus will have an altered tropism due to the presence of the gp120 component of gp160, will this increase or decrease infectivity?

Dr Daniels replied that what has been learned from expressing ENV/HA in the vaccinia system has confirmed what was anticipated, ie it retains the receptor binding characteristics of gp160 but the fusion characteristics of influenza HA. As a consequence of this, the tropism of the proposed recombinant influenza virus to be produced will be altered compared to the wild type influenza. The recombinant influenza will be tropic for CD4+ cells and therefore have a more limited host range than wild type influenza. As a consequence of this the recombinant influenza should be attenuated and no longer be transmissible by aerosol routes. Further to this CD4+ cells of the host immune system are poor hosts for wild type influenza. Therefore it is anticipated that the recombinant influenza will not grow to the same high titre as the wild type. Additionally the majority of the human population will have immunity to influenza that will still function against the products of the genes conserved (6 or 7 out of 8 depending on the particular influenza recombinant) between the wild type and the recombinant influenza. In view of this the recombinant form can be considered an attenuated influenza vaccines.

The committee were satisfied with Dr Daniels answers to these questions and recommended that the project be forwarded to the HSE for consideration as a class 3 activity.

INVESTIGATION OF GENE FUNCTION AND REGULATION IN MYCOBACTERIUM BOVIS BCG.

The analysis of gene function and regulation in Mycobacterium bovis BCG will involve the construction and characterisation of deletion mutants, the characterisation of individual proteins and their interactions, and the characterisation of gene expression and regulation using reporter genes.

Constructs of selected genes which have been deleted or interrupted by an antibiotic selection marker will be transformed into M. bovis BCG. The resultant recombinants will be screened to identify those in which the gene has been deleted by allelic exchange. Phenotypic analysis of the resultant mutants, and complemented strains in which the mutated gene is reintroduced on an integrating plasmid containing a further antibiotic selection marker, will include growth characteristics in bacteriological media under various conditions and in macrophages and mice to assess any changes in virulence. They will also be used to test their ability to vaccinate against challenge with a virulent M. tuberculosis strain in mouse models of TB.

Tags allowing purification of individual proteins, possibly along with any associated proteins, will be added to the protein of interest via cloning on a plasmid which will then be reintroduced into M. bovis BCG. Following growth, sterile cell lysates will be prepared and the protein of interest isolated in vitro.

Gene expression and its regulation will be investigated by introducing plasmids containing fragments of M. bovis BCG or M. tuberculosis DNA linked to reporter genes which allow ready monitoring of expression levels.

Recipient or parental organism
Mycobacterium bovis BCG.

Host/vector system
For knockout construction, plasmids based on pBluescript which do not replicate in mycobacteria will be used for delivery of the mutation.
For complementation and introduction of tags or reporters, plasmids will be based on the mycobacterial integrating vectors or on replicating plasmids containing the replicon of the mycobacterial plasmid pAL5000 or pMF1.

**Origin & function**

Origin is M. bovis BCG or M. tuberculosis.

For knockout construction the intended function is to permit recombination to delete genes of interest from the chromosome thus creating a mutant strain defective in a defined gene or genes.

For complementation the intended function is to restore a specific gene or genes to confirm that the phenotype of a mutant strain is due to the targeted mutation rather than a secondary mutation elsewhere on the chromosome.

For tag insertions the intended function is to permit the isolation of an individual protein, and maybe associated proteins, from cell lysates of M. bovis BCG for further analysis in vitro.

For reporter insertion the intended function is to drive the expression of a readily assayed reporter gene by mycobacterial expression signals to study regulation of gene expression.

**Evaluation of foreseeable effects**

Hazards to human health.

The recipient microorganism is Mycobacterium bovis BCG, the strain that is used as a live vaccine to protect against TB. All work with this organism is carried out under the Containment Level 2 Code of Practice.

Deletion of genes involved in virulence is expected to decrease virulence in comparison with the parent strain. BCG has genomic deletions compared with the parental M. bovis strain, which result in attenuation. It is most unlikely that deleting further genes will result in increased virulence although this cannot be formally excluded.

For tag insertions, the DNA being added will result in the addition of a harmless tag to a single protein. However, in some cases the protein will be expressed from a non-native promoter and therefore we cannot rule out the possibility of generating a strain with increased virulence owing to the unnatural expression of the protein. However, since pathogenicity in mycobacteria is not due to the acquisition of a single gene, for example a toxin, it is most unlikely that such an increase in virulence will result.

For reporter insertions, the DNA being added will result in the expression of a harmless reporter gene and therefore the virulence of the pathogen is not expected to be altered.

The parent strain to be used is the vaccine strain M. bovis BCG, which is sensitive to all anti-TB drugs. None of the antibiotics used to make the genetic constructs are front-line TB antibiotics, hence the transfer of these resistance markers will not compromise any treatment.

All work will be carried out at Containment Level 2.

Hazards to the environment

The genetically modified organisms would be expected to survive in the environment but not to displace other organisms. They would not be pathogenic to other species.
The control measures used for the human health risk mean that any escape is highly unlikely, and hence that the estimated environmental risk is effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be autoclaved at 121 degrees C in accordance with the code of practice for the containment level 2 laboratory where the work is carried out, to give 100% kill.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

### Purposes of the contained use

In order to study these viruses, individual genes of these viruses will be cloned into expression vectors and studied individually at first, and eventually in concert. This is to provide a clear picture of the workings of these viruses in the cell.

### Recipient or parental organism

**List of recipient strain**
- **Bacteria**
  - E.coli strains: DH5α, DH10B, Sure, TG1, TB1
- **Viruses**
  - E1-deleted adenovirus
  - Defective retroviruses-all the viral genes have been removed from the vector
  - Defective lentiviruses-all the viral genes have been removed from the vector and self-inactivating
- **Cell lines**
  - HeLa, W12, S12, SiHa, CaSki - All derived from human cervix
  - U2OS, Saos-2 - All derived from human bone
  - FSK, NEK - All derived from human skin
  - COS, CHO - All derived from hamster

### Host/vector system

**List of vectors**
- Vectors without promoters: pSP72, pSP64, pGEM,
- Vectors with promoters that function in mammalian cells: MV11, pCDNA, pBabeNeo, pBabePuro, pBabeHygro, pBabeBlast, LXSN, pJ5 p81, p277, p274
- Vectors with promoters that function upon induction in bacteria: pGEX2T, pMALc, pET

### Origin & function

The genetic materials that are involved are of either viral or human origins. They are genes that will be used in the context of understanding how they affect the life cycle of HPV or AAV. They are not expected to alter pathogenicity, host range, tropism of mode of transmission of the cell of the viruses.
### Evaluation of foreseeable effects

Three types of organisms will be genetically modified, namely bacteria, viruses and human cell lines. Bacteria will be modified to carry either viral or cellular genes of interest. The effect of these genes on the bacteria is not the aim of the exercise. Instead, the bacteria will be used as a convenient host that carries genes of interest that will be eventually extracted from the bacteria and then transferred into human cell lines for analyses.

Human cell lines that receive genes of interest either via infection by recombinant viruses described above or via transfection will be generated. They will either be short-lived cells, which means that they will not be propagated for more than a month or they will be made to be stable lines, which means that they will be cultured for longer than a month. Whether short-lived or stable lines are to be generated will depend on the nature of the experiment and also on the property of the gene of interest that is introduced into the cell.

There is no single or even several GMM that will be made that can be deemed as particularly hazardous because the vectors that will be used are themselves already very safe (e.g., self-inactivating vectors, defective/non-replicating viruses), and the genes of interest that will be studied are not known to be toxic or oncogenic. Instead, several of the genes of interest will be studied as "anti-oncogenic" or tumour suppressor genes.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable to this programme.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Project Additional Information

**Purposes of the contained use**
Modification of listeria monovytogenes to include a protein epitope for the study of ovalbumin specific immune responses.

**Recipient or parental organism**
Listeria monovytogenes is a Gram positive bacterium that causes disease in mice and humans generally when administered in high doses (about 10 (to the power of 8) bacteria) orally. The organism can be pathogenic for pregnant or immunosuppressed individuals. In sublethal infections of mice the bacterium is cleared by innate and specific immune responses and the animal retains long-term immunity.

**Host/vector system**
The host sequence is derived from the ovalbumin gene that is fused to the signal sequence and promoter of the Listeriolysin hly gene. Ovalbumin is non hazardous for humans or animals and will not alter the pathogenicity of the host.

**Origin & function**
Coding sequence introduced into Listeria is derived from ovalbumin. The intended function is for ovalbumin to elicit specific immune responses in the context of a pathogen, which would allow the role of memory T cells in protection against pathogen-associated antigen.

**Evaluation of foreseeable effects**
No effects beyond the effects of Listeria parent organisms are expected.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Containment and control measures as detailed in the attached code of practice covering the use of Listeria will be applied.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management measures are described in detail in the attached Code of Practice covering the use of Listeria monocytogenes.

### Project Additional Information

#### Purposes of the contained use

To investigate the role of eph receptor/ephrins in hippocampal plasticity.

#### Recipient or parental organism

**Donor organism:** mouse

#### Host/vector system

**Vector system:** modified Semliki Forest Virus vector system (replication incompetent, conditionally infectious). Plasmids used: pSFV2gen and pSFV-Helper2.

**Host cells:** BHK-21 cells

**Tissue to be infected:** mouse/rat hippocampal slices.

#### Origin & function

**Origin of vector:** wild-type SFV

**Origins of inserted genes:** mouse embryonic cDNA (eph receptor/ephrins) green fluorescent protein (aequoria victoria)

#### Evaluation of foreseeable effects

The eph receptor/ephrin proteins are not inherently toxic, nor do they have any known oncogenic or allergenic functions. They are normally widely expressed in diverse cell and tissue types in both vertebrates and invertebrates. They are unlikely to have significant harmful effects although this would be impossible to exclude, especially in view of their known roles in development and signalling properties. However, the disabled virus vector systems to be used should render this risk negligible. The viral genome is encoded on two separate plasmids, making virions produced replication incompetent. Additionally, specific mutations in the helper plasmid mean that these virions only become infectious following treatment with high, non-physiological concentrations of chymotrypsin. Under careful test conditions, non replication competent infectious particles have been seen to be generated when using this dual-safety system.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This work has been assigned to Containment 2.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection and waste disposal: 1) Effective disinfectants must be available at all times. The disinfectant of choice will be a chlorine based one. However see notes on
the disinfection of delicate equipment. 2) Work surfaces must be cleaned and disinfected after use. 3) All waste materials must be rendered non-infectious before disposal. 4) Material for autoclaving must be transported by nominated persons direct to the discard autoclave in robust containers. Care must be taken to ensure that the external surface of the container is rendered safe prior to removal from the contaminated area. The container must then be placed immediately into the autoclave by the nominated person. 5) Pipettes and other disposable items must be treated with disinfectant. 6) Liquid wastes must be thoroughly disinfected before disposal via the drains.

Disinfection:
- For routine decontamination (Infected material)
  1) Chloros - 2,500 ppm available chlorine changed daily and made up fresh weekly. Note: Chloros is readily deactivated by organic material. Caution: Not be be used on equipment subject to corrosion.
  2) For delicate equipment - 2% glutaraldehyde. Caution: This material is toxic and must be used with care. The Safety Section must be consulted before use.
  3) For the decontamination of the microscope objective 70% ethanol with an overnight contact time is suitable.
  4) Follow the disinfection by washing with a suitable detergent.
  Adequate contact time must always be allowed for effective disinfection.
  If necessary, contact the Safety Section for further advice.

For spillages and accidents
- Minor spillages - 1) Precept granuals 2) 10,000 ppm available chlorine 3) 2% glutaraldehyde
  Followed by washing with a suitable soap.

AUTOCLAVE CODE OF PRACTICE
1) The temperature at the centre of any load must be maintained at the following minimum times/temperatures: 121ºC = 15 minutes, 126ºC = 10 minutes and 134ºC = 3 minutes.
2) Instructions for the use of the autoclave must be displayed locally.
3) Containers must be of a solid construction and allow for adequate steam penetration throughout the contents.
4) If autoclave bags are in use, then these must be supported in solid containers. The opening must be turned back over the supporting container to allow steam penetration. Discord container lids must be removed unless the steriliser cycle has been designed to cope with the tops in place.
5) Effluent discharge: a) The drainage system must avoid dispersal of splashes and steam into the working area. b) Exhaust from the chamber, together with any discharge from the vacuum pump and any chamber cooling the water, should lead to a cooling/dilution tank which in turn should be connected directly to the foul drain. This pipe should be vented.
6) CYCLE FAILURE
   Should the autoclave fail during the cycle, the safety section must be informed immediately and no attempt must be made to open the chamber until a proper risk assessment has been made.
7) The autoclave must be filled with a safety interlock to prevent access to the contents whilst the temperature of the material inside is above 80ºC.
8) Tests - An annual calibration and validation (under worst load conditions) shall be carried out by an approved contractor. A thermocouple test must be carried out monthly to confirm the satisfactory operation of the autoclave. This test should be carried out under worst load conditions.
   The performance of the autoclave will be recorded to ensure that it meets laid down requirements.
9) Any fault with the autoclave, such as steam leaks, perished seals, etc., must be reported immediately.
10) As the autoclave falls within the provision of the Pressure Systems and Transportable Gas Container Regulations 2000, work on it must only be carried out by a competent person in accordance with the manufacturer's requirements. All such work must be adequately documented and the records retained.
   A written maintenance system must be established and periodic routine examinations of the autoclave must be carried out with the manufacturer's instructions and a Certificate of Examination provided.
11) Unloading - Operators must wear a visor and heat-resistant gloves together with an apron and laboratory coat whilst removing materials from the autoclave. Loads must be easy to handle or be able to be transferred directly to a trolley for final disposal.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

CU2 Project Title Genetic manipulation of the human malaria parasite Plasmodium falciparum.

Class 3

Culture Class

Volume Class

<1 litre

Consent Granted Yes

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
**Purposes of the contained use**

We plan to transfect *P. falciparum* parasites with plasmid DNA (vectors) containing all or part of selected *P. falciparum* genes. The products of these genes are important in the maturation of the parasite, the invasion process and/or development within the invaded erythrocyte. We plan to use vectors of the pH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH series, or their derivatives, which contain different selectable markers for cloning and selection in bacteria and subsequently the malaria parasite. These vectors are designed to allow: single crossover homologous recombination events where the entire vector is inserted into the parasite genome; double crossover events where the input DNA directly replaces the target parasite gene(s); autonomous plasmid replication and expression (as episomes) or insertion of the target gene with a tag, into a non-essential site within the parasite genome to allow expression of the tagged target gene independent of the native gene. A fuller description is given in the Risk Assessment (attached). The target genes will be those that encode proteins located on the surface of mature parasites or the infective stage of the parasite (the merozoite), proteases important in parasite development and merozoite release, organelle specific proteins and factors involved in the parasite’s metabolism. All of these are involved in maturation of the parasite, the invasion process or developmental events in the invaded erythrocyte.

**Recipient or parental organism**

*P. falciparum* is a protozoan parasite of the phylum Apicomplexa, and is one of the agents responsible for causing human malaria. It is normally found in tropical and sub-tropical regions and is transmitted by mosquitoes of the *Anopheles* spp. It is possible to cultivate the asexual and sexual erythrocytic stages (human host) in tissue culture in vitro.

**Host/vector system**

**Host:**
The host sequence is derived from genes encoding proteins involved in the development and maturation of the parasite, parasite metabolism, or recognition and invasion of erythrocytes by the merozoite.

**Vector:**
The vectors are of the pH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH series or their derivatives, which are derived from pUC series plasmids of *E. coli*. These have been modified to include drug resistance cassettes, 5' and 3' malarial untranslated regulatory sequences (UTR) and appropriate multiple cloning sites. The vectors may also contain sequences encoding reporter proteins; these include widely used enzyme reporters such as firefly luciferase and chloramphenicol acetyl transferase (CAT), fluorescent proteins (e.g. GFP, DsRed, RFP varieties) or epitope tags (e.g. cmyc, HA3, FLAG or Tyl).

**Origin & function**

**Origin of coding sequence:**
Culture adapted cloned *P. falciparum* parasite lines;
3D7, D10, A4, CIO, FCBI, T996 T994
Parasite lines imported: Dd2at and 3D7

**Intended function:**
1) To disrupt the gene of interest in order to ascertain its function (i.e. perform a gene knock out).
2) To ‘tag’ the gene with a marker in order to detect and study the function and activity of the gene product.
   1) This can be done using sequences for GFP or related proteins cloned into a part of the target sequence in order to produce a fusion protein that can be detected by optical techniques such as fluorescence.
   2) Similarly this can be done using short peptide epitope tags (e.g. HA, cmyc, FLAG, Tyl tags). Gene products modified with these tags can be readily detected using immunochemical techniques.
3) Further functional studies on the protein by gene modification or truncation, or replacement with orthologous genes of other species of malaria parasites. This will help to determine the parts of the molecule that are required for its biological function. These truncated genes can also be tagged as in b).
4) To overexpress genes of interest which are otherwise of low abundance (as episomes or integrated into a non
essential site of the parasite genome)
Origin of vector: pHH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH plasmid series. These contain selectable
markers (drug-resistance) and regulatory or mRNA stabilising elements (5' and 3 malaria UTRs).

Evaluation of foreseeable effects
The main concern when considering this project is that P. falciparum is pathogenic to man. A code of practice (COP) is
already in place (attached) to minimise accidental infection of laboratory workers. The parasite can only be transmitted through the mosquito secondary host or by direct
contact with infected blood by injection or through cuts. No P. falciparum work on these premises involves exposure to sharps such as needles or broken glass. All parent
parasite lines have been screened for drug susceptibility and are known to be sensitive to quinine sulphate. This characteristic will not be altered by any of the work
described above. In the unlikely event that a person is believed to have been accidentally infected, treatment with the appropriate anti-malarial drug will commence
immediately. All used equipment and reagents are decontaminated before leaving the containment 3 tissue culture room (see COP) and thus no live modified parasite will
discarded and transported out of the room. If it is necessary to transport live parasites to another facility, e.g. for centrifugation or microscopy, the parasites are sealed
(in a centrifuge bottle or sealed coverslip on a microscope slide) and transported in a sealed container.
Work with P. falciparum is undertaken under containment 3 guidelines and modification of the parasite does not pose greater risks of infection to humans. These modified
parasites will not be put through the mosquito cycle and thus there is no risk that they will enter the wild population. Most of the genes under study are unique to P.
falciparum and thus it would be difficult to transfer these genes to another organism The parasite will only be cultivated in vitro; no insect transmission will be undertaken.
The work with live parasites is carried out in a sealed room so there will be no possibility of mosquitoes being infected and infecting the wider populace. The parasite is not
viable ex vivo except in the special in vitro culture conditions used. All parasite material is rendered non-infectious with reagents such as phenol or detergents before further
analysis is carried out in non-category 3 containment facilities. The vectors contain drug-resistance cassettes. The drugs most used in the parasite selection process
(WR99210, neomycin, blasticidin and puromycin) are not in general use for the clinical treatment of humans or animals and thus the problem of drug resistance appearing
in the humananimal population is not an issue. Less often, pyrimethamine is also used in selection of transgenics. Resistance to this drug in wild parasite populations is
widespread, and it is not recommended for use alone for either prophylaxis or treatment of acute malaria. Ampicillin is used in the cloning of the vector in the bacterial host.
This antibiotic has been in widespread use in standard laboratory molecular cloning protocols for a number of years and there have been no recorded cases of drug
resistance linked to using these vectors in bacteria.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The work with live parasites is required to be performed under Containment 3 facilities. However, once the parasite has been treated with denaturing reagents, such as
phenol or detergents, the parasites are non-infectious and can be worked with under Containment 1 facilities.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Refer to Code of Practice, attached. All lab ware (pipettes, flasks, tips and tubes) and culture waste (spent growth medium) are treated by immersion in sodium
hypochlorite solution (2,500 pp million of chlorine) for a minimum of 30 minutes. The medium is rendered colourless, or dark brown precipitates (parasitised erythrocytes)
are observed as the killing process occurs. Lab ware is also autoclaved at 121° C for 15 minutes before being discarded. There is 100% destruction of infectious material
after these treatments.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
This project has been approved by the Biological Safety Committee for work at Class 3. Please see attached comments.

**Project Ref** 542/09.1

- **Date Ackn’d:** 21/08/2009
- **CU2 Project Title:** Investigation into xenotropic murine leukaemia virus-related virus (XMRV) and its role in disease

**Class**

- **CultureVolClass2:** Class 3
- **CultureVolumeClass3-4:** < 1 Litre

**Consent Granted**

- **Non-GMM:** Yes

**Historical Significant Changes**

- **Historical Date of Additional Info:** 21/08/2009

**Project Additional Information**

- **Purposes of the contained use:**

  In 2006 a novel retrovirus was isolated from patients with familial prostate cancer (Urisman et al. PLoS Pathog 2006). This virus is very similar to several endogenous murine leukaemia viruses (MLV) found in mice and murine cell lines, and was named Xenotropic MLV-related virus (XMRV). The presence of XMRV seems to correlate...
with a deficiency in Rnase L, a molecule involved in the anti-viral response induced by interferon. At this time, it is not known whether the prostate cancer in these patients is linked to infection by XMRV and whether this is related to a loss of Rnase L function. The goals of this project are to investigate the link between XMRV and prostate cancer as well as with Rnase L.

A plasmid containing a DNA copy of the XMRV RNA genome under the control of the CMV promoter has been synthesized previously (XMRV VP62 viral molecular clone, Dong et al. PNAS 2007). When transfected into mammalian cells, this plasmid will express viral properties and nucleic acid which will assemble into viral particles. For the purposes of creating a safer, replication incompetent XMRV stock, deletions and mutations will be made in the RNA packaging signal and/or promoter regions of the XMRV sequence in the VP62 plasmid. This modified VP62 plasmid will then be used to transfect mammalian cells (along with an MLV based vector and in some cases a plasmid expressing a viral envelope gene) to produce pseudotyped virus-like particles.

**Recipient or parental organism**

VP62/pcDNA3.1 plasmid - encodes full length XMRV genomic DNA. This will be mutated to contain deletions in the RNA packaging signal and/or U3 promoter regions to create a modified VP62 plasmid.

**Host/vector system**

Vectors to be used:
- KB4 - contains the murine leukaemia virus (MLV) gag pol sequences. These are structural and enzymatic proteins of the virus.
- LacZ-LTR - contains the gene lacZ, which encodes the protein β-galactosidase, under the control of the MLV long terminal repeat (LTR)
- VSV-G - encodes the vesicular stomatitis virus G protein (viral envelope protein)
- MLV-X - encodes the xenotropic MLV viral envelope proteins
- FBdelMOSAF - encodes the Moloney MLV viral envelope proteins

Three plasmids i) either KB4 or modified VP62, ii) LacZ-LTR and iii) one of the envelope plasmids, will be co-transfected into 293T cells (human embryonic kidney cell line) to produce pseudotyped retroviral particles. These virus like particles will be used to infect various mammalian cell lines including Mus dunni (murine cell line), D17 (canine osteosarcoma cell line), 293T (human embryonic kidney cell line), He La (human cervical carcinoma cell line). However, they will be capable of a single integration event only and are not capable of causing a spreading infection. The RNA genome to be packaged, the viral envelope and other viral proteins are encoded on separate plasmids thus eliminating the possibility of reversion to replication competence with a single recombination event. These clones can therefore be used to synthesize virus-like particles at containment level 2.

**Origin & function**

Plasmids expressing various genes from MLV have been used for several years to synthesize retrovirus-like particles, both for basic scientific research and for gene therapy. We will now include a plasmid expressing the genes from XMRV, a recently identified retrovirus, in order to study this novel virus.

In some instances, it may be desirable to produce replication competent virus by transfecting the parental VP62/pcDNA3.1 plasmid into mammalian cells. As the consequences of an XMRV infection are unclear at the present time, this will be done in containment level 3 facilities. These viral preparations will be treated in a similar manner to HIV.

**Evaluation of foreseeable effects**

Our genetic modifications of the VP62 plasmid will significantly decrease the hazard associated with the XMRV clone: By removing the U3 region, the viral promoter will be deleted and by removing the packaging signal, the encapsidation of viral RNA will be severely diminished. Loss of either function will lead to replication incompetency. We therefore feel that it is safe to work with this modified XMRV clone in a Microbiological Safety Cabinet at containment level 2.

It is unlikely that the XMRV sequences will be transferred to any other microorganism.

The effects in humans of infection with replication competent XMRV are under investigation.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All tissue culture waste (cells that have been transfected or infected, culture supernatants that may contain virus or virus-like particles and plastic waste), will be treated with Chloros or Super Q disinfectant and autoclaved.

To prove that this treatment is sufficient to kill virus, supernatant containing virus-like particles will be treated with Chloros or super Q prior to infecting cells, and viability measured using our infectivity assay for LacZ activity.

When we use the three plasmid system, no infectious virus should be produced after the initial integration event. Also, as no experiments require long term passage of cells, it is extremely unlikely that any recombination events could occur. (Reference: The SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms (other than those associated with plants)).

Project Ref 542/10.2
We plan to transfect P. knowlesi parasites with plasmid DNA (vectors) containing all or part of selected P. knowlesi genes. The products of these genes are important in the maturation of the parasite, the invasion process and/or development within the invaded erythrocyte. We plan to use vectors of the pHH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH series, or their derivatives, which contain different selectable markers for cloning and selection in bacteria and subsequently the malaria parasite. These vectors are designed to allow: single crossover homologous recombination events where the entire vector is inserted into the parasite genome; double crossover events where the input DNA directly replaces the target parasite gene(s); autonomous plasmid replication and expression (as episomes) or insertion of the target gene with a tag, into a non-essential site within the parasite genome to allow expression of the tagged target gene independent of the native gene. A fuller description is given in the Risk Assessment (attached).

The target genes will be those that encode proteins located on the surface of mature parasites or the infective stage of the parasite (the merozoite), proteases important in parasite development and merozite release, organelle specific proteins and factors involved in the parasite's metabolism. All of these are involved in maturation of the parasite, the invasion process or developmental events in the invaded erythrocyte.

P. knowlesi is a protozoan parasite of the phylum Apicomplexa, and is one of the agents responsible for causing human malaria. It is normally found south-east Asia and is transmitted by mosquitos of the Anopheles spp. It is possible to cultivate the asexual and sexual erythrocytic stages (human host) in tissue culture in vitro.

The host sequence is derived from genes encoding proteins involved in the development and maturation of the parasite, parasite metabolism, or recognition and invasion of erythrocytes by the merozoite.

Vector:
The vectors are of the pHH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH series or their derivatives, which are derived from pUC series plasmids of E. coli. These have been modified to include drug resistance cassettes, 5' and 3' malarial untranslated regulatory sequences (UTR) and appropriate, multiple cloning sites.

The vectors may also contain sequences encoding reporter proteins: these include widely used enzyme reporters such as firefly luciferase and chloramphenicol acetyl transferase (CAT), fluorescent proteins (e.g. GFP, DsRed, RFP varieties) or epitope tags (e.g. cmyc, HA3, FLAG or Ty1).
### Origin & function

**Origin of coding sequence:**
Culture adapted cloned *P. knowlesi* parasite lines:
A1, Nuri, Washington and H strain
Parasite lines cloned and adapted from Malaysian clinical isolates

**Intended function:**

a) To disrupt the gene of interest in order to ascertain its function (i.e. perform a gene knock out).

b) To 'tag' the gene with a marker in order to detect and study the function and activity of the gene product.

1) This can be done using sequences for GFP or related proteins cloned into a part of the target sequence in order to produce a fusion protein that can be detected by optical techniques such as fluorescence.

2) Similarly this can be done using short peptide epitope tags (e.g. HA, cmyc, FLAG, Ty1 tags). Gene products modified with these tags can be readily detected using immunochemical techniques.

C) Further functional studies on the protein by gene modification or truncation, or replacement with orthologous genes of other species of malaria parasites. This will help to determine the parts of the molecule that are required for its biological function. These truncated genes can also be tagged as in b).

D) To overexpress genes of interest which are otherwise of low abundance (as episomes or integrated into a non-essential site of the parasite genome)

**Origin of vector:** pHH, pARL, pLN, pSSPF, pXL-BACII-hDGFR and pHTH plasmid series. These contain selectable markers (drug-resistance) and regulatory or mRNA stabilising elements (5' and 3' malaria UTRs)

### Evaluation of foreseeable effects

The main concern when considering this project is that *P. knowlesi* is pathogenic to man. A code of practice (COP) is already in place (attached) to minimise accidental infection of laboratory workers. The parasite can only be transmitted through the mosquito secondary host or by direct contact with infected blood by injection or through cuts. No *P. knowlesi* work on these premises involves exposure to sharps such as needles or broken glass. All parent parasite lines have been screened for drug susceptibility and are known to be sensitive to chloroquine. This characteristic will not be altered by any of the work described above. In the unlikely event that a person is believed to have been accidentally infected, treatment with the appropriate anti-malarial drug will commence immediately. All used equipment and reagents are decontaminated before leaving the containment 2 tissue culture room (see COP) and thus no live modified parasite will be discarded and transported out of the room. If it is necessary to transport live parasites to another facility, e.g. for centrifugation or microscopy, the parasites are sealed (in a centrifuge bottle or sealed coverslip on a microscope slide) and transported in a sealed container.

Work with *P. knowlesi* is undertaken under containment 2 guidelines and modification of the parasite does not pose greater risks of infection to humans. These modified parasites will not be put through the mosquito cycle and thus there is no risk that they will enter the wild population. Most of the genes under study are unique to *P. knowlesi* and thus it would be difficult to transfer these genes to another organism.

The parasite will only be cultivated in vitro; no insect transmission will be undertaken. The work with live parasites is carried out in a sealed room so there will be no possibility of mosquitoes being infected and infecting the wider populace. The parasite material is rendered non-infectious with reagents such as phenol or detergents before further analysis is carried out in non-category 2 containment facilities.

The vectors contain drug-resistance casettes. The drugs most used in the parasite selection process (WR99210, neomycin, blasticidin and puromycin) are not in general use for the clinical treatment of humans or animals and thus the problem of drug resistance appearing in the human/animal population is not an issue. Less often, pyrimethamine is recommended for use alone for either prophylaxis or treatment of acute malaria.

Ampicillin is used in the cloning of the vector in the bacterial host. This antibiotic has been in widespread use in standard laboratory molecular cloning protocols for a number of years and there have been no recorded cases of drug resistance linked to using these vectors in bacteria.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The work with live parasites is required to be performed under Containment 2 facilities. However, once the parasite has been treated with denaturing, such as phenol or...
detergents, the parasites are non-infectious and can be worked with under Containment 1 facilities.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Refer to Code of Practice, attached. All lab ware (pipettes, flasks, tips and tubes) and culture waste (spent growth medium) are treated by immersion in sodium hypochlorite solution (2,500 pp million of chlorine) for a minimum of 30 minutes. The medium is rendered colourless, or dark brown precipitates (parasitised erythrocytes) are observed as the killing process occurs. Lab ware is also autoclaved at 121°C for 15 minutes before being discarded. There is 100% destruction of infectious material after these treatments.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The parental strain used as the background for reverse genetics experiment is classified as Hazard Group 2 and has a very long history of safe use - it was derived from the first human influenza virus isolated as a virus comparable of replication in the mouse brain following intracerebral inoculation. This is an inconsistent phenotype that was observed in some, but not all, influenza viruses isolated in the 1930s.

The genes from the 1918 virus that will be inserted into this background are those of the HA and NA of the 1918 pandemic virus.

The Contained Use will involve the propagation in the allantoic cavity of embryonated hens’ eggs and subsequent purification of virus using standard centrifugation techniques. The biophysical assays are to measure using the Octet apparatus involves detection of virus binding by interferometry.

Recipient or parental organism

The recipient virus is a long-established laboratory strain of a 1933 influenza virus. To our knowledge, no adverse events have been reported using this strain of virus.

The 1918 was responsible for first pandemic 20th century and was highly virulent in humans.

Host/vector system

A/WSN/33 is the host/vector system

Origin & function

Influenza viruses have an RNA genome composed of eight RNA segments. The engineered virus will have either six or seven of its RNA segments derived from the widely used laboratory strain of influenza virus A/WSN/33 (H1N1). The other RNA segment or pair of segments will be derived from the reconstructed virus derived from the H1N1 virus that was responsible for the 1918 pandemic. The gene or gene pair will be the segment that encodes the haemagglutinin glycoprotein either on its own or in combination with the gene that encodes the neuraminidase glycoprotein. The haemagglutinin is responsible for binding of the virus to receptors on the host cell and the fusion of the virus lipid envelope with the lipid envelope of the cell. The neuraminidase is responsible for the release of progeny virus from an infected cell and the disaggregation of viruses as they leave the infected cell. The haemagglutinin is the major determinant of neutralising antibodies; the neuraminidase is the target of the antiviral drugs, oseltamivir and zanamivir. The project is to examine the interaction of the engineered virus with receptor analogues.

Evaluation of foreseeable effects

The viruses produced may be hazardous to humans. The parental virus is not considered likely to pose a hazard but the newly constructed viruses containing the glycoproteins from the 1918 virus may have increased virulence for humans. No increase has been observed in mouse experiments with the viruses that we will use. Single gene replacement of the HA and the NA in two other viruses with a different genetic backgrounds, in contrast, has been observed to result in an increased virulence in a mouse model.
Our risk assessment of handling the WSN virus with the 1918 HA and/or NA genes is based therefore on the studies in mice but we recognise that the mouse is not an ideal model of human infection.

The GMO as a replication competent influenza virus is able to re-assort in mixed infections and it is not possible to predict the behaviour of the resultant progeny. To ensure that any such risk is minimised, no other influenza viruses will be handled at the same time as the virus is being propagated, or during its use. In addition, anyone with influenza-like symptoms will be excluded from using the virus. As an additional precaution against mixed infection all workers will be offered seasonal influenza vaccination. In addition, in the event of accidental exposure anti-viral drugs will be available; the 1918 neuraminidase and the WSN neuraminidase are both sensitive to zanamivir and oseltamivir.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work will be carried out under Con 4 conditions as per the attached manual.

Solid waste material is collected and placed in secure boxes and autoclaved. This will be followed by offsite of incineration.

Liquid waste is chemically treated with Super Q, collected in an effluent tank and treated at 134°C

See manual for further details

### Project Ref 542/11.1

**Date Ackn’d** 07/03/2011

**CU2 Project Title** Vaccination of laboratory mice with Recombinant DNA Vaccinia virus (rVV) expressing heterologous viral proteins

**Class** Class 2

**CultureVolClass** < 1 Litre

**CultureVolumeClass** Class 2

**Consent Granted**

#### Project notified under transitional arrangements

**Non-GMM**

### Project Additional Information

**Purposes of the contained use**

Vaccinia virus has been used extensively as a vaccine against smallpox, in a global campaign that led to the eradication of smallpox. Vaccinia virus is since being used as a vector for heterologous microbial proteins in recombinant forms that are used for vaccination against the original donors of those proteins. The purpose of the contained use of rVV strains is to study the immunological basis underlying vaccination of laboratory mice with rVV carrying either the envelope gene of Friend murine leukaemia virus (F-MuLV env) or the hemagglutinin gene of influenza A virus (IAV HA) or a green fluorescent protein (GFP) gene.

**Recipient or parental organism**

The parental microorganism is VV, a member of the poxvirus family.

**Host/vector system**

The production and selection of infectious VV recombinants expressing foreign genes was carried out with the use of plasmid vectors. These vectors contain all or part of the VV thymidine kinase (TK) gene interrupted by multiple unique restriction endonuclease sites placed adjacent to the TK promoter. After transfection of vaccinia virus-infected cells with such plasmids, homologous recombination occurs between the VV sequences flanking the chimeric gene and the same sequences within the virus genome. Recombinants formed in this manner have the chimeric gene inserted within the body of the vaccinia virus TK gene under control of a vaccinia virus promoter. Since recombinants have an interrupted TK gene, they are selected on the basis of their TK-phenotype and then checked for the presence and expression of the foreign gene.
Two rVV strains will be used, each expressing either the envelope gene of Friend murine leukaemia virus (F-MuLV env) or the hemagglutinin gene of Influenza A virus (IAV HA) or a green fluorescent protein (GFP) gene. The expressed foreign proteins serve as a source of antigenic peptides for immunisation. Although both proteins have biological functions in their native context (virus binding to its receptor and membrane fusion), their functions do not manifest in the heterologous context of rVV. Therefore, these foreign proteins expressed by rVV are considered biologically inactive.

**Origin & function**

**Intrinsic effects of VV**

The known effects of VV infection are derived from vaccination studies. Typically, vaccinia multiplies in the basilar epithelium after vaccination, causing a local cellular reaction. A papule appears 4-5 days after vaccination secondary to local replication of the virus. The papule becomes pustular within 7-10 days and reaches a maximum size of 2-4 cm; this is known as a Jennerian pustule. At this time, associated axillary lymphadenopathy and mild fever may occur. The pustule contains fluid with live viral particles that can spread by direct contact. Two to 3 weeks after vaccination the pustule dries from the centre and forms a scab. A characteristic scar that is approximately 1 cm in diameter usually remains as evidence of prior vaccination. Revaccination yields a similar, yet accelerated, course of events. No evidence exists for systemic viremia during administration of vaccinia virus in immunocompetent individuals. Most adverse reactions to vaccinia administration involve the skin and central nervous system (CNS). Progressive vaccinia also known as vaccinia necrosum is a rare complication in which viremia can lead to metastatic infection of the organs, necrosis of the skin, and, in some cases, death in immunosuppressed patients, particularly those with T-cell deficiencies. In children younger than 15 years who have eczema, vaccinia virus can also replicate rapidly in the eczematous lesions, leading to eczema vaccinatum (also termed Kaposi varicelliform eruption). The sequelae of eczema vaccinatum include prolonged hospital stays and, occasionally, death.

VV does not pose any hazard to the environment other than to human health. Since the resumption of smallpox vaccination by the US military in 2002 several cases of VV infection have been reported and it is therefore accepted that VV exist in the environment.

**Effects of genetic modification of rVV**

Insertion of the foreign proteins resulted in TK gene inactivation of rVV to be used in this study. In comparison with wild-type VV TK-deficient strains of rVV have been well-documented to be attenuated in laboratory mice. However, despite the wealth of data on the degree of attenuation in laboratory mice achieved by the deletion of the TK gene, similar data from human studies are lacking, and it currently thought, but not proven that TK-deficient strains of rVV are also attenuated in humans.

As the foreign proteins expressed by the rVV lack biological function in this context, other than the provision of immunogenic peptides, their presence does not modify the properties of rVV.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Derogation from full Class 2 "Autoclave required I (Table 1a Part II, Section 8) the building"

(see attached)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be autoclaved at 121°C in accordance with the code of practice for the containment level 2 laboratory where the work is carried out, to give 100% kill

Date of Significant Change

Project Additional Information
**Purposes of the contained use**

We will investigate the generation and recognition of Toxoplasma antigens and epitopes derived from them, through use of transgenic and knock-out Toxoplasma parasites and Toxoplasma-specific CD8 T cells derived from cloned mice.

**Recipient or parental organism**

Toxoplasma gondii

None of the genetically modified Toxoplasma strains are expected to present an increase in hazards to humans compared to the initial parent strains used to derive the genetically modified form from. The inserted gene products are all derived from different Toxoplasma strains or encode non-infectious, non-hazardous proteins (e.g. green fluorescent protein, ovalbumin).

**Host/vector system**

Toxoplasma gondii/All Toxoplasma GMOs used in this study were either commercially available or were previously constructed. The 4 transgenic strains we plan on constructing will use the vector gra1-PCNA-YFP/HXGPRT.

**Origin & function**

Toxoplasma gondii poses a containable threat for human health (see next paragraph). None of the Toxoplasma forms to be kept in the laboratory (tachyzoites and bradyzoites) pose a threat for the environment as they are short-lived and will not survive outside of their host (tissue culture cells for tachyzoites, mouse brains for bradyzoites). None of the genetically modified Toxoplasma strains are expected to present an increase in hazard to humans compared to the initial parent strains used to derive the genetically modified form from.

Toxoplasma gondii is an obligate intracellular protozoan parasite, which infects a diverse range of tissues and organs within many animal species. Although the sexual cycle of this organism occurs only in cats, the asexual forms are capable of infecting human. Toxoplasma infection can be contracted by three routes:

- Ingestion of sporulated oocysts from material contaminated with feline faeces.
- Oral ingestion of bradyzoites (tissue cysts) from infected animal tissue.
- Direct introduction of tachyzoites (or infected cells) into the bloodstream, or direct contact with the eye.

In most cases human infection is readily controlled by the cellular immune response and remains asymptomatic (approximately one-third of all British become infected at some point in their life without ever realizing it, usually from cat litter boxes, gardening, or eating rare meat). Individuals unable to mount an effective immune response are potentially at risk, however. This includes:

- Pregnant women - while not themselves unusually prone to Toxoplasma infection or clinical disease, parasite invasion across the placenta can result in severe neurological abnormalities in the fetus; congenital toxoplasmosis as a cause of birth defects.
- Individuals infected with the Human Immunodeficiency Virus (HIV; the AIDS virus). Toxoplasmic encephalitis (in most cases a reemergence of latent bradyzoite cysts rather than a new infection) is a leading cause of death in AIDS patients.
- Other individuals who are immunosuppressed, either through infection of the immune system, or by treatment with immunosuppressive drugs for cancer chemotherapy, treatment of allergic disorders, organ transplant, etc

**Evaluation of foreseeable effects**

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material in contact with Toxoplasma tachyzoites, as well as Toxoplasma bradyzoite cysts will be decontaminated (chlorine based disinfectant or by autoclaving) after use. Chlorine based disinfectant or autoclaving destroys the parasite’s infectious potential

Date Project Ceased: 02/03/2022
Embryonic stem cells (ESC) are established from preimplantation embryos and have the unique potential to self-renew indefinitely and to generate all of the differentiated cell types that compromise the embryo (mesoderm, endoderm and ectoderm cells). The ability to maintain ESC in vitro offers a tremendous opportunity to study the molecular mechanisms of mammalian lineage specification and provides exciting clinical potential including the establishment of novel in vitro models for drug discovery and sources of cells for regenerative medicine. Moreover, the recent description of a method to establish induced pluripotent stem (iPS) cells from foetal and adult somatic cells by ectopic expression of a small set of transcription factors represents a breakthrough in the field of ESC research. iPS cell approaches offer the possibility of generating disease specific cells to model and ultimately treat diseases such as Alzheimer's disease, Parkinson's disease and diabetes. Moreover, fundamental questions regarding the plasticity of cell identity can be addressed by reprogramming, transdifferentiating and directing the differentiation of cells via gene overexpression or downregulation to manipulate cell fate.

Our objective is to understand the molecular mechanisms that regulate early embryonic cell fate specification and to generate functional cells to model and facilitate the treatment of human diseases. Towards this goal, we plan to work with human and mouse iPS, ES and extraembryonic cells to identify shared and divergent mechanisms that drive lineage specification in these species. These fundamental insights would facilitate the generation of therapeutically relevant cell types such as cardiomyocytes, neurons, pancreatic cells, haematopoietic stem cells, etc. We plan to use highly efficient vectors (including recombinant viral vectors derived from gamma-retroviruses, lentiviruses and adenoviruses) to genetically modify numerous human and mouse cell types towards the following specific aims:

- **PROJECT 1. Factors controlling cell fate specification of pluripotent stem cells**
- **PROJECT 2. Transcription factor mediated reprogramming of somatic and embryonic stem cells**
- **PROJECT 3. Gene targeting in human embryonic stem cell**

### Recipient or parental organism

- **E. coli, K12 derived strains** - disabled
- **Mammalian cells (primary cells and cell lines)** - disabled
  - Human, murine embryonic stem cell lines (H9, H2, H7, HuES3, HuES9, HuES12, …)
  - Human, murine induced pluripotent stem cell lines (produced by the lab)
  - Human murine primary cells (embryonic and adult skin fibroblasts, keratinocytes, peripheral blood cells, …)
  - Human, murine somatic cell lines (HEK-293T, HCT-116, …)

### Host/vector system

- **Gamma oncoretroviruses** - MuLV derived, replication defective
- **Lentiviruses** - HIV-1 derived, replication defective
- **Adenoviruses** - Ad5 derived, replication defective
- **Sendai viruses (SeV)** - Paramyxoviridae-neuraminidase (HN) and M genes inhibiting the formation of non-transmissible virus-like particles (NTVLP)
- **pUC derived plasmids** (pWPT, pR8.2, pMD2.G, …) - non-mobilisable, carrying insert and recombinant viral genome

### Origin & function
Type of inserts:
1. Human, murine, xenopus cDNA (x - TAG sequences) coding for transcription factors, signal transducers, growth factors and surface receptors.
2. shRNA and miRNA sequences against cell endogenous coding sequences
3. Reporter genes (GFP, RFP, LacZ, Luciferase, possibly fused to cDNA (type 1 inserts),…)
4. Selection genes (Neomycin, Puromycin, Hygromycin,..)
5. Functional non-coding sequences (promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral origin)
6. Neutral non-coding sequences (introns, isolated exons)

- cDNAs (Type 1 inserts) will code for transcription factors, signal transducers, growth factors and receptors that function in pluripotency and lineage specification. shRNAs (Type2 inserts) will produce non-coding RNA sequences targeting endogenous mRNAs. Expression of both insert types may enhance/block commitment and differentiation of pluripotent stem cells (PSCs towards one of the three primary germ layers and further differentiated cell types.
- Reporter genes (Type 3 inserts) will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect.
- Selection genes (Type 4 inserts) will produce enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no deleterious biological effect.
- Functional non-coding sequences (Type 5 inserts) will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) in viral expression cassettes to control transgene expression.
- Neutral non-coding sequences (Type 6 inserts) will be used to facilitate homologous recombination at defined genomic loci (intronic/exonic genome sequences). They are thought to have no deleterious biological effect

Evaluation of foreseeable effects:
TYPE1, cDNA
Type1 inserts will code for transcription factors, signal transducers, growth factors and receptors that are expected to play a role in pluripotency, lineage specification and differentiation from pluripotent stem cells (OSCs). It is difficult to predict in vivo consequences of ectopic expression of these genes on human health. However, since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. Moreover, several of these genes are involved in oncogenic processes and uncontrolled expression could subsequently initiate tumor transformation. However, malignancy is a complex multistep process that involves multiple genomic alterations and a single hit is unlikely to alone trigger the oncogenic process. Experiments involving co-transduction or even co-expression by the same vector of several inserts should consequently be considered a higher risk for personnel. Notably, reprogramming experiments of somatic cells via co-transduction with OCT4, SOX2, MYC and KLF4 could imply a specific risk since accidental genetic modification could theoretically lead to teratoma formation.

TYPE2, shRNA/miRNA
Type2 inserts will produce non-coding RNA sequences able to inhibit expression from the group of genes mentioned as Type1 insert. As for Type 1 insert, it is difficult to predict in vivo consequences of ectopic expression of these sequences on human health. However, since they target key regulators of cell identity, their expression could lead to pathological modifications of cell phenotype/function. Notably, several miRNAs have been implicated in oncogenic processes.

TYPE3, reporter gene
Type3 inserts will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells except acute toxicity at a very high concentration.

TYPE4, selection gene
Type4 inserts will code for enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no pathological effect on expressing cells except acute toxicity at a very high concentration.

TYPE5, functional non-coding sequence
Type5 inserts will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers
TYPE6, neutral non-coding sequence
Type6 inserts do not have any foreseeable deleterious biological effect. They will be used for gene targeting projects to promote homologous recombination at defined genomic loci.

Evaluation of foreseeable effects of the Viral Vectors:

GAMMA-RV: amphotropically packaged MuLV derived Gamma-Retroviruses
Gamma-retroviruses stably integrate into the host cell genome. This property is associated with a risk of insertional mutagenesis, i.e. ectopic activation/inhibition of host gene expression after localized provirus integration. For example, development of leukemia was reported in 4 patients where hematopoietic progenitor cells were transduced by MLV vectors encoding the γc-IL2R chain in the context of SCID-X1 gene therapy. Moreover, the genes were used to generate gamma-RV vectors are functional in pluripotency and represent an additional oncogenic risk. Recombinant particles will be VSV-G packaging alters the tropism of the retroviral particles, requiring interaction only with phospholipids present in the plasma membrane of all cells rather than interaction with a cognate receptor as occurs with ecotropic packaging, thus, VSV-G pseudo-typed gamma-retroviruses acquire the ability to efficiently infect human cells. Moreover, VSV-G pseudo-typing improves stability of the viral particle and may represent an aerosol means of transmission in addition to percutaneous risk.

The above risks will be tempered by the fact we will use replication defective gamm-RV unable to propagate further after transduction. In addition, in the event of an accidental contamination (percutaneous, aerial), the amount of viral vectors available to effectively contaminate personnel will be smaller and transduction much less efficient compared to in vitro transduction protocols used on cultured cells. Notably, VSV-G pseudotyping results in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. Moreover, gamma-RV vectors are only efficient in transducing proliferating cells that limits the number of potential accidental targets. Together these considerations suggest that only very few cells may be effectively transduced through accidental contamination. Moreover, malignancy is a complex multistep process that involves multiple genomic alterations. It is thus unlikely that any single hit corresponding to an accidental infection would initiate transformation. Notably, our protocol will involve co-transduction of several inserts that are coded by separate vectors, making accidental multiple infection of the same human cell unlikely. Finally, cells exposed to non-percutaneous accidental infection (stratum corneum, respiratory epithelium) are terminally differentiated cells with limited lifespan and high turnover, which greatly limits the risk of effective tumoral transformation.

Adenovirai: Ad5 derived Adenoviruses
Replication competent virus (RCV) could be generated by recombination with the E1A sequences in the complementing cell line (293A) or another virus. However, all inserts will be integrated into the site of disablement (E1A deletion) and any recombination would result in the loss of the inserts. Adenoviral vector infection is of short duration and integration events leading to long-term transgene expression extremely rare. However risk associated with transient expression should be considered. However, our protocol will involve co-transduction of the inserts encompassed by separate vectors, making accidental multiple infection of the same human cell unlikely as well as concomitant reprogramming. In addition, cells exposed to non-percutaneous accidental infection (stratum corneum, respiratory epithelium are terminally differentiated cells with limited lifespan and high turnover, which greatly limits the risk of effective tumoral transformation. Strict adherence to Class2 containment and safety measures (see appendixD) will be undertaken to minimize the risk of infection (percutaneous, aerosol) during handling of high titer adenoviral vectors. However, the adenoviral vector purification procedure will involve collection of CsCl gradient purified vectors by plastic tube punctured with a needle. This procedure will be assigned the higher risk and will be performed by experienced personnel only. Alternatively, filter based methods may be used to reduce risk.

SENDAI: ΔF temperature sensitive Sendai virus derived vectors
Sendai virus does not stably integrate into the host cell genome thereby avoiding the risk of insertion mutagenesis commonly associated with retroviral vectors. However, Sendai virus can infect cells including human cells very efficiently and the vector is self-replicative in the cytoplasm of transduced cells. Moreover, proteins encoded by
DeltaF/TS-SeV used for this project are functional in pluripotency and represent oncogenic risk. However these risks will be tempered by using all the necessary aerosol containment and also by using infection defective DeltaF/TS-SeV unable to propagate further after transduction and with limited capacity for cytoplasmic replication. In addition, in the likelihood of an accidental contamination (percutaneous, ariel), the amount of viral vectors able to effectively contaminate personnel will be smaller and transduction much less efficient compared to in vitro transduction protocols used on cultured cells. Notably, DeltaF/TS-SeV express viral proteins (including HN on the cell surface) increases the likelihood of immunological neutralisation in human hosts. Additionally as the virus life cycle is cytoplasmic and of short duration, transgene expression will be transient in nature. Moreover, malignancy is a complex multistep process that involves multiple genomic alterations. It is thus unlikely that any single hit corresponding to an accidental infection would initiate transformation. Finally, cells exposed to non-percutaneous accidental infection (stratum corneum, respiratory epithelium) are terminally differentiated cells with limited lifespan and high turnover, which greatly limits the risk of effective tumoral transformation.

Environment considerations
VSV-G pseudotyping of recombinant gamma-RV particles would enable vectors to infect a variety of animal cell types including those of different animal species. Moreover, environmental stability tends to be increased by VSV-G pseudotyping compared to gamma-RV encompassing the native envelope. However, recombinant gamma-RV will be replication defective and cannot produce progeny viruses able to spread.

Adenoviruses are generally species specific. Indeed, serotype 5 Adenoviruses infect humans and are not known to infect other animals. Therefore, the risk of accidental infection of other organisms is very low. Because recombinant adenoviruses will be replication incompetent, they could not spread. The native Sendai virus is a known pathogen for rodents and occasionally pigs and the common route of infection is aerial and lung airway epithelium. DeltaF/TS-SeV may be able to infect a variety of animal cell types including those of different animal species. However, DeltaF/TS-SeV will be F protein defective and temperature sensitive and thus could not produce progeny viruses able to spread. Nevertheless, a risk of mobilization of recombinant vectors by native sendai virus infection may remain (notably, latent enzootic infections has been detected in laboratory mouse strains), All precautions will be taken to avoid DeltaF/TS-SeV vectors to enter animal facilities. It is very unlikely that vector genomes would be propagated significantly in natural rodent populations hosting wild type Sendai virus.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

During the production and concentration of recombinant lentiviral particles and viral transduction of cells, CL2 conditions will be strictly adhered to. Experimental work involving direct virus handling (production, transduction) will be carried out by trained personnel only. If culture supernatants are demonstrated virus free (gamma-RV; serial eventually removed from CL2 containment to carry on further work in CL1 containment rooms following good laboratory practises, using class ll microbiological safety cabinet for opened handling of cells and autoclaving/disinfection of GM discarded cells at the end of the process.

**Human Health**

- All gamma-RV (i.e. Vectalys), lentiviral (produced by the lab) and adenoviral (i.e. Hybrid systems) batches will be tested for absence of replication competent particles.
- Standard measures (absence of sharps, needles) and good laboratory practises will be undertaken to decrease the likelihood of percutaneous infection (virtually to zero)
- All work involving opened viral containers (handling of virus batches, cell cultures, contaminated tips, waste bottles will be performed within a class ll microbiological safety cabinet to decrease the likelihood of aerolised transmission of recombinant viral particles.
- All work including waste disposal will be carried out under the relevant Code of Practice (COP).

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- None required

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- All work including waste disposal and inactivation measures will be carried out under the relevant Code of Practice (COP), attached

**Is an emergency plan required according to regulation 20?**

- N

**If yes, tick to confirm that it is attached to this form**

- N
The Biological Safety Committee have approved this project for work at Containment level 2. (see attached comments)

### Purposes of the contained use

1. We will investigate the functional consequences gamma interferon induced p65GTPases have on the host defence to intracellular pathogens (Salmonella typhimurium and Shigella flexneri).
2. We will identify novel players that tune the recognition of intracellular pathogens and thereby influence the resulting immune response (Salmonella typhimurium).

### Recipient or parental organism

**Salmonella typhimurium and Shigella flexneri**

Wild-type Salmonella Typhimurium causes gastroenteritis and can cause septicemia in humans. Species of the genus Shigella are the cause of shigellosis, a diarrhoeal disease that is endemic in developing countries. The major site of Shigella pathology is the colon, where bacteria invade the intestinal mucosa, spread to the adjacent epithelial cells and cause much tissue damage, fluid secretion and inflammation.

None of the bacterial strains we will use present an increase in hazard to humans compared to the initial parent strains.

### Host/vector system

All bacterial strains used in this study are published and common laboratory strains.

### Origin & function

We will obtain the bacterial strains from collaborators (DH and SM, Imperial College).

1. We want to probe if host p65 GTPases influence the propagation of these bacteria in mouse and human tissue culture cells. We will infect mouse or human cells with these bacterial pathogens and analyse the fate of the bacteria by measuring their growth and checking for host immune consequences by standard cell biological and biochemical assays (immunoblots, immunofluorescent microscopy) (Salmonella typhimurium and Shigella flexneri).
2. We want to study what consequences inflammasome recognition has on the resulting long-term immune response and if novel cytokine molecules fine-tune this response. We will infect mice or cells with bacterial pathogens and study the production of these cytokines. We will investigate which molecules on which cells sense these cytokines and how that fine-tunes the specific immune response to these pathogens. This work will be done in vitro in murine cells as well as in vivo mouse models.

### Evaluation of foreseeable effects

Both Salmonella typhimurium and Shigella flexneri cause disease in humans by ingestion only. Common laboratory practices prevent accidental ingestion of laboratory material including these bacterial pathogens.

In the extremely rare case that accidental ingestion should occur, for both Salmonella and Shigella common medical advice can be sought. For both Salmonella and Shigella in the case of infection treatment consists of fluid replacement therapy combined with the potential administration of antibiotics. None of the laboratory strains used in this work will cause more severe human disease than the wild-type strains.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All material in contact with Salmonella and Shigella will be decontaminated by bleach or autoclave. Both methods destroy the infectious potential of the pathogens.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All material in contact with Salmonella and Shigella will be decontaminated according to the relevant Code of Practice attached.
There was a meeting of the Biological Safety Committee to discuss this project. The Committee approved the project for work at Class 2.

**Project Ref** 542/14.2

- **Date Ackn’d**: 29/04/2014
- **CU2 Project Title**: Reverse genetics of the novel zoonotic avian influenza A/H10N8 virus to examine the properties of the haemagglutinin and neuraminidase genes
- **Consent Granted**: Yes
- **Project notified under transitional arrangements**: No

**Historical Significant Changes**

- **Historical Date of Additional Info**: 29/04/2014
- **Significant Change ID**
- **Date of Significant Change**
**Project Additional Information**

**Purposes of the contained use**

The aim is to investigate the balance between the receptor binding properties of the HA and NA glycoproteins of the H1N9 virus and the receptor destroying (sialidase) activity of the NA. The ability of the virus to bind to both human and avian sialic acid receptor analogues has shown that two patterns of binding emerge. One that is typically avain and one that has increased binding to the human receptor. Moreover, based on sequence signatures of the H10N8 NA, it is likely that the NA plays a role in the binding of virus to receptor. We need to assess the contribution of both the HA and the NA to the virus binding activity. To do this it is proposed to produce a virus in which the ability of the NA to bind sialic acid has been modified or removed. Binding of receptor through the NA glycoprotein affects the balance between the virus haemagglutinin (HA), the primary receptor binding protein, and the NA, with sialidase (receptor destroying enzyme) with additional receptor binding activity. If the NA mediates significant binding of virus to the receptor then the analysis of the antigenic properties of the virus can be compromised. Antigenic analysis of the virus is key to the development of effective vaccines against influenza.

Our purpose is to examine the ability of genetically modified virus to interact with virus receptor analogues in biophysical studies, to examine how these affect the ability of virus to infect cells in culture, to examine the antigenic properties of the modified viruses in in vitro studies and to examine the antibody response in ferrets of the modified viruses.

**Recipient or parental organism**

The genetic background into which the novel H10 HA and N8 NA genes are used to be inserted is one of two well-characterised influenza viruses, A/PR/8/34 or A/WSN/33. These are the usual background into which influenza reverse genetics is carried out.

**Host/vector system**

The reverse genetic viruses will be propagated in tissue culture and/or in ovo.

**Origin & function**

The genes from the zoonotic H10N8 virus that will be inserted into one of the above genetic backgrounds are those of the haemagglutinin (HA) and the neuraminidase (NA).

The HA is responsible for binding of the virus to the cell and the fusion of the virus to the cell membrane to enable the virus nucleic acid to enter the cell and replicate.

The NA is responsible for the release of progeny virus from the infected cell and is the target for the new anti-neuraminidase antiviral drugs. The NA gene of the zoonotic H10N8 virus is expected not only to cleave sialic acids from glycoconjugates but also to bind sialylated glycoconjugates.

**Evaluation of foreseeable effects**

The novel H10N8 virus in China is a low pathogenicity avian influenza virus that has emerged as a zoonotic infection in two cases in China, one was fatal but the patient had several co-morbidities. Alteration of the virus through reverse genetics is likely to influence its ability to infect humans and spread between humans.

The genetic background can reduce the virulence of wild-type viruses. The PR8 background is known to attenuate many viruses and, for example, reduces the levels of virus replication of reverse genetics-derived novel H7N9 viruses in the respiratory tract of ferrets (personal communication) and is less virulent in ferrets causes far fewer disease signs; the ferret is the optimal animal model for human influenza. However, changing of the balance between the receptor binding activities of the HA and the NA might promote infection and transmission.

It is unlikely that changes will affect its pathogenicity for poultry or wild birds, there is no plan to introduce nucleotides that encode a poly-basic cleavage site of the HA into the HA gene which is associated with highly pathogenic influenza viruses of H7 or H5 viruses. No other sub-types have been associated with 'typical' highly pathogenic...
avian influenza viruses.

The GMO as a replication competent influenza virus is able to reassort in mixed infections and it is not possible to predict the behaviour of the resultant progeny. To ensure that any such risk is minimised, no other influenza viruses will be handled in the same microbiological safety cabinet at the same time as the virus is being propagated, or during its use. In addition, anyone with influenza-like symptoms will be excluded from using the virus. As an additional precaution against a mixed infection, all workers will be offered seasonal influenza vaccination. In addition, in the event of accidental exposure anti-viral drugs will be available.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Management  and Containment of virus.

All this work is to be carried out under Containment 3 conditions to contain virus and prevent exposure of the worker. Further all work is carried out in accordance with the manual the Management of the Containment 4 Facility at the National Institute for Medical Research.

Infection of cells with Listeria monocytogenes to study both the cell biology of infection as well as the immune response.

**Project Additional Information**

**Purposes of the contained use**
Modification of Listeria monocytogenes to introduce the green fluorescent protein GFP.

**Recipient or parental organism**
Listeria monocytogenes is a Gram positive bacterium that causes disease in mice and humans generally when administered in high doses (about 10^6 bacteria) orally. The organism can be pathogenic for pregnant or immunosuppressed individuals. In sublethal infections of mice the bacterium is cleared by innate and specific immune responses and the animal retains long-term immunity.

**Host/vector system**
The green fluorescent protein is introduced in a chromosomally integrated pAD vector.

GFP is non hazardous for humans or animals and will not alter the pathogenicity of the host.

**Origin & function**
The sequence for the green fluorescent protein (GFP) is introduced into Listeria. This allows visualisation of Listeria by immunofluorescence.

**Evaluation of foreseeable effects**
No effects beyond the effects of Listeria parent organism are expected.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Containment and control measures as detailed in the Containment 2 code of practice will be applied see attached.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Retroviral replication requires stable insertion of the viral genetic material into cellular genome. The catalytic events associated with this process are carried out by the virus-derived enzyme integrase (IN). A multimer of IN assembles on viral DNA ends forming a stable nucleoprotein complex known as the intasome (reviewed in ref. 1). Over the past 10 years, we determined a range of crystal and cryo-EM structures that illustrated the basic mechanism of the retroviral integration process. Unfavorable biochemical properties of HIV-1 IN necessitate the use of hyperactive and/or solubilizing mutations, which, by their nature, dramatically change the properties of the protein. Therefore, most of our studies focused on IN from Prototype Foamy Virus (PFV, a member of the Spumavirus genus), which is soluble and active in vitro. Unfortunately, PFV IN is highly divergent from its counterpart from the human lentivirus HIV-1. Recently, we discovered that the IN from the Maedi-Visna Virus (MVV), an ovine lentivirus, readily assembles into functional intasomes in vitro (2). Because MVV belongs to the same genus as HIV, it serves an excellent model for the human pathogen. Based on our structures, we designed a series of MVV IN mutants, the functionalities of which will need to be characterized in the context of viral infection. We are planning to do these experiments using a single-cycle MVV vector system.

Given that MVV is not known to be infectious to humans, and that the vector system is highly disabled, with vector particles requiring transfection with 4 separate vectors (expressing VSV-G envelope, GFP reporter, GAG-POL, and Rev) the planned experiments will pose no significant risk to personnel or to environment. Two types of experiments are envisaged: 1) Experiments with modified MVV vector particles. We will introduce a range of point mutations into the IN coding region (present within the packaging construct) and compare abilities of the resultant viruses to transduce human HEK293T, HeLa or sheep CPT-Tert cells. The packaging constructs are used to produce structural and enzymatic components of the viral particles, but their genetic material, plasmid DNA itself or RNA transcripts are not incorporated into viral particles, which makes this type of experiment inherently safe. 2) Experiments with modified human cells. We will knock-down expression of a range of cellular genes using short interfering RNA (siRNA) or short-hairpin RNA (shRNA) constructs, to test their potential importance for retroviral integration. In the first instance we are planning to knock-down PSIP1 and CPSF6 genes. Upon knock-down, cells will be subjected to infection with GFP MVV vectors. Following FACS analysis or antibiotic selection cells will be either discarded or processed for isolation of genomic DNA. References: 1. Lesbats, P., Engelman, A.N. and Cherepanov, P. (2016) Retroviral DNA Integration. Chem Rev, 116, 12730-12757. 2. (2017) A supramolecular assembly mediates lentiviral DNA integration. Science, 355, 93-95.

Recipient or parental organism

Human HEK293T, HeLa or sheep CPT-Tert cells

Host/vector system

We are planning to produce MVV vector particles by transfection of HEK293T cells with 4 constructs (maps of the plasmids are attached to this document):

1) pMD2.G, a VSV-G envelope glycoprotein expressing plasmid
2) MVV Gag-Pol expression vector (and its mutant forms carrying point mutations within the IN coding region)
3) GFP transgene construct (self-inactivating [SIN] and full-length LTR versions) with CMV-GFP-WPRE expression cassette
4) Visna Rev expression plasmid.
Retrovirus derived enzyme integrase (IN).
Green Flourescent protein. This is non hazardous fro humans or animals and will not alter the pathegenicity of the host.

Evaluation of foreseeable effects

MVV vector particles should be considered most hazardous GMM produced in this project. The risk to human health from the use of any lentiviral vectors is gauged to be low and is primarily a risk only to the researchers involved in the work. The ability of the pseudotyped virus to transduce both dividing and non-dividing primary human cells does mean there is a potential risk of gene disruption by insertional mutagenesis if exposure was to occur. However, following any such accidental exposure, it is not likely that any incidental reduction in the expression of a single tumour suppressor will be deleterious to the afflicted cell. It has been experimentally established that multiple genetic alterations (between 4 and 6) are required to obtain neoplastic transformation, and there are cell intrinsic safeguard mechanisms that impede the accumulation of such alterations. Moreover, the risk of actual exposure is low as (a) lentiviruses require close contact or percutaneous inoculation for their transmission; (b) their survival in the general environment is poor as they cannot readily survive outside of closed controlled cell culture conditions and they are rapidly inactivated by dehydration or other environmental insult.

The cell lines used in these experiments are extremely sensitive to environmental conditions such as temperature, gas atmosphere, desiccation, pH, extensive light exposure, substratum, and medium composition. Therefore, the cell lines to be used are not expected to survive outside the culture dish and incubator. Therefore, it is considered that these micro-organisms pose no significant hazard to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management will be in line with the measure outlined in the institutes' containment level 2 code of practice (see attached)

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

Comments from committee meeting 30 May 2017

- Good scientific review
- Clarification required whether SIN or not
- Add plasmid map – a description of the organism
- Final assignment of containment measures and risk class – explain that once infected cell has gone through 3 passages - CL1

Project Containment
Understanding the host-pathogen interaction of Cryptosporidium, a protozoan parasite that causes diarrheal disease

The aim of this project is to investigate the host-pathogen interactions of the protozoan parasite Cryptosporidium, which is a major cause of diarrheal disease in humans and other animals. These parasite strains will be used to answer fundamental questions regarding infection, including: How does the immune system recognize and respond to a crypto infection? How does the parasite evade immune detection and cause disease?

All strains were derived from wild-type Cryptosporidium parvum and Cryptosporidium tyszzeri strains and the following genetic modifications have been made using Cas9 driven homologous recombination:

- expression of the fluorescent proteins mCherry, mNeon, tdTomato, and mScarlet
- expression of the luminescent proteins nanoluciferase and luciferase
- expression of the CRE recombinase protein (to enable genetic recombination)
In order to select for transgenic parasites, the neomycin resistance gene has been also been inserted into the parasite genome of all strains.

At the Francis Crick Institute, my research group will work with the above strains, and new transgenic strains that we develop as the project proceeds, including:
- lines with HA epitope tags on the C- and N-termini of proteins
- lines where genes have been removed or knocked out
- lines where Cas9 has been inserted into the genome (to increase gene editing efficiency)
- lines with proteins fused to affinity-purification tags (e.g. SNAP-tag technology from NEB)

### Recipient or parental organism
Cryptosporidium parvum and Cryptosporidium tyzzeri strains.

### Host/vector system
Cryptosporidium parvum and Cryptosporidium tyzzeri strains.

### Origin & function
All strains were derived from wild-type Cryptosporidium parvum and Cryptosporidium tyzzeri strains.

### Evaluation of foreseeable effects
Cryptosporidium parvum is infectious to humans and causes moderate to severe diarrheal disease. There is a drug available for treatment, nitazoxanide, which has good efficacy with the exception of patients that are severely immunocompromised.

Cryptosporidium tyzzeri is infectious to rodents and is commonly found in mice across the world. There is one reported case of zoonotic human infection, but the methods and conclusions from this report are highly dubious Rašková JCM 55(1) 2013:360-362.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management will be in line with the measure outlined in the institutes' containment level 2 code of practice (see attached)

| Is an emergency plan required according to regulation 20? | N |
| If yes, tick to confirm that it is attached to this form | N |
| Tick to confirm that you have attached a risk assessment to this form | Y |
| Tick if you are claiming exemption from disclosure for section of the risk assessment | N |
As far as I can tell there is nothing of concern in the proposal. But what must be got right are development of codes of practice to protect the investigators.

**Project Additional Information**

**Purposes of the contained use**

To use Sindbis virus packaged in mammalian cells to carry out directed evolution of proteins of interest in mammalian cells (primarily the baby hamster kidney cell line BHK21) using a protocol called VEGAS. We want to use the Sindbis virus because of its poor replication fidelity—each time the virus replicates, it introduces mutations to its genome at a high rate. This allows us to generate a large number of different variations of our gene of interest. In our first experiments, we will be evolving a bacterial protein—Cas13d. However, future work may use other CRISPR proteins, or other RNA binding proteins.
Different variations of the Sindbis virus will naturally be created as the Sindbis virus mutates. These Sindbis viruses will also carry our transgene, along with any mutations that it has accrued.

**Recipient or parental organism**

Mammalian cell lines, primarily baby hamster kidney cells

**Host/vector system**

Replication incompetent Sindbis virus

3 plasmids from addgene will be used to produce replication incompetent virus.

- **pTSin EGFP plasmid** contains the entire replication competent Sindbis genome with the structural genome components replaced by Enhanced Green Fluorescent Protein (EGFP) in an MCS locus.
- **pSin Helper plasmid** contains the Sindbis glycoprotein genes and can be converted to mRNA for initiating Sindbis virus packaging.
- **pSin Capsid plasmid** contains the Sindbis capsid gene and can be converted to mRNA for initiating Sindbis virus packaging.

**Origin & function**

Infection with Sindbis virus causes a rash-arthritis syndrome with symptoms including fever, rash, headache and joint pain. The disease is a self-limiting febrile illness that resolves in 1-2 weeks. Relatively little is known about the pathogenesis of this virus. However, the pathogenesis of other related alphaviruses is well understood and disease manifestations are thought to result from a combination of direct cellular damage caused by virus replication and indirect immunemediated damage in the target tissues. After inoculation via mosquito bite, alphaviruses spread through the circulation to liver, spleen, muscle, lymph nodes and connective tissues around bones and joints. The viral replication is followed by an inflammatory response characterized by infiltration of lymphocytes, Natural Killer (NK) cells, neutrophils and, especially, macrophages to the target tissues.

Use of a fourth plasmid pSRE-SSG plasmid which expresses the Sindbis Structural Genome (SSG) via the serum response element (SRE) promoter, is required to create replication competent virions. This plasmid will not be used and thus only replication incompetent virus will be produced in these experiments.

Thus we will be producing viral stocks that are infectious, but they are incapable of productive infection outside of our specific cell lines due to the viruses not containing the structural part of their genome.

The Cas13d transgene they carry will be inert in a mammalian system as mammalian cells do not express the necessary guide RNAs to make the Cas13d active. The Sindbis virus will not come in to contact with bacterial cells, which may express the relevant guide RNA.

Furthermore, as this is an arthropod borne virus, the natural carrier of the virus (Culex spp. mosquitoes) will not come in contact with the virus. We will not perform procedures using sharps, and so there is an extremely low risk of transmission for the virus.

**Evaluation of foreseeable effects**

Please enter comments on the GM safety committee on the risk assessment
Comment 1
I have read the proposal as the virus will not be replicative competent based on packaging on different plasmids, I think the use of cat 2 lab for the production is a good idea (but in reality, might not be necessary).

Comment 2
If they naturally create different variations of the virus could they potentially produce a variant that does replicate in wild type cells. If so do they have a way to test this to be sure this isn’t going to happen?

Response
Regarding the potential for viruses to gain replication competency: this an extremely low risk scenario. The structural genome is separated from the Sinbis particles that we produce and the Sinbis virus does not have the machinery necessary to incorporate the structural genome back in to its own genome. We don't think there is even such machinery in existence. So the virus would have to mutate in such a way that the whole structural genome is re-evolved de novo - something that would take an obscene amount of time even if it were possible to happen.

Comment 3
The project briefly mentions that one of the plasmids they intend to use expresses GFP. My guess is that fluorescence will be used as a marker to identify transfected cells, but there is no explicit description of how fluorescence will be used experimentally. It does not appear that they will do any microscopy. Will they use the GFP to sort cells?

Response
Regarding the GFP viruses: these virus will be the first virus we produce, but we'll quickly stop producing them once we're confident that we are able to produce the Sindbis virus efficiently. We have no intention of sorting these cells, so flow cytometry STP don't need to be involved. We will use basic microscopy to identify GFP+ cells in our CL2 room. Future viruses will not encode GFP, but dCas13d.

Comment 4
I believe the proposal is sound as is the work proposed. As far as I can tell, I think the authors have rightfully described potential issues and measures to avoid that. I think CL2 is the correct level of containment based on the proposed work. I do not have anything else to add at this stage.

Comment 5
The work described is outside my area of expertise however, as it’s a new methodology and involving a viral system which is introducing a high rate of mutation, I would err on the side of caution-and ensure all work is done in cat 2 with a high degree of monitoring.

Comment 6
I thought this was a well written, comprehensive proposal. I have no problem with this being assigned to CL2.

Comment 7
They specify there are no problems for individuals with eczema in working with this. If someone has broken skin and the virus becomes modified is there no risk? Have they specified users will wear gloves when working in CL2 (I know they should be but maybe they should note broken skin should be covered?).

Response
Regarding eczema/broken skin: we will certainly be using lab coats and gloves as required by CL2 procedures. We will not be using sharps in any of the procedures, so it is unlikely that there would be an incident in which skin is broken. However, all skin will be adequately covered by the appropriate PPE.
We want to understand the lifecycle of SARS-CoV-2, the causative agent of COVID-19. While a novel pathogen that must be handled under high levels of biological containment, VLP assays will allow biological understanding of SARS-CoV-2 entry and release without requiring handling of infectious replication competent virus.

SARS-CoV-2 is a large (29kB), positive sense, single stranded RNA virus. Its genome encodes 29 separate proteins from 14 separate open reading frames (ORFs). A major 5' ORF encodes polyproteins that are predicted to be proteolytically processed into 16 non-structural proteins that assemble to form an enzymatic replicase/transcripase complex (e.g., Proteases (Nsp3 and Nsp5), primases (Nsp7 and Nsp8), RNA-dependent RNA polymerase (Nsp12), helicase (Nsp13), exoribonuclease (Nsp14), endonuclease (Nsp15)). Subgenomic RNAs at the 3' end of the genome encode 4 structural proteins (Spike (S), Membrane (M), Envelope (E) and Nucleocapsid (NC)) and 9 accessory factors (Gordon, et al., 2020). The capsid formed by NC possesses the ability to package the RNA-genome. Like SARS-CoV, SARS-CoV-2 enters human cells through binding the plasma membrane receptor Angiotensin Converting Enzyme (ACE)-2.

Study of the cell biology of other pathogenic viruses have been significantly derisked by using VLP, rather than viral or pro-viral, assays. E.g., VLP systems have allowed...
work on HIV and Ebola under BSL-2 conditions (Hoenen et al., 2014; Burgt et al., 2013; Watanebe et al., 2003). Because of this safety enhancement, VLPs have also been utilised in human vaccine studies for diseases spanning influenza to HIV (e.g., Fuenmayor et al., 2017; Lopez-Macias et al., 2011; Doan et al., 2005; Tacket et al., 2003). In VLP assays, structural components of the virus are expressed in-trans from individual mammalian expression vectors, rather than from live virus or a provirus (a cDNA copy of the full length viral genome). Typically, these structural proteins assemble within cells and are released as particles. Inclusion of the viral envelope proteins (in this case, S, M and E) allows the released particles to enter target cells, but because no viral genome is packaged and no enzymatic proteins are included, these particles can neither mount a productive infection, nor replicate the target cells. VLP assays have been described for SARS-CoV, where by S, E, M and NC proteins are expressed in mammalian cells, and particles can be harvested from the supernatant (Tseng et al., 2014; Hsieh et al., 2005). Given the extensive similarity between SARS-CoV and SARS-CoV-2, (S, 76% identical (95% identical in transmembrane and cytosolic region); M, 91% identical; E, 95% identical; NC, 91% identical), VLP assays likely represent a viable experimental strategy to study SARS-CoV-2 biology. Despite this enhancement in safety, we must be minded that VLPs have the potential to trigger an immune response and as this is a novel virus we don’t know the immunological consequences of exposure to the viral structural proteins.

Gordon et al., (2020) bioRxiv, DOI: https://doi.org/10.1101/2020.03.22.002386

Recipient or parental organism

Plasmids for the VLP system will be transfected into mammalian cells (e.g., Hek293, CaCo-2 and Vero, and their derivatives). The combination of 4 different stable plasmids supplying viral structural proteins, with no regions of homology to prevent undesirable recombination, no genome or viral RNA sequences and no enzymatic
genesynthesis and cloned using standard molecular techniques into individual mammalian expression vectors (e.g., pCR3.1 and derivatives). To enable single-round infectivity assays to be performed, a 580 bp packing sequence from SARS-CoV (Hsieh et al., 2005) or the analogous sequence from SARS-CoV-2 will be inserted into the 3' UTR of a 5th mammalian expression vector encoding GFP (e.g., pEGFP-N1) or a similar reporter (e.g., luciferase, pOL3) to allow VLP-mediated transduction of target cells. Packaged mRNAs from these transcripts will be our surrogates of infection in the target cells and will allow us to discern whether modifications (e.g., co transfection with alternate non-enzymatic proteins, siRNA/CRI/SPR reagents, or host cell overexpression plasmids) result in altered VLP transfer to target cells. In total, we will express approx. 6kB of DNA out of 29kB of viral genome. Separating this into 4 separate mammalian expression plasmids and not including any viral RNA or proviral cDNA will limit the risk of recombination. It may be necessary to additionally transfect a vector encoding a generic viral envelope protein (e.g. VSVG), as is used to pseudotype retro- or lentiviral particles. While ACE-2 is the receptor for this virus very few commonly used cell lines express this protein (https://web.expasy.org/cellosaurus/sars-cov-2.html) and to maximise transfer of VLPs to target cells, we will use VSVG pseudotyping to expand the range of target cells in case necessary target cells are refractory to transduction with SARS-CoV-2 VLPs. To facilitate biological understanding of the other viral gene products, mammalian expression vectors encoding non-enzymatic genes may be co-transfected into producer cells. Importantly, no viral RNA or proviral DNA will be included in these studies.

Example Procedure
Typically, 600,000 293T cells grown in 6-well tissue culture plates will be transfected with 500 ng each of pCR3.1-S, pCR3.1-E, pCR3.1-M and pCR3.1-NC. 48 hrs later, supernatants (approx 2 ml) containing the recombinant VLPs will be harvested, clarified by centrifugation using aerosol-tight lids on centrifuge buckets (300 x g for 2 minutes). These will be opened only within a Class 2 MSC and decontaminated after use. Supernatants will be filtered through a 0.45 micron syringe filter. VLP-containing supernatants will be layered on top of a 20% sucrose cushion and centrifuged in a refrigerated benchtop centrifuge at 20,000 x g for 2 hours. The supernatant will be removed and the pellet will be resuspended in denaturing 2xLDS-sample buffer. Alternatively, VLP containing supernatant will be used to transduce 300,000 target cells grown in 6 well plates in the presence of 0.8 ug/ml polybrene. 48 hours after transduction, viral supernatants will be removed, the monolayer washed in PBS and the cells lysed for assessment of reporter activity. Routes of exposure include inhalation and ingestion. Access to these routes is minimised by proper working practices and by using appropriate PPE. All VLP generating work will be performed under containment level 2 (CL2) conditions in a dedicated viral TC-suite, using a class II microbiological safety cabinet.

Containment level 2 (CL2) is provisionally assigned to this project in order to protect human health. Production of VLPs and their use for infection of target cells will be carried out in a CL2 laboratory with safeguards in place, and a standard operating procedure (SOP) defining the safe handling of biohazardous material, decontamination and waste disposal. It is not thought that coronaviruses are airborne, however they may be transmitted by contact or by procedures generating droplets or aerosols. We assume that the VLP’s transmission routes are similar. CL2 work will be carried out in class II microbiological safety cabinets (MBSC) with personnel wearing protective equipment (gloves, labcoat, and eye protection). Cuts and abrasions will be covered. No material that came in contact with VLPs will leave the MBSC without decontamination. No sharps will be used. Transport, centrifugation and storage will be carried out in closed and sealed and decontaminated containers not to be opened outside of CL2. Procedures that may allow aerosolisation (eg vortexing) will not be permitted. Any spills will be decontaminated using 1% Virkon, a recognised all-purpose antibacterial and antiviral product. Surfaces and instruments will be disinfected using an approved disinfectant as defined by the CL2 SOP. All contaminated disposables will be autoclaved prior to disposal off site. Fixation of transduced cells with 4% PFA or methanol will allow downstream analysis at CL1. Cell lysates will be generated at CL2 using 2xLDS-sample buffer or washed with PBS to remove VLPs and lysed in 1% Tx100 containing luciferase assay buffer (Promega). Liquid waste will be decontaminated using 1% Virkon.

Origin & function
We will express ORFs encoding SARS-CoV-2 S, M, E and NC transcripts. Sequences will be purchased from commercial suppliers or will be obtained by custom genesynthesis and cloned using standard molecular techniques into individual mammalian expression vectors (e.g., pCR3.1 and derivatives). As outlined above, a 580bp
packaging sequence from SARS-CoV (or the analogous region from SARS-CoV-2) will be obtained by genesynthesis and cloned into the 3' UTR of reporter vectors to allow packaging of their transcripts. STR-profiled, mycoplasma free cell lines (described above) will be obtained from Crick Cell-Services STP. These lines will be used as transfection hosts for the above described cDNAs and will generate the VLPs. These cells will also be transduced with VLPs that have packaged the reporter constructs, as outlined above and luciferase activity or GFP transduction will be analysed in these cells after lysis.

Evaluation of foreseeable effects

The most dangerous of the GMM are the SARS-CoV-2 VLP particles since these are capable of infecting human cells. However, there is no risk of viral production or productive infection as genomic components are not transferred and the VLPs will lack 25 of the 29 viral proteins. There is no risk of insertional mutagenesis as the plasmids expressing these genes are standard mammalian expression vectors and unlike retro and lentiviruses, coronaviruses do not replicate by integrating into the genome. The risks identified here relate to the fact that this is a novel emerging pathogenic infection and we don’t yet understand the immunological consequences of exposure to the structural proteins that will present within the VLPs.

Hazards to human health associated with the recipient microorganism (e.g. bacterial host or viral):
Biosafety measures render VLPs single-round infectious and replication incompetent. Given the absence of enzymatic components, there is no risk insertional mutagenesis. The genes inserted in any packaged vector (e.g. luciferase, or GFP) do not encode for toxic or hazardous proteins and only standard reporters with a long history of safe laboratory use will be used. The packaging sequence itself (580nt) is a fragment of Nsp15, an endoribonuclease, and will be placed in a 3' UTR, preventing its translation. The recipient organism (cultured human cell lines) will be cultured under CL2 conditions and so present minimal risk to human health.

Hazards to human health arising directly from the inserted gene product (e.g. cloning of a toxin gene or oncogene):
The genes used in this study are not expected to cause malignant transformation as they are not capable of performing insertional mutagenesis. There is a risk that viral structural proteins transferred by the VLP would be recognised as foreign and could cause an immune response if transferred to humans. As VLPs are replication incompetent, productive infection will not be possible.

Hazards to human health arising directly from the alteration of existing traits (e.g. alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response):
Use of the WT viral envelopes are required for generation of the VLPs. Pseudotyping with the heterologous amphotrophic or ecotrophic viral envelope proteins will allow transduction of a wide range of cell types from many species, including humans, and this will only be used if infection of target cells cannot be achieved with WT VLPs. We do not anticipate pseudotyping will alter the pathogenicity of the VLPs, however, it will increase the tropism. The mode of transmission will be unaltered and while a host-immune response is possible, it is likely to be limited by the lack of productive infection.

Hazards to the environment associated with the recipient microorganism (e.g. bacterial host or viral vector):
The genetically modified mammalian cells are highly unlikely to survive outside the controlled environment of tissue culture and thereby pose no threat to the environment. Due to the replication-incompetence of the VLPs, they do not pose any hazards to the environment.

Hazards to the environment arising directly from the inserted gene product:
The genes to be packaged do not encode for toxic or hazardous products that could affect the environment.

Hazards to the environment arising from the alteration of existing traits (e.g. alteration of pathogenicity, host range or tissue tropism):
None identified

The potential hazards to human health of sequences within the GMM being translated to related microorganisms:
We do not envisage a route by which sequences inserted into the GMO could be translated to related microorganisms and thus do not identify a hazard here.

The potential hazards to the environment of sequences within the GMM being transferred to related microorganisms:
The vectors are not able to transfer genetic material to other microorganisms.
Are any of the work procedures likely to generate aerosols?
No

How will waste materials be disposed of?
Producer and target cells will be inactivated using 1% Virkon. Tissue culture waste will be inactivated using Chemgene. Liquid waste and any spills will be decontaminated using 1% Virkon. Surfaces and instruments will be disinfected using Chemgene. Solid waste will be autoclaved prior to disposal off site

Will it be necessary to use sharps?
No

Have any disinfectants been validated under the actual conditions of use?
Yes

Does the nature of this work preclude it being undertaken by any workers who have a serious skin condition (e.g. eczema) or other health problems that might make them more susceptible to infection (e.g. some kind of immunological defect)?
Yes

Will workers receive any vaccinations or health surveillance?
Yes

Consideration of whether there is a need to assign additional measures over and above the provisional level of containment.
Standard CL2 health surveillance.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Please enter comments on the GM safety committee on the risk assessment
Comment 1
In my view the proposal should indeed be characterised as CL 2 as the possibility is there to infect human cells and despite no RNA or enzymatic activities, the VLP structural proteins could induce an immune reaction of unknown amplitude.

I understand that they might want to use pseudo vector env to boost infectivity of VLP, I am not sure what they will learn here as I thought they wanted to use structural protein to study the normal natural infection route of the Cov.2 which is though the ACE.2 receptor. By using VSVG they will boost infectivity of any human cell type with or without ACE.2 receptor. Also as there is no info on what will be studied using the VLP particles infected cells, it is difficult to understand why pseudo-vector is a potential option. Thus, will asked clarification on the use of pseudo vector env such as VSVG.

Full PPE should clearly be used by investigators.

Comment 2
I have no safety issues with the proposal (privately I think CL1 would not be unsafe but working under CL2 is probably a good idea from the culturing perspective). Any coronavirus antigen would likely be in far too low a concentration to stimulate a dangerous immune response. However, I have at least one concern from the scientific perspective but with no information about the scientific aims I don’t know how important this is. I worry that the use of VSV-G, amphotropic or ecotropic might give cell entry unrepresentative of coronavirus entry. Further, in the absence of RNA transcription, will enough GFP/luc be expressed to yield a useful marker of entry?

Response to comments 1 and 2
Re the need for pseudotyping, we want to use VLPs to study the natural viral assembly route (budding). However, once the VLPs are released, we are less concerned about how they get into other cells. We want to couple a reporter to the budding virus and want to maximise infection of target cells as a surrogate for how many viruses were produced. While ACE-2 is the receptor for this virus very few commonly used cell lines express this protein (https://web.expasy.org/cellosaurus/sars-cov-2.html I’ve listed Caco-2 and Vero as models that do) and VSVG pseudotyping will help us transduce a broader range of target cells, some of which (eg 293 derivatives) will be useful for large scale screening for factors affecting viral production, but which aren’t naturally infected by SARS-CoV-2.

Re what will be studied in infected cells, the GMRA described using the packaging sequence of SARS-CoV and/or SARS-CoV-2 inserted into the 3'-UTR of luciferase or GFP-reporter vectors to link mRNAs from these transcripts to the budding particle. These will be our surrogates of infection in the target cells.

Comment 3
Reviewed and no comments from me.

Comment 4
Only found one potential issue with the proposal: I think Simon needs to OK the use of facemask (written under Comments). We do not use facemasks even in CL3 with an airborne pathogen, so I don’t know why someone should use it in CL2, with a replication incompetent VLP. I am convinced beyond doubt that the work is CL2, no higher or lower.
Response
It has been agreed that the use of face masks will not be permitted for this work.

Comment 5
I thought it looked fine. There were I just put a couple of points in the attached.
- Do the [cultured] cells express ACE-2 receptors naturally or are they engineered?
- I'm not sure. If someone is unaccustomed to wearing a face mask they may be more inclined to fiddle with it. May be counter productive (this comment addresses the possible use of face masks).

Response
These two questions have been answered previously in the responses to comments 1 and 4 respectively.

Comment 6
I have no comments to add, allocation of CL1 & CL2 work is fine.

Comment 7
“To facilitate biological understanding of the other viral gene products, mammalian expression vectors encoding these genes may be co-transfected into producer cells”.

Response
Sorry, I meant any of the many non-structural proteins that may alter the viral biology in the producer cell, not the infected cell. The proposal is to make VLPs, not a virus. How about saying that ‘non-enzymatic viral gene products may be transfected into producer cells to investigate their role on VLP biogenesis’

Comment 8
Given the absence of transferred enzymatic activity or the viral genome, replication will not be possible. If something went wrong and replication occurred is there something in their method that would indicate this has happened and therefore further processing could be terminated.

Response
It's not clear what could go wrong here, so the comment is a little non-specific. Without replicating enzymes, replication won't be possible. The only thing that could bring this about would be if someone co-transfected a provirus (which doesn't exist) or infected the culture with live virus (which I would hope no one would do!)
Comment 9
"To boost infectivity, it may be necessary to additionally transfect a vector encoding a generic viral envelope protein (e.g. VSVG), as is used to pseudotype retro- or
lenti-viral particles".
This virus model is new is there any way this could result in modifications and or induction of replication?

Response
No, without a genome present, there is nothing for the envelope supplied in-trans to incorporate into. In total, we will be expressing 6kB of DNA out of 30kB of genome and
on 4 separate plasmids, so addition of a 5th plasmid expressing VSVG isn’t likely to induce replication.

Comment 10
"Aerosol-tight containers".
Are they referring to aerosol tight lids on centrifuge buckets? If so are these only being opened inside the MSC and decontaminated before removal for others to then use?

Response
I will add the aerosol tight lids on centrifuge buckets and the MSC direction for opening/closing. This will be useful for spinning down supernatants. I was actually meaning
that a sealed container would be used to transfer from one room to another if needed, because I don’t think many CL2 rooms have a refrigerated microcentrifuge, which we
would need.

Comment 11
"We do not anticipate pseudotyping will alter the pathogenicity of the VLPs, however, it will increase the tropism. The mode of transmission will be unaltered and while a
host-immune response is possible, it is likely to be limited by the lack of productive infection".
Given that this virus could potentially act differently to the other coronaviruses and test models being used to provide guidance on the safety for this study. Are there
methods to be sure that a productive infection isn’t occurring?

Response
I appreciate the concern, although am not sure that I understand the syntax around the “test models”. However, I come back to the point that without supplying the
replicative machinery, it won’t be possible to mount a productive infection. We are also not generating virus, we are generating VLPs. It would be possible to utilise some of
the Covid19 testing protocols in place at Crick (or even develop our own), but as this relies on looking for viral RNA, if we don’t supply the viral RNA, then we won’t be able
to find it.

Comment 12
"facemask (seems prudent)". Is it not the case that recommendations from HSE would suggest this isn’t necessary and could result in complacency?

Response
This comment has been answered previously in the response to comment 4

Comment 13
It appears that all the required proteins should never be present together to produce replicating virus. However as this virus could behave unexpectedly would be it
possible for them to determine safely if they have altered the system in any way to increase pathogenicity, transmission or induce viral replication.

Response
Again, this proposal is not to generate virus, it is to generate VLPs, hence it is hard to see how these VLPs could behave unexpectedly. To test pathogenicity and
transmission you would need an animal model, which wouldn’t be sensible to set up, especially as you would be asking to infect it with replication-incompetent VLPs. The
inclusion of a packaged Luciferase or GFP reporter (as outlined in the molecular biology section) would allow us to determine if infectivity was enhanced, so I can bring this
up.
Purposes of the contained use

The present project aims to examine the impact of Kaposi's sarcoma-associated herpesvirus (KSHV) infection on host telomeres to elucidate mechanisms of viral oncogenesis. To this end, infection of cancer cell lines with KSHV de novo will be carried out to analyse the effect of infection on these model systems.
The work will include the use of well-established genetically modified KSHV strains such as rKSHV.219 (Myoung et al., 2011) as well as KSHV derived from bacterial artificial chromosomes (BACs) such as BAC16 (Kevin et al., 2012).

Origin & function

Kaposi's sarcoma-associated herpesvirus (KSHV) is a human herpesvirus formally known as HHV8 and is listed as a hazard group pathogen by the Advisory Committee on Dangerous Pathogens' Approved List of biological agents. KSHV HHV8 infection is asymptomatic in immunocompetent individuals. KSHV can be transmitted via sexual contact and non-sexual routes, such as transfusion of contaminated blood and tissues transplants, or via saliva contact. There is now a general consensus that salivary transmission is the main route of transmission.

Potential infection of uninfected lab worker through oral ingestion of high titres of free virus. Normal containment level 2 (CL2) procedures and low titre of virus are sufficient to avoid this. About 5-15% of individuals in the UK are infected with KSHV (Cesarman et al., 2019). Upon profound immune suppression, such as AIDS or immunosuppressive treatment post-transplantation, individuals infected with KSHV have a significantly higher risk of developing certain virus-associated cancers.

KSHV life cycle is divided into lytic and latent phase. During latent phase, the virus does not replicate and persists in the form of an episome (a plasmid-like genome). This is the predominant form of the virus in infected cells and it does not enter productive replication without specific drug treatments or ectopic expression of viral gene products. For the majority of the work only the latent phase form the virus will used. However, in order to generate new KSHV-infected cell lines, a small amount of virus in its lytic will be produced by transfecting a doxycyclin inducible plasmid containing the main lytic promoter RTA into cells. After that, the cells still need to be treated with doxycyclin as well as sodium butyrate to initiate production of virions. This is the only stage where the virus has even a theoretical capacity to infect humans. The low amount of virus required for such procedures and local standard operating procedures (SOPs) are sufficient to mitigate this risk.

None of the new gene products which we anticipate to insert into the KSHV genome have any documented health hazard associated with them. This includes the aforementioned fluorescent or antibiotic selection markers such as GFP.

Modification of viral gene products for the purpose of interrogation of biological mechanisms as described in sections above may include alterations which have not been performed previously. Therefore, by default, it is a theoretical possibility that these modifications induce a change in the hazard associated with the virus. No such incident of drastic changes in pathogenicity has been reported in the literature thus far and the work is carried out with low amounts of the virus using established SOPs to prevent infection in the first place.

We do not anticipate any hazard to the environment as the gene products which will be inserted into the viral genome do not have the capacity of altering the behaviour of the pathogen. No broadening of viral tropism has been reported upon experimental modification of KSHV. We therefore deem it unlikely that the experiments carried out in
this project will result in generation of virions which may pose any increased hazard to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management will be in line with the measure outlined in the institutes’ containment level 2 code of practice (see attached)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee raised no concerns with this proposal although it asked for further clarification on routes of transmission and whether specific disinfectants would be required for this work. Additional information has been added to this application regarding transmission routes and the existing disinfectants approved for use at the institute have been confirmed as suitable for the work.

Project Ref 542/21.3

Date Ackn’d 22/07/2021  CU2 Project Title Exploration of Zika target cell susceptibility and resistance factors  Class 2  CultureVolClass2 < 1 Litre  CultureVolumeClass3-4
### Project Additional Information

**Purposes of the contained use**

Researching questions around target cell identity, susceptibility and resistance

**Recipient or parental organism**

Human and mouse primary tissue, cells and cell lines derived from glioblastoma tumours and embryo brain tissue.

**Host/vector system**

Zika Virus (HG2)

**Origin & function**

1) Fluorescent reporter transgenic strains (Zika-mCherry). These incorporate an mCherry reporter cassette within the Zika virus structural sequences. The transgenic strain is well characterised (Mutso et al., 2017 doi: 10.1099/jgv.0.000938) and is mildly attenuated compared to wildtype strains, as evidenced by a tendency to eject the mCherry reporter cassette over serial passage in culture.

2) Adapted Zika strains. We have derived adapted Zika virus strains, incorporating single base substitutions predominantly in virus structural sequences, through serial passage of the wildtype and mCherry reporter virus in glioma stem cells. This process of directed evolution in vitro is predicted to confer attenuated replication and transmission in other human cell types compared to the host-adapted wildtype virus.

**Evaluation of foreseeable effects**

The GMO variants described are predicted to achieve reduced viral levels and pathogenicity in hosts compared to wildtype virus strains. Human infection would require direct inoculation, and ongoing transmission of this bloodborne virus depends on Aedes Aegypti mosquitoes not native to the UK. Infection of non-pregnant adults is typically asymptomatic (80%) or associated with mild flu-like symptoms (20%): more serious sequelae including Guillain Barre syndrome are reported but very rare. This is reflected in the HG 2 classification

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Lipid enveloped viruses are sensitive to 70% (v/v) ethanol, sodium hypochlorite, formaldehyde, glutaraldehyde, phenolics, iodophors, and quaternary ammonium compounds. Zika virus will be inactivated with an equal volume of 2% Virkon for a minimum contact time of 10 minutes. Virkon solution is then disposed down the sink. Solid waste (excluding pipettes) will be placed in the appropriate waste disposal bags prior to disposal by a licensed contractor. Pipettes and stripettes will be placed in a dedicated pipette waste bin prior to disposal. Pre-treatment (autoclaving) of solid waste prior to disposal as medical waste. See attached COP for CL2 work

### Project Additional Information

**Purposes of the contained use**

To target and inhibit gene expression in *Klebsiella pneumoniae* to define novel essential gene functions, map gene-gene interactions, and to discover novel molecular tools to probe infection mechanisms. Constructing genetic knockout and knockdowns are standard ways of demonstrating the link between genes and phenotypes in bacteria.

**Recipient or parental organism**

*Klebsiella pneumoniae*

**Host/vector system**

*Klebsiella pneumoniae*

**Origin & function**

1. CRISPR interference mutants - where expression of endogenous genes (one or more) will be selectively inhibited using an inactivated *Streptococcus pyogenes* dCas9 protein expressed from an integrated or episomal vector.

2. Deletion mutants - where specific endogenous genes (one or more) will be selectively deleted from the genome.

3. Spontaneous mutants - where point mutations, deletion or duplications will be selected and propagated by screening for mutants that arise when cells are exposed to particular stress conditions (e.g. low pH, low oxygen, antibiotics, etc).

4. Recombinant mutants - where specific genes (one or more) derived from the same species or other bacteria will be introduced using an episomal or integrative vector. This will be predominantly for complementation.

**Evaluation of foreseeable effects**

*K. pneumoniae* is both an opportunistic pathogen and a commensal organism. Inhibition, deletion, mutation or introduction of genes, is unlikely to alter the bacteria’s ability to infect humans and cause disease.

It is possible that by changing endogenous genes this species could become more host-adapted, but these are not likely to alter the susceptibility to available antibiotics. All gene products will be of bacterial origin and therefore pose very low human health risks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste containing Klebsiella pneumoniae will be treated with either Distell or Virkon prior to disposal. Contaminated laboratory waste generated during this project will be autoclaved before being sent off site for disposal by our waste contractors.

**Project Additional Information**

**Purposes of the contained use**

The purpose of this activity is to study the intracellular signalling mechanisms that mediate the response of cells to growth factors and extracellular matrix molecules, including proliferation and migration, and thus play a role in the development of human cancers and in cellular differentiation.

**Recipient or parental organism**

1. E. coli
2. murine cells (NIH3T3, and the NIH3T3 variants 293T, GP+E86, GP+EnvAm12)
3. human primary keratinocytes and carcinoma cell lines
4. monkey cells (COS-7)

**Host/vector system**

1. Host: E. coli DH5a; Vector: pCEV27, pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr, pRcCMV, pc1, pGET-T, pPCR-Script
2. Host: GP+E86 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid
3. Host: GP+envAm12 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid
4. Host: Murine and human mesenchymal cells (osteoblasts, chondrocytes, fibroblasts, and adipocytes) either as established cell lines or primary cultures, as well as osteoclasts, osteoclast precursors, haematopoietic stem cells, and embryonic stem cells. Vector: pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr virus
5. Host: NIH3T3 murine fibroblasts; Vector: pBABEneo/puro virus
6. Host: HNEK, H357, A431, HN12, HN4 & MCF7 human keratinocytes; Vector: pBABEneo/puro virus
7. Host: 293T cells; Vector: PINCO (modified from plasmid LZRSpBMN-Z)

**Origin & function**

Mouse and human cDNAs encoding signalling intermediates, cell cycle control genes, and AP-1 transcription factors, as well as novel cloned target genes, will be obtained by PCR, or excised from existing plasmid vectors, subcloned into viral plasmids, and used to produce amphotropic/ecotropic viruses as a means of expressing them in the target cells (see above).

The intended function is to investigate growth factor and extracellular matrix-dependent signalling pathways that regulate cellular differentiation, proliferation and motility, all of which are key aspects of cancer development.

**Evaluation of foreseeable effects**

The vectors to be used in these studies are replication-defective recombinant retroviruses, and have been well characterised and extensively used (Morgenstern & Land, Nuc Acids Res 18: 3587, 1990; Gasperi et al., Journal of Leukocyte Biology 66: 263-267, 1999). They are non-mobilisable in mammalian cells, and are rapidly inactivated by serum. The cell lines (GP+E86 and GP+envAm12 are third generation packaging cell lines, and have been specifically constructed to prevent recombination events between introduced constructs and endogenous viral structural sequences. Investigators using this system have not observed production of any replication-competent virus (RCV) (Markowitz et al., Virology 167: 400, 1988). The recipient cell lines are free of helper virus, and transduction of these lines with replication-defective viruses will not generate RCV. In spite of these findings, assays to detect RCV will be carried out as a matter of course. Thus, although the vectors will be packaged with ecotropic and amphotropic envelopes, and could conceivably infect rodent (ecotropic) and human cells (amphotropic), such viruses would be incapable of replication. Furthermore, these viruses are unstable at ambient temperatures, with a half-life of around 2 hours. Some of the gene products encoded by cDNAs cloned into these vectors have oncogenic potential. Therefore, the assessment is that work with both ecotropic and amphotropic viruses will be carried out at level 2. The containment level and procedures proposed for the study, together with the inherent safety of the packaging systems, will make the environmental risk effectively zero.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach (Haztabs; 1 tablet per litre = 2,500 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines which are extremely liable. In addition, the retroviruses and cell lines have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed, and placed within and autoclaved in a closed metal container. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136 degrees C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services, the use of autoclave indicator tape (which measures a temperature of 134 degrees C for 3 minutes) during every run. Autoclaved waste will then be incinerated by White Rose. |

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The GMSC accepted the risk assessments for these projects.

Project Ref  295/03.1
**Project Additional Information**

**Purposes of the contained use**

Mycobacterium tuberculosis (MTb) is a class 3 human pathogen and requires level 3 containment facilities for use. The recombinant MTb expressing luciferase gene would be used to significantly decrease the experimental times for bacterial determination in infected cultures and BCG expressing either luciferase or green fluorescent protein (GFP) would allow additional flexibility in substituting pathogenic MTb in certain types of assays. Luciferase and GFP are biologically harmless genes but as the recipient strain is pathogenic the containment level 3 would be required for the use of recombinant strains as for the wild type MTb. The same applies to Mycobacterium bovis (MB) expressing luciferase gene which would be used to uncover differences in pathogenesis between these two closely related species.

**Recipient or parental organism**

The recipient organism is bacterium Mycobacterium tuberculosis (MTb) or the attenuated strain of Mycobacterium bovis (MB) known as BCG (Bacillary of Calmette and Guerin). MTb and MB are class 3 organisms and BCG is Class 2.

**Host/vector system**

pSMT1 and pSMT3, both non-mobilisable vectors.

**Origin & function**

Luciferase gene is of bacterial origin and its function in the intended recombinant strains of Mycobacteria is to serve as reporter gene for quantitative determination of bacteria. The green fluorescent protein (GFP) is derived from jellyfish and is a fluorescent marker for tracking down the recombinant bacteria during infection of cells.

**Evaluation of foreseeable effects**

The recombinant Mycobacterium tuberculosis and Mycobacterium bovis expressing luciferase and BCG expressing luciferase or GFP are generated several years ago in the laboratory of Douglas Young at Imperial College London (Lab GM77). They have been used since then worldwide and several publications have quoted the use of these strains. Both genes are reporter constructs. Luciferase is an enzyme that converts certain type substrates into chemiluminescent products and GFP is a fluorescent protein that can be easily identified by fluorimetric techniques such as flow cytometry (FACS). These two genes have been used in numerous experimental systems with no biologically harmful effects every being reported. The use of these two genes would normally require level 1 containment measures but as the recipient...
strains are class 3 (MTb and Mb) or class 2 (BCG) organisms, it is necessary to apply the class 3 or respectively, class 2 containment measures. There is no indication from the originator or from the others who have used these strains that they are in any way different in terms of virulence from the corresponding wild type strains. Therefore, the environmental or personal risk from using these strains is no different from that of wild type strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Re: APPLICATION FOR DEROGATION FOR AUTOCLAVE FACILITY FOR CONTAINMENT LEVEL 3 LABORATORY**

During a recent inspection by HSE, it was pointed out to us that there had been a change in the regulations defining what constitutes a laboratory suite, and as a result our containment level 3 facility (room 311, floor 28 Guy’s Tower) contravened the new interpretation under the Genetically Modified Organism (Contained Use) Regulations 2000 (CU2000). I therefore am applying for derogation from Schedule 8 of CU2000.

The relevant features, following the guidance attached to Newsletter 30 are:

a) Both the autoclave and the containment facility are located at the far end of the building remote from the main access to the floor. They are joined by a short corridor that is not used by students, non-scientific staff or members of the general public. There are no offices at this end of the building, only laboratories.

b) The infection with Mycobacterium tuberculosis and mycobacterium bovis occurs through respiratory route. The infectious dose has not been firmly established but it is thought that the size of aerosol-born droplets containing bacteria is critically important (i.e several droplets containing 3-5 bacteria each, if inhaled by an immuno-susceptible person may establish an infection). Only 5% of infected individuals develop the disease.

c) The highest concentration of bacteria ever present in the waste is $10^7$/ml which is the remaining stock solution from the experiment (the stock solution is 1 ml, thus the amount of this waste is always less than 1 ml). The unused stock solution is routinely treated with hycolin for several hours prior to disposal. Typical concentration of bacteria in the experimental liquid waste is $10^5$/ml or less.

d) The waste is in loosely tied autoclave bags contained in metal autoclave bins.

e) Following the inspection we have purchased autoclave tins with clip-on lids to replace the identical ones without clip-on lids.

f) as in (e) above.

g) The container will be placed on a trolley following an agreed procedure that has been in place for the last 2 years.

h) the removal of waste from the Containment Laboratory does not take place unless it is clear that the autoclave is available for use. After this waste has been loaded into the autoclave low level waste may also be added, but only by the staff loading the level 3 waste.

i) As in (h) above.

j) The container is placed directly in the autoclave and the tray that sits on the trolley is then also placed in the autoclave.

k) The only personnel that move the waste are trained for work at containment level 3.

l) The SOP (revised to include the use of clip-on lids) for use of the Containment facility is attached. This contains an emergency procedure to be followed in the event of a...
spillage during waste transport.

DECONTAMINATION

1. All glassware and plastics must be autoclaved on a cycle to reach 126 degrees C before removal from the laboratory suite. Autoclave bins with properly fitting clip on lids containing the waste in loosely tied autoclave bags must be taken from the CL3 laboratory to the autoclave immediately prior to autoclaving. The following procedures will be follows:

i) at least two trained staff must be available to carry out these procedures
ii) the autoclave is room 3245 must be available for use
iii) one member of staff will act to open doors; one will move the autoclave tins from the CL3 facility onto the transport trolley
iv) the autoclave tins will be removed from the CL3 facility and placed on a tray on a trolley outside the CL3 laboratory
v) autoclave bins from the CL3 laboratory will be taken directly to the autoclave and placed in the autoclave
vi) when all autoclave bins have been loaded into the autoclave, the tray will also be placed in the autoclave and the autoclave cycle will be started.

2. If a spillage of CL3 infectious material occurs during transport of waste, the area will be disinfected by treatment with Presept, and/or by swabbing with disinfectant.

i) Any contaminated clothing must be removed and any affected skin should be washed with soap and water. In the event of cuts, the First Aid Officer should be contacted.
ii) Notification of the Biological Safety Officer and the relevant Line Manager must then take place. They will decide if any further action is required.

The waste consisting of disposable plastics and liquid waste in volumes of 100 ml or less in plastic containers will be placed in plastic bags, sealed and transferred to metal tins with clip-on lids. The standard internal operating procedure for removal and autoclaving of waste will then be applied (for details please see above application for derogation of autoclave facility for CL3 room).

The autoclave will operate the cycle at 126 degrees C for 80 min at 2.5 bar. The waste will then be placed in bags and disposed to designated bins.

This procedure is effective for complete killing of Mycobacterium tuberculosis wild type as determined by re-plating of the autoclaved material on microbiological plates. Similar test will be conducted for GM strains of MTb and MB (ie following completion of the cycle the metal been containing the waste will be returned to CL3 room in a reverse of the removal of waste procedure and the waste placed in Microbiological Safety Cabinet. An aliquot of the liquid waste and a swab from the solid waste will be tested for the presence of live bacteria by microbiological methods. Only following the negative result of the test will the remaining waste be removed from the room in a repeat of standard procedure and autoclaved prior disposal. This test-procedure will be repeated each time when the nature or the quantity of the waste significantly differs from the routine waste.
The proposal was looked at by two members of Safety Committee who were satisfied with risk assessments and proposed risk categorization.

The class of activity is 2/3 as detailed in the KCL GM RA.

Historical Significant Changes: PROJECT TRANSFERRED BACK TO GM386 FROM GM543 ON MERG

02/03/2022
Purposes of the contained use

To determine the effect of SV40 Large T antigen and tumour-suppressor genes such as Apoptin (VP3), p53, p16, p19ARF and pRB proteins on a range of cells, when added exogenously as fusions with the TAT protein transduction peptide.

Recipient or parental organism

SV40 Large T:
Bacteria - Attenuated and mobilization defective E. coli (K-12) derivatives such as ER 1647, DH5-a and XL1 Blue, unable to survive in the absence of specialised growth conditions.
Human fibroblasts - Detroit 551 cells, non-immortalized, limited replicative life span, unable to colonize human hosts, unable to survive outside specialized tissue culture environs.

Apoptin (VP3), p53, p19ARF and pRB proteins:
Retroviral packaging cells: GP+E86, murine fibroblast derived with split helper function, ecotrophic for mouse, sensitive to human complement. PG13 murine fibroblasts derived, split helper function, restricted amphotropic, sensitive to human complement.
Established and primary mouse and human tissue culture cell lines: epithelial, fibroblasts and myeloid types. These cell lines are spontaneously immortalised, unable to colonise in human hosts, unable to survive outside special tissue culture environments.

Host/vector system

SV40 Large T:
* Cloning vector - pET22b (Novagen Ltd), in bacterial host, unable to replicate in nonbacterial cells. No expression of specific gene products in the absence of exogenously provided T7 polymerase AND isopropyl-thiogalacto-pyranoside (IPTG).

Apoptin (VP3), p53, p19ARF and PRB proteins:
* PBABE and MFG series of retroviral vectors with murine leukaemia virus derived LTR promoter. These vectors are produced by safe packaging cell lines such as GP+E68 and PG13. These vectors have an LTR promoter and infect only rodent cells (GP+E68) or a wide range of cells including human (PG13). No inherent pathogenicity other than low risk of insertional mutagenesis is associated with these viruses.
* Mobilisation defective pUC based vectors with large array of different promoters such as SV40, CMV. Bacterial expression vectors such as pTriEx-1, in disabled bacterial hosts such as E. coli K-12 auxotrophic mutants for propagation.
* Spontaneously immortalised human and mouse tissue culture cell lines, unable to colonise humans. There is no evidence of the ability of these cells to secrete transmissible agents. These cells are unable to supply helper functions to disabled retroviral vectors.

Origin & function

SV40 Large T
* The genetic material originates as mRNA from human and/or mouse cells. The indicated function of the genetic materials is growth stimulatory.

Apoptin (VP3), p53, p16, p19ARF and pRB proteins:
* The genetic material originates as mRNA from human and/or mouse cells. The indicated function of the genetic material is that the full length cDNA products are tumour suppressors, including FHIT, p16/INK4a, p19/ARF, p21/waf1 and p53. These are cloned into mobilisation defective plasmid vectors including bluescript pCDNA3.1, pTRE2, pSVNeo and/or pBABE replication incompetent retroviral vector and will be expressed in human and mouse tissue cancer cell lines to determine their ability to
apoptose.

Evaluation of foreseeable effects

Waste - All waste material is dealt with as described under Section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental escape into the environment;

a) from bacteria: All manipulations with bacteria will take place at containment level 2. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. In the absence of combination stimulation of induction, expression of the protein in bacteria will be virtually zero. Protein preparations from induced bacteria will be via detergent lysis, to avoid aerosol production.

b) From tissue culture - All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOPs for dealing with accidental spillage. All manipulations with human tissue culture cell lines take place at containment level 2. Cell lines are unable to survive outside the laboratory environment. White coats and gloves are mandatory. In the event of escape of disabled retroviral vectors, hazard is unlikely because they are unable to replicate in the absence of helper function and are sensitive to dessication and have a half life of only 5-8 hours under optimum laboratory conditions. In addition, PG13 derived vectors are unable to infect recipient permissive cells in the presence of normal complement. GP+E86 derived vectors are unable to infect cells other than mouse. In the event of infection and integration, the protein products of the cDNA being examined in this way (eg apoptin(VP3), p53, p16, p19ARF and pRB proteins) do not have deleterious effects in normal animal cells.

Accidental contamination of workers in the suite - Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. The vector DNA is unable to propagate or express in human cells. Established cell lines used are unable to colonize human hosts.

Security - The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - all contaminated waste is autoclaved in the departmental autoclave that is used only for waste. The moist heat autoclave is used at 121 degrees C for 40 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced annually by Meadowrose Scientific and documentary evidence of correct function stored on site. Under these conditions complete kill of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by Medical School contractors (White Rose).

Liquid Waste - All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours, after which it is disposed of down the designated sink. Under these circumstance complete kill of organisms is guaranteed.

Is an emergency plan required according to regulation 20? N

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMSC approved the RA for this project Activity Class 2.

Project Ref 386/03.1

Date Ackn'd 12/01/2004

CU2 Project Title UTILISATION OF GENE MEDIATED APPROACHES TO DESTROY RESIDUAL CANCER.

Class 2

CultureVolClass2 1-50 litres

Consent Granted not applicable

Project notified under transitional arrangements N

Withdrawn N

Historical Significant Changes Project transferred to GM543 on 12/01/2004  PROJECT TRANSFERRED

Project Additional Information

Purposes of the contained use

Studies designed to find effective ways of destroying tumour cells that remain in the body after surgery that are resistant to conventional radiotherapy.

Recipient or parental organism

Human, rat and mouse cells maintained in vitro. The overall containment level that will be applied to these studies is 2.
Host/vector system

Host: human, murine or rat squamous cells.

Vector systems:
A. Adenovirus and selectively replicating adenovirus.
B. Salmonella species modified to carry either the cytosine deaminase gene or anti-angiogenic peptides.

Origin & function

The vectors all induce lysis of rodent and human tumour cells. In the case of the salmonella derived vectors tumour lysis occurs after exposure of the host to the pro drug 5 Fluorocytosine. Treatment with vectors carrying anti-angiogenic peptides is designed to prevent outgrowth of blood vessel sprouts. It is anticipated that this treatment will prevent tumour outgrowth and spread.

Evaluation of foreseeable effects

Non-replicating adenoviruses or selectively-replicating adenoviruses and Salmonella species are all used with the intent of destroying tumour but not normal cells. There are no foreseeable hazards to human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste. Solid waste will be double-bagged and autoclaved at 121 degrees C for 90 minutes followed by incineration. Sharps are discarded into designated sharps containers for incineration off site by White Rose Environmental.

Surgical instruments. Surgical instruments will be treated with a chlorine-releasing agent (for example HazTabs) and then scrubbed and autoclaved. All our autoclaves are on a service contract and are tested annually to ensure they meet the required specification for temperature and time holding.

Liquid waste. Decontamination with a chlorine-releasing solution at a concentration of greater than 10,000 ppm available chlorine for greater than 10 minutes prior to disposal down a designated sink.

The disinfectant to be used will be a chlorine-releasing cyanurate (Haz Tabs or PreSept), an agent that has good activity against Salmonella species and adenovirus.

The activity of HazTabs against Salmonella was demonstrated by Bloomfield and Miles (Journal of Applied Bacteriology 1979, 46:65-73) using a capacity test which demonstrated a 9log reduction following treatment of a test innoculum of 2.5 x 10 (to the power of 10) cfu/ml of Salmonella typhi. When 20% plasma (equivalent to serum) was included in the test 3,000mg/l of available chlorine was needed to kill Staphylococci. As HazTabs generate 10,000 ppm available chlorine (equivalent to 7,000 mg/l) and the concentration of serum in media will typically be less than 2%, this is a good disinfectant for the work to be carried out and is unlikely to become exhausted (Bloomfield and Uso 1985, Journal of Hospital Infection, 6@20-30).

The efficacy of HazTabs against viruses is shown by studies incorporating dried suspension of Polio virus and demonstrating a 5 log reduction following treatment with 9,200 ppm available chlorine after 1 minute, and at 5 and 10 minutes no virus was recovered, (Tyler R., Alylisse G.A.J., Bradley C. Virucidal activity of disinfectants:
The work proposed will not generate "high-hazard" waste and we do not propose to test whether organisms can be grown from the waste. However, every care will be taken to ensure that the concentration of chlorine is appropriate and liquid waste is treated for a minimum of 10 minutes to compensate for the presence of serum.

The local GMSC approved this as a class 2 activity.

Historical Significant Changes
PROJECT TRANSFERRED TO GM386 ON MERGER OF GM543 WITH GM386

Recipient or parental organism
1. E.coli
2. Streptococcus mutants
3. Streptococcus pneumoniae
4. Streptococcus gordonii
5. Streptococcus mitis
6. Fusobacterium nucleatum
7. Tannerella forsythensis
8. Porphyromonas gingivalis
9. Enterococcus faecalis
10. Lactobacillus spp
11. Candida albicans

Host/vector system

Purposes of the contained use
Mucosal surfaces of the oral cavity, gastrointestinal and genital tracts are the main routes of entry of infectious microorganisms as well as being the sites for mucosal infections that may also have systemic effects. This activity will investigate the mechanisms by which both pathogenic microorganisms and those that form part of the normal mucosal flora may cause disease. In addition novel approaches to treatment by using genetically engineered commensal bacteria to deliver microbicidal agents will be investigated.
2. Host: Strptococcus spp; Vector: pALH109, pALH122, pNE1gfp, pEVP3, pSMB55, pMHL120, pCMG8 or related plasmids.
3. Host: T.forsythensis; Vector: pMJF/ΔR II or related plasmids
4. Host: F. nucleatum; Vector: pKH90, pOR19, pH17 or related plasmids

Origin & function

1. Fragments of genomic DNA derived either directly or by polymerase chain reaction amplification derived from Streptococcus spp., T. Forsythensis, F. nucleatum will be used for mutagensis to generate microorganisms that are defective in gene function either as a result of random mutagensis or targeted mutagensis.
2. Gene fragments identified as having functions of interest as above, may be cloned and used for expression of the gene products in E.coli. To understand function of such gene products, mutagensis may also be performed with expression in E.coli. Similarly, DNA encoding proteins with antimicrobial potential e.g. single domain antibodies, cyanovirin and derived from human, animal, plant or algae sources will be used for expression of the gene product in heterologous hosts.

The aims are to identify genes that contribute to virulence of mucosal pathogens and to express proteins that may be used for treatment or prevention of mucosal infections.

Evaluation of foreseeable effects

The microorganisms that will be modified are part of the normal flora to be found at mucosal surfaces in healthy individuals. Mutagenised microorganisms, Streptococcus spp., T. Forsythensis, F. nucleatum, Candida albicans show or are expected to show loss of function compared with wild type organisms. Streptococcus pneumoniae is a class 2 pathogen and work with virulent strains (i.e. TIGR4 derivatives) will be carried out in a microbiological safety cabinet.

Engineered Streptococcus gordonii and Lactobacillus strains may have comparable colonizing activity to wild type strains but cannot transfer antibiotic resistance since the genes are stably integrated into the chromosome of the modified host and cannot be mobilised. To reduce exposure and risk for the researcher to negligible levels, liquid cultures will be handled in a microbiological safety cabinet.

In all studies, genetically modified material will be destroyed on site by autoclaving.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from GMM cultures will be aspirated and treated with Haztabs (1 tablet/litre = 2,500 ppm chlorine) for 12 hours. Concentrated solutions will be made freshly on the day of use according to manufacturers instructions. Inactivated culture supernatents will be discharged to the drainage system. Solid waste will be double bagged, sealed and placed in a closed metal container. Waste will then be autoclaved in the closed metal container at 136°C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave tape will be used to indicate that the material has been autoclaved. Autoclave function is monitored by services performed at 3 month intervals by Health Services Associates. Autoclaved waste will be placed in yellow bags for off-site incineration by White Rose.
The local GMSC approved the Risk Assessment for this project on and signed off the component activities on 11th March 2006 and 11th July 2006. The class of activity is 2.

### Project Additional Information

#### Purposes of the contained use

Identification and study of the host contribution to bacterial infection and pathogenesis. This is done by infection of the fruitfly Drosophila melanogaster with the class 2 pathogen Mycobacterium marinum. Both host (Drosophila) and pathogen (M. Marinum) can be genetically modified.

#### Recipient or parental organism

<table>
<thead>
<tr>
<th>Mycobacterium marinum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drosophila melanogaster</td>
</tr>
</tbody>
</table>

#### Host/vector system

- **M. marinum vectors:** pVK173T, pFPV2, and equivalents/derivatives thereof.
- **D melanogaster:** crippled P-element-derived transposable elements (carried in vector pUAST and equivalents/derivatives thereof).

#### Origin & function

- **M. marinum:** transgenes encoding fluorescent proteins such as dsRed and GFP, from corals or jellyfish, used for tracking bacteria cells.
- **D melanogaster:** transgenes encode a variety of molecules (signal-transduction molecules, fluorescent proteins, etc.) of heterologous (human, mouse, jellyfish, coral, bacteria) or homologous origin; used to alter the course of infection and hence to be informative as to the genetic basis of susceptibility to infection or of pathogenesis.

#### Evaluation of foreseeable effects

- **M. marinum:** in our hands, fluorescent derivatives typically grow more slowly and are slightly less pathogenic than wild-type strains; they will also be resistant to some aminoglycoside antibiotics (apramycin or kanamycin), the net effect should be a mild decrease in pathogenicity for these strains, since primary treatment for M. marinum does not typically depend on aminoglycosides.
- **D melanogaster:** transgenic files should exhibit reduced fitness relative to other laboratory strains; since lab strains of drosophila are already poorly-adapted for life in the environment, these flies should present no environmental risk.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We are very careful to prevent release of any pathogen-infected Drosophila.

1. Individual infected flies are tracked.
2. In most cases flies are infected, placed in culture vials and never again removed. Once the experiment is completed, the entire vial (including contained flies) is frozen to kill flies, then autoclaved to kill bacteria, and finally incinerated.
3. In cases where an experiment requires removal of live infected flies as samples, all flies within the vial are anethetized before the vial is opened, preventing inadvertent escapes.
4. Fly-traps will be placed at frequent intervals in the fly room to attract and contain escaped flies.

Using these techniques, in the course of 6 years doing similar experiments at Stanford University, I observed fewer than 10 escapes of a total of more than 100,000
Infected flies. All of these escapes were due to defective vial closures; I have now changed the type of vial-closure to one that is more secure, so fewer escapes are expected.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids: Waste will be double-bagged and autoclaved at 124C for 15 minutes. Appropriate autoclave indicator tape will be used to monitor autoclave function. After autoclaving, waste will be incinerated by White Rose. Waste containing live flies as well as pathogens will be frozen for at least 6 hours at -20C before autoclaving.

Liquid: Addition of disinfectant (chlorine bleach to 5% or 1 haztab/litre) followed by pouring down designated sink.

Both procedures are expected to achieve 100% killing.

Monitoring will be done by attempting to culture M. marinum using standard techniques either after autoclaving or after addition of bleach, as appropriate.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

GMSC approved at meeting of 1 May 2007.

Pathogenesis and treatment of infections at mucosal surfaces

Mucosal surfaces of the oral cavity, gastrointestinal and genital tracts are the main routes of entry of infectious microorganisms as well as being the sites for mucosal infections that may also have systemic effects. This activity will investigate the mechanisms by which both pathogenic microorganisms and those that form part of the normal mucosal flora may cause disease. In addition novel approaches to treatment by using genetically engineered commensal bacteria to deliver microbicidal agents will be investigated.

</tbody>
</table>
1. Fragments of genomic DNA derived either directly or by polymerase chain reaction amplification derived from Streptococcus spp., T. Forsythensis, F. nucleatum will be used for mutagenesis to generate microorganisms that are defective in gene function either as a result of random mutagenesis or targeted mutagenesis.

2. Gene fragments identified as having functions of interest as above, may be cloned and used for expression of the gene products in E. coli. To understand function of such gene products, mutagenesis may also be performed with expression in E.coli. Similarly, DNA encoding proteins with antimicrobial potential e.g. single domain antibodies, cyanovirin and derived from human, animal, plant or algae sources will be used for expression of the gene product in heterologous hosts.

3. DNA encoding partial or complete HIV-1 genome to be used for the production of pseudovirus (non-replicating) or intact HIV-1.

The aims are to identify genes that contribute to virulence of mucosal pathogens and to express proteins that may be used for treatment or prevention of mucosal infections.

Evaluation of foreseeable effects

The microorganisms that will be modified are part of the normal flora to be found at mucosal surfaces in healthy individuals. Mutagenised microorganisms, Streptococcus spp., T. Forsythensis, F. nucleatum, C. albicans show or are expected to show loss of function compared with wild type organisms. Streptococcus pneumoniae is a class 2 pathogen and work with virulent strains (i.e. TIGR4 derivatives) will be carried out in a microbiological safety cabinet.

Engineered Streptococcus gordonii and Lactobacillus strains may have comparable colonizing activity to wild type strains but cannot transfer antibiotic resistance since the genes are stably integrated into the chromosome of the modified host and cannot be mobilised. To reduce exposure and risk for the researcher to negligible levels, liquid cultures will be handled in a microbiological safety cabinet.

HIV-1 pseudovirus is non-replicating. Intact HIV-1 is infectious and therefore work will be carried out in microbiological safety cabinets in the class 3 laboratory.

In all these studies, genetically modified material will be destroyed on site by autoclaving.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

SOP for use of autoclave external to CL3 laboratory:

All material for disposal will be autoclaved outside of the Cat 3 facility on a cycle that reaches 126°C. Autoclave bins with properly fitted, locking lids containing the waste will be taken from the CL3 laboratory to the autoclave immediately prior to autoclaving. The following procedures will be followed:

i) two trained staff must be available to carry out the procedure

ii) the autoclave room must be available for use.

iii) one member of staff will act to open doors; one will move the autoclave bins from the CL3 facility onto the transport trolley.

iv) the autoclave bins will be sprayed with 70% alcohol before being removed from the CL3 facility and placed on a tray on a trolley outside the CL3 laboratory. Gloves used for transferring the bins must be placed on top of the closed bins

v) autoclave bins from the CL3 laboratory will be taken directly to the autoclave and placed in the autoclave, the lids are then unlocked & turned over to allow steam penetration
when all autoclave bins have been loaded into the autoclave, the tray will also be placed in the autoclave and the autoclave cycle will be started.

at the end of the cycle, the print-out should be kept as a record of adequate sterilisation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from GMM cultures will be aspirated and treated with Haztabs (1 tablet/litre = 2,500 ppm chlorine) for 12 hours. Concentrated solutions will be made freshly on the day of use according to manufacturer's instructions. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed and placed in a closed metal container. Waste will then be autoclaved in the closed metal container at 136°C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave tape will be used to indicate that the material has been autoclaved. Autoclave function is monitored by services performed at 3 month intervals by Health Services Associates. Autoclaved waste will be placed in yellow bags for off-site incineration by White Rose.

Please enter comments on the GM safety committee on the risk assessment

The Local GMSC approved the Risk Assessment for this project on and signed off the component activities on 11th March 2006 and 11th July 2006

The class of activity was 2.

The Risk Assessments relevant to this revision were approved, subject to minor changes, by the Dental Institute GMSC on 7th July 2009.

HIV pseudotype virus production was assessed as a class 2 activity and Production of Replication competent HIV stocks was assessed as a class 3 activity.

For activities involving GMMs, describe the waste management measures which will apply to the activity.

Liquid waste (maximum culture volumes of 500 ml) will be chemically treated with an appropriate disinfectant (Hycolin, Chloros or Virkon), used at the manufacturers specified concentration for the appropriate length of time, before disposing of via the drainage system.

Solid waste will be placed into yellow, printed clinical waste bags meeting BS6642 and BS381C or sharps containers conforming to BS7320. Waste bags/bins will be secured using numbered ties and transported by designated staff to a registered on site facility for incineration.

02/03/2022
Contaminated dry waste is placed in suitable containers or bags and collected by an independent contractor for incineration. For the purposes of laboratory hygiene, some dry waste is disinfected using commercial disinfectants (Virkon, Tegodyne) according to manufacturers' recommendations prior to incineration.

Agar plates and semi-dry waste is collected in leak-proof containers and autoclaved prior to collection by an independent contractor for incineration.

Liquid waste is inactivated using commercial disinfectants (Virkon, Tegodyne) according to manufacturers' recommendations and disposed in laboratory sinks.

The maximum culture volume that could be released at any one time is 20 litres.

Validation of incineration is through the authorisation certification of the contractor.

Validation of autoclaving is through an independent annual validation and monitoring of fault condition indicators.

Validation of inactivation of liquid waste is through data supplied by the manufacturer.
TRANSCRIPTIONAL CHANGES ASSOCIATED WITH THE KNOCKDOWN OF GENE FUNCTION IN HAEMopoietic CELL LINES USING RETROVIRAL-BASED RNA INTERFERENCE (RNAI)

We will generate double-stranded oligonucleotides for genes involved in transcriptional regulation of the blood lineages including a number of known transcription factors which control cell division, growth and proliferation. We will insert these oligonucleotides into an RNAi compatible retroviral expression vector and transfect a human cell line K-562. We will monitor the suppression of target gene activity to identify downstream transcription changes using cDNA expression microarrays. In this way, we will be able to generate information which relate to the transcriptional networks which regulate the development of the blood lineages from stem cells.

The human K-562 cell line is a myelogenous leukaemia cell line established in 1970 (Univ. of Tennessee, U.S.A.) from a pleural effusion of a patient with chronic myeloid leukemia (CML) and has been characterised as a highly undifferentiated cell of the granulocytic type.

Retroviral vector pMSCVpuro (ClonTech cat. No. K1062-1) is based on the murine stem cell virus (MSCV), an amphotropic retrovirus deleted for all the gene products required for replication. The basic retroviral backbone used is derived from the Murine Embryonic Stem Cell Virus (MESV) and the LN retroviral vectors MoMuLV. Upon transfection into a packaging cell line, pMSCVpuro transiently expresses or intergrates and stably expresses, a transcript containing the extended viral packaging signal w the puromycin.
resistance gene, and a gene or oligonucleotide of interest inserted into multiple cloning sites. The vectors achieve stable, high-level gene expression in haemopoietic and embryonic stem cells through a specifically designed 5’ long terminal repeat (LTR). The 5’LTR is from the murine stem cell PCMV virus, and it differs from the MoMuLV LTR used in other retroviral vectors by several point mutations and a deletion. These changes enhance transcriptional activation and prevent transcriptional suppression in embryonic stem and embryonal carcinoma cells. The murine phosphoglycerate kinase (PGK) promoter controls expression of the puromycin resistance gene for antibiotic selection in eukaryotic cells. pMSCVpuro also contains the pUC origin of replication and E. coli Amp gene for propagation and antibiotic selection into bacterial hosts DH5a and HB101. These markers do not have deleterious effects on cells which carry them. pMSCVpuro will be transfected into a packaging RetoPack PT67 Cell line (Clontech cat. No K1060-D). Once in the cell, RNA from the vector is packaged into infectious, replication-incompetent retroviral particles. pMSCVpuro does not contain the gag, pol, and env structural genes necessary for particle formation and replication: these genes are stably intergrated into the PT67 genome. The intergration of these structural genes into the packaging cell lines minimizes the chances of producing replication-competent virus due to recombination events during cell proliferation.

Origin & function

The human K-562 cell line ia a myelogenous leukemia cell line established in 1970 (Univ of Tennessee, U.S.A.) from apleural effusion of a patient with chronic myeloid leukemia(CML).
Retroviral vector pMSCVpuro and RetroPack PT67 packaging cell line are from a commercial company BD Biosciences Clontech (Palo Alto, California, USA; cat No, K1062-1 and cat. No, K1060-D respectively.) All the above mentioned genetic material are intended for scientific/medical research and have extremely limited use or survival outside of laboratory conditions.

Evaluation of foreseeable effects

The pMSCVpuro retrovirus is replication defective but will be packages with amphotropic protein. Packaging cell lines are helper virus free and the chance of the generation of replication competent retrovirus or wild type virus is low. These cell lines will have limited survival outside the laboratory culture conditions. However it is recognised that naked proviral DNA is potentially infective although this risk is negligible. It is likely that the supression of the genes of interest in the K-562 cell line using the proposed retroviral RNAi system may cause change in terms of the proliferative abilities of cells in culture (increased/decreased cell growth and division, possibly even cell death). Furthermore, there is a negligible risk of the modification of the human cell line K-562 by the retrovirus constructs rendering these cells pathogenic. There is no risk of introducing entire harmful functional genes into human target tissues. However the RNAi system employed could potentially result in suppression of endogenous gene expression of some functionally important oncogenes if introduced to the appropriate human target cells. However, this risk is very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GMMs are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The genetically modified bacterial micro-organisms (GMMs) are being grown at small scale (typically 1ml) using good microbiological practice. Culture plates, tubes and other laboratory disposables in contact with the GMMs will be inactivated by incineration or autoclaving and cultures supernatants will be inactivated in Vikron or Tegodyne before disposal. pMSCVpuro constructs will only be transfected into packaging and K562 cell lines in tissue culture hood in a class 2 containment facility. Once pMSCVpuro constructs are converted into infective retroviral particles in packaging cell lines and are introduced into the K562 cell line, all culture flasks, tubes and other laboratory disposables and culture suprtnatants will be treated with Virkon or Tegodyne and autoclaved. Tissue culture hoods willl be cleaned with Virkon and/or Tegodynprior to and after use. Ultimately all laboratory disposables coming into contact with GMMs will be incinerated subsequently to the above forms of treatment. The above mentioned treatments will give 100% kill of all bacterial, retroviral and human cells used for experimentation. Routine monitoring procedures will include (i) assaying the ability of waste supernatants/swabs of laboratory equipment to produce viable bacterial colonies on agar plates and (ii) assaying the ability of waste supernatants/swabs of laboratory equipment to infect human cell lines with viable retroviral particles in cell culture under selective pressure. We will also monitor the presence of polymerase chain reaction (PCR). Proretroviral naked DNA will be handled using appropriate personal protective equipment including gloves and eye protection and sharps avoided where possible and care taken to avoid needlestick injuries.
The safety committee noted that suitable precautions for naked DNA had been considered. Approved as a class 2 activity 12th November 2002.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use

The aim is to establish the role of the putative human lung cancer tumour suppressor genes (TSGs) using conditional mouse models. The conditional mouse models will be generated by standard gene-targeting techniques in mouse embryonic stem (ES) cells (to insert loxP sites either side of the gene of interest). Recombination between the loxP sites will be achieved in vivo (using mice generated from these modified ES cells) by intranasal administration of an adenovirus expressing Cre recombinase. This will lead to ablation of the gene of interest only in lung tissues, and hence will more accurately recapitulate the sporadic nature of lung tumourigenesis in humans.

The reason for having contained usage is that the adenovirus, although replication-defective, is a pathogen of respiratory and gastrointestinal mucous and eye membranes, and may cause corneal and conjunctival damage.

Recipient or parental organism

The parental organism is an adenovirus expressing Cre recombinase, AdCreM1 (from Microbix; Cat: PD-01-43). AdCreM1 is deleted for all the gene products required for replication. AdCreM1 is a severely attenuated first-generation adenovirus (33 kb) containing a Cre expression cassette. It was constructed from the adenovirus type 5 (Ad5) deletion mutant (which contains complete deletions in the E1 and E3 portions of the adenoviral genome) by adding to the left end (via homologous recombination) the Cre expression cassette. The expression cassette contains the murine cytomegalovirus immediate-early gene promoter (MCMV), the cre open reading frame and the SV40 polyadenylation signal.

Host/vector system

The system that will be used is based on the method developed by Anton, Graham and colleagues (Anton, M. and Graham, F. L. Site-specific recombination mediated by an adenovirus vector expressing the Cre recombinase protein: a molecular switch for control of gene expression. J. Virol. 69:4600-4606, 1995). The adenovirus expressing Cre recombinase, AdCreM1 will be transfected into the packaging cell line, 293T*. Once in the cell, RNA from the vector is packaged into infectious, replication-incompetent adenoviral particles (within 7 to 12 days); the desired viral recombinants will be identified by screening individual plaques generated in a lawn of packaging cells. The recombinant viruses will be titered and then intranasally administered to mice.

* 293T cells are a highly transfectable derivative of the 293 cell line (human kidney epithelial cells transformed with adenovirus 5) into which the temperature sensitive gene for SV40 T-antigen has been inserted.

Origin & function

The function of the adenovirus is, once administered intranasally to the mouse, to infect the cells of the lung. Once inside the cell the adenovirus will produce the enzyme, Cre recombinase. This enzyme will then catalyse recombination between the loxP sites that have been inserted in the gene of interest, resulting in excision of the loxed segments of the gene and hence the ablation of its function. Thus we will see a loss of production of the protein of interest only in the lung (other body tissue will be unaffected), and determine whether such a situation leads to the development of lung cancer.

Evaluation of foreseeable effects

The effects of adenoviral infection of the mouse will be monitored in several ways:

1. The genetic background of the mice is such that at the ubiquitously-expressed Rosa-26 locus, they have a LacZ gene which has the promoter sequences separated from the coding sequences by a loxP-flanked STOP site. Thus exposure to Cre recombinase will excise the STOP signal and induce expression of the lacZ gene, which encodes the enzyme, B-galactosidase. Upon exposure to substrate, B-galactosidase produces a blue coloured strain. Thus in the initial stages, mice will be sacrificed at weekly intervals and tissue sections exposed to the substrate to confirm that the adenovirus has only infected the lung (ie blue staining will only appear in lung tissue, and no other body organ).

2. Mice that have been administered the adenovirus will be monitored daily for signs of ill health or discomfort by the staff at the animal house (and the visiting Vet). However, this adenoviral Cre recombinase system has been widely used for many years, and there are no reports in the scientific literature of any side-effects.
Mice that have been administered the adenovirus will also be routinely monitored for signs of distress/discomfort due to the formation of lung tumours and will be sacrificed if it is deemed they are suffering in any way.

Packaging cell lines are helper virus free and the chance of the generation of replication competent retrovirus or wild-type virus is low. The cell lines will have limited survival outside of laboratory culture conditions. There is negligible risk of the modification of these cell lines by the adenovirus constructs rendering these cells pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Signs and labels will be placed to indicate each area where adenovirus is used or stored (including Biosafety cabinets, incubators, refrigerators, laboratory entrance doors, etc.).

When administering the adenovirus, the mice will be anaesthetised and instilled intranasally with 10-100 uL sterile phosphate-buffered saline (PBS) containing adenoviral particles at a viral dose of up to 1x10^8 pfu per mouse. The PBS will be administered drop-wise (20-25 uL over 15 sec) into the noses of mice using a regular pipetteman (0-200 uL) with the appropriate pipette tip. The pipette tips will be filtered so as to prevent aerosol formation. This entire procedure will be performed in a Class 2 Hood.

The mice will be housed in individually-ventilated cages (IVCs), in which the air entering and exiting the case is sterile-filtered. Since infected animals can excrete adenovirus (especially in the first 72 hours after infection), the changing of the food, water and bedding will be performed in Class 2 Hoods. All laboratory and animal staff coming into contact with the adenovirally-infected mice will wear protective clothing, including lab coats, masks, goggles, gloves, special training will be given to all animal husbandry personnel on adenovirus, the hazards associated with the work, required practices and procedures and proper handling of bedding, cage washing, and all other husbandry materials associated with the experiment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The most effective adenoviral germicides (with a minimum 15 min. contact time) are 1% sodium hypochlorite for bench surfaces and liquid wastes; and autoclaving for 1 hour at 121 degrees C or 250 degrees F (15 lbs per square inch of steam pressure) for plasticware, animal bedding and gloves, etc.

The pAdCreM1 vector will only be transfected into packaging cell lines in a tissue culture hood in a Class 2 containment facility. All culture flasks, tubes, other laboratory disposables and culture supernatants will be treated with 1% sodium hypochlorite. The plastic ware will subsequently be autoclaved before disposal.

Once the pAdCreM1 construct has been converted into infective adenoviral particles in packaging cell lines, it will be administered intranasally to mice (in a tissue culture hood in a Class 2 containment facility at the animal house) [this procedure is detailed in our Home Office-approved Project Licence]. The mice will then be returned to their individually ventilated cages, and the tissue culture hoods will be cleaned with 1% sodium hypochlorite after use. All case bedding from the adenovirally-treated mice will be handled in a Class 2 hood and disposed of by incineration. Any mice that die or are sacrificed, will also be incinerated.

The monitoring of adenoviral infection of mouse tissues will be examined by B-galactosidase staining (as detailed in Section 7: Evaluation of foreseeable effects).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

02/03/2022
After review of the risk assessment, the investigator was asked whether a later, more completely disabled variant of AdCreM1 could be substituted for the intended purpose thus reducing the possibility of homologous recombination with wild type. The investigator replied that later variants that also expressed cre are not available.

The risk assessment was approved as a Class 2 activity requiring HSE notification on 9 January 2002.

### Project Additional Information
Purposes of the contained use

We will use classical gene replacement technology, based on PCR or suicide vector mediated gene conversion, to generate specific mutations in specific genes encoded within the genomes of selected enteric bacteria. Also we will introduce genes encoding non-toxic reporter molecules including Green Fluorescent Protein, Luciferase, Chloramphenicol acetyl transferase, beta-galactosidase and non-toxic vaccine antigens into different enteric bacteria. These reporter genes will be expressed from either constitutive or regulated bacterial promoters. The aim of the work is to use the reporter gene products to (1) track bacteria to different cells or sub-cellular locations within eucaryotic hosts; (2) to detect the activity of different promoters under different conditions.

Recipient or parental organism

The reporter genes will be supplied from existing plasmids as cloned DNA sequences or purchased from commercial suppliers. They will be introduced into any enteric bacteria other than those classified as Class III or above. Examples will be Escherichia coli (other than verotoxigenic forms), Shigella spp. Salmonella enterica (other than class III agents such as S. Typhi and S Paratyphi), Citrobacter spp etc.

Host/vector system

The host bacteria will be any enteric bacteria. The genes will either be introduced directly into the chromosome of the bacteria (via suicide vectors or PCR methodologies). Alternatively the genes will be cloned onto non-transferable plasmids such as those based on ColE1 replicons or pAYC184 (pUC plasmids for example).

Origin & function

The genetic material involved is from a variety of sources such as jelly fish (Green Fluorescent Protein), bacterial (beta-galactosidase, Luciferase, chloramphenicol acetyl transferase) but will not be cloned from these sources. We will use well-defined existing plasmids or genes from commercial sources. The DNA is simply to be used to report gene expression activity in enteric bacteria under different conditions.

Evaluation of foreseeable effects

The genes we have selected are all extremely well characterised and have been used without incident in thousands of research laboratories around the world. We will only use the named reporters associated with this application. If we decide to use any novel reporters we will amend the local risk assessment. To our knowledge there have been no foreseeable effects of these reporters other than high level expression could cause toxicity to the host bacteria (as with over expression of many proteins).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No applicable other than to disabled S. Typhi derivatives specifically derogated to CL2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the experiments will be performed in a well maintained CL2 facility either in the laboratories or the in vivo facility at The Sanger Institute. A copy of the protocol for handling enteric pathogens in these facilities is enclosed for inspection and has been approved by the local safety committee. Briefly we have detailed policies for handling contaminated liquid and solid waste that involved the contained removal of materials for autoclaving. Hence, all contaminated material is autoclaved or inactivated using chemical disinfection procedures using a variety of accepted and validated disinfectants including phenolics (hycolin etc), Virkon S or chloros. All disinfectants are made up and utilised as described in the enclosed protocol. We routinely validate inactivation using a viable count method based on the killing of control cultures of bacteria within accepted ranges. All waste material is removed using clinical waste disposal methodologies in place at The Sanger Institute.

Date of Significant Change

Project Additional Information
Purposes of the contained use

The aim of the use is to study S. Typhi using a safer attenuated derivative suitable for use at CL2. This will facilitate further examination of (a) the vaccine potential of these derivatives (b) the mechanisms of pathogenesis of S. Typhi.

Recipient or parental organism

Both S. Typhi BRD948/CVD908-htrA (aroC aroD htrA) and ZH9 (aroA aroC ssaV) or similar derivatives have been extensively studied in human volunteers and have been shown so far to be safe and highly attenuated vaccine candidates. ZH9 is through phase II clinical study and is being prepared for an efficacy study in phase III in the field. Both BRD948 and ZH9 harbour at least three independently, non-reverting attenuating mutations. Both strains fail to colonise the human host and, as S. Typhi, are unable to colonise animals or plants. Both are base on the well characterised S. Typhi strain Ty2 which has been recently fully sequenced. Both strains harbour deletion mutations that are fully sequenced and inactivating. Both strains have been shown to be attenuated in mice as well as humans.

Host/vector system

Both BRD948 and ZH9 are fully antibiotic sensitive and harbour no foreign DNA.

Origin & function

All DNA is derived from S. Typhi Ty2 with no foreign DNA. The derivatives harbour specific DNA deletions intended to stably attenuate.

Evaluation of foreseeable effects

These derivatives have been shown to be highly attenuated in many scores of human volunteers and similar mutations attenuate S. Typhimurium in mice and other species. We see no reason why these organisms should loose there attenuated phenotype as the genetic lesions have been well characterised in multiple in vivo and in vitro systems. The derivatives have been used by different groups in the UK for many years safely at CL2. For example, BRD948 has originally recognised by HSE as disabled in 1993.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The microorganisms will be derogated to CL2 as they are unable to colonise the human host and are highly attenuated but are derived from S. Typhi. The derivatives now have an excellent safety record of being safely handled at CL2 with no evidence of human infection both in the UK and abroad. The microorganism will be handled at CL2 or a higher level of containment at all times.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We operate a number of comprehensive and proven waste management measures which are conducted according to our local protocol for handling CL2 pathogens. This protocol has been in use for many years and involves autoclaving of clinical waste material, chemical inactivation of liquid waste followed by autoclaving and careful management of waste movement. The GMM will be used within a containment level 2 laboratory in which all bacterial cultures, glassware etc. is decontaminated prior to disposal. Thus drains, sinks etc. do not pose a mode of transmission to the environment. Air movement is also strictly regulated in the laboratory environment. Solid biological waste is autoclaved using temperatures, cycles and conditions appropriate for the inactivation of biological material. Autoclaving is performed by departmental
staff using approved conditions. Temperature is 134°C for 3 minutes per cycle. Glassware etc. is decontaminated, as described above, prior to being autoclaved.

The committee agreed with the classification and containment level assigned to this project.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

**Purposes of the contained use**

This project will investigate the molecular and cellular basis of disease caused by the hazard group 2 respiratory pathogen *S. pneumoniae*. The basic approach is to identify and characterise capsular genetic loci with possible importance in the disease process. We will use a non-capsular *S. pneumoniae* TTGR4 isolate as recipient to generate a range of recombinant derivatives with the specific aim of expressing these distinct capsular genes/loci independently in one background strain only. Previous studies have involved methods where the different capsules are expressed in a variety of background strains; this has made direct comparisons of virulence or capsule expression difficult to analyse. This is because with a non-isogenic background the role of other pathogenic factors encoded on the chromosomes could not be ruled out as affecting the conclusions of any studies.

**Recipient or parental organism**

*Streptococcus pneumoniae* TIGR4 non-capsular mutant strain (and related non-encapsulated mutants) obtained from Tim Mitchell (Univ. Glasgow).

**Host/vector system**

*Streptococcus pneumoniae* chromosomal DNA will be supplied to us by Lotte Larnbertsen of the Statens Serum Institut, Copenhagen, Demark. Genes involved in capsule biosynthesis will be amplified from isolated chromosomal DNA from capsulated *S. pneumoniae* by PCR. Purified PCR products will be used to directly transform non-capsular naturally competent *S. pneumoniae* TIGR4. As the genes targeted for amplification by PCR will only be those involved with capsule biosynthesis no antibiotic resistance markers or non-*S. pneumoniae* DNA is transferred.

**Origin & function**

*Wild-type Streptococcus pneumoniae* is classified by ACDP as HG2. It can colonise the human respiratory tract and sometimes cause disease. The antibiotics of choice for treatment are Penicillins. The recipient strain, *Streptococcus pneumoniae* TIGR4, is penicillin sensitive. The donor DNA will not carry any antibiotic resistance markers. TIGR4 is also sensitive to erythromycin so this antibiotic would be a suitable treatment for workers sensitive to penicillin. Vaccines are available but they do not cover all capsular types and hence all *S. pneumoniae* strains.

Infectivity of *S. pneumoniae* TIGR4 compared to wild-type is greatly reduced due to this loss of capsule. Any recipient strains expressing capsule may regain a degree of virulence but virulence would not be enhanced compared to capsulated wild-type strain.

The aim of the experiment is to insert native genes in situ on the chromosome and no intermediate cloning steps or conjugative plasmids are required. Thus, it is unlikely that genes will be transferred to inadvertent recipients. Theoretically DNA could be exchanged by natural transformation.

The capsulated form of *S. pneumoniae* can elicit infections in some individuals. The capsules themselves are non-toxic. Researchers in the study will not be knowingly immune deficient, suffering from lung disorders etc. which could cause them to be at a greater risk from infection. An immune response mounted against *S. pneumoniae* TIGR4 recipient expressing capsule operons is not expected to be greater than that mounted against wild-type capsulated forms that exist as commensals in the general population. Immunity can be capsule-specific although non-capsular antigens can contribute to protection.

**Evaluation of foreseeable effects**

Wild-type *Streptococcus pneumoniae* is classified by ACDP as HG2. It can colonise the human respiratory tract and sometimes cause disease. The antibiotics of choice for treatment are Penicillins. The recipient strain, *Streptococcus pneumoniae* TIGR4, is penicillin sensitive. The donor DNA will not carry any antibiotic resistance markers.

TIGR4 is also sensitive to erythromycin so this antibiotic would be a suitable treatment for workers sensitive to penicillin. Vaccines are available but they do not cover all capsular types and hence all *S. pneumoniae* strains.

Infectivity of *S. pneumoniae* TIGR4 compared to wild-type is greatly reduced due to this loss of capsule. Any recipient strains expressing capsule may regain a degree of virulence but virulence would not be enhanced compared to capsulated wild-type strain.

The aim of the experiment is to insert native genes in situ on the chromosome and no intermediate cloning steps or conjugative plasmids are required. Thus, it is unlikely that genes will be transferred to inadvertent recipients. Theoretically DNA could be exchanged by natural transformation.

The capsulated form of *S. pneumoniae* can elicit infections in some individuals. The capsules themselves are non-toxic. Researchers in the study will not be knowingly immune deficient, suffering from lung disorders etc. which could cause them to be at a greater risk from infection. An immune response mounted against *S. pneumoniae* TIGR4 recipient expressing capsule operons is not expected to be greater than that mounted against wild-type capsulated forms that exist as commensals in the general population. Immunity can be capsule-specific although non-capsular antigens can contribute to protection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only 0MM will be utilised in this study.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A
Genetically modified S. pneumoniae TIGR4 will be grown on a small lab scale of up to 25 rids and will be handled and inoculated using aseptic technique and good microbiological practice. All lab disposables that come into contact with GMM will be chemically inactivated with Virkon (as per manufacturer’s protocol) before disposal by incineration. All contaminated glassware will be inactivated by autoclaving. Bench areas used will be cleaned using 1% Virkon (as per manufacturer’s protocol) before and after use. Autoclave facilities have undergone 12 point validation and give 100% kill. Chemical inactivation using 1% Virkon using manufacturer’s protocol will give 100% kill of bacteria.

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Following review of the risk assessment the GMSC agreed that the investigator had satisfied all required criteria for a CL2 GMM activity. The few suggestions to changes in protocol that were made by the GMSC (for example, investigator initially proposed using crude chromosomal extract to introduce genes into non-capsulated S. pneumoniae. The GMSC suggested the use of purified PCR products, rather than use crude chromosomal extract, in order to avoid the risk of introduction of unknown genetic material and help maintain isogenicity of host strain. Following discussion with the investigator, where deemed relevant to reduce the risk of the investigation, these suggestions were incorporated into the attached risk assessment.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The aim of these experiments is to characterise the genetic factors expressed by *Clostridium difficile* that are associated with enteric infection or intestinal colonisation. Disease associated with *C. difficile* infections are normally acquired by oral infection. This work may lead to the development of new antibiotics or vaccines. Functional analysis of virulence-associated factors requires that their genes be mutated and the phenotype characterised. It is also essential to confirm that any reduction in virulence is indeed due to the mutation. This is done by reintroducing the wild type gene on a plasmid and confirming restoration of the wild type phenotype in the complemented strain. *E. coli* K12 routinely acts as an intermediate host for manipulating cloned DNA prior to reintroduction into the recipient pathogen. Antibiotic resistant genes and other non-toxic biological reporter genes (LacZ, CAT, GFP, Lux etc) can be introduced into the recipient during manipulation. The OMOs are, however, sensitive to the antibiotics recommended for therapy of infection.

**Recipient or parental organism**

*Clostridium difficile* strains 630 (as well as erythromycin sensitive variant), DI-1, CF5, CD196 and SM027 will be obtained from Prof. Brendan Wren (London School of Hygiene and Tropical Medicine).

**Host/vector system**

*Host bacteria*

*K-l2 derived E. coli* (for the purposes of this project will be used only under containment level 2 requirements).

*Clostridium difficile* strains 630, BI-l, CF5, CD196 and SM027

**Vectors**

- pMTL54O1F (AmpR, Mob, Tra-, Bom-, shuttle vector that can replicate in *B. coli* and *C. difficile*)
- pMTL54O2F1acZTTEEmIBtdRAM1 (AmpR, Enn’, Mob, Tra-, Bom- shuttle vector that can replicate in *B. coli* and *C. difficile*)
- pMTLOO7 (Cm’, Enn’, Mob’, Tra-, Bom- shuttle vector that can replicate in *B. coli* and *C. difficile*)
- pçMT, (Amp’, Mob, Tra-, Bom-, *E. coli* cloning vector)

**Origin & function**

The aim of the experiment is to inactivate target genes in *C. difficile*, the origin of the required genetic material will be *C. difficile*. Target genetic material will be cloned initially into *B. coli* K12 in order to produce the quantity of genetic material (vector plus insert) required for successful transfer and integration into *C. difficile*. Target genes introduced into *B. coli* K12 are unlikely to cause harm when removed from the normal environment of their natural host bacteria. However, it should be recognised that...
deliberate large scale production of some of the cloned proteins could be hazardous but this is not the aim of these experiments. Thus, the risk is negligible. It is not likely that an allergic response could be induced.

### Evaluation of foreseeable effects

**C. difficile** is classified by the ACDP as a hazard group 2 pathogen; it is able to cause disease in humans and domestic animals. In this work, inserted DNA will normally come from **C. difficile** with the exception of the non-toxic biological reporter genes. Inserted genes can encode potential virulence genes but during the construction of the GMMs virulence genes may be inactivated and attenuated variants generated. It is unlikely that the manipulation procedures will enhance the virulence of any of the GMMs to a higher level than that of the donor, as a consequence all work will carried out at containment level 2. Although the eventual aim of the experiment is to integrate genes (inactivation) onto the chromosome, inserted DNA will also be harboured on plasmids. However, such plasmids will be non-conjugative and consequently they will be unlikely to transfer on to unintended recipient bacteria.

Target genes will be cloned initially into E. coli 112. Genes and gene products are unlikely to cause harm out of the context of their natural host bacteria, **C. difficile**. However, it should be recognised that deliberate large scale production of some of the cloned proteins could be hazardous but this is not the aim of these experiments or within the remit of this assessment.

Although antibiotic resistance genes such as erythromycin will be used in the experiments as markers genetic transfer and gene inactivation, the GMMs will be sensitive to appropriate therapeutic antibiotics, such as vancomycin and metronidazole. Under certain conditions, **C. difficile** is able to form spores. These are resistant to certain traditional methods of inactivation, such as 70% ethanol. Spores, however, are sensitive to 1% Virkon, this will be used routinely for inactivation.

As **C. difficile** is classified as a hazard group 2 pathogen, it would be advisable for anyone knowingly immunosuppressed not to undertake this work. All individuals involved with these experiments will be expected to register with the Sanger Institute occupational Health Department and complete a pre employment health surveillance questionnaire.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only 0MM will be utilised in this study.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Not applicable**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Genetically modified **C. difficile** and E. coli K12 will be manipulated, cultured and handled by trained staff, experienced at working at CL2. Cultures will be handled and inoculated using aseptic technique and good microbiological practice.

All lab disposables that come into contact with 0MM will be chemically inactivated with Virkon (as per manufacturer’s protocol). Where the manufactures supplied data on inactivation is not applicable for intended use, viable counts of microorganism will be taken after exposure to working dilutions of Virkon to assess the percentage kill.

All contaminated glassware will be inactivated by autoclaving.

Bench areas used will be cleaned using 1% Virkon (as per manufacturer’s protocol) before and after use.

Autoclave facilities have undergone 12 point validation and give 100% kill. Chemical inactivation using 1% Virkon using manufacturer’s protocol will give 100% kill of bacteria.

**Project Ref** 552/08.1

- **Date Ackn'd**: 06/10/2008
- **CU2 Project Title**: Plasmodium falciparum - erythrocyte interactions: GM Plasmodium falciparum parasites
- **Class**: Class 3
- **Culture**: 100ml
- **Consent Granted**: Being Processed
- **Project notified under transitional arrangements**: N

**Historical Significant Changes**

- **Historical Date of Additional Info**: 552/08.1a
- **Date of Significant Change**: 17/02/2010

**Project Additional Information**

- **Purposes of the contained use**: Genetically modified Plasmodium falciparum parasites will be generated in order to understand the molecular mechanisms of the parasite-erythrocyte interactions that play a major part in malaria pathogenesis and disease. A better understanding of these critical interactions may lead directly to the development of new prevention and control strategies.
measures such as new drugs and/or vaccines.

Receptor or parental organism

Plasmodium falciparum

Host/vector system

Plasmodium falciparum transfection vectors are not commercially available. Vectors are available from American type Culture connection (ww.mr4.org) and vectors to be used in this study will be obtained from this source, or from research colleagues.

Origin & function

Inserts:
Plasmodium falciparum merozoite proteins, including invasion ligands (EBL family, RBL family, AMA1), merozoite surface proteins (MSPs), invasion proteins (MyoA, MTIP, GAP45, GAP50) and components of the post-translational modification apparatus such as kinases and palmitoyl transferases that are involved in regulating erythrocyte invasion.

Constructs containing modified P.falciparum genes or fragments of such genes will be introduced into P.falciparum strains by transformation and selected for using anti-microbials. Constructs will either be maintained as episomes, or will integrate in a targeted manner into the P.falciparum genome. The effect of genetic modification will be assayed using standard cell biology (growth rate, microscopy, invasion assays) or biochemical (immunoprecipitation protein detection) techniques. By experimentally modifying specific P.falciparum genes, whether by tagging, gene ablation, or allele exchange, we will be able to generate and test hypotheses about the role of these genes in erythrocyte invasion and other parasite-erythrocyte interactions.

Evaluation of foreseeable effects

Potential source of additional risk in the generation of GM P. falciparum parasites is the introduction of drug resistance cassettes to P. falciparum strains, producing parasites that are resistant to one or more anti-microbial drugs, either anti-folates (pyrimethamine or derivatives such as WR99210), gentamicin or blasticidin. However, the impact of this is minimized by the fact that none of these drugs are in widespread use for P. falciparum control, and all strains generated will still be susceptible to more than one anti-malarial, including quinine, mefloquine and artesininin based compounds, and combinations thereof. In the extremely unlikely event of accidental worker infection (unlikely given the no sharps policy, the route of infection being only blood mediated, not aerosol mediated, and the use of CL3 techniques), GM P. falciparum parasite strains will therefore have exactly the same susceptibility profile to commonly prescribed anti-malarials as non-GM P. falciparum strains.

The other potential source of additional risk is the impact of experimental genetic modification on the virulence of the P. falciparum parasite itself. Based on past experience, it is our assessment that almost all genetic modifications planned will have if anything a negative impact on virulence. We will be modifying genes involved in the erythrocyte invasion process by tagging (GFP, epitope tags such as HA or c-myc), gene ablation or allele exchange (exchanging one natural allele variant for another or mutating specific codons in a gene to assess the effect on function). Erythrocyte recognition and invasion is essential for parasite growth and operates in a highly efficient manner in wildtype strains. Experimentally modified versions of proteins involved in erythrocyte invasion are therefore not likely to operate more efficiently than the unmodified proteins, and are much more likely to operate less efficiently. This has certainly been our past experience working with GM P. falciparum parasites in other institutions, and is the published experience of other labs — such modified lines tend to grow more slowly, and are rapidly outgrown by wildtype parasites if drug pressure is removed. We therefore think that in the majority of cases it unlikely that GM P. falciparum parasites will pose a risk or hazard to humans over and above the general risks of P. falciparum in vitro culture, and it anything the GM strains generated as part of this project are likely to be less fit than their wildtype counterparts.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from the requirement to carry out this activity na laboratory sealable for furnigafon (as per "Biological agents: Managing the risks in laboratories and healthcare premises"; Appendix 3.2 Work with Hazard
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste in contact with live P. falciparum material is disinfected by treatment with Virkon, disposed of in biohazard bags, placed in an autoclave bin, sealed, and autoclaved prior to final disposal. Spillage containment kits will be maintained in the derogated CL3 room. MSCs will be disinfected after every use and given a final clean before shut-down each day.

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

Mike Quail (08/09/08) - With the P. falciparum work they limit sharps to microscope slides. Has every alternative here (plastic/acrylic slides) been considered?
Response: The use of glass slides will only be permitted for the assessment of parasites that parasites have been inactivated by the staining process.

Christian Johnson (08/09/08) - Apart from some minor spelling corrections on part A I am quite happy for this assessment to stand as a class 3 GM activity.
Jo Butler (16/09/08) - I am completely happy with the risk assessments, though I did spot a few typos.
I think that the Class 3 assessment, GM Plasmodium falciparum parasites, is appropriately carefully argued and that all likely risks, including those from allele exchanges of erythrocyte invasion ligands, have been appropriately considered.
No other comments were received from the GMSC.

Project Additional Information

Purposes of the contained use

Analysing infection ability of different types of lentiviruses and retroviruses on the host cells.
GFP encoding lentiviral or retroviral vectors are introduced into 293 cells together with helper plasmids. The resulting supernatant, which contains virus, is used to infect target cells. Appropriate period after infection, cells are harvested for fluorescent detection and DNA, RNA or proteins are extracted.

Recipient or parental organism

Mouse embryonic stem cells: AB1, AB2.2, JM8 and their derivatives
Fibroblast cells: MEF, STO-derived cell lines.
   HEK293 and its derivatives.
   Primary mouse cells from various tissues.

Host/vector system

Vectors: 1, Lentiviral expression vector encoding enhanced green fluorescent protein (eGFP), SIN CSGW
   2, SIVmac (Simian Immunodeficiency Virus macaque) vectors (SIV-eGFP)
   3, MLV (Murine leukemia virus) vectors (MLV-eGFP)

Helper vectors: 1, pMDG (vesicular stomatitis virus envelope protein (VSV-G) expression vector),
   2, HIV-1 and HIV2 gag-pol expression vector (expressing packaging protein)
   3, SIV3+ (SIVmac gag-pol expression vector)
   4, pCIG3 N or B (MLV gag-pol expression vector)

Other viral vectors: FIV (Feline immunodeficiency virus and EIAV (Equine Infectious Anemia Virus)

Origin & function

Human or Mouse retrovirus which are self-inactive and infectable to mammalian cells

Evaluation of foreseeable effects

This viral system can infect most mammalian cells, but they are self-inactive, and have less risk to survive out of lab.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For liquid waste, decontamination will be carried out by addition of Virkon to waste solutions, which will then be stored overnight at room temperature in the Class II MSC. The resultant inactive waste will be disposed to drain.

All solid wastes will be autoclaved using a validated cycle prior to disposal.

Project Ref 552/09.2

Date Ackn’d 16/12/2009

CU2 Project Title Mouse models and screens to understand and visualize the consequences of chromosome mis-segregation

Date Project Ceased

Class CultureVolClass CultureVolumeClass

Class 2 < 1 Litre

Non-GMM Consent Granted
Chromosomal instability (CIN) occurs in the vast majority of cancers. The goal of this project is to find genes that protect the genome against numerical chromosome instability (whole chromosome losses and gains). For this purpose we will use established human cancer cell lines and mouse ES cells to perform screens in that aim to identify such genes. Additionally, we are developing tools to visualize chromosome segregation and ongoing CIN in vivo.

Recipient or parental organism

- MCF10A human breast cells
- MBL human mammary cells
- HT1080 cancer cell line
- HEK293T human embryonic kidney cells
- Mouse embryonic stem cells AB1, AB2.2, JM8 and their derivatives.

Host/vector system

1. Retroviral vectors
   a. Based on pRetrox or pBabe (Moloney-derived).
   b. Replication incompetent due to use of co-transfection of split genome vectors (Gag-Pol, Env) in 293T cells.
   c. Co-transfected with vector expressing Amphotropic envelope (pAmpho) or Ecotropic envelope (pEco) (Clontech), for expression in human or mouse cells, respectively.
   d. Self-inactivating LTRs to minimise risk of insertional activation of host genes and unwanted expression of the insert
   e. Chimeric Tet-ON/CMV promoter to restrict gene expression to the presence of doxycycline
   f. Puromycin (or a neomycin, blasticidin or zeocin) cassette under a constitutively active PGK promoter, allowing for selection of integration of the retroviral vector, while the introduced transgene is not expressed.

2. Lentiviral vectors
   a. 3rd generation HIV-based TRIPZ system (Open Biosystems).
   b. Replication incompetent due to use of co-transfection of split genome vectors (Tat, Gag, Pol, Rev, VSV-G) in 293T cells.
   c. Self-inactivating LTRs to minimise risk of insertional activation of host genes and unwanted expression of the insert
   d. Contain WPRE element expressing fragment of WHBV protein X (unmodified)
   e. Tightly-regulated Tet-ON promoter to express shRNA sequences only in presence of doxycycline

Origin & function
Inserts

a. Ras and c-Myc: In order to predispose cells for oncogenic transformation, cells will be transduced with either conditional RasV12 or conditional c-Myc. Both are well established oncogenes. Their expression will be tightly-regulated by use of the Tet-ON promoter, and only after selection of stable clones has been performed.

b. Mitotic checkpoint and machinery proteins p31CMT2, Cdc20, Mad1, Hec1, Mps1, BubR1, Bub3, ROD, Zwilch: I am studying the effect of several point mutants of the spindle checkpoint protein Mad2 which show decreased binding to other checkpoint proteins such as p31CMT2, Cdc20 and Mad1, which will be expressed in an inducible fashion. Other proteins that will be expressed are Hec1, Mps1, BubR1, Bub3, ROD complex. The role of these proteins in the development of cancer is still obscure, none of these proteins have been identified as potent oncogenes. Germline inactivation (as far as tested) has unequivocally resulted in early embryonic lethality in mouse models.

c. shRNAs to Mad2, Mps1 and Blm: Whereas loss of Mad2 or Mps1 expression results in cell lethality, rather than oncogenic transformation, Blm deficiency has been shown to result in a five-fold increase in tumour predisposition in a mouse model. As all three genes are important guardians of the genome, their loss will result in chromosome instability and are therefore likely to be oncogenic.

d. Fluorescent protein (GFP/CFP/YFP/RFP) fusions with Histone H2B, Tubulin and Centrin 3.

e. rTTA Tetracycline repressor protein.

Evaluation of foreseeable effects

Retroviral vectors retargeted to the amphotropic receptor, and lentiviral vectors are capable of transducing human cells, and becoming integrated into the genome of the host cell as a provirus. This is theoretically capable of causing insertional activation or disruption of host genes close to the site of insertion. Inappropriate activation of potentially harmful genes is minimised by the use of vectors containing deletions in the LTR regions (so-called self-inactivating or SIN vectors).

The presence in the lentiviral vectors of an unmodified post-transcriptional regulatory element (WPRE) derived from the woodchuck hepatitis B virus (WHBV) genome gives the potential for tumorigenesis due to expression of a fragment of WHBV gene X.

The retroviral vectors will be used to deliberately express the known oncogenes Ras and c-Myc, and several other genes involved in chromosome instability, which are potentially oncogenic. Lentiviral vectors will be used to express shRNA sequences capable of knocking down the expression of other mitotic checkpoint genes, an event which has been shown to be associated with tumour predisposition.

The following have also been taken into consideration:-

The viral vectors are produced by co-transfection with split genome helper plasmids, so are replication incompetent, with an extremely low risk of recombination events leading to infective capability.

The viral vectors will be produced at low titre, and will not be concentrated, e.g. by harvesting from a density gradient.

The potentially harmful gene inserts are under the control of a tightly-regulated inducible promoter, and will only be expressed in the presence of the antibiotic doxycycline.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid cultures will be chemically inactivated by the addition of a validated disinfectant (e.g. Virkon S) and leaving for the required time (>20 minutes), before being disposed via the drains.

Contaminated solid waste (culture dishes, serological pipettes, disposable gloves, etc) will be autoclaved using a validated cycle prior to disposal.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N
I note that the RA considers the work to be Class 2, with which I fully agree. (As pointed out in the RA, they are cloning potential oncogenes into amphi retro- and lentiviral vectors, and also their lentiviral vector contains an intact WPRE.).

This work doesn't seem to pose much of a safety risk. However it is quite a complex study so class 2 seems appropriate.

Project Ref 552/10.2

Date Ackn'd: 10/11/2010

CU2 Project Title:

Lentivirus vectors encoding sgRNAs to achieve knockdown of cancer gene expression

Class: Class 2

CultureVolClass2: < 1 Litre

Consent Granted: Non-GMM

Date Project Ceased: 18/08/2016

Tick if notifying a connected programme of work: N
**Project Additional Information**

**Purposes of the contained use**

Identification of genotypes in human cancer cell lines that are associated with sensitivity to anti-cancer therapeutics. The validity of sensitizing genotypes (to anti-cancer therapeutics) in a small subset of cell lines will be determined by using a shRNAi strategy to silence gene expression and the effect on cell growth measured. We will generate lentiviral particles from hairpin-pLKO.1 plasmids in the 293T packaging cells. These will be used to transduce human cancer cell lines and specificity of knockdown assessed by western blot or Q-PCR.

**Recipient or parental organism**

Human embryonic kidney 293 T cells (for virus propagation); Human cancer cell lines displaying sensitivity to targeted anti-cancer compounds - purchased from commercial repositories (ATCC, DSMZ, HPACC, ICLC, RIKEN and JHSF).

**Host/vector system**

Replication incompetent, disabled lentivirus, pseudotyped with VSV-G protein. The lentivirus will contain pLKO.1, an HIV-based plasmid that does not contain the WPRE (Woodchuck Post-transcriptional Response Element), with an insert that will be integrated into the host cells’ genomes. The lentiviral vector contains a self-inactivating 3' LTR that renders it further unable to produce infectious virus once it integrates into the host chromosome.

**Origin & function**

Two products will be generated: -
(1) Green Fluorescent Protein, which has a long history of use with no documented adverse events associated with it
(2) Short hairpin RNA (shRNA) molecules, which are designed to be capable of reducing the expression of targeted genes in a sequence specific manner. The use of shRNA molecules targeted to genes implicated in cancer, including known tumour suppressor genes

**Evaluation of foreseeable effects**

Lentiviral vectors pseudotyped with the VSV-G envelope protein are capable of transducing multiple human celltypes (i.e. not just the CCR, CD4+ cells of the immune system that are the normal target of wildtype HIV), and becoming integrated into the genome of the host cell as a provirus. This is theoretically capable of causing insertional activation or disruption of host genes close to the site of insertion. Inappropriate activation of potentially harmful genes is minimised by the use of vectors containing deletions in the LTR regions (so-called self-inactivating or SIN vectors).

The lentiviral vector system has ben developed with enhanced safety features. It is a three plasmid system consisting of : (1) pCMV-dR8.91 - the packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions. (2)pCMV-VSG - the vesicular stomatitis virus G-protein envelope vector, which provides the heterologous envelope for pseudotyping, and (3) pLKO.1 - shRNA transfer vector, which contains he sequence of interest as well as the cis acting sequences necessary for production and packaging of the RNA genome. The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus. It also means that the resulting lentiviral vectors are, as far as reasonably foreseeable, entirely incompetent for replication and productive infection.

Lentiviral vectors will be used to express shRNA sequences capable of knocking down the expression of genes implicated in cancer, including known tumour suppressor genes. This has unpredictable, but potentially oncogenic outcomes, even as a single event.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was discussed at a meeting of the Biological Agents and GM Safety Committee held on 22nd September 2010.

There was one specific comment from a member of the Committee not able to attend the meeting: "I have no problem with this a Class 2. I also note the absence of WPRE elements, but even if present these would still leave it at Class 2".

It was therefore approved by the Committee as a Class 2 GM activity.

Project Ref 552/11.1

Date Ackn'd 29/06/2011

CU2 Project Title Investigating host and viral genetic variation and the effect of such variation on virus pathogenesis in vitro and in vivo

Class 2

CultureVol Class 2 < 1 Litre

CultureVolume Class 3-4

Non-GMM Consent Granted

Date Project Ceased 02/03/2022
**Project Additional Information**

**Purposes of the contained use**

This connected programme of work aims to investigate how genetic variation in the host (gene mutation, gene expression differences, gene deletion and gene duplication) and in medically important human viruses affects the host response to infection, virus virulence and pathogenesis. The viruses we will investigate are all classified by the Advisory Committee on Dangerous Pathogens (ACDP) as hazard group two organisms and will include:

1. Human herpesviruses, including Kaposi's sarcoma associated herpesviruses (KSHV), Epstein Barr Virus (EBV), and Herpes Simplex Virus (HSV-1), both wild type viruses and viruses derived from recombinant bacterial artificial chromosomes.
2. Murine herpesviruses, including murine herpesvirus 68.
3. Human orthomyxovirus, influenza viruses
4. Human paramyxovirus, measles virus.
5. Lentiviral vectors

The result of sequencing host and virus genomes is the identification of mutations that may be linked to a particular phenotype of infection. However, such association must be mechanistically investigated to determine their true biological effect. This connected programme of work will facilitate such mechanistic investigation. Specifically we will study how herpesviruses are able to infect, persist in a latent state, reactivate into a lytic cycle of virus production and in some cases immortalise certain cell types. We will study how host genes prevent or limit infection of a variety of viruses.

This connected programme will use a number of standard molecular biology/virology methods to produce viruses in some cases derived from defined genotype recombinant sources such as herpesviruses BACs, reverse genetics influenza virus and virus engineered to express non-toxic marker genes. We will monitor virus infection in vitro by over-expression or ablation through RNAi different virus and host genes and in vivo by infection of wild type and gene knockout mice. These methods will be used to determine the phenotypic outcomes of virus and host interaction.

The foreseeable hazards of transduction of the eukaryotic cells with expression vectors to overexpress viral or host proteins, or to ablate their expression by RNAi, and/or the infection of these cells with wild type or recombinant viruses, would be the production of a cell line with altered properties able to establish an altered infection profile facilitating the selection of viruses with altered pathogenicity or host range, the infection of laboratory works and subsequent transmission to other people.

In vitro work:

**Lentiviral vectors:**

This project aims to clone human or viral genes of different functions and genotypes and produce plasmid expression and lentivirus vectors for gene delivery and expression in eukaryotic cells. Genes will be cloned from human and viral DNA or cDNA into bacterial vectors that contain bacterial and/or eukaryotic selectable markers and bacterial or eukaryotic expression signals. To generate lentiviral vectors the gene of interest will be transferred into a modified HIV vector, with viral genes deleted.
containing a CMV or SFFV promoter driving the expression of GFP and the single human gene from the bacterial plasmids. This will be transfected into eukaryotic cells together with an HIV packaging plasmid encoding gag/pol, tat and rev with virulence gene vif, vpu and nef deleted and an envelope expressing plasmid (VSV-G). We will use the lentivirus vector system to transduce cell lines and primary cells producing cells which transiently express the gene of interest and after selection or sorting produce stable cells.

Identifying host-virus interactions:

This work aims to identify the function and mechanism of action of host or viral genes which affect the phenotype of virus infection, using a number of different ADCP hazard group 2 viruses (see section 7.). These viruses will include those which are genetically modified to contain non-toxic marker genes, such as GFP or luciferase or that have been attenuated in comparison to parental strains.

In vivo work:

The aim of the in vivo experiments is to characterise host genetic factors that affect virus infection using a mouse model. We will study hazard group 2 viruses including influenza and herpes simplex virus, which may be genetically modified. The mice to be infected are housed in the Research Support Facility (RSF) building at the Wellcome Trust Sanger Institute (WTSI) in a purpose built CL2 facility. Mice are normally inbred but on occasions approved outbred mice may be used. The WTSI has a large scale programme for generating knockout mice. Some of the mice harbour defined mutations in different murine genes and some express reporter molecules such as drug resistance or B-galactosidase markers. All details of the infection procedures are approved by the Home Office Licence held by Professor G D/Dr S C and infections will be performed in accordance with this approved licence and appropriate project licence holder.

Recipient or parental organism

The recipient/parental viruses are all CL2 organisms, no CL3 work will be undertaken in this coordinated programme of work.

In vitro work:

Lentiviral vectors - The genes for expression will be from a variety of different cellular pathways and will include transcription factors, innate and adaptive immune system genes, oncogenes and tumour suppressor genes. The cloned genes will on occasion be modified by either single mutations, partial deletions and fusion to tags (e.g. antigen tags, GST functions) or controllable expression tags (e.g. tetracyclin inducible promoter plasmids or tamoxifen inducible fusion proteins). As this work will always focus on single human genes it is unlikely that such genes will have the capacity to alter bacterial cell function during cloning on their own. However, we are aware of the low risk posed by the expression of human genes that will alter cellular functions (i.e. oncogenes, hormones, tumour suppressor genes, cytokines, etc) in bacteria and their potential for plasmid mobilisation.

Cells transfected with lentiviral vectors, either for the production of virus vector stocks or following transduction, will contain viral genes on split plasmids therefore making the vector attenuated by lack of intact full length genomes that would require extensive recombination events to produce a replication competent virus. There is good evidence that such replication defective viruses are not pathogenic when tested in mice and a minimum of 3 recombination events are necessary to produce replication competent, recombinant virus. In addition such virus vectors are single cycle infection agents not able to form productive infections or to recombine with endogenous retroviruses and become productively infectious. Therefore, although exposure to such viral vectors is a possibility this would be a self limiting/dead end infection.

There is a very low likelihood that exposure to any components of this project will cause harm. The main risk is accidental infection and transfer of the human gene expressing lentivirus to the laboratory personnel directly handling the lentivirus. This risk is extreme low but in the event of such a transmission a subset of the human gene expressing clones may cause potential harm by insertional mutagenesis/overexpression of cellular genes by random integration acting to deregulate normal cell function, for example, expression of cytokines or oncogenes. The lentiviral vectors have a broad host range due to the receptor independent VSVG envelope. Again the likelihood that this will cause harm is low as the replicative defective nature of the HIV vectors ensures that even in the case of a breach of containment and accidental injection, no virus can spread within or between individuals. Also more than one genetic lesion is required for most cell transforming and altering events. As we will be working with only one human gene at a time the risks are low.
Level 2 containment for both the molecular biology and tissue culture work is sufficient for both the production of lentivirus plasmids and replication defective viral vectors. This level of containment is also sufficient for the transduced cell lines that result from exposure to the viral vector preparations.

Identifying Host-Virus Interactions.

For all viruses within this body of work genetic modifications will involve insertion of marker genes such as GFP, luciferase or deletion/modification of viral genes to cause attenuation. The foreseeable effects from the production of such recombinant viruses will be to produce a virus that is equivalent to or attenuated relative to wild type virus. It is very unlikely that a virus with increased pathogenicity will be created through the manipulation of viral genes. All viruses used are ACDP hazard group 2 and will be worked with in CL2 containment facilities.

Virus to be worked with include:

**HERPESVIRUSES (wild type and recombinant including from BAC):**
- Herpes Simplex Virus Type 1
- Kaposi's sarcoma associated herpesvirus
- Epstein Barr Virus
- Murine herpesvirus 68

These are transmitted primarily as cell free virus in saliva and through close physical contact. As such the potential for accidental exposure comes from virus containing medium that is ingested exposing the oral cavity. However, most people are already seropositive and latently infected with Human Cytomegalovirus and Epstein Barr Virus. Infection with any of the human viruses causes a self limited primary infecton with the potential for the virus to sporadically reactivate. Epstein Barr virus can cause infectious mononucleosis (glandular fever) in adults, which can have long term effects, including fatigue syndrome. Generally no disease symptoms arise, however herpes simplex virus causes cold sores and Kaposi's sarcoma associated herpesviruses and Epstein Barr Virus can cause lympho,as and other cancers. The primary risk of these viruses results from immunodeficiency or in the case of human cytomegalovirus infection of a seronegative mother during pregnancy. As such, the policy of immunosuppressed or pregnancy being exclusion criteria for work with these organisms will be enforced. Murine herpesvirus 68 and murine cytomegalovirus do not infect humans and do not cause disease in mice.

**ORTHOMYXOVIRUS (wild type, produced from reverse genetics systems and recombinant Influenza A)**

No influenza viruses classified above containment level 2 will be used. All people that work in the laboratories which use influenza will receive annual influenza vaccinations. Only low pathogenicity laboratory strains of influenza will be used and these may be genetically modified. Different strains of influenza virus will not be worked with at the same time to avoid the possibility of reassortment between viruses.

Influenza viruses are airbourne viruses transmitted primarily as foamites. Therefore the primary risk from GM influenza viruses is exposure to tissue culture medium either as an aerosol or as a large volume exposure to the nose, mouth and eyes (mucous membranes). These risks are minimised by the enforcement of no unsealed tubes and flasks outside of the Class II microbiological safety cabinets. A risk of onward transmission if infected exists, although due to the nature of the viruses used this will pose no greater risk to the general population than normal circulating influenza. Nevertheless, anyone with flu like symptoms will be requested to seek medical advice and minimise contact with others.

**PARAMYXOVIRUS**
- Measles
Measles is highly contagious and spread by coughing and sneezing. An infected person can transmit measles any time from about 4 days prior to the onset of the rash to 4 days after the onset. However, infection can be completely prevented by vaccination and therefore all workers in the laboratory who work with or in the environment where measles viruses are used will be required to have, or demonstrate existing immunity to measles.

The primary risk from GM measles virus is exposure to tissue culture medium either as an aerosol or as a large volume exposure to the nose, mouth and eyes (mucous membranes). These risks are minimised by the enforcement of no unsealed tubes and flasks outside of the class II microbiological safety cabinets.

In vivo work:
The GM viruses are to be used are those described above - these will include viruses harbouring specific mutations in selected viral genes and/or the expression of reporter genes. Some viruses will express non-toxic reporter molecules such as GFP or luciferase. Some viruses may be attenuated in comparison to their parental strains (see above).

The mice for infection may harbour mutations in specific murine genes and may also express non-toxic reporter molecules. The WTSI is currently undertaking mouse gene knock out of hundreds of genes using conventional gene replacement technology and some of these mice will be screened for altered susceptibility to infection using the virus in the coordinated programme of work and the associated risk assessments and Home Office licenses. None of the genetically modified mice pose a higher risk to human health or the environment than the parental strains.

We anticipate that mice will become infected by the viruses used for challenge and some will go on to develop clinical symptoms. Such mice will be humanely sacrificed according to the methods outlined in our Home Office Licence if their clinical symptoms reach a certain well documented level of severity. We foresee no unusual outcomes other than that some infections will be altered in severity or duration of infection in KO mice in comparison to wild type mice. If any of the mice show usually high susceptibility to infection they will be humanely sacrificed.

The primary risk will be infection of laboratory workers and other mice as a result of the infection of wild type or KO mice. We estimate this risk is very low and is managed by all work being carried out in purpose built CL2 facilities. Tissues and samples are fixed and virus inactivated before removal from the CL2 facilities, animal cadavers autoclaved before disposal and infectious material transported between the animal CL2 and virology CL2 laboratories in approved transport containers, according to risk assessments that are in place.

Host/vector system

Plasmids
Cloning plasmids will be pGEM derivatives, pUC series, pBLUESCRIPT series, pcDNA, pCMV/Zeo, and pEGFP-1. The lentiviral vectors use the tripartite packaging plasmid pCMVR89.1 (packaging plasmid), (pMDG (envelope VSV-G plasmid) and pCSGW (pHR-CMV-IRES-eGFP vector plasmid), pCSGW contains the promoter-mutated form of the woodchuck hepatitis virus post-transcriptional regulatory element (WRE), which is incapable of expressing the putative oncogene encoding protein X.

All plasmids are non-mobilisable.

Bacterial hosts
Bacterial hosts for all plasmid propagations within this programme of work are derived from E. coli K12, so are disabled in key bacterial functions (i.e. recombination defective) and are unable to survive in the environment. These will include E. coli - XL-Blue, TOPO10, JM109, SURE.

Host cell lines
Host cell lines and primary cells will include: 293T, HeLa, NIH3T3, B-cell lines from all stages of B-cell including BJAB, Ramos, Rajo Tom -1, DEL RPMI-8226, BCP-1, BCBL, HBL-6, BC3, T cell-lines including C8166, CEM, SupT1, monocytic cell lines including knockout cell lines, murine embryonic fibroblasts, PSNL 76/7-4.

NO cell lines or primary cells used will be from the workers.
The foreseeable effects of transduction of the eukaryotic cells with expression vectors, or the infection of these cells with recombinant retroviruses would be the production of a cell line with altered properties able to establish a tumour in the laboratory workers, but the likelihood of this hazardous event with the control measures in place is estimated to be LOW.

Mice
The mice may harbour deletions, which will have been characterised in the WTSI phenotyping pipeline and may also express non-toxic reporter gene products such as β-galactosidase. All infectious work will be carried out in purpose built CL2 facilities and animal cadavers will be autoclaved before disposal.

Origin & function

Origins of herpes viruses - Herpes simplex virus and murine herpesvirus 68 are supplied to us as a gift from Dr S E, University of Cambridge. KSHV and EBV are already available in the Kellam Lab.

Influenza viruses are supplied to us as a gift from Prof W B, Imperial College, London and P D, University of Cambridge.

Measles viruses are supplied to us as a gift from Prof P D, Department of Microbiology, Boston University School of Medicine.

The intended functions of the genetic modified material listed above is to attenuate or add a marker gene (e.g. GFP, luciferase) with the resulting GM virus having an altered phenotype in host cells or mice.

Lentivirus vector systems - These are standard laboratory reagents which are supplied to us as a gift from the Kellam laboratory at UCL. They originated from infectious retroviruses of humans and animals but have been extensively engineered to be self-inactivating and capable of only a single round of infection.

The function of retroviral expression vectors is to change the level of expression of host proteins within the cell.

Evaluation of foreseeable effects

Bacterial hosts
Bacterial host for all plasmid propagations within this programme of work are disabled in key bacterial functions (i.e. recombination defective) and are unable to survive in the environment or pass genetic material onto host bacterial flora following a breach of containment.

For the production of lentiviral vectors the lentiviral genome is split into three separate plasmids such that virus production is only initiated when all three plasmids are present in a eukaryotic cell. Therefore there is no risk of lentiviral particles being produced from bacterial culture.

OVERALL THE RISK OF ADVERSE EVENTS FROM THE HANDLING OF PLASMIDS OR BACTERIA (INCLUDING THOSE CONTAINING KNOWN OR POTENTIAL ONCOGENES) IS LOW.

Lentiviral Gene expression
For the lentiviral gene expressions and gene ablation vectors production of infectious viral particles only occurs following transfection of the three plasmid system into eukaryotic cells. Therefore the control of virus particle production can be contained both physically in a CL2 tissue culture laboratory and by prevention of virus production by the absence of all three plasmid vectors. Lentiviral vectors are therefore unlikely to be transmitted onto the laboratory workers during routine laboratory experiments involving the retroviral vector plasmids or following disposal of laboratory waste. The main risk is accidental exposure of laboratory workers to recombinant lentiviruses. As these lentiviral vectors are self-inactivating the risk of onwards transmission to another person is almost zero. The main risk is therefore alteration of the cellular function of the exposed person through insertional inactivation/activation of tumour suppressor genes/oncogene respectively, or the alteration of cellular function by gene overexpression or ablation from the transferred genetic material within the vector. THESE ARE EXTREMELY UNLIKELY EVENTS THAT HAVE ONLY OCCURRED IN A CLINICAL SETTING FOLLOWING PROLONGED INFECTION WITH HIGH TITRE RETROVIRAL VECTORS AND SELECTION IN VIVO FOR CELLS WITH ALTERED GROWTH POTENTIAL THEREFORE THE OVERALL RISKS ARE LOW

GM viruses
For all viruses within this body of work genetic modifications will involve insertion of marker genes such as GFP, luciferase or deletion/modification of viral genes to cause
attenuation. The foreseeable effects from the production of such recombinant viruses will be to produce a virus that is equivalent to or attenuated relative to wild type virus. It is very unlikely that a virus with increased pathogenicity will be created as we only intend to inactivate viral genes. All viruses used in this programme of work are ACDP hazard group 2 pathogens and both wild type and GM viruses will be handled in CL2 containment facilities. If available, laboratory workers will also receive vaccinations against parental virus strains. Immunocompromised or pregnant workers will not be allowed to work in the laboratory. OVERALL THE RISKS OF ADVERSE EVENTS FROM HANDLING GM VIRUSES WITHIN THIS PROJECT are low.

Mice
All infectious work will be carried out in purpose built CL2 facilities and animal cadavers will be autoclaved within this facility before disposal. If available, laboratory workers will also receive vaccinations against parental virus strains. Immunocompromised or pregnant workers will not be allowed to work in these facilities. OVERALL THE RISKS OF ADVERSE EVENTS FROM HANDLING GM VIRUSES FOR MURINE WORK ARE LOW.

Together the risk identified within this integrated programme of work can be minimised to acceptable LOW levels by working to existing laboratory standards and practices in designated Containment Level 2 laboratories. This is supported by the accompanying risk assessments.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All mice are housed in a CL2 laboratory suite built for purpose. Animal cadavers will be autoclaved within this facility before disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
We operate a number of comprehensive and proven waste management measures which are conducted according to our local protocol for handling CL2 pathogens. This protocol has been in use for many years and involves autoclaving of solid waste material, chemical inactivation of liquid waste and careful management of waste movement. The GMM will be used within a containment level 2 laboratory in which all cultures/liquid waste is decontaminated prior to disposal using a final concentration of 1% Virkon solution for at least 16 hours (concentration validated by manufactureres) before disposal to the drains. Thus drains, sinks etc do not pose a mode of transmission to the environment. Air movement is also strictly regulated in the laboratory environment. Solid biological waste (including cadavers) is autoclaved using temperature cycles and conditions appropriate for the inactivation of biological material. Autoclaving is performed by departmental staff using approved conditions, (134 degrees C for 3 minutes per cycle). Plasticware etc is decontaminated with 1% Virkon solution prior to being autoclaved as described above.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Regarding the programme as a whole, the Biological Agents and GM safety Committee (BAGMSC) discussed the circumstances under which exclusion from the work activity should be considered, and agreed to adopt the wording "knowingly immunosuppressed".

SIBAGMRA11_06 and 07: The original risk assessments contained reference to lentiviruses being susceptible to desiccation. It was stated by BAGMSC that this has long since been established not to be the case, with dried blood smears being infectious for up to 14 days, and desiccation should not be relied upon as a control measure. This has now been deleted, and the team advised. Clarification was requested on the status of the WPRE, which is confirmed as protein x minus.

A change to the wording in Section 1.1 of SIBAGMRA11_06 has been introduced to satisfy a degree of confusion on the part of the Committee regarding transient vs stable expression from lentiviral vectors.

SIBAGMRA11_08: EBV can cause glandular fever which can have long lasting effects in adults as fatigue syndrome. Therefore, this is not a 'mild' risk and this needs to be considered in the risk assessment. Due to the possible persistence of measles virus within safety cabinets, it was agreed that there is a need to establish immunity to measles for those undertaking work and those in vicinity of work. Vaccination would then only be required for those without an appropriate titre level. If workers who are not immune to measles are to be excluded, the work with this virus must be restricted to room D2-34 only.

There were no further requests by BAGMSC for changes to be made to any of the other attached risk assessments.
Next generation sequencing has identified multiple genes harbouring activating heterosygous mutations in different types of human cancers. To validate these gene targets in a biological setting, we aim to introduce cDNAs encoding mutated proteins into human cancer cell lines using a retroviral vector. This will mimic heterozygous gene expression, thus replicating the consequences of the mutational event that occurs in cancer. Cell biology assays will then allow us to determine whether expression of the mutated gene is critical for malignant transformation.

The recipient used for retroviral vector production will be GP2-293 cells, a HEK293-based packaging cell line that stably expresses the viral gag and pol genes, and the VSV-G amphotropic envelope.

Retroviral vectors will be introduced in human haematopoietic cell lines (e.g. HL60, H562, HEL).

The parental organism is the retrovirus Mouse Embryonic Stem Cell Virus (MSCV), which in its native form is pathogenic only to mice.

The MSCV vector backbone is derived from the Murine Embryonic Stem Cell Virus (MSCV). The MSCV vector is a self-inactivating retroviral vector optimized for introducing and expressing target genes into pluripotent cell lines. It contains a specifically designed long terminal repeat from the murine stem cell PCMV virus. PVMV stands for PCC4-cell-passaged myeloproliferative sarcoma virus (Hilberg et al., 1987, Hawley et al., 1994) This LTR differs from the MMLCV LTR by several point mutations and a deletion. These changes enhance transcriptional activation and decrease transcriptional suppression in embryonic stem and embryonal carcinoma cells. As a result, the LTR drives high-level constitutive expression of a target gene in stem cells and other mammalian cell lines (Hawley et al., 1994).

Inserted cDNAs:-
SRSF2 (wild-type)
SRSF2-P95H
SF3B1-(wild-type)
SF3B1-K700E
To validate these gene targets in a biological setting, we aim to introduce cDNAs encoding mutated proteins into human cancer cell lines using a retroviral vector. This will mimic heterozygous gene expression, thus replicating the consequences of the mutational event that occurs in cancer. Cell biology assays will then allow us to determine whether expression of the mutated gene is critical for malignant transformation.

**Evaluation of foreseeable effects**

**Production of replication-competent retrovirus (RCR):** The viral genome is divided such that the backbone vector carries only the LTRs, the packaging signal and the transgene of interest, with all other elements required for viral vector production (gag, pol and amphotropic VSV-G envelope genes) stably integrated into the genome of the packaging cell line. This will significantly reduce the likelihood of recombination events leading to the production of replication competent viral particles, compared with multiple plasmid transfections. Batches of retroviral vector will be tested for production of cytopathic effect on monolayer cultures, and for gag-pol-env RT-PCR products, both of which would indicate the presence of RCR. If these are detected, the batch will be destroyed and the risk assessment will be reviewed.

**Insertional mutagenesis by vector:** Additional refinements of the vector system selected include the self-inactivation (SIN) system in which U3 enhancer sequences are completely removed from the 3' LTR thus reducing the chances of transactivation of cellular genes as a result of insertion. However, the risk of insertional activation or silencing cannot be excluded.

**Inserted genetic material:** The cDNAs that are to be studied have been identified in genomic screens as potential oncogenes. Both mutant and wild-type forms will be used. There is a risk that the oncogenic DNA could act as the first "hit" in an oncogenic pathway.

The viral backbone vector is a non-mobilisable plasmid which will be manipulated in E. coli K12. While the plasmid will contain a putative oncogene under the control of a eukaryotic promoter, the likelihood of harm by its introduction into workers or others is very low.

All of these effects are dependent upon the retroviral vectors (or the parental plasmids) being introduced into the lab workers by inoculation. This risk will be minimised by the work being carried out in a Containment Level 2 laboratory which operates a no sharps policy, confirmed by the assurance programme conducted by the Campus Health & Safety Service.

To prevent the development of aerosols, tubes and culture plates with viral supernatant will be sealed and centrifuged in certified aerosol-tight buckets, which will only be opened following transfer to a microbiological safety cabinet.

The risk to the environment would be by virtue of the VSV-G envelope retroviral particles being capable of infecting a wide variety of species and cell types. This would be unlikely given the labile nature of retroviruses, and the inactivation methods in place.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

*Not applicable*

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

*Not applicable*

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid waste is treated by addition of Virkon to a final concentration of 1% (w/v), which is validated by the manufacturer to give 100% kill in all the species in this study. All solid waste is autoclaved with a hold time of 20 minutes at 134 Celsius in autoclaves which undergo 12-point 100% kill of thermostable strains of bacteria such as Bacillus stearothermophilus. All resulting material is destroyed by incineration. |
It was agreed by the BAGMSC, at its meeting held on 17th October 2012, that this risk assessment could be discussed via email, unless there were serious doubts raised about the validity of the classification. There were no such doubts raised in a number of emails corresponding to the quorum of the Committee, and was therefore approved as a Class 2 activity.

Significant Change ID
### Purposes of the contained use

Genetic modification of organisms is critical to understand the impact of individual genes on the phenotype and lifestyle of the organism. This research is only just beginning in Chlamydia trachomatis. Generation of fluorescently labelled strains will help us to develop new techniques for understanding the lifecycle of this complex organism. It will also aid our understanding of the ease, degree and mechanisms of recombination in Chlamydia. Knockouts, either targetted or random as in TraDIS will help us to determine key genes for the lifestyle and infectious cycle of this organism.

### Recipient or parental organism

C. trachomatis is an HG2 pathogen, causing trachoma eye infections, sexually transmitted urogenital infections and invasive lymphogranuloma venereum (LGV) infections. This is a human-restricted pathogen.

### Host/vector system

For the TraDIS screen, transposon mutant libraries will be generated using derivatives of Tn5 and Mu that carry a gene conferring resistance to a single antibiotic, including kanamycin, gentamicin or chloramphenicol, but NOT tetracycline. Transposons will be introduced at one copy per cell by electroporation. The transposon derivatives possess outward-orientated promoters which allow the in vitro transcription of RNA at the insertion sites using genomic DNA extracted from pools of mutants. Whole genomic sequencing can then indicate the position of all the transposon insertion sites for many mutants simultaneously. Using this technology, pools of many mutants can be used to identify which genes are required for growth under different selective conditions. Transposon vectors will be pre-loaded with transposase enzyme to achieve the transposition event, obviating the need for the expression of a transposase gene, meaning that the inserted element cannot be re-mobilised.

### Origin & function

Transmission is thought to be by direct contact, although exact transmission methods for trachoma are unknown. Tissue tropism is epithelial for trachoma (eye)/STI strains and the invasive LGV strains can go on to infect lymphatic tissue. Conjunctivitis (through eye infection) can lead to scarring and trachoma; reproductive tract infections which may be asymptomatic, yet lead to pelvic inflammatory disease, scarring and infertility in females; proctitis in the case of LGV. The opportunity for infection in the laboratory is minimal, other than by the ocular route, which will be controlled by the use of microbiological safety cabinets and eye protection. There is a no-sharps policy in the laboratory, other than the use of capillaries for micro-manipulation, as detailed in the risk assessment.

Post-exposure treatment is via the use of a single dose of azithromycin, or doxycycline taken for up to 2 weeks. Tetracycline can also be used. There is no known resistance to these antibiotics in the clinical setting. The use of plasmids or transposon cassettes will induce resistance to a single antibiotic, but no constructs will be used which confer resistance to any of the frontline clinical treatments for Chlamydia infection.

It is not the aim of this project to specifically affect virulence. Little is known to date about the specifics of C.trachomatis virulence, but it is not anticipated that insertion of fluorescent cassettes as proposed will increase virulence. Almost all naturally occurring strains of C. trachomatis carry a plasmid, which is the basis of the recombinant
A plasmid proposed as a vector, therefore this is not anticipated to increase virulence. Potential creation of genome-wide knockouts (TraDIS) will involve the inactivation of genes, and will not create new functions. This is unlikely to increase pathogenicity.

Re-mobilisation of the inserted element cannot occur in the absence of the transposase exnzyme, so is unlikely to be capable of horizontal transmission to other bacterial species in the environment.

The vector itself is unlikely to be capable of causing direct harm to humans or other animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Please enter comments on the GM safety committee on the risk assessment.
This risk assessment was discussed at a meeting of the BAGMSC held on 17th October 2012. The committee made the following requests for clarification:-
* Further detail on frequency of screening for antibiotic resistance should be added to section B1.3.

RESPONSE: There is no documented antibiotic resistance in clinical samples, antibiotic resistance screening of isolates is very difficult to perform and does not give consistent results.
* Clarify those techniques performed in the microbiological safety cabinet which result in aerosol generation (Section B3.3).
* Eyes are a target organ and eye protection needs to be stated in risk assessment and associated procedures as mandatory when working with Chlamydia, including protection from splashes as well as aerosols.
* Include symptoms in local handbook and re-iterate to those working with this risk assessment.

The risk assessment and local handbook have been amended in accordance with these requests.
NB The use of the genus name Chlamydia (chlamydia-like), which is referred to in the ACDP classification list, is no longer regarded as appropriate by the clinical and research community, and all species are reverting to Chlamydia

Historical Significant Changes

Historical Date of Additional Info
### Project Additional Information

**Purposes of the contained use**

| Various activities in genomics research in the field of human health and disease, including, but not limited to expression of oncogenes, siRNA knockdown of genes implicated in disease pathways, and induction of cells into pluripotency, within the limits defined in the attached risk assessment. |

**Recipient or parental organism**

| Lentiviral and retroviral vectors based on a range of human and animal viruses, including HIV, EIAV, MMLV, MMTV and MSCV. The split vector systems and packaging cell lines to be used will conform to designs of second generation or later, and will be demonstrably incapable of replication in humans or the environment. Vectors may have wider tropisms compared to the parental organisms by virtue of the inclusion of amphotropic envelope proteins such as VSV-G. Wild-type WPRE elements in lentivector systems will be excluded wherever possible, but their inclusion would still be within the scope of the connected programme, as defined in the attached risk assessment. |

**Host/vector system**

| Viral vectors will be generated by introducing plasmids containing elements of the virus genome into established packaging cell lines, such as human embryonic kidney (HEK) 293 cells. In some cases, the essential packaging functions will be expressed stably by the packaging cell, with a single plasmid carrying the vector backbone being introduced by transfection, and in other cases the viral functions and the vector backbone will be encoded on separate plasmids which will be transfected together. Viral vectors produced in this way will then be used to transduce a range of human and animal (principally of mouse origin) cells. This will include established cell lines from various lineages, mouse embryonic stem (ES) and haematopoietic cells, and primary human samples. Transduced cells may be introduced subsequently into animal models of human disease. |

**Origin & function**

| As this is a connected programme of work, the genetic material to be introduced will be from a range of origins and have a variety of functions. This will include putative and known oncogenes and tumour-suppressor genes, short hairpin RNA (shRNA) molecules intended to inhibit the expression of a range of genes including those known or suspected to be involved in pathways of oncogenesis. |
Evaluation of foreseeable effects

The use of modern (i.e. second generation or later) vector systems in which reverse transcriptase, envelope protein and accessory genes are deleted from the sequences that are packaged into viral vector particles (and are provided in trans-, either on additional accessory plasmids or integrated into the genome of packaging cell lines) render them incapable of infection and of replication. However, it should be noted that a transduction event, even by a viral vector that is non-infectious and replication-defective, will result in integration of the inserted gene into the genome of the host cell. If the expression of the gene is driven by a constitutive promoter, that expression will be permanent. While the vector itself will not proliferate, cell division may result in a population of cells expressing the transgene.

Specific hazards associated with inserted genes include:-
Expression/over-expression of known or potential oncogenes: while oncogenesis is known to be a multi-factorial process, the risk of insertional activation of other oncogenes by the vector, or of insertional inactivation of tumour suppressor genes is unpredictable, and could act in concert to contribute to oncogenic pathways.

Expression of short hairpin RNAs designed to knock down known or potential tumour suppressor genes: similar risk to oncogene expression, above.

Expression of cytokines and growth factors: these proteins have the potential to cause inappropriate growth, differentiation or apoptosis of cells, which are associated with oncogenesis. Growth factors and cytokines may also be teratogenic, and have other effects on the immune response, so consideration will have to be given during the individual risk assessment as to whether expectant mothers and workers with other health issues should be excluded from such work.

The most severe outcome associated with these hazards is administration of the viral vector to a worker, the likelihood of which must be reduced as far as possible, for example by the adoption of a zero sharps policy (except during the administration of these vector systems to mouse models, or for activities such as excising gel slices where there is no direct contact with the GMM), and other control measures required at Containment Level 2. The risks to workers associated with the plasmids used to generate the viral vectors are considerably less than the virus itself, as the passive uptake of circular DNA into human cells is a very inefficient process, chromosomal integration will not occur, and the plasmids will not be maintained episomally in a dividing cell population.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Some aspects of this connected programme will include the administration of lentiviral and retroviral vectors, and cells transduced with such vectors, to GM mice (which represent no increased risk to human health or the environment compared to wild-type).

The animal facility (RSF) has been purpose built to house mice and was designed in consultation with the Home Office and HSE. Control measures include:
- Use of perimeter rodent control measures (bait boxes), to control escaped laboratory mice and prevent wild type mice entering the building.
- Rodent barriers to rooms containing mice to prevent escaped lab mice exiting the immediate area.
- Air scissors on the extract auger pipe for the automated bedding removal station to prevent large objects from passing through.
- Computerised auditing of the facility murine population, ensuring absence of a mouse (or mice) is quickly detected.
- SOPs to monitor for, react to, and record escapes.
- All rooms are subject to strict access control.
- Staff are trained to handle animals in accordance with Home Office requirements.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste contaminated with GM material will be bagged, and transported to autoclaves within the same building in closed rigid boxes within lidded trolleys. All of the autoclaves are subjected to annual inspection to written schemes, annual validation reports, and quarterly servicing. Waste runs are validated to achieve a minimum hold time of 3 minutes at 134°C, equivalent to a 30-log reduction in viability of indicator spores. Waste inactivated by autoclaving is removed from site for incineration or deep land-fill only after examination of the autoclave run report. Additional validation has been performed of the autoclaving of mouse carcasses to ensure the entire body has reached the validated temperature and hold time. Mouse carcasses are incinerated. All liquid waste is subject to treatment with Virkon-S, at a minimum concentration of 1% (w/v) and minimum contact time of 1 hour, before dilution and disposal via the drains. The degree of kill is effectively 100%.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The first draft of the risk assessment was discussed at the meeting of the Biological Agents & GM Safety Committee of 6th February 2013. The Committee were in agreement that creating a risk assessment for this connected programme of work was a sensible approach. JB suggested an additional sentence be inserted into the 'outline of process' section to indicate that all risk assessments will go the Committee for review and to decide if they fall within the scope of this connected programme of work. JB proposed that a list of those risk assessments that are applicable to this connected programme should be included as an Annex.

There was a discussion on whether the virus should be considered as the recipient organism or the vector system. IG stated that after discussion with HSE, the virus could be considered as the recipient.

JR asked if the vector system could be specified, JB agreed that ‘2nd generation or later vectors’ be stated in ‘Outline of Process’ and in answer to the question ‘have the pathogenic traits of the recipient organism been altered?’.

The risk assessment was amended, and approved by BAGMSC at the meeting held on 16th April 2013, subject to a further exception to the zero sharps policy in respect of excision of gel slices.

The aim of the project is to identify the function of genes encoded by Mycobacterium tuberculosis. To this end we will exploit highly attenuated and genetically validated M. tuberculosis host bacteria generated by our collaborator Prof W J (Albert Einstein College of Medicine, New York). These host bacteria (MC(2)6030, MC(2)6030 and further mutant derivatives) harbour disabling deletion mutations in RD1 (associated with the attenuation of bacilli Calmette-Gurin BCG vaccine), panCD (associated with pantothenate synthesis) and other auxotrophic mutations within lysA. RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in part in humans through use of the BCG vaccine, panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria, essentially starving them.

We will exploit these background strains in phenotypic screens. Our collaborators have introduced null deletion mutations in ALL mapped protein coding genes within M. tuberculosis H37Rv (the most commonly-use lab strain with a fully -sequenced genome). We will exploit this library to identify the function of these genes using eukaryotic cell invasion assays performed at relatively high throughput (96-well and 384-well format) to observe the impact of such bacterial mutations on the eukaryotic host cell phenotype. All experiments will be conducted on simple cellular phenotyping platforms, available within the CL2 facilities at the WTSI.

Recipient or parental organism

Mycobacterium tuberculosis H37Rv is a fully sequenced laboratory strain of TB classified as a Hazard Group 3 pathogen. The route of transmission is by aerosol, but the host bacteria can also infect via oral or parenteral routes.

NB: This parental strain will not be used as part of this notified activity, and no further modifications to the strains MC(2)6020 and MC92)6030 and the derivatives thereof will be performed at our premises. The sole GM activity in this notification is growth, challenge of eukaryotic cell cultures, and storage of GM strains.
The gene deletions in these strains of M. tuberculosis were generated as follows. The gene of interest, disrupted by a selectable marker, is cloned into a conditionally replicating (temperature-sensitive) shuttle plasmid to generate a specialised transducing mycobacteriophage. The temperature-sensitive mutations in the mycobacteriophage genome permit replication at the permissive temperature of 30 degrees C but prevent replication at the non-permissive temperature of 37 degrees C. Transduction at a non-permissive temperature results in highly efficient delivery of the recombination substrate to virtually all cells in the recipient population. The deletion mutations in the targeted genes are marked with antibiotic-resistance genes that are flanked by gamma delta-res (resolvase recognition target) sites. The transductants which have undergone a homologous recombination event can be conveniently selected on antibiotic-containing media.

The specific strains of bacteria (MC(2)6030, MC(2)6020 and further mutant derivatives) harbour disabling deletion mutations in RD1 (associated with the attenuation of bacilli Calmette-Gurin BCG vaccine), panCD (associated with pantothenate synthesis) and other auxotrophic mutations within lysA. RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in part in humans through use of the BCG vaccine. panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria. Our collaborators have subsequently introduced null deletion mutations in all mapped protein coding genes within M. tuberculosis H37Rv (the most commonly-used lab strain with a fully-sequenced genome).

Origin & function
The only genetic material in the GMMs is a hygromycin resistance cassette flanked by resolvase recognition sites integrated into the host chromosome. No other exogenous sequences are present.

Evaluation of foreseeable effects
Since no additional changes will be made to the bacterial strains as part of this notified activity, the foreseeable effects arise from the strains which will be imported.

Forseeable effects on human health: Whereas the background strain H37Rv is capable of causing TB, the deletions of RD1, lysA and panCD are well-documented in peer-reviewed papers as attenuating the ability of these strains of M. tuberculosis to colonise and cause infection in mammals (see accompanying summary of relevant literature). Furthermore, no biologically active product will be generated in humans (with the exception of hygromycin resistance), and there is no reduction in the susceptibility of the GMMs to frontline treatments for TB.

Likelihood of disabling mutations being overcome: The specialised transduction mechanism used to generate the deletions is such that reversion or rescue of any deletion is extremely unlikely. Given that each strain has two such disabling deletions, the likelihood of generation of a fully infectious Tb strain is effectively zero.

Possible impact on the environment: Since the disabling mutations have been introduced by a gene replacement event in the Mtb chromosome, the likelihood of mobilisation of the genetic modification, or its transfer into other species in the environment in the event of a release is very small. This is reduced further still when the waste control measures are taken into consideration.

Theoretical modes of transmission to the environment: Drains, aerosols, faulty autoclaves, and carried on individuals, but these risks are moderated by (a) the disabling mutations within the bacteria, which reduce the likelihood of survival outside the laboratory, and (b) the control measures used in the contained environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste contaminated with GM material will be bagged, and transported to autoclaves within the same building in closed rigid boxes within lidded trolleys. All of the autoclaves are subjected to annual inspection to written schemes, annual validation reports, and quarterly servicing. Waste runs are validated to achieve a minimum hold time of 3 minutes at 134°C, equivalent to a 30-log reduction in viability of indicator spores. Waste inactivated by autoclaving is removed from site for incineration or deep land-fill only after examination of the autoclave run report.

All liquid waste will be subject to treatment with Surfanios, at a minimum concentration of 5% (v/v) and minimum contact time of 3 hours, before dilution and disposal via the drains. The degree of kill has been validated as a minimum of a 9-log reduction.

Activities will be separated from those which use Virkon for chemical disinfection, as Virkon is documented as being ineffective against Mycobacteria.

Please enter comments on the GM safety committee on the risk assessment
This risk assessment was compiled in conjunction with advice from Dr L M, Safety Advisor for TB Reference Laboratories, Public Health England, who provided specific advice on the use of appropriate disinfection methods, but agreed that the assessment was comprehensive and appropriate.

The risk assessment was discussed at length at the meeting of BAGMSC held on 6th September 2013, having been circulated to the Committee by email in advance of the meeting.

OH Physician stated the importance of the strains retaining antibiotic resistance, and further that the organisation should decide on the requirement for TB vaccination of affected staff, as is provided in the healthcare sector. The Committee agreed that the risk posed by these strains was sufficiently low to obviate the need for vaccination, but this would be discussed as part of the initial health surveillance interview.

The Committee agreed that the evidence for the effectiveness of the attenuation mutations was compelling, but the following requests for clarification were made:

1. There is no mention in the risk assessment of how the gene deletions in the MC(2)6020 or MC(2)6030 have been made. Please clarify whether any additional antibiotic resistance markers have been introduced as part of the process, and whether there is a risk of any reversion.

Response: The mutations within the Mycobacterium tuberculosis strains are null (totally inactivating) deletion mutations designed to be stable and minimise any risk of reversion. Furthermore, the deletion mutations were made with an antibiotic resistance cassette flanked by resolvase sites, which then deleted the antibiotic resistant gene, so the end mutants have no additional antibiotic resistance.

2. There was concern that if the activity is to be performed in an area shared with other work, there is a risk that staff may use Virkon inadvertently to disinfect TB, instead of the required Surfanios. Can you clarify how this will be controlled (e.g. by using a separate area)?

Response: We will be using room b in the CL3 suite E235 or E376 (Cgap CL3). If these TB strains are being used we will NOT be using other bacteria or viruses within the same suite at the same time. Indeed, we would decontaminate the rooms before or after switching to using these strains. We would also ensure that only Surfanios is available within the active room for disinfection.

It was agreed at the meeting that the activity should be assigned to Class 2, subject to satisfactory clarification of the above points.

Activity approved at Class 2, subject to this notification.

**Project Ref** 552/14.1
Investigating SNP mutations in human lymphoblastoid cell lines using Cas9/CRISPR targeting

Purposes of the contained use

1) To validate computationally-predicted causal single-nucleotide polymorphisms (SNPs) by genome editing using a Cas9/CRISPR system.
2) To knockout specific loci to investigate regulatory elements and gene functions.

HapMap lymphoblastoid cell lines are an invaluable resource for studying genetic variation within populations and between individuals. It is possible to computationally predict SNPs that are responsible for a given phenotype. In this study, a given phenotype will be assessed by mRNA expression. To validate a causal SNP in vitro, a Cas9/CRISPR system and homologous recombination will be used to edit SNPs to assess the effect on phenotype (mRNA expression). To knockout a given locus, the Cas9/CRISPR system will be used to promote non-homologous end joining (NHEJ) to alter specific genomic targets. These processes will involve tranfection/nucleofection of lymphoblastoid cell lines with plasmids which will drive expression of pairs of locus-specific guide RNAs (gRNA) along with the mutant D10A Cas9 (nickase activity). gRNA and D10A Cas9 expression will be driven from the human U6 and cytomegalovirus (CMV) promoters, respectively. To promote homologous recombination, a single-stranded oligonucleotide harbouring the altered SNP sequence will also be co-transfected with the gRNA and D10A Cas9 plasmids. The use of pairs of gRNA co-expressed with D10A Cas9 and a single-stranded oligonucleotide homology donor in human cell lines has previously been demonstrated (1). Using Cas9/CRISPR to stimulate NHEJ in human cells has also been shown (1).

1. Ran et al., Cell 154, 1380-1389 (2013).

Recipient or parental organism

A selection of EBV-transformed human lymphoblastoid cell lines.

Host/vector system

Plasmid: Cas9(D10A)-NLS-IRES-puro (vector backbone is plRESpuro3 from Clontech).
Plasmid: U6 Bsal gRNA (vector backbone is pDONR201 from Life Technologies).
Homology donor: ~ 180 bp single-stranded oligo nucleotide

Origin & function

A selection of EBV-transformed human lymphoblastoid cell lines.
### Evaluation of foreseeable effects

**Forseeable effects on human health:**
Lymphoblastoid cell lines are EBV-immortalised B-lymphocytes transformed with Epstein-Barr virus (EBV). EBV causes infectious mononucleosis, which can lead to chronic fatigue in adult humans. Transmission is predominantly via the oral route and it is therefore unlikely that the virus would be transmissible under Containment Level 2 conditions. There is the potential for lymphoblastoid cells to shed EBV particles in culture, but by following the correct CL2 culture procedures the risk of transmission to humans is expected to be low.

The Cas9D10A would need to be co-expressed with a gRNA for it to be active in humans. This is extremely unlikely to happen, given that Cas9D10 and gRNA will be expressed for different plasmids. Also, given that the vectors are plamids and not viral backbones, the change of uptake in humans is extremely unlikely.

Consideration was also given to a theoretical, but extremely low risk off-target double strand breaks in the vicinity of a tumour suppressor gene, but this would not be expected to be sufficient to induce tumour formation.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**None**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid cultures will be chemically inactivated by the addition of a validated disinfectant (e.g. Virkon) and leaving for the required time (>20 minutes), before being diluted and disposed via the drains.

Contaminated solid waste (culture dishes, serological pipettes, disposable gloves, etc) will be autoclaved using a validated cycle prior to incineration off site.

### Please enter comments on the GM safety committee on the risk assessment

The risk assessment was discussed at a meeting of the Biological Agents and GM Safety Committee held on the 5th December 2013. JR was aware of other projects in the pipeline and that checks should be made to ensure that this assessment fulfils all work envisaged. JB added that a connected programme of work should be considered.

The applicant did not want to broaden the scope as it covered all the work envisaged. The risk assessent was then circulated to the committee, a number of emails corresponding to the quorum of the committee were received in agreement of the classification as a Class 2 activity.

### Project Containment

| Laboratory Activities | Glass Houses | Growth Rooms |
This project will utilize the fish pathogen *Mycobacterium marinum* to investigate the pathogenesis of Mycobacterial and related infections, in the following ways:

1. To identify *M. marinum* genes that contribute to pathogenesis and infection
2. To identify host genes (zebrafish with equivalents in humans or mammals) involved in response to or controlling the infection.
3. To explore the immune and physiological response to infection and understand how this works in the context of intracellular Mycobacterial infections.

*Mycobacterium marinum* is a fish pathogen although serious systemic infections could occur in severely compromised humans, and is classified as Hazard Group 2. Superficial infections on the extremities/exposed surfaces can occur in immunocompetent humans causing a well-recognized disease called fish-tank, aquarium-tank, or swimmer’s granuloma.

Mode of transmission is through skin, particularly from sites of abraded skin. The host range is wide. Ectotherms get systemic disseminated disease. Warm-blooded animals get superficial, localized disease on the skin of their extremities. Human disease presents as a nodular or ulcerating lesion on the site of infection.

A number of very safe, well-tolerated antibiotics can be used effectively against *M. marinum*. We have tested the strain we use formally at a reference laboratory so that we...
can have its antibiotic sensitivity profile. It is susceptible to clarithromycin, rifampicin, ethambutol among other antibiotics.

M. marinum will be used to infect human derived cell lines such as THP1, Monomac6 an NHBE cells, human induced pluripotent stem cells (hiPSC), and Zebrafish embryos up to 5 days post-fertilisation.

Host/vector system

Vectors & inserts:
1. Extrachromosomal and integrating plasmids that express various fluorescent reporters and/or the antibiotic resistance markers for kanamycin and/or hygromycin. A variety of derivatives may be used in which 1) hygromycin resistance replaces Kanamycin and/or 2) other fluorescent proteins (eg, dsRed tdTomato, wasabi) replace gfp.
2. Transposon insertions throughout the genome; transposon MycoMar encodes a kanamycin resistance cassette, and transposon MycoMme encodes hygromycin resistance cassette flanked by gamma-delta resolvase sites. Strains carrying such insertions have been previously generated and lack the transposase required for further transposon mobilization.
3. Spontaneous mutants that have antibiotic resistance to isoniazid, rifampicin
4. Extrachromosomal and integrative plasmids that are used for genetic complementation of mutants. Eg. Complementation in which the mutation has been rescued by inserting the relevant native gene back into the genome at the L5 attB site. Sequences of several such commonly used vectors are attached.
5. Marinum mutants will be generated using various well-established mutagenesis techniques including targeted approaches driven by recombination (e.g. CRISPR).

Origin & function

Green fluorescent protein and beta-galactosidase will be used as reporter genes, and antibiotic resistance genes will be used as selectable markers. Cas9 will be used to generate sequence-specific mutations via the CRISPR.

Evaluation of foreseeable effects

Wild-type M. marinum is capable of causing infections in fish and other ectotherms in the environment. Some of the mutations will compromise the virulence and the infectivity of the pathogen. An increase in virulence or infectivity is unlikely and is not selected for. During complementation tests, we will be inactivating genes, some of which will be associated with virulence but there will be no attempt to alter host range or enahnce virulence beyond the level of that seen in the wild-type strain. Mutant strains could possibly revert back to wildtype virulence potential, however it is highly unlikely that any strain would mutate to an enhanced level of virulence. Furthermore, all mutant strains are treated with the same biosafety precautions as the fully virulent wild-type strain, so in the event of a reversion to virulence, no additional risk is posed to labworkers or the environment. Although some antibiotic resistance markers may be used they will not be those encoding resistance to currently commonly used antibiotics and have defined antibiotics that can be used to treat these M. marinum.

Transfer of DNA or antibiotic resistance to other organisms is very unlikely as the genes are not on a mobilisable element and mycobacterial DNA being GC-rich and having specialized promoters does not thrive in most other organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. Zebrafish embryos may contain mutations, but these have been generated by techniques not covered by the definitions of the Contained Use Regulations.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste contaminated with GM material will be bagged, and transported to autoclaves within the same building in closed rigid boxes within lidded trolleys. All of the autoclaves are subjected to annual inspection to written schemes, annual validation reports, and quarterly servicing. Waste runs are validated to achieve a minimum hold time of 3 minutes at 134°C, (equivalent to a 30-log reduction in viability of indicator spores). Waste inactivated by autoclaving is removed from site for incineration or deep land-fill only after examination of the autoclave run report. All liquid waste from Mycobacterium species will be subject to treatment with BioCleanse, at a minimum concentration of 5% (v/v) and minimum contact time of 1 hour.
before dilution and disposal via the drains. The degree of kill has been independently validated as a minimum of 6 log reduction in viable organisms.

The risk assessment was circulated by email to the BAGMSC on 26th August 2014.

The following comments were received:-

CS: I'm happy with the work being classified as Class 2 as it will not be carried out in the RSF (answer to B4.5 - there would be a great potential for the generation of water droplets in the zebrafish room in the RSF which might carry the pathogen, and it is definitely a ‘damp environment - B2.4).
There is justification for using lass capillary needles with care.
It is important that gloves and masks are worn when the pathogen is being handled due to the potential to infect humans.

OHP: This is ok by me. Antimycobacterial drugs can be used in pregnancy.
Just to clarify at end of document (not just immunosuppressed individuals); may need to specify in text box that if eczema on hands or forearms, need to avoid work with this organism until eczema adequately treated. (This has no been revised).

JB: I note that M. marinum is correctly classified as HG2 and am happy that the suggested GM work will not increase the risk. I am therefore in agreement with it being classified as Class 2.

JO: Happy for this to be CL2.

JR No concerns - a very well written and clear application, and risks seem well controlled. The only thing that was somewhat puzzling was mention of the human derived lines (QB3.2) will be used for - not discussed at other points in the application, which focus on infection of 0-5 day zebrafish embryos. If the intent is to try to infect human stem cells (not sure whether this is possible with M. marinum or not), this either needs to be clarified in other sections (e.g. not listed as host in overview), or be filed in a separate assessment - happy with either option. (This has now been revised).

JL: Section on autoclaving needs amending. This has now been revised.

Human Clinical Applications
Luciferase-expressing trypanosomatid parasites as a toll in vaccine screen against nagana and visceral

Protozoan parasites of the Trypanosomatidae family are the causative agents for some of the most neglected diseases such as African trypanosomiasis and leishmaniasis. These parasites have a wide range of hosts and can infect both animals and humans. African trypanosomiasis is caused by Trypanosoma spp. parasites and is transmitted through the bite of infected Tsetse fly (Glossina spp.) vectors. Our research will focus on Trypanosoma congolense and T. vivax which are non-pathogenic to human but causes trypanosomiasis (also known as nagana) in animals. Nagana affects many economically important livestock species such as cattle and goat, causing a marked impact on agriculture and development of Africa. Related trypanosomatid parasites of the genus Leishmania cause leishmaniasis which is transmitted through the bite of infected sandfly (Phlebotomus spp and Lutzomyia spp) vectors. Over 20 Leishmania species are capable of infecting humans. Leishmaniasis can be subdivided into 3 main forms (cutaneous, mucocutaneous and visceral). Visceral leishmaniasis (VL) is the most severe form of the disease and causes an annual death toll of ~50,000. Our research will focus on Leishmania donovani and L. infantum which causes VL in human.

A common problem with these neglected diseases is that no vaccine is available and their control is largely dependent on chemotherapy/chemoprophylaxis treatments, as well as insect vector control. Treatments for these diseases have inherent limitations such as severe toxicity, drug resistance and prohibitively high costs. Thus, the development vaccines for VL and nagana is considered a safe and cost-effective method to prevent and reduce the impact of these diseases in endemic areas. To identify possible vaccination candidates, libraries of recombinant parasite cell surface proteins will be expressed and used to immunise rodent models of VL and nagana. Immunised animals will subsequently be infected with parasites to identify immunogens that confer protection to infections. Accurate quantification and monitoring of parasitaemia in animals following infections will be extremely challenging and labour-intensive, with respect to the number of proteins to be screened. The use of transgenic- parasites expressing luciferase will allow us to visualise and quantify parasitaemia through bioluminescence on an In Vivo Imaging System (IVIS, Perkin Elmer) without altering the infection pathology of the parasites. It will also have the advantage that the infection can be followed longitudinally, significantly reducing the number of
animals used for this research.

**Recipient or parental organism**

The recipient organisms will be Leishmania spp that are classified as ACDP Hazard Group 3* and animal African trypanosomes which include Trypanosoma congolense and Trypanosoma vivax. These parasites are both classified as SAPO Group 2 pathogens.

**Host/vector system**

Luciferase-expressing Trypanosoma vivax parasites: Firefly luciferase-expressing T. vivax parasites will be obtained from Pasteur Institute. This parasite strain has been published and is described in Genetic engineering of Trypanosoma (Dutonella) vivax and in vitro differentiation under axenic conditions. D'Archivio S, Medina M, Cosson A, Chamond N, Rotureau B, Minoprio P, Goyard S. PLoS Negl Trop Dis. 2011 Dec;5(12):e1461.

Briefly, these parasites were generated by transfecting the wild type T. vivax strain, TvY486, with a T. vivax-specific luciferase vector which was designed to express the luciferase reporter gene and the neomycin phosphotransferase gene that confers resistance to G418.

Luciferase-expressing Leishmania donovani parasites will be obtained from the same group from the Pasteur Institute which were produced in an analogous manner.

Luciferase-expressing Trypanosoma congolense parasites: Firefly or red shifted firefly luciferase-expressing T. congolense parasites will be generated from cultivated T. congolense parasites of the reference strain IL3000 and by using an appropriate T. congolense-specific vector.

**Origin & function**

Luciferase-expressing parasites of Leishmania spp and animal African trypanosomes will either be obtained from collaborators such as colleagues working in the Pasteur Institute (Paris) or selected on site.

These genetically modified strains of leishmania and trypanosomes will be used in experimental protocols aiming at identifying new vaccine candidates against trypanosomatid infections. Systematic screenings of recombinant proteins predicted to be associated with trypanosomatid cell surfaces will be performed by immunising mice and subsequently challenge them with trypanosomatid parasites. To determine if recombinant protein immunisations confer protection against trypanosomatid infections, parasite load of infected mice will be evaluated during the infection course of visceral leishmaniasis and animal trypanosomiasis.

Luciferase-expressing trypanosomatid parasites represent efficient tools for monitoring experimental infections in real time and at the whole organism level. Their use will highly improve the sensitivity and the spatial resolution of infectious processes studies and also provide reliable means to quantify parasites in vivo. They will also reduce the number of animals required for these experiments.

**Evaluation of foreseeable effects**

Hazard/risk to human associated with the recipient parasites depends on species. Over 20 different Leishmania species are pathogenic to humans with L. donovani and L. infantum classified as ACDP Hazard Group 3*. The animal African trypanosomes (T. congolense and T. vivax) are non-pathogenic to humans, but can cause disease in livestock and are classified as SAPO Group 2 pathogens. Genetic manipulation of L. donovani and L. infantum are not expected to increase their risk to humans, and may, in fact, attenuate virulence. Leishmania parasites are transmitted to the host through the bite of an infected sandfly. This insect vector is not indigenous to the United Kingdom and colonies are not maintained at the Sanger Institute. There are three different forms of leishmaniasis dependant on the species of Leishmania. All forms result in development of sores at the site of infection and can be accompanied by cold-like symptoms. The diseases they cause range from mild self-healing skin ulcers in cutaneous leishmaniasis through to the life-threatening visceral form. The cutaneous and mucocutaneous forms of leishmaniasis are self-healing but usually result in disfiguring scars. Visceral leishmaniasis is the most severe form of the disease due to disseminated infection of the bone marrow, liver and spleen and is often fatal. There is no effective vaccination available, and treatment heavily reliant on chemotherapy. Current drugs used for treatment include meglumine antimoniate, sodium stibogluconate, amphotericin B, ketoconazole, miltefosine, paramomycin and pentamidine. All stages (promastigotes and amastigotes) of the Leishmania life-cycle are hazardous and will be treated directly. The introduction of the luciferase gene is not expected to alter the virulence, infectivity and stability of the leishmania parasites.

Genetically modified Leishmania spp should maintain the same sensitivities to the standard drugs used for the treatment of leishmaniasis both in vitro and in vivo.

Hazard/risk to human arising directly from the inserted gene product is very limited as genetically modified trypanosomatids will express the reporter gene luciferase. The
The luciferase gene is not an oncogenic gene and its gene product is not known to be harmful to health. The luciferase inserted gene should not alter the pathogenicity of the kinetoplastid parasites to humans. In addition, mobilisation of the inserted genetic material within the same species of kinetoplastids would be highly unlikely. Transfer of genetic material in Leishmania spp. have only been known to happen when the parasites are in their sandfly hosts which are not used in our studies. It is also considered very unlikely that the luciferase gene could be horizontally transferred to other organisms; however, there is a theoretical but very limited risk that the antibiotic resistance associated with the luciferase gene could cause harm through transfer to another organism.

A conceivable hazard/risk to the environment that is associated with recipient trypanosomatids exists as these parasites can infect animals. Wild-type Leishmania spp. are known to parasitise animals such as dogs and rodents. Animal African trypanosomes can infect domestic animals such as cattle, sheep, goats, pigs, horses and dogs and wild animals. It is considered very unlikely that genetically modified kinetoplastid parasites will have a different host tropism to the parent. Hazard/risk to environment arising directly from the inserted gene product is not considered a risk, since the luciferase gene does not encode for hazardous products and does not cause gene silencing of a gene encoding a crucial metabolic enzyme in susceptible hosts.

Hazard/risk to environment arising from the alteration of existing traits is also extremely unlikely as the transgene encoding luciferase does not encode for a pathogenic determinant. Luciferase expression will not confer additional cell binding properties to trypanosomatid parasites and will not alter their host tropism nor mode of transmission. Insertion and the selection process of the luciferase gene in other trypanosome species such as Trypanosoma cruzi has, in fact, led to a decrease in virulence.

Potential hazard/risk of sequences within the GMM being transferred to related microorganisms is very unlikely as luciferase-expressing trypanosomes can only survive outside the laboratory in a suitable animal host which requires specific transmission vectors (in this case sandflies and tsetse flies) which are not endemic to UK. In addition, no theoretical modes of transmission of the genetically modified parasites to the environment are known and the environment cannot support their survival.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Application for derogation from infected mice to be held within the CL3 laboratory at all times:

1. Mice infected with Leishmania to be transferred from the CL3 to be housed at CL2 if capacity is required. Mice will not be handled at any time in CL2. Cages will not be opened and only handled to be removed from racks to fulfill Home Office observation requirements. Cages will be transferred back to CL3 for cleaning out and for mice to be handled in a Class I MSC only.

2. Mice to be transferred from the CL3 laboratory to the IVIS imaging CL2 laboratory and imaged in this area. Mice will be held in a sealed container with filtered CO2 provision and extraction at all times.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste which includes tissue culture flasks, media bottles and tubes, will be pre-treated with 1% (w/v) Virkon with a contact time of at least one hour to eliminate live trypanosomatid parasites. Treatment with 1% (w/v) Virkon kills the vast majority of organisms in 10 minutes and achieves 100% kill in 1 hour. Inactivated solid waste will be placed in a robust, secure and leak-proof container and then autoclaved. Solid waste such as used tips and pipettes will be collected in plastic bags loosely closed with tape, and transferred in an appropriate container for autoclaving. Sharps and syringes will be disposed of in suitable storage containers and placed, when nearly full, in an appropriate container for autoclaving.

Solid waste that does not require a disinfectant pre-treatment step such as other disposables, gloves, paper towels or tissues will be directly placed in an appropriate container before autoclaving. Infected animal cadavers will be stored frozen in bags until fully inactivated by autoclaving.
For liquid waste decontamination, Virkon will preferentially be used as it is the disinfectant commonly in use on site. Any liquid waste will be inactivated with a 1% (w/v) final concentration Virkon solution for at least one hour. Inactivated liquid waste will be diluted 1:5 with water before being disposed of down the drain.

Any spills involving trypanosomatid parasites will be inactivated using 70% (v/v) ethanol with a contact time of at least 1 hour. The degree of ‘kill’ achieved with 5 min exposure with 70% (v/v) ethanol is 100% of trypanosomes in liquid waste. 15-17.5% ethanol (v/v) has been shown to kill trypanosomes within 5 min exposure (Wang et. al. (2008) “Efficacy of common laboratory disinfectants and heat on killing trypanosomatid parasites.” Parasites and Vectors 1:35). As a precautionary measure, squirt bottles containing 70% (v/v) ethanol will be kept within easy reach in the containment room RI-125 of the Blue suite where the infection challenges and blood samplings will be performed and in the containment 2 laboratory B315 where in vitro culture work of the parasites will be performed. Bottles containing 2% Virkon giving a final concentration of 1% (w/v) can also be used for inactivation of spills.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Amendments/clarifications

Description: Please reference the associated RA for use of the wild type trypanosome.

B3.1 Centrifugation is given as a technique for concentration, but nowhere is any mention made of sealed leak proof buckets or rotors, or where these might be opened. This needs to be added in.

B3.4: Suggest that outer carriers should be opened in the MSC as primary vessel may have broken. If these will not fit in the MSC then double containment is required inside the transport box.

B4.3.2: What is ‘rinse flow’? Is this the Virkon from the previous sentence or something that will need decontaminating?

B4.3.2: Part (a) states treatment with 1% (w/v) Virkon kills most organisms in 10mins, but 100% in one hour. Why then is exposure to Virkon in the section above only for 5 minutes?

B4.3.2: a dwell time of 5min is given for chemical disinfection, while the data presented shows that 1hr is needed for fully effective killing. Why is a shorter time being proposed for use?

B4.3.2: Also we have “pre-treatment” with no description of the subsequent “treatment” – is this autoclaving or something else?

Approved by committee at SAPO2 subject to amendments

Leishmania GM Risk Assessment reviewed by BSGMSC:
15th-22nd January 2016

Amendments/clarifications

Description: Reference risk assessment for WT Leishmania work.

B1.2: Mention of human cancer cells could be confusing. Remove the first line from this paragraph?

B2.4 (third box): The Leishmania manual states that the eyes could be a route of transmission so would need to be protected from potential aerosols – add in sentence regarding all open work in MSC.

B3.3 (second box): Further to the above, state that that eye protection is not required as no open work is performed outside of the MSC at all. Although not required the handbook and the WT risk assessment already included safety specs as a PPE. I would prefer to keep it. Added a line about safety specs in 3.3 (first box).

Approved by committee at CL3 subject to amendments

Our goal is to develop and apply methods for genome-scale genetic manipulation of two human infective parasites, *P. falciparum* and *P. knowlesi*. By experimentally modifying the sequence or expression levels of specific Plasmodium genes, we will be able to generate and test hypotheses about the role of these genes in general parasite viability and fitness, as well as specific phenotypes including erythrocyte invasion, drug resistance, sexual development and transmission to mosquitoes, as well as other aspects of malaria biology. A better understanding of these critical interactions may lead directly to the development of new prevention and control measures such as drugs or vaccines.

This work covers the generation, propagation, and transmission of genetically modified *Plasmodium falciparum* and *Plasmodium knowlesi* parasites. Manipulations will include tagging with epitope tags or fluorescent proteins (e.g. GFP), gene knockout, and CRISPR/Cas genome editing. We will also explore approaches to increase or repress gene expression, including CRISPR/Cas approaches called CRISPR-i and CRISPR-a, as well as promoter modification and replacement, and overexpression from extrachromosomal elements.

Constructs containing modified Plasmodium genes or fragments of such genes will be generated and propagated in *E. coli* (vector generation is covered under a separate and linked GMM risk assessment). Constructs will then be introduced into Plasmodium strains by transfection and selected for using drugs. Constructs will either be maintained as episomes, or will integrate in a targeted manner into the Plasmodium genome. For CRISPR/Cas genome editing, parasites will be co-transfected with a plasmid to express the Cas9 endonuclease and specific guide RNA (gRNA), as well as a gene targeting vector. Note that Plasmodium parasites lack the non-homologous end-joining DNA repair (NHEJ) pathway, meaning that co-expression of Cas9 and gRNAs alone would not normally induce modifications in the genome. To facilitate NHEJ-mediated gene disruption, the two component system from bacteria will be introduced. To use CRISPR/Cas to regulate gene expression (CRISPR-a and CRISPR-i), we will first create parasite lines expressing a nuclease-dead version of Cas9 into which we will introduce either individual or pools of gRNA-expression plasmids to target Cas9 to specific regions of the genome.
The effect of genetic modification will be assayed using standard cell biology (growth rate, microscopy, invasion assays, flow cytometry), biochemical (immunoprecipitation, protein detection, mass spectrometry), or biological (mosquito susceptibility) techniques. Phenotyping of live GM \( P. \) falciparum parasites will only be carried out in approved \( P. \) falciparum CL3 facilities; all other phenotyping will use material that has been inactivated using documented validated methods, in accordance with the approaches used for non-GM \( P. \) falciparum parasites.

**Recipient or parental organism**

\( \text{Plasmodium falciparum} \)

\( \text{Plasmodium knowlesi} \)

**Host/vector system**

**Hosts:**

\( \text{Plasmodium falciparum} \) parasite strains. Standard lab-adapted strains will be used, primarily 3D7, as that is the strain from which the \( P. \) falciparum reference genome sequence was generated, or NF54, the parental strain of 3D7. In certain limited circumstances other lab-adapted strains will be used in place of 3D7, such as 7G8, HB3, DD2, or strains recently adapted from clinical isolates. In some cases these strains may be resistant to one of more currently used antimalarial drugs, but none are resistant to all frontline drugs so clinical treatment options are always available.

\( \text{Plasmodium knowlesi} \) parasite strains. Currently only a single \( P. \) knowlesi line is available for in vitro culture in human erythrocytes (PMID: 23267069); if others become available they will be tested and used if they have advantages, such as increased transfection efficiency. There is no currently known drug resistance in \( P. \) knowlesi parasites, and the in vitro cultured line is susceptible to all current frontline antimalarials.

**Vectors:**

\( \text{Plasmodium} \) transfection vectors are not commercially available, although some previously produced vectors are available from ATCC through the Malaria Research and Reference Reagent Resource Center (www.mr4.org). Vectors to be used in this study will be obtained from this source, or from colleagues, then adapted to contain the gene or gene fragments of interest. Essentially all vectors consist of three elements: antibiotic resistance gene with associated expression elements to allow propagation in \( E. \) coli (usually encoding Ampicillin or Kanamycin resistance); drug resistance cassette with associated \( \text{Plasmodium} \) expression elements to allow positive selection in \( P. \) falciparum and \( P. \) knowlesi (usually anti-folate drug resistance encoded by \( T. \) gondii or \( H. \) sapiens DHFR, or genes that enable resistance to Blasticidin or Gentamicin); an expression or gene targeting cassette to either express the gene of interest in \( \text{Plasmodium} \) falciparum or \( P. \) knowlesi or direct insertion of the construct to a specific genomic location in order to ablate or modify the endogenous gene. The vectors may be based on a number of scaffolds, including the \( \text{pJazz linear vector system} \) (Lucigen) that can accommodate large genomic inserts (on average ~8 kb). For \( \text{CRISPR/Cas} \) mediated genome editing, two additional components will be included – a cassette expressing Cas9 endonuclease and a cassette expressing target-specific gRNA. We currently plan to include both Cas9 and gRNA cassettes on a single vector that will be co-transfected into parasites together with a “donor homology” region supplied on a second vector (e.g. \( \text{pJazz linear vector} \) or conventional circular plasmid) or as a PCR product, which will direct the desired genome modification. However, alternative designs incorporating the gRNA into the donor homology construct are also possible.

**Origin & function**

**Inserts:**

Inserts will include the general vector components noted above – antibiotic resistance genes (Ampicillin or Kanamycin) for plasmid propagation in \( E. \) coli, selectable markers (DHFR, Blasticidin S Deaminase, or neo) for positive selection in \( P. \) falciparum and \( P. \) knowlesi, fluorescent or bioluminescent proteins (including GFP, mRFP, mCherry, BFP, iLOV, firefly luciferase, Nanoluc), and \( \text{Plasmodium} \) promoter regions (including PfCam, PbEF1alpha, PfSec12, PfHsp86, PfBip, among others).

CRISPR/Cas elements include the Cas9 nuclease, or the nuclease-dead version of dCas9 in isolation or as a fusion with a transactivation domain (for CRISPR-a applications), and the gRNA sequences (20 nucleotides of variable sequence to target Cas9).

In most organisms, CRISPR-mediated gene disruption uses the error-prone NHEJ pathway, which has been lost in \( P. \) falciparum. To enable this method, which would bypass the need for donor homology templates for each target gene, a well-characterised bacterial NHEJ system will be expressed.
A variety of Plasmodium falciparum or P. knowlesi inserts will be used, depending on the experimental goal. These will be either large genomic inserts of 4-8 kb in linear pJazz vectors, the complete coding region of an individual gene (e.g. as a fusion with a reporter protein for localization experiments), or partial fragments of genes, to serve as donor homology regions for gene knockout or gene editing. We aim to scale up these studies to the whole genome level, so genes and/or gene fragments incorporating every gene in the P. falciparum and P. knowlesi genome may be included.

**Evaluation of foreseeable effects**

Plasmodium falciparum is classified by the ACDP as a Hazard Group 3 human pathogen. Plasmodium knowlesi is classified as Hazard Group 2. Both organisms will be cultured in the same facility and under the same controls and procedures. The only way to infect humans in the lab is by injection into human blood circulation or by a bite from a late-stage (10 days+ post bloodmeal) infected mosquito, and there is no evidence for aerosol-based transmission. Therefore, sharps are banned in the lab, with the exception of glass microscope slides, used in a standardised process that inactivates the parasite. Work with P. falciparum infected mosquitoes is restricted to a high security CL3 insectary, where the mosquitoes are in double containment at all times, the only exception to this being during the feeding procedure, where they are singly contained. If infection did occur, there are several standard antimarial drugs that can be used for treatment. No vaccine is available.

GM Plasmodium strains will have no increased ability to infect humans relative to non-GM strains. In some GM parasites a product will be expressed, for example fluorescent or luciferase-based reporters, either individually or fused to parasite proteins. These products are unlikely to be biologically active in humans. There is no evidence that P. falciparum or P. knowlesi proteins can act as toxins or allergens in humans or can act as oncogenes.

Gene inserts could theoretically alter the pathogenicity of the modified line relative to the parental parasite line. However in the majority of cases these modifications will generate GM parasites that are essentially equivalent to non-GM lab or field strains or are less fit than their wild-type counterparts. Introduction of the transfection vectors will make the GM parasite resistant to one or more drugs used for positive selection (typically the antifolate WR99210, Blasticidin, or G418). However, none of these drugs used for plasmid selection in Plasmodium parasites are in wide use as frontline anti-malarials. In the case of introducing the bacterial NHEJ genes, there is no expectation that the NHEJ machinery will alter pathogenicity of the parasite, and the genes themselves are not associated with pathogenicity.

P. falciparum and P. knowlesi are only able to infect humans and certain species of non-human primates. Given the inability of free-living parasites to survive in the environment, and the absence of non-human primates from the Institute or its surroundings, there is no risk of release of genetically modified parasites to the environment. GM parasite stocks held in liquid nitrogen are not infectious in that state. The risk of releasing mosquitoes that are infected with GM parasites is negligible because we only work with infected mosquitoes in our CL3 insectary. This unit is highly secure requiring swipe card and PIN code to gain access, which is only granted to several highly skilled users who have gone through specific induction procedures. Infected mosquitoes within the unit are held within two containers, thus providing added security in the unlikely event of one containment method failing. In a brief moment, mosquitoes that have just been fed on parasites are briefly out of secondary containment, but these mosquitoes would take 10 more days to become infectious and would be highly unlikely to survive for 10 days in the insectary where there is no access to sugar or water. Additionally, infectious feeds take place beyond an additional door within the CL3 insectary that acts as a further barrier. Infected mosquitoes never leave the CL3 insectary while alive, so present negligible risk to the public. In the extremely unlikely case of an escape of a mosquito that carries GM parasites, the ability of the mosquito species we work with to transmit parasites requires temperature (26°C) and humidity (80%) conditions rarely seen in England.

Further detail is provided on the GM Risk Assessment 'Plasmodium experimental genetics: GM Plasmodium falciparum and Plasmodium knowlesi parasites'

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request derogation from the following requirements:
- To carry out this activity in a laboratory sealable for fumigation
- To hold the laboratories at negative pressure relative to the pressure of the immediate surroundings
- An autoclave to be required in the laboratory suite
- Extract air to be HEPA filtered
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste in contact with P. falciparum and P. knowlesi culture whether GM or not, will be disinfected via approved methods and disposed of using WTGC waste policies.

Disinfection is primarily carried out with 1% Virkon for 20 minutes, but in certain circumstances (namely, when downstream work involves infecting mosquitoes as even slight Virkon exposure is detrimental to those stages) 5 minutes exposure to 5g/L Klorsept is used as an alternative. Both treatments have been validated to kill parasites and render them uninfectious, and specifics are listed in the CL3 biological safety procedures.

All biological waste that cannot be disinfected (e.g. blood bags) and all solid waste from the CL3 will be autoclaved prior to final disposal. Once a biohazard bag is full, the neck of the bag is folded over and the bag placed in an approved rigid sealed metal waste bin. All workers wear appropriate PPE when handling waste. Sealed full bins are kept inside the CL3 laboratory suites until ready to be collected in the designated waste area in the CL2 by the Waste Team.

On arrival of the waste team, the CL3 metal waste bins are passed to them, and taken in a sealed trolley for immediate autoclaving in the waste autoclaves in the same building. The trolley does not contain any other forms of waste during this operation.

All of the autoclaves are subjected to annual inspection to written schemes, annual validation reports, and quarterly servicing. Waste runs are validated to achieve a minimum hold time of 3 minutes at 134C, equivalent to a 30-log reduction in viability of indicator spores.

Waste inactivated by autoclaving is removed from site for destruction by incineration only after examination of the autoclave run report.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The Chair declared a conflict of interest as he may collaborate with the applicant in the future. The Deputy Chair therefore took over the chairing of this discussion. The Deputy Chair asked that the Chair be included in the discussions as the committee would benefit from his expertise.

Amendments:
Where appropriate, please cross reference relevant risk assessments covering CL3* Plasmodium and mosquito transmission work in general. You should include WT BA risk assessment for plasmodium and any other relevant plasmodium GM risk assessments, also the CRISPR connected program.

B2.4 Species of Anopheles mosquitoes have lived and bred in the wild in the East of England and in the past have been known to be infected by Malaria parasites. While the committee agrees that adequate measures are in place to prevent the release of mosquitos from the laboratory, the text needs to be amended to reflect this in this section (highlighted in pink).

B2.4 It is stated that mosquitos are double contained at all times – this can't be true for when mosquitos are actually handled. Please rephrase text appropriately.

B4.3.3: Where disinfectant is referred to as ‘bleach’ please name the disinfectant being used and indicate the concentration and contact time required for disinfection.

B4.3.3 Also indicate concentration and contact time for Virkon S

Typos
B1.2: ‘These products are unlikely to be biologically active…’
B3.4: ‘cryobank facilities in G140/141’ (not ‘in the G140/141’).

The committee commented that this was a well thought out and written risk assessment and that there didn’t seem to be any additional risks using GM parasites compared to the risks associated with using the wild-type parasites.

Approved at Containment Level 3* subject to amendments

Notification to HSE Required

Study of maternal-fetal interactions in placental (trophoblast) organoids and primary placenta/decidua cells pre and post wild-type (WT) and genetically-modified (GM) Plasmodium falciparum infection

GM Plasmodium falciparum parasites will be generated in order to monitor the infection of the placental organoids and primary cells from placenta and decidua. We propose to profile the transcriptome of the host (placental organoids, primary cells) and the fluorescence-labeled GM parasites during the course of infection by single-cell transcriptome profiling. This study of malaria parasite co-infection using human primary placenta organoid model and primary fetal and maternal cells will enable us to better understand the critical host-pathogen interaction mechanism that may directly lead to the development and/or control measures for new drugs and vaccine targets.

GM Plasmodium falciparum parasites will be generated in order to monitor the infection of the placental organoids and primary cells from placenta and decidua. We propose to profile the transcriptome of the host (placental organoids, primary cells) and the fluorescence-labeled GM parasites during the course of infection by single-cell transcriptome profiling. This study of malaria parasite co-infection using human primary placenta organoid model and primary fetal and maternal cells will enable us to better understand the critical host-pathogen interaction mechanism that may directly lead to the development and/or control measures for new drugs and vaccine targets.

### Project Additional Information

**Purposes of the contained use**

GM Plasmodium falciparum parasites will be generated in order to monitor the infection of the placental organoids and primary cells from placenta and decidua. We propose to profile the transcriptome of the host (placental organoids, primary cells) and the fluorescence-labeled GM parasites during the course of infection by single-cell transcriptome profiling. This study of malaria parasite co-infection using human primary placenta organoid model and primary fetal and maternal cells will enable us to better understand the critical host-pathogen interaction mechanism that may directly lead to the development and/or control measures for new drugs and vaccine targets.

**Recipient or parental organism**

Plasmodium falciparum

**Host/vector system**

Plasmodium transfection vector are not commercially available. Vectors are available from American Type Culture connection BEI resources (https://www.beiresources.org/Home.aspx) and vectors to be used in this study will be obtained from this source or from research colleagues.

**Origin & function**

Inserts or "genetic material" involved include the general vector components; antibiotic resistance genes (Ampicillin or Kanamycin) for plasmid propagation in E. coli, selectable markers (DHFR, Blasticidin S Deaminase, or neo) for positive selection in P. falciparum, fluorescent or bioluminescent proteins (including GFP, mRFP, mCherry, BFP, iLOV, firefly luciferase, Nanoluc), and Plasmodium promoter regions (including PfCam, PbEF1alpha, PfSec12, PfHsp86, PfBip, among others).

**Evaluation of foreseeable effects**

The inserted gene product will be expressed in GM P. falciparum infected red blood cells. These include the fluorescence reporter gene either individually or fused to parasite proteins. If using the CRISPR-cas9 approach, the Cas9 nuclease will be integrated and expressed within the parasite to generate double-strand breaks in the parasite genome. These products/proteins are not known to be biologically active in humans because Plasmodium-specific expression sequences and regulation is unique and very divergent from the human gene expression and regulation system. There is no evidence that P. falciparum proteins (either alone or fluorescence-tagged) can act as a toxin or allergen in humans.
Drug resistance cassette with associated Plasmodium expression elements to allow positive selection in P. falciparum (usually anti-folate drug resistance encoded by T. gondii or H. sapiens DHFR, or genes that enable resistance to Blasticidin or Gentamicin). An expression or gene targeting cassette to either express the gene of interest in P. falciparum or direct insertion of the construct to a specific genomic location in order to ablate or modify the endogenous gene. For CRISPR/Cas mediated genome editing, two additional components will be included: a cassette expressing Cas9 endonuclease and a cassette expressing target-specific gRNA. The planned GM parasites fused with a reporter construct will be resistant to the vector drug selection cassette, but this will typically not alter the overall virulence of the parasites. In the case of introducing the bacterial Cas9 NHEJ (non-homologous end joining) genes, there is no expectation that the NHEJ machinery or process is involved in pathogenicity as the overall impact on the parasites will be either to cause disruptive insertion or deletions. Therefore, GM changes will predominantly be neutral, or if any, result in a negative impact on pathogenicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

B320, B319 and B213, are CL3 laboratories with approved structure and/or process derogations. These rooms are designed to comply with all of the requirements of CL3 with the following exceptions, which have been agreed by the Health & Safety Executive (HSE) on 18th July 2016:-

- The laboratories are not sealable for fumigation
- An autoclave is not present in either lab

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste in contact with P. falciparum culture will be disinfected via approved methods and disposed of using WSI waste policies. Disinfection is primarily carried out with 1% (w/v) Virkon (final concentration) for 20 minutes. Treatments have been validated and specifics are listed in the CL3 laboratory handbook.

Sharps

Used slides and Femtotips® will be soaked in 100% methanol to inactivate any live parasite and then disposed in appropriate sharp bins which are then autoclaved as solid waste.

All biological waste that cannot be disinfected (e.g. blood bags) and all solid waste from the CL3* will be autoclaved prior to final disposal. Once a biohazard bag is full, the neck of the bag is folded over and the bag placed in an approved sealed metal waste bin. All workers wear appropriate PPE when handling waste. Sealed full bins should be kept inside the CL3* laboratory suites until ready to be collected in the designated waste area in the CL2 by the Waste Team.

Spillage containment kits will be maintained in the derogated CL3 room. MSCs will be disinfected after every use and given a final clean before shut down each day.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Risk assessment reviewed by Biological Safety Committee at meeting on 17th October 2019.

Comments / Amendments

Use of sharps in CL3 – the team is planning to use a microinjector for this piece of work and one member of staff will be trained to use it. The risk of a stick injury will be minimised by staff wearing cut proof gloves and the use of disposable microinjection glass capillaries.

Suggested that the microinjector should be used on a non-vibrating bench and the fact that the sensitivity of the microinjector may make the time allowed for work to take place quite restricted.

Brief description: ‘vector generation is covered under a separate and linked GMM risk assessment’ Please include reference.

1.2: Human blood, organoids & E.coli should be included in this section.
Included, please refer to section 1.2.

B1.1, box 1: No work is covered by SIBAGMRA09_BLOOD+TISSUEv3, this is a guidance document only.

B1.1, box1: Primary cells (decidual and placenta cells) & Human trophoblast organoid cultures from placenta are not required here as you have already stated in Brief description that these are covered by SIBAGMRA19_46.

B1.1, box1: Incorrect statement ‘Any risks associated with research involving the use of GM P. falciparum parasites are covered by risk assessment number SIBAGMRA15_37v2’. This risk assessment covers your team for these risks; you cannot work under another teams risk assessment.

B1.1: The risk from blood should be discussed throughout this section use SIBAGMRA09_BLOOD+TISSUEv3 for guidance.

B1.1, box 3: Reword the following as does not make sense ‘ensure processes Receive additional monitoring (if deemed necessary) and all risk is understood.’

B2.4, box 3: Include here that insectary is a separate area to the microscope room where work will be carried out.

B3.1, box 1: Large volume is this correct or a typo?

B3.3, box 1: It is not clear what the tweezers will be used for, ‘Using a tweezer’ this needs to be clarified.

B3.3, box 1: Latex gloves are not permitted on site please replace with nitrile.
B3.3, box 2: In the section that refers to using the centrifuge, it needs to be included that the sealed leak proof buckets are only opened inside an MSC.

B3.4, box 3: Include that the secondary transport container will contain enough absorbent material to absorb the full volume should a spill occur.

B4.5: Reference specific procedure by replacing ‘CL3 biological safety procedures’ with ‘CL3 laboratory handbook’.

B4.5: Add sharps disposal information.

B4.7: Reword first sentence so it excludes work rather than describing what is included.

B4.7: Exclude work above a specific volume of parasite culture.

B5: Please confirm that this risk assessment has been read and approved by team leader.

C1: Emergency procedures need to be more specific especially regarding glass breakage. Add further information regarding glass clean up, ensuring that any pieces of glass were wiped down with wet tissue and Klorsept. The person undertaking the cleaning should also wear the appropriate gloves.

Approved at Containment Level 3 subject to amendments and HSE approval

#### Purposes of the contained use

Genesis of lentiviral HCV pseudotypes: To investigate how HCV infects liver cells and the role of the humoral immune response plays in controlling HCV replication. This assessment covers the generation of lentiviral pseudotypes using a disabled lentiviral vector by transient expression of HCV gps from an independent promoter.  

Genesis of HCV DNA and RNA: This seeks to generate synthetic HCV strain JFH RNA for subsequent recovery at CL3.

---

#### Host/vector system

**Genesis of lentiviral HCV pseudotypes:** Hosts include E. coli (Top 10 strains, Invitrogen); 293T embryonal kidney cell line; Human hepatoma cell lines (HepG2, Huh-7, HepH, HH29); Primary hepatocytes.

**Genesis of HCV DNA and RNA:** E. coli (JM 109 derivative strain, Top10, Invitrogen).
Genesis of lentiviral HCV pseudotypes: Vectors - pCDNA3 and pNL4.3R-E-lentiviral vector (based on a lab strain of HIV-1 from which the vpr and envelope genes have been deleted).

Genesis of HCV DNA and RNA: Vector - pUC19 (Stratagene).

Origin & function

Genesis of lentiviral HCV pseudotypes: Insert - HCV envelope gps - The E1E2 gps mediate viral attachment and fusion of the viral and host cell membranes necessary for infection of a target cell. The E1E2 region will be PCR amplified from clinical material and synthetic start and stop codons added to enable expression. Donor - Human (plasma samples and liver biopsies).

Genesis of HCV DNA and RNA: Insert - HCV DNA encoding the full length genomic sequence is not infectious for chimpanzees. However, synthetic RNA derived from plasmid DNA can lead to infection and seroconversion if delivered directly into the liver of a chimpanzee. The JFH strain of HCV will be used at this time. Donor - Human (plasma samples and liver biopsies).

Evaluation of foreseeable effects

Genesis of lentiviral HCV pseudotypes: 1) Transfected 'producer' 293T - Transfection of the pE1E2 expression constructs into 293T cells will result in the expression of HCV gps, which pose minimal risk to human health. Co-transfection of 293T cells with the lentiviral pNL4.3R-E- and vectors encoding the viral gps (HCV, VSV and MLV) will lead to expression of the reporter gene luciferase and the HIV proteins (gag, pol) which will drive assembly of pseudotyped particles. None of these viral proteins or luciferase have been associated with toxicity. 2) Lentiviral pseudotype infected target cells - The pseudotypes can only undergo a single cycle of infection and so the 'infected' target cells do not release new rounds of progeny virus. These cells do express lentiviral proteins and luciferase, which have no reported toxicity for humans. Accidental exposure by injection of these antigen expressing cells could lead to an immune response to the viral expressed genes. Whilst not harmful the detection of these immune responses is used in diagnosis of HIV infection, and so could lead to a false positive. Risks will be contained by handling materials at CL2. Environmental risks - The E coli hosts used are disabled and require a supplemented media for growth. The 293T and hepatoma cell lines are only viable within tissue culture media and in the presence of CO2. The pseudotyped viral particles are not desiccation resistant and are incapable of replication. No risk to the environment.

Genesis of HCV DNA and RNA: HCV JFH plasmids bearing E1E2 sequences will constitute new GMOs. The E1E2 ORF(s) will be derived from naturally occurring sequences present within infected patients and will be unlikely to possess biologic properties not already present within nature. DNA encoding HCV genomic length sequences are not infectious for chimpanzees and constitute minimal risk to human health. Synthetic HCV genomic RNA transcripts can be infectious for the chimpanzee if delivered intrahepatically. Other routes of delivery have not led to infection. Consequently the risk to human health at generating the RNA is minimal and can be contained at CL2. All experiments involving the delivery of the RNA into mammalian cells will take place at CL3 (to be submitted in due course). Environmental risk - The E. coli strains are disabled and are transfected using non-mobilisable vectors. The naked DNA generated by in vitro transcription will be unprotected from environmental RNAases and will degrade rapidly if released.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Surfaces to be wiped with 10% Trigene which has been shown to be an effective agent for inactivation of a wide range of enveloped viruses. Disposable plasticware will be rinsed in 10% Trigene, autoclaved and disposed of as clinical waste by incineration. Disposable gloves, paper towels etc will be deposited in autoclave bags and autoclaved before disposal.
Centrifuges and other equipment will be disinfected by wiping with 10% Trigene. If necessary the buckets can be totally immersed in this disinfectant.

Autoclaving of waste achieves 100% kill.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Originally the assessments were circulated in a different format with different titles, but the GMSC felt that those assessments were repetative and lacking in clarity. Comments were passed back to the Pis and meetings were held to discuss the comments in detail. The assessments were revised and recirculated for final approval. The GMSC has now approved the work.

Project Ref 116/05.2

Date Ackn'd: 16/09/2017

CU2 Project Title: Cell culture propagation of Hepatitis C virus:

Class: Class 3

Culture Volume: <50mls

Non-GMM Consent Granted: Yes

Project notified under transitional arrangements: [N]

Tick if notifying a connected programme of work: [N]
**Project Additional Information**

**Purposes of the contained use**

This proposal seeks to deliver HCV strain JFH RNA into human liver derived cells and to characterise the resulting particles. This follows on from the recently notified Class 2 proposals. "Genesis of HCV virus DNA and RNA" & "Genesis of lentivirus pseudotype particles bearing HCV glycoproteins". This proposal includes expression of HCV strain JFH in human liver cells. Translation of viral RNA will lead to expression of HCV proteins, particle assembly and release.

**Recipient or parental organism**

As section below.

**Host/vector system**

Host: Primary and transformed human liver cells: screened and found to be negative for known human pathogens (HIV, HBV etc). After RNA transfection, the cells will be monitored for HCV infection for up to 14 days before being discarded.

Vector: The JFH strain of HCV is the only known HCV sequence capable of autonomous replication in hepatoma cell lines without adaptive mutation. Recent experiments suggest that the JFh strain can assemble and release viral particles at low titre in cell culture, which can be passaged in human cells. It is not known if these particles are infectious for humans.

**Origin & function**

Donor: HCV within clinical material from infected patients.

Genetic material: The investigators plan to transflect synthetic HCV RNA generated by run off transcription into liver cells to generate virus particles. Construction of these HCV genomes has been described in previously notified proposals. Plasmid DNA encoding the full length HCV genomic sequence is not infectious for chimpanzees. However, synthetic RNA derived from this DNA can lead to infection and seroconversion if delivered directly into the liver of a chimpanzee (Kolykhalov 1997).

**Evaluation of foreseeable effects**

Hazards to human health: Transfection and delivery of HCV RNA transcripts into human liver cells will lead to the expression of viral proteins which will result in the assembly of viral particles. Plasmid DNA encoding HCV JFH with heterologous E1E2 sequences will constitute new GMOs. The E1E2 ORF(s) will be derived from naturally occurring sequences present within infected patients and will be unlikely to possess biological properties not already present in nature. Synthetic HCV genomic RNA transcripts can be infectious for the chimpanzee if high doses are delivered intra-hepatically. Other routes of HCV RNA delivery have not led to infection. All experiments involving the delivery of genomic RNA into mammalian cells will take place under CL3 containment.
Environmental Hazards: The GMOs generated by this work pose no threat to the environment. The eukaryotic cells and cell lines used will be unable to survive in the external environment. The naked DNA used in electroporation will be unprotected from environmental RNAases and would be degraded rapidly if released into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Human Clinical Applications

Project Ref 165/10.1

Date Ackn’d CU2 Project Title 21/07/2011 Lentiviral expression systems as a tool for studying intracellular signalling pathways in

Class CultureVol Class 2 CultureVol Class 3-4

Class 2 ≤ 1 Litre
This is a study undertaken in order to investigate the mechanisms of pro and anti-inflammatory signaling in immune cells such as macrophages, dendritic cells and lymphocytes.

We have previously generated lentivirus particles using 3rd generation transfer vectors and a 3rd generation packaging system. This system is designed to minimise the possibility of replication competent virus particles arising during lentivirus production, where the gag/pol and rev gene products are expressed from separate plasmids that are co-expressed with the envelope (VSVg) vector following co-transfection with the lentiviral backbone vector into packaging cells (KEK293T/17). Substitution of the HIV-1 envelope protein with the Vesicular Stomatitis Virus envelope glycoprotein (VSV G) not only results in the production of a higher virus titre with a significantly broadened host cell range but also contributes to an enhanced safety of the system. The resulting retrovirus is replication-defective. However, the improved safety features of 3rd generation packaging systems are off-set by considerably lower virus titre yields obtained with this configuration. Therefore to improve viral titres we obtained a 2nd generation packaging system from the Trono Lab (Switzerland), in this case, all the auxiliary genes are expressed from one plasmid, which also incorporates the transactivator gene tat (absent in the 3rd generation system), namely psPAX2 or PDCMV8.91. Together with the envelope protein encoding plasmid (pMD2.G) these 2nd generation packaging systems are compatible with packaging of 3rd generation lentiviral transfer vectors containing SIN LTRs and are widely used to produce small scale amounts of lentiviral particles of in vitro transduction of primary mammalian cells.

Viruses will be assembled and packaged in the HEK293T/17 cell line and the conditioned supernatants (containing mature lentivirus) will be concentrated by centrifugation and titred prior to use in experiments. Virus titres will be determined using a FACs-based assay using either GFP fluorescence assay or labelled tNFGR (truncated nerve growth factor receptor) marker genes to calculate the amount of lentivirus infectious units. This will be carried out in HT1080, Jurkat and SupT1 for 3-6 weeks and monitoring the culture supernatants for p24 expression by ELISA. A positive control for p24 protein will be incorporated in this assay. Once generated, lentiviruses will be used to infect a range of cell lines and primary cells over a range of MOI (multiplicity of infection). In the first instance we plan to study innate immune receptors, including TREM-1, DAP12, CD38, CD164, transmembrane protein123 (TMEM123), TLRs, tyrosine kinases., IRF family memebrs, NFKB signalling components (e.g. Myd88), p38 MAP kinase, and reporter genes such as TNF-luc, IL-6-luc, Stat3-luc. All these targets represent non-oncogenic, non-secreted cell components.

Recipient or parental organism

293T/17 cells (highly transfectable cell line derived from the 293T cell line established from human embryonic kidney cells)
RAW 264.7 (murine macrophage line)
HeLa (human epithelial carcinoma cell line)
HT1080 (human fibrosarcoma cell line)
MonoMac6 (monocytic cell line)
SUP T -1 (human T Lymphoblast cell line)
HUVECS (Human Umbilical Vein Endothelial Cells)

Primary human monocytes, acrophages, dendritic cells osteoclasts & lymphocytes derived from elutriated blood packs
Cells derived from dissociated human synovial membrane tissue taken from rheumatoid arthritis or osteoarthritis patients (primarily fibroblasts, monocytes, macrophages, dendritic cells & lymphocytes)
Alveolar macrophages from sarcoid patients

**Origin & function**

The gene and promoter sequences used are of human and rat origin. We have constructed lentiviral transfer vectors encoding (1) reporter genes (e.g. TNF-luciferase); (2) cDNAs (e.g., human Foxp3, p38) and; (3) shRNAs 9p38):
(1) Reporter genes will be used to measure promoter activities of the TNFα, IL-6 and Stat-3 genes in primary human immune cells (monocyte/macrophages, T cells). Constructs will contain the promoter(s) and deletion mutants thereof in the presence and absence of the 3′ UTR (untranslated region). These experiments will be short-term and result in destruction of target (infected) cells. We will also perform short-term (8-hour) co-culture experiments with adenovirus-infected primary human macrophages (expressing TNF-luciferase reporter genes) and primary human CD4 T cells transduced with Foxp3-expressing lentivirus. Macrophages will be infected with adenovirus for 1 hour and cultured for 24 hours in the absence of virus. Similarly, VD4 T cells will be transduced with lentivirus 14 days prior to co-culture and washed extensively prior to co-culture. The end-points for these experiments will necessitate cell lysis, resulting in destruction of the target (infected) cells. Lysates will be frozen prior to subsequent luciferase activity determination.

(2) Short-term (<4 weeks) transgene expression in human and rat immune cells using lentiviral vectors will be employed to study the role of human genes Foxp3, TREM-1, DAP12, CD38, CD164, transmembrane protein 123 (Tmem123), TLRs, tyrosine kinases, IRF family members, NFKB signaling components (e.g. Myd88), p38 MAP kinase and rat CD16A.

Immortalized human cell lines will be transduced and selected for stable expression of Foxp3. Such cell lines will be tested for replication competency using the p24 ELISA method, and all handling and disposal will be as outlined in the associated GM risk assessment.

(3) Lentiviral vectors expressing shRNA sequences (targeting the same genes as in (2) - above) and embedded in the miR30 backbone will be employed to perform specific gene knockdown in target cell populations.

The above-mentioned gene sequences will be inserted into lentiviral vectors in order to infect human and rat cells of the immune system.

**Evaluation of foreseeable effects**

None of these gene inserts transfer vector(s) should present a hazard. One of the transgenes, Jund is a member of the proto-oncogene Jun family however it is an atypical member as it has a negative effect on cell proliferation and thereby poses little risk (Hernandes et al., 2008; PGM081, section2).

The WPRE sequence located in transfer vectors encodes the potentially oncogenic X-protein sequence. There is a risk of recombination with other viruses and/or latent viral sequences in the target cells although the lentivirus produced is replication incompetent. Routine testing for replication competency of all virus produced will be performed to assess for this possibility and any such virus will be destroyed.

The use of Class II microbiological safety cabinets for II procedures involving the handling of lentivirus vectors will minimize the risk of accidental exposure to workers should a replication competent lentivirus arises during virus production and/or use.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste: inactivation by the addition of Microsol3 to a final concentration of 10%, or 1% (final concentration) Trigene/Virkon, as per manufacturers’ instructions. The effectiveness of each reagent is checked on any change in procedure. Inactivated waste will be disposed of via sink into the drains.

Solid waste: plasticware such as plates, culture flasks, are double bagged and either autoclaved at 136ºC for 6 minutes under vacuum. The run number is recorded and chart paper traces and printouts kept. The autoclaves are serviced bi-annually and validated yearly by contract using representatives dummy loads in order to check that all areas of the load are reaching the required temperatures. Autoclaved waste then proceeds via the Imperial College clinical waste route.
Part 1: PI CID number missing and the GM Centre is: GM165.
1.22: Change last strain to: Murine bone-marrow-derived cells.
1.25: Third before last paragraph, Typo: 'tehse'
1.3: Please answer the questions in this section
2.1.1.2: Associated hazards: The WPRE element has oncogenic potential and then there is the risk of recombination with other viruses. Although the vectors are replication incompetent.
2.1.1.3: Explain why the answer is 'no'
2.1.1.4: Answer is 'n/a'
2.1.1.5: Answer: None associated.
2.1.1.6: Answer: None associated.
2.1.1.7: Explain why the answer is 'none'
2.1.1.8: Answer: None, recombination incompetent
2.3.1.1: Change answer to "Working with/handling of viral vectors containing WPRE".
2.3.3.2.b: Question is unanswered
2.3.3.3.d: Leave aerosols to settle first, then disinfect and finally use soapy water.
2.3.3.4.a: Typo: 'tehn'
2.3.3.5, 2.3.3.6 and 2.3.3.7: Questions are unanswered.
2.3.3.8.b: Remove 'Latex gloves'
2.3.3.8.c: Change answer to "No other PPE is used".
2.3.6: Tick box: 2
Part 3: Fill in Tick box.
3.1.1.a: Waste container should be 'sealed' and remove reference to sharps.
3.1.1.b: Change Autoclave cycle details to 136°C for 6 minutes. Change 'temperature recorder' to 'print out'
Location of backup is: Basement and BSU, in event of a breakdown list the secondary autoclave.
3.2.a: Change answer to, "tubes carried in a rack".
3.31.a: Answer is 'None', delete the answers in rest of the section.
3.32: Answers are: n/a
3.4: Answer is 'no'
3.5.a: Spillage during transport: disinfect first.
3.5.b: Skin surface contamination: Use microsol wipe, then soapy water.
Medical intervention/prophylaxis: Change answer to section 2.3.5 of the form.
3.7.1: Remove staff that have left and add the CID numbers of those missing.
3.7.2: Question is unanswered: cleaners etc…
Agreed Class 2, Containment Level 2. This project is notifiable to the HSE.

All of the comments of the two committees have been addressed and the requested amendments incorporated into the risk assessments forwarded with this form.

Project Ref 207/06.2

Date Ackn’d 16/12/2015

CU2 Project Title The contribution of RNA secondary structure to the replication of mammalian positive-stranded RNA viruses

Class 2

CultureVolClass2 < 1 Litre

Consent Granted Yes

Project notified under transitional arrangements
### Project Additional Information

#### Purposes of the contained use

To carry out functional investigations of predicted RNA secondary structures in positive-stranded RNA viruses. For the investigations planned, infectious clones from hepatitis C virus (HCV), Theiler’s murine encephalitis virus (TMEV), human enterovirus (Coxsackie A21 CVA21) and other non-polio human enteroviruses will be manipulated to investigate a range of potential replication elements and other larger scale RNA structures associated with virus persistence. All manipulations are designed to modify RNA structure without altering the coding capacity of the region altered. All changes will therefore be made at synonymous sites in codons so that the proteins produced by the modified viruses are unchanged. The replication ability of viruses with modified RNA structure will be investigated in cell culture, and where appropriate, in a mouse model (TMEV).

#### Recipient or parental organism

**Bacterial**  
Disabled E. coli K12-derived strains for cloning mutated DNA copies of the viruses used for RNA structure investigations. All bacterial strains are unlikely to be harmful to man or the environment.

**Mammalian**  
A variety of standard continuous and primary cell lines will be used for virus expression. (3TC, Huh7 and a range of other human hepatoma-derived cell lines, Vero cells and other continuous or primary fibroblast cell lines).

#### Host/vector system

Infectious clones of TMEV, human enteroviruses and HCV.

#### Origin & function

Transfection of in vitro-generated RNA into mammalian cells allows the full replicative cycle of TMEV, other non-polio virus enteroviruses and HCV to be initiated. These cell lines will therefore produce infectious virus, whose replication abilities can be compared to those of wild-type viruses.

#### Evaluation of foreseeable effects

All bacterial strains are disabled and therefore unlikely to be harmful to man or the environment. All mammalian cell lines for virus expression are in standard use and are known to be non-harmful for human health or safety.

RNA transcribed from clones generates potentially infectious virus particles when transfected into the appropriate mammalian cell line, which are capable of being further propagated in cell culture and on passage into animals. However, none of the mutations introduced to investigate the role of RNA structure on virus replication alter protein coding of the viruses, and no steps lead to the production of chimaeric viruses, the insertion of foreign genes in the viral genomes. Furthermore, none of the mutants are
Likely to alter virus tropism or host range, nor increase infectivity, virulence or transmissibility. Since all mammalian expression uses transfected viral RNA sequences, no antibiotic resistance genes or gene products will be introduced into mammalian cells. We therefore anticipate that the mutant viruses will generally show impaired replication ability or at most, restored fitness to wild type levels.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Solids (eg plasticware such as pipettes, flasks, tubes etc).** All solids exposed to potentially infectious TMEV, CVA21 and other non-polio enteroviruses at containment level 2 will be immersed in 3% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then disposed of via the clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill. Used agar plates will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Any excess liquids will be discharged to drains, and solid then disposed of via clinical waste stream for incineration of microwave treatment or via the industrial (black bag) waste stream for landfill. All HCV-exposed solid materials in the containment level 3 laboratory will be autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Any excess liquids will be discharged to drains, and solid then disposed of via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

- **Liquids (eg samples, culture supernatants, tissue culture media).** All culture fluids and other liquids containing potentially infectious TMEV, CVA21 and other non-polio enteroviruses at containment level 2 will be mixed with 3% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then disposed of through the drain. HCV culture fluids, and other liquid waste originating from work on HCV at containment level 3 will be mixed with 5% Trigene for >12 hours or autoclaved using a make safe cycle as specified in BS2646, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) and then discharged to drains.

- **Sharps (in sharps bin, eg needles, syringes, scalpels).** These will be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), disposed via clinical waste stream for microwave treatment.

- **Animal bedding and carcasses.** These will be autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Carcases will be disposed of via clinical waste stream for incineration and bedding via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

**Degree of kill:**

- **Autoclaving - effectively 100% kill of HCV.**
- **Disinfectant - Trigene is used for disinfection and has proven efficacy (> 5 log reduction in infectivity) against highly resistant non-enveloped viruses such as enteroviruses, and also flaviviruses (Sources: MediChem, Abbott Analytical)**
- **Microwaving or Incineration - not applicable, all waste is autoclaved or chemically disinfected prior to disposal by microwaving or incineration.**
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.

### Project Additional Information

#### Purposes of the contained use

We wish to investigate several key questions about the evolution of social behaviour using the opportunistic pathogen Pseudomonas aeruginosa and go on to use our understanding of social evolution theory to understand observations of behaviour in bacterial infections. Specifically, we will investigate the extent to which social behaviour of bacteria effects their ability to infect hosts and cause disease. The social traits we focus on are the production of the iron-scavenging molecule pyoverdine and cell-to-cell communication systems. We will measure the extent to which clinical strains isolated from the sputa of cystic fibrosis patients exhibit these and other social behaviours.

### Recipient or parental organism

| Pseudomonas aeruginosa |

### Host/vector system

| Bacterial host/plasmid vector |

### Origin & function

#### Inserted genetic material:
- standard non-harmful reporter genes such as green fluorescent protein (GFP) gene derived from the jellyfish Aequorea Victoria and luciferase a gene derived from the firefly Photinus pyralis.
- Muc A gene which suppresses the production of alginate in wild type P. aeruginosa strains; insertion of this gene restores phenotype of mutant clinical strains to wild type phenotype.
- antibiotic resistance genes for selection purposes.

#### Gene deletions:
- Siderophore (pyoverdine and pyochelin) knockouts are no longer able to chelate bound iron. The ability to chelate iron is crucial to bacterial metabolism and the ability to colonise host tissue where iron is withheld by powerful chelators such as haemoglobin or transferring. The fitness and virulence of these strains is therefore, significantly reduced relative to the wild type in monoculture.
- Quorum sensing knockouts no longer have functioning QS systems. Bacteria with knockouts of these regulatory genes are less able to sense their bacterial neighbours and are disabled with respect to biofilm production, swarming motility and production of secreted virulence factors. As a result, strains that have QS systems disrupted have significantly reduced virulence relative to wild type in monoculture.

### Evaluation of foreseeable effects

The OMMOs with lux or gfp reporter genes inserted are likely to display comparable properties to wild type organisms. The GMMOs with social functions disabled by gene deletions or disruptions are either likely to have or have been demonstrated to have reduced fitness and virulence relative to wild type strains. Tissue tropism and host range are not likely to be affected. Consequently, harmful properties associated with the GMMOs are at the most comparable to those of the wild type organism. Antibiotic resistance genes will not be ones that are used therapeutically for P. aeruginosa.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates and including lettuce leaves, warm oth pupae and C. elegans) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) — autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation using 12 point thennocouple of worst case loads)
Heat treatment or Incineration — not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by SACGM to control the risks to human health and safety and to the environment.

Project Ref 31/01.7

02/03/2022
The aim of this project is to identify, and characterise the function of Streptococcus pneumoniae genes required for virulence. This necessitates the construction of plasmid vectors containing segments of S. pneumoniae DNA, which are used to transform wild type S. pneumoniae to make GMM strains with specific gene disruptions. The phenotype(s) of these strains will then be assessed using animal and cell culture models of disease.

Recipient or parental organism

The recipient microorganism in Streptococcus pneumoniae, which is a human pathogen. It is placed by the ACDP in Hazard Group 2.

Host/vector system

Host. Streptococcus pneumoniae.

Vectors: pJPC9111, pJPC9112, pLS1GFP, pLS70GFPcat, pucMUT, pDE1, pEVP3, pACH74, p10701

Origin & function

Source of Host Cells - Smithkline Beecham; Prof. James Paton, University of Adelaide
Source of Genetic material: inserts - PCR of Streptococcus pneumoniae DNA
Source of the material: vectors - Prof. James Paton, University of Adelaide; commercial sources.

Evaluation of foreseeable effects

The GMM is likely to pose no increased risk to human health in comparison with the wild type parental strain. On the contrary, since a putative virulence gene will have been mutated the GMM is likely to be attenuated in its ability to cause disease; and therefore be functionally disabled. The insertional mutagenesis protocol utilised in this project renders the GMM resistant to chloramphenicol, spectinomycin, erythromycin or kanamycin. However, there are a wide variety of alternative antimicrobial agents available which are effective against S. pneumoniae infections should infection by the GMM occur. S. pneumoniae is essentially restricted to the human nasopharynx and there is no recognised environmental source. The environmental survivability of the GMM is envisaged to be the same as the wild type, with the caviat that without...
appropriate selection pressure reversion to the wild type is likely, and there is no increased risk to the environment posed by the GMM compared to the wild type.

All work carried out under this project will take place in appropriate Containment level 2 premises, together with appropriate waste control and management systems.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Chemical disinfection of liquid GM waste: 2% hycolin solution, as per manufacturer's recommendations, overnight exposure. 100% kill validated by periodic plating out of cultures after exposure to hycolin disinfectant.

- Autoclaving of solid GM waste: Large autoclave; solid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

- Autoclaving of liquid GM waste: Large autoclave; liquid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Additional Information

Purposes of the contained use

The aim of this project is to isolate genes important in parasite survival in order to design vaccines against them. The strategy is concentrated on a family of protein that the parasitic nematode uses to maintain its environment within its human host. This appears to be a pore forming protein that in sufficient amounts lyses cells in a localised area.

This project involves the cloning and expression of the proteins of interest for subsequent purification and analysis.

Recipient or parental organism

The AD494 host is a K12 derivative of Escherichia coli and as such is regarded as a non-colonising, disabled host that is not pathogenic to humans and unlikely to survive outside laboratory culture.

Host/vector system

pET System available from Novagen
pET vectors are mobilisation defective plasmid vectors derived from pBR322

Origin & function

Excretory/secretory protein produced by Trichuris worms that induce pore formation in planar lipid bilayers in the host caecum.

The purpose of cloning and expressing the genetic material in the E.coli pET expression system is to produce active protein that can be purified for characterisation.

Evaluation of foreseeable effects

The insertion of the gene into the E.coli host is likely to make the E.coli more hazardous in so far as it is expressing a harmful protein. However it is a disabled host that is unlikely to colonise humans and survive in the environment. The modification is not expected to overcome disablement of the E.coli, nor effect host specificity, tissue tropism or susceptibility to host defence mechanisms. Exposure to the recombinant E.coli would therefore be expected to have only localised and transient effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill: Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licenced incinerator)
Please enter comments on the GM safety committee on the risk assessment

### Project Additional Information

#### Purposes of the contained use

The aim of this project are generally to study the control of expression, functions and cell biology of *Plasmodium falciparum* parasite encoded proteins. These questions will be studied through altering the expression of genes within the organism. This will be carried out by transfection with DNA, generating transient (episomal) expression of exogenous genes or stable integration (functional knockout of endogenous genes, or insertion of known coding sequences). Additionally, attempts will be made to inhibit gene expression through transfection with single or double stranded RNA. Using these methods, the project aims are:

- to study the functions of various *Plasmodium falciparum* genes and control sequences,
- to investigate the mechanism of antigenic switching, and endothelial adherence of variant antigen genes and their products, and
- to examine the mechanism of protein export of the variant antigens and other gene products which have a destination exterior to the parasite.

#### Recipient or parental organism

*Plasmodium falciparum* - the causative agent of human malaria

#### Host/vector system

Nucleic acid sequences will be transfected as either plasmid constructs or as RNA. Plasmids for transfection will be generated in disabled *Escherichia coli*. Vectors are pUC and pBS-based non-mobilisable bacterial plasmids.

#### Origin & function

**i) Target and control sequences from*Plasmodium falciparum* and *P. chabaudi* (rodent malaria):**

- *P. falciparum* -- var genes, exported proteins, non-coding regulatory regions, genes involves in transcriptional control or translational control
- *P. chabaudi* -- non-coding regulatory regions

Non-coding putative regulatory sequences should have no biological action. var genes code for erythrocyte surface proteins, which are involved in antigenic variation and in some cases, binding to various human host receptors. Other putative red cell surface proteins have unknown functions.

Sequences will be either placed adjacent to reporter genes or epitope to study gene expression, switching and trafficking, or alongside a selectable marker for stable transfectants:

**ii) Standard reporter genes and epitope tags: functions as indicated by names.**

- *E.coli* -- chloramphenicol acetyltransferase [CAT], Influenza virus -- hemagglutinin epitope [HA tag], firefly (Phontinus pyralis) -- luciferase [LUC]
- jellyfish (Aequorea victoria) -- green fluorescent protein [GFP; and derivatives]

**iii) Drug resistance and selection marker:**

- a) Dihydrofolate reductase (DHFR) from *Toxoplasma gondii* - pyrimethamine resistance, *P. falciparum* -- pyrimethamine resistance
- Human -- resistance to analog of pyrimethamine

#### Evaluation of foreseeable effects

The pathogenicity, virulence, infectivity and invasiveness of the modified parasites are not expected to be increased when compared to the parent microorganisms. The inserted genes will not affect host range and tissue tropism. No adverse effects are anticipated in terms of altered interaction with host defences. Parasites will remain fully susceptible to a range of first line treatment drugs.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

a) Laboratory not sealable for fumigation:
There is no foreseeable need to fumigate the laboratory.

b) No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination:
The organism presents no hazard of infection by the airborne route.

c) Autoclave and some other equipment not within the laboratory:
Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated with the dedicated facility. In all cases a safe system of transport involving secondary containment is in use, any equipment used is cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A) General procedures.
Consumables (mainly plasticware eg pipettes, flasks, tubes) *excluding radioactive items (see below) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) *excluding radioactive items (see below) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

B) For waste items that are both radioactive and contain P. falciparum
Solids - disinfect with 2% Virkon for at least 30 minutes, discharge any excess liquid to drains as aqueous radioactive waste subject to limits contained in an authorisation granted under the Radioactive Substances Act 1993, dispose of solids as solid low level radioactive waste under an authorisation granted under the Radioactive Substances Act 1993.

Liquids - disinfect with 2% Virkon for at least 30 minutes, discharge to drains as aqueous radioactive waste subject to limits contained in an authorisation granted under the Radioactive Substances Act 1993.

C) Degree of kill
i) Autoclaving:
Effectively 100% kill (annual validation).

ii) Incineration:
Effectively 100% kill (licensed incinerator).

iii) Chemical disinfection with Virkon:
This is used only for the disposal of radioactive waste from metabolic and surface labeling experiments, the waste could possibly contain live parasites but cannot be autoclaved.

Current control measures of adding the chemical disinfectant Virkon, according to manufacturer's instructions, should be sufficient to kill any live organisms. Virkon is added to waste from parasite cultures because of the possible risk of contamination from blood products (known viruses, bacteria, etc.) and is not necessary to kill the...
parasites. Dilution in a sufficiently large volume of water kills the parasites. However, since both parasites and blood products are present, chemical disinfection is used.

Determination of the degree of kill (the percentage kill or log reduction in viability) after Virkon treatment would be impossible. The addition of Virkon to live (parental) cultures of parasites congeals the infected and uninfected red cells to a slurry. It would be impossible to remove the Virkon from this slurry and attempt to continue culture of any potentially living organisms (centrifugation reduces this slurry to a semi-solid, muddy lump and any traces of Virkon in a culture would render the host red blood cells inviable) making any living parasites undetectable. Any viability is thus reduced to below in vitro detectable limits. The only means of absolute detection of any living parasites would then be injection of this slurry into a primate, which would be highly unethical, and the Virkon itself would be highly toxic.

As stated above, the parasites have an absolute requirement for viable host red blood cells for their survival. Since Virkon contains a surfactant, no mammalian cells remain intact in a solution of Virkon (used as directed by manufacturer), and therefore no parasite can remain viable in this same solution.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Date Project Ceased: 02/03/2022
**Project Additional Information**

**Purposes of the contained use**
The project builds on recent advances made by our laboratory in the field of prion research. We have isolated novel, nucleic acid ligands for PrP that bind more strongly to the conformation associated with prion diseases such as BSE and CJD (PrPsc) than they do to the normal form found in healthy animals and humans (PrPc). These ligands have been patented and we are developing them for use in diagnostic and therapeutic applications relating to BSE and CJD. As part of this process, we need to be able to express and purify normal forms of PrP from humans, cattle and other species, in order to maximise the disease-selectivity of our ligands.

The genes encoding normal PrP will be amplified from primary cells using PCR and sequence-specific primers. The PrP genes isolated will then be sub-cloned into E. coli for expression with subsequent purification and refolding of recombinant PrP.

**Recipient or parental organism**
K12 and B derivatives of Escherichia coli - these are disabled strains that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ACDP hazard group 1.

**Host/vector system**
E. coli bacterial host with plasmid vector.

**Origin & function**
The inserts will encode normal alleles of a widely-expressed gene of humans and other animals, PrP. Diseases associated with this gene are either:

a) genetic, in which specific mutations destabilize the structure of the encoded protein leading to increased possibility of spontaneous prion formation. Such alleles will not be used in this study.

b) infectious, in which abnormally folded PrP in the tissues of a human or animal infected with a transmissible spongiform encephalopathy (eg BSE) is associated with the ability to transmit the disease to healthy humans or other animals. No tissues from infected animals or humans will be used in this study.

**Evaluation of foreseeable effects**
The resulting genetically modified micro-organisms will be disabled strains of E. coli with normal human or animal PrP genes inserted. The exact pathogenesis of the prion diseases remains unclear and a strong hypothesis, as yet unproven, is that the infectious agent is simply a specific, mis-folded version of the normal PrP protein. If true, misfolding of normal PrP in vitro might yield infectious material. In spite of extensive attempts to generate infectious material from in vitro-expressed PrP in many laboratories world-wide, it has not been possible to do so to date. Moreover, the in vitro refolding methods to be used in this project are very widely used in the field and have been demonstrated not to yield infectivity. There is no reason to suspect that the genetically modified E. coli or the expressed PrP will be harmful but ACGM recommends a precautionary approach is taken and suggests that a level of containment equivalent to Containment Level 2 is appropriate for the time being for this type of work (see ACGM Compendium of Guidance, Part 2A, Annex III, Table 5A).
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Consumables (mainly plasticware eg pipettes, flasks, tubes ) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 156 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 165 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The main aim of this project is to understand the mechanisms by which HIV evades the immune response. Nef, an HIV accessory protein, is believed to play a major functional role in protecting infected cells against killing by CTLs and downregulation of MHC class 1 expression. Whilst various mechanisms have been proposed whereby nef regulates T cell activity and contributes to the pathogenesis of HIV, the function of nef at the molecular level remains poorly understood. This project is directed at a better understanding of the role of nef and how it interacts with host function. SIV will also be modified and investigated for comparative purposes.

Recipient or parental organism

Human immunodeficiency virus (HIV) and Simian immunodeficiency virus (SIV)

E coli K12 and B derivatives (disabled).

Human and mammalian cell lines.

Host/vector system

Proviral HIV and SIV DNA constructs will be made in disabled E.coli

Recombinant HIV and SIV will made by transfecting the provirus DNA into 293T cells, a human fibroblast cell line with high transfection efficiency for producing infectious virus. These viruses will be subsequently used to infect human and mammalian cell lines.

Origin & function
Constructs will comprise HIV and SIV under the control of the CMV promoter with
i) whole or partial deletions of the nef genes,
ii) point and/or multiple mutations in the nef gene,
iii) replacement of the nef gene with full length or partial sequences of nef from HIV isolated from patients infected with HIV (or SIV from macaques).

Standard reporter genes such as green fluorescent protein (GFP, and other coloured derivatives) and placental alkaline phosphatase (PLAP) will be inserted for detection of infected cells.

Nef downregulates the surface receptors CD4 and MHC 1, increases viral infectivity and stimulates T cell signaling pathways. The genetic modifications in nef are made for the purpose of studying changes in gene expression or in the modulation of immune response molecules.

There will be no switching of genes or transfer of genetic material between HIV and SIV.

**Evaluation of foreseeable effects**

The pathogenicity, virulence, infectivity and invasiveness of the modified viruses are not expected to be increased when compared to the parent microorganisms. The assessment of risk to human health and safety indicates no greater hazards than those with wild type unmodified viruses. In many cases the modified viruses are expected to be attenuated.

The genetic modifications will not affect host range and tissue tropism since there will be no alterations in genes coding for the envelope glycoproteins. No adverse effects are anticipated in terms of altered interaction with host defences, many of the modifications will result in improved immune response in infection because the mechanism by which the virus evades immune surveillance will be lost or reduced. Modified viruses will remain susceptible to anti-retroviral chemotherapy.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There is no autoclave within the laboratory. An autoclave validated for disposal of waste is located within the same building and a safe system for transport of waste to the autoclave is used.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excelle liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3 1993 (either 121-125oC for at least 15 minutes of 126-130oC for at least 10 minutes of 134-138oC for at least 3 minutes), discharge to drains.

Degree of kill
Autoclaving: effectively 100% kill (annual validation).
Incineration: effectively 100% kill (licensed incineration)

### Project Ref 553/01.3

- **Date Ackn'd**: 27/02/2001
- **CU2 Project Title**: CELLULAR IMMUNE RESPONSES TO FOREIGN ANTIGENS
- **Class**: Class 2
- **Culture Vol**: 1-50 litres
- **Consent Granted**: not applicable

### Project Additional Information

- **Historical Significant Changes**
- **Historical Date of Additional Info**
- **Significant Change ID**
- **Date of Significant Change**
### Purposes of the contained use

Vaccinia virus and adenovirus recombinants will be used as plastic tools to facilitate studies into the function and interaction of genes involved in antigen presentation, processing and regulation. A wide range of gene sequences will be inserted into these vectors to gain a better understanding of their function and effect on the immune response. The role and responses of the various components in disease processes will also be studied. This will form the basis for the development of control strategies such as vaccines.

### Recipient or parental organism

- **K12 and B derivatives of Escherichia coli** - disabled strains that cannot colonise the human gut and have a history of safe use.
- **Mammalian cell lines** - low hazard, regarded as especially disabled hosts.

### Host/vector system

- **Western Reserve (WR) strain of vaccinia virus** - a replication competent strain that is able to infect humans and cause disease. Genes are inserted into the thymidine kinase (TK) locus.
- **E1 deleted Ad5 adenoviruses** - The adenovirus Ad5 vector has a deletion removing most of the E1 region and as such is unable to replicate except in complementing cell lines. Gene inserts are put into the E1 site. E1 deleted hosts are regarded as unlikely to cause disease.

### Origin & function

#### i) Cloning and expression of mammalian genes involved in immune responses will be undertaken to elucidate the biology and immunology of the systems:
- Fragments and full length proteins of MHC class I molecules, NK receptors, cell surface receptors expressed by T cells, molecules involved in antigen presentation and processing, tumour antigens.

#### ii) Many viral genes have the potential to modulate immune responses and their effects will be studied:
- Fragments and full length proteins of Human cytomegalovirus genes modulating immune responses, Herpes simplex virus genes modulating immune responses, Influenza A virus genes (also used to identify what the CTLs recognise and to expand CTLs in vitro).

#### iii) Interaction with host immune response plays an important role in the pathogenicity of some viruses. Pathogenesis and interaction with immune response will be studied:
- Individual whole HIV or SIV proteins and their truncations, also polypeptide and chimaeric fusions (joining several HIV or SIV proteins into one open reading frame), Dengue virus genes, Plasmodium falciparum genes.

#### iv) Understanding infectious disease processes leads on to the development of vaccines. Similar strategies are being used in the understanding of tumour processes and development of vaccines directed towards these:
- Genes from HIV, SIV, Dengue virus, Plasmodium falciparum, CTL epitopes (sequences coding for short peptide epitope derived from HIV, SIV, influenza virus, Plasmodium falciparum or melanoma-associated antigens).

#### v) Marker and selection genes. A variety of the commonly used marker and selection genes will be used. These include marker genes such as lack Z, luciferase, fluorescent tags (green, red, yellow fluorescent proteins), antibody epitope tags (Flag, histidine, myc). Fc portion of immunoglobulin, glutamine synthetase transferase (GST) etc and antibiotic resistance etc.

### Evaluation of foreseeable effects

For the mammalian cell line and bacterial hosts no significant hazards have been identified in the risk assessment. The resulting GMOs are not expected to carry any additional risks compared to that of the unmodified recipients.

Inserts code for normal mammalian and viral functional genes, or selective alterations of those genes, and standard markers. None of the products of gene expression are
expected to be harmful. Some of inserts are from pathogenic micro-organisms but these are not expected to be hazardous when expressed in isolation. None of the inserted sequences are expected to have toxic or oncogenic properties. Some of the inserts are referred to as tumour proteins and are called this because they are over-expressed or co-expressed in tumours. Whilst the function of these proteins is not known it is unlikely that they are oncogenic since they are also expressed in normal cells. In many cases the genes will be altered such that the expressed sequences will not be biologically active because, for example, they are synthesised as modified or disrupted coding sequences or the expression products will be rapidly degraded. There is no intention to modify the tissue topism or host specificity of the viral vectors and it is thought unlikely that any of the modifications would affect these.

In some cases the insertion of the foreign sequences may lead to altered interaction with host defence mechanisms. Some of the viral genes that will be expressed are known to modulate immune responses. In the majority of cases the effect will be to upregulate the immune response resulting in a less virulent virus. Some of the inserted sequences may downregulate the immune response. For recombinant adenovirus, since this is a replication defective adenovirus, downregulation of the immune response does not present significant additional risk. Particular attention will be paid to ensure no gene sequences are expressed in vaccinia virus whereby it is reasonably foreseeable this would increase the virulence of the virus by downregulating the immune response.

Insertion of the foreign sequences into the viral vectors is unlikely to result in additional hazards associated with replication or integration of the modified virus into a host cell, beyond those normally expected with the parent virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NOT APPLICABLE

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware e.g. pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Sharps (e.g. needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - either autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% (licensed incinerator)
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Purposes of the contained use

The aim is to study the detailed function of the type III secretion system of Shigella flexneri serotype 5a in relation to this organism's ability to invade eukaryotic cells in culture (as a simplified model system for how it causes disease). Type III secretion systems (secretons) are widely distributed, essential virulence determinants of Gram-negative bacteria. They are encoded by approximately 25 genes, which share homology with those encoding flagellar basal bodies. Type III secretion systems serve to translocate, upon contact with eukaryotic host cells, proteins from the bacterial cytoplasm into the host cell cytoplasm. The protein effectors of virulence are thought to be moved directly from the bacterial cytoplasm through the secreton (embedded in both bacterial membranes) to insert within the host membrane and form a pore through which other bacterial proteins are then translocated into the host cytoplasm. The following questions will be addressed:

1. What is the detailed structure of the secretion machinery and how is it assembled?
2. How tight is the connection between secreton and pore?
3. What signal(s) initially target Shigella substrate proteins to the secretion machinery and are they sufficient to mediate protein insertion/translocation in eukaryotic host cells?
4. How, in molecular detail, does type III secretion occur? and
5. What powers type III secretion and how is the energy utilised for substrate export?

Recipient or parental organism

Shigella flexneri serotype such as 5a and 2a, wild-type and mutants.

Host/vector system

Non-mobilisable plasmid vectors.

Origin & function

Inserts:
DNA from pWR1000 (S. flexneri 5a large virulence plasmid) carrying genes or fragments of genes from the ipa, mxi/or spa operons.

Normal/expected biological action of inserted DNA.RNA or transcribed/translated gene product: Formation of a part of the type III secretion machinery (each gene produce alone can not lead to biologically active structure int erms of secretion). Localisation in either the bacterial cytoplasm, inner or outer membrane of bacterial surface. Alternatively generation of a complete or a fragment of the known translocated effector proteins (IpaA-D and IpgD) in the bacterial cytoplasm.

Evaluation of foreseeable effects

The modifications to the Shigella flexneri are likely either not to affect the organism's fitness/virulence or to actually decrease it. Since the mutations made or planned expression of tenes resulting in the loss of a normal function, in no instance would the work to be undertaken be expected to increase fitness or virulence. Antibiotic markers will be used that are not the primary therapeutic agents. The reporter genes will be either neutral or lead to a reduction in bacterial fitness. Gene transfer in this species does not necessitate the use of vectors that will increase the subsequent movement of altered genes. In each instance the donor and recipient species are the same except during gene construction and manipulations in disabled E. coli. Therefore, no new or additional potential risks will be created through the movement of any virulence gene to a new potentially pathogenic species background. For these reasons none of these manipulations will affect the host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - optionally pre-treat using 2% Virkon then always autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels)- dispose via clinical waste stream for incineration.

Degree of kill-
Autoclaving, effectively 100% kill (annual validation);
Incineration, effectively 100% kill (licensed incinerator).

Project Ref 553/01.5
Variation in the genes that are expressed within bacterial populations has a significant impact on their ability to interact with their hosts and the environment. This is influenced by changes in the repertoire of genes that are expressed over time within clonal populations, and differences in the gene complement of different strains within a bacterial species. The aim of this project is to use the variability between bacterial strains and species as a marker for a functional genomics based approach to the investigation of bacterial pathogenesis. This has several inter-related aspects:

1) The presence of potentially unstable repetitive sequences is a marker for phase variable gene switching which is a marker for genes involved in niche adaptation, host interactions and immune evasion.
2) Comparative genome analysis (between strains and between species with different pathogenic potentials) reveals groups of genes that are potentially behaviour specific with regards to the capacity to cause disease and evade the immune response.
3) Analysis of genomes for sequences that have been recently acquired by horizontal gene transfer identifies genes that are likely to be involved in adaptation to, or altered interactions with, their hosts. Alternatively they are likely (although not certain) to increase the general fitness of the strain that has acquired them, which can itself be associated with alterations in virulence.
4) Intergenic elements that affect the expression of genes have been identified in association with recognised virulence genes, these may also be markers of altered virulence.
5) Similarities in the promoter regions of genes that regulate and co-ordinate expression can be used to identify genes that are co-expressed, and therefore part of a wider response of the bacteria to the host. Identifying these regulatory networks enables us to get a better understanding of the programmed response of the bacterium to the host during infection. Searching for common feature with those genes that are identified as virulence associated from the other analyses will extend the way in which we understand how these genes function.

We have advanced genome-based data for some of these groups of genes and are continuing to work on the others. However, sequence analysis alone can only generate hypotheses about the roles and functions of the genes that are identified. These now have to be investigated using traditional experimental laboratory methodology to determine their actual roles in virulence.
<table>

<tbody>
<tr>
<td>Neisseria spp., Helicobacter spp., Haemophilus influenzae, and Escherichia coli.</td>
</tr>
</tbody>
</table>

The organisms that have been selected for study each possess recognized phase variable gene systems involved in virulence. Three (Haemophilus, Neisseria and Helicobacter) are naturally transformable, possess many variable genes, and switch genes largely through varying the length of similar simple sequence repeats. The fourth (E. coli) is included because although it does use phase variation, it contrasts with the other species in that it is clonal, has few phase variable genes, and mediates switching using a different molecular mechanism (local sequence inversion). In addition to being the most highly characterised Gram-negative bacterial species it is therefore being used as a comparative / control organism.

<table>
<thead>
<tr>
<th><strong>Origin &amp; function</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Two main approaches will be used in this work.</td>
</tr>
</tbody>
</table>

1) A common experimental strategy to address the functions of phase variable genes

The investigation of different phase variable genes will involve a common experimental strategy. The gene will be put into a permanent expression state using site directed mutagenesis. Genes will be altered to remove the sequences that mediate ON-OFF switching following cloning into standard 'disabled' laboratory strains of E. coli. These permanently switched-ON genes will either be used as they are, or linked to selectable antibiotic markers. The genes will also be knocked out either using insertion-deletion mutants containing selectable antibiotic markers, or by complete deletion of the open reading frame from the flanking sequences.

2) Strategy for the investigation of other candidate virulence genes identified by genome analysis

Candidate virulence genes identified by the other genomics approaches will be investigated using the classical knock-out and complementation strategy. Genes of interest as determined on the basis of genome sequence analysis (identified as being candidate virulence genes, or fitness changing genes acquired by recent horizontal transfer) will be deleted and the resultant phenotypes studied and their fitness compared with 'wild-type' bacteria.

Modifications will be made to host genes and these returned to the same host, there will be no transfer of genes between pathogenic species. The only foreign DNA to be inserted into a host will be that of standard reporter and selectable markers.

<table>
<thead>
<tr>
<th><strong>Evaluation of foreseeable effects</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Investigations into the functions of phase variable genes:</td>
</tr>
</tbody>
</table>

In each instance the mutants will differ from the wild-type bacteria in one of two ways. They will either lack the candidate virulence / niche adaptive genes, or they will invariably express these genes. No phenotype would be created by this process that would not be expected to occur as a result of the normal random switching of these genes in vivo. In addition, in each case the phase variability that was the reason for the selection of these genes for study, it itself a marker that the ON-OFF switching is itself adaptive. Each mutants' ability to make the environmental transitions for which each gene is adaptive, such as moving between different host niches, immune evasion, environment-host and host-to-host transfer, is likely to be seriously impaired. The overall fitness of these mutants for the aspects of its life style that involve these genes is likely to be seriously reduced. For this reason, the altered strains would be expected to be less fit and therefore ultimately less virulent that the 'wild-type' in these contexts.

Investigation of other candidate virulence genes:

In each case the mutants are expected to have 'neutral' or 'loss of function' phenotypes. Therefore these mutants are expected to have reductions in fitness and virulence when compared to the parent strains. However, although unlikely, there is a possibility that a gene that reduces virulence would be deleted but this is unlikely to necessitate
additional control measures for safe working. It should also be noted that it is likely that each of the single gene knock-out phenotypes that are viable have probably already been made by others who have been using the signature tagged mutagenesis methodology where these have been used in the same species. The main difference in mutants described in the currently proposed experiments is that we will know de-novo what the mutations that have been generated are.

General summary
The mutations that are to be introduced are each likely to result in a reduction rather than an increase in fitness and/or virulence. The majority of mutations will either fix a gene ON that it is normally present within the species and where the removed variability of the gene confers fitness, or will ablate expression of genes resulting in the loss of a normal function. Antibiotic markers will be used that are not normally the primary therapeutic agents. The reporter genes and counter-selectable markers will be either neutral or lead to a reduction in bacterial fitness. Gene transfer in these species does not necessitate the use of vectors that will increase the subsequent movement of altered genes. There will be no introduction of genes from one pathogenic species to another. For these reasons none of these manipulations will effect the host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consuables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, dyringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving: effectively 100% kill (annual validation).
Incineration: effectively 100% kill (annual validation).

**Purposes of the contained use**

The work is part of a wider project to understand the genetic changes in the pathogenesis of ovarian cancer. A strong candidate tumour suppressor gene has been identified and we wish to examine the effect of transfecting constructs containing this gene (RSK-3) into various cell lines to determine if it is a tumour suppressor gene. We have previously shown that RSK-3 can significantly inhibit colony formation in 4/6 ovarian cancer cell lines when a plasmid construct was transfected into cells. This result was obtained in spite of the low transfection efficiency (~20%) obtained when using plasmid vectors. Adenoviral vectors consistently show a higher degree of transfection efficiency, up to 100%, and greater gene expression. Therefore, the use of an adenoviral construct could provide more convincing evidence of the ability of RSK-3 to inhibit cell growth.

**Recipient or parental organism**

K12 and B derivatives of Escherichia coli - disabled strains that cannot colonise the human gut and have a history of safe use.

Mammalian cell lines - low hazard, regarded as especially disabled hosts.

**Host/vector system**

E1 deleted Ad5 adenovirus - the adenovirus Ad5 vector has a deletion removing most of the E1 region and as such is unable to replicate except in complementing cell lines. Gene inserts are put into the E1 site. E1 deleted hosts are regarded as unlikely to cause disease.

**Origin & function**

The inserted genes and gene sequences (RSK's) are of human origin and are serine Threonine kinases activated by the Ras-ERK pathway. Substrates phosphorylated by RSK include nuclear proteins such as c-FOS, histones and the CAMP-responsive-binding element protein (CREB), the oestrogen receptor and NFkB. RSK's are thought to regulate protein synthesis by phosphorylation of polyribosomal proteins and glycogen synthase kinase-3. It has been shown that the RSK's are involved in diverse functions as proliferation, growth arrest and differentiation.

**Evaluation of foreseeable effects**

For the mammalian cell line and bacterial hosts no significant hazards have been identified in the risk assessment. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients.

The inserted sequences are being assessed as putative tumour suppressor genes and it is considered unlikely that the resulting genetically modified adenoviral vectors would cause harm. No alteration in tissue tropism, host specificity or interaction with host defences is anticipated. However, since RSKs have been shown to be involved in various functions including proliferation and are dominantly transforming, a cautious approach is being taken until experimental evidence supports the view that these are not likely to be harmful if delivered into human cells by the adenoviral vector.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project Ref 553/01.8

Date Ackn’d 19/07/2001

CU2 Project Title VIRUS-INDUCED GENE DELIVERY AND SILENCING IN WOODY PLANTS

Class 2 Culture Volume Class 2 < 1 litre
Little is known about how trees resist viral pathogens. It is an open question as to how, over the duration of their lifetime, trees resist pathogens that evolve at a rate that is orders of magnitude faster than their hosts. This work aims to determine if a recently discovered mechanism that functions in virus resistance in herbaceous annual plants (such as tobacco and the weed, arabidopsis), also functions in woody perennial plants (ie trees).

The discovery that plants can use post-transcriptional gene silencing (PTGS) as a defence against viral pathogens has been one of the most interesting discoveries in plant pathology in recent years. To date, examination of virus-induced PTGS, also known as virus-induced gene silencing or VIGS, has been limited to herbaceous annuals of the Solanaceae and Brassicaceae. These studies have revealed that VIGS is systemic and persistent, but that VIGS is not dependent on either systemic infection by, or persistence of, the viral pathogen. It is thought that this defence strategy is widespread, and is likely to be used by many diverse plant genera. If this is true, the implication of VIGS as a defence mechanism in perennial plants are significant. The ability to mount and sustain a defence against pathogens, for the lifetime of the plant, could be an important component of survival for woody perennial plants, which may live for decades, or even hundreds, of years. A defence mechanism like VIGS could account for the durability of resistance to viral pathogens that is characteristic of many woody perennials. However, it remains to be determined if VIGS operates in woody perennial plants. This project will test the hypothesis that VIGS operates in a woody perennial. This will involve an examination of the relationship between woody perennial tree species, poplar and eucalyptus, and two viruses, Tobacco Rattle Virus (TRV) and Poplar Mosaic Virus (PopMV). TRV will be used as a vector to induce VIGS in woody plants as it represents the best-characterised vector for VIGS in plants. The interaction between TRV and Solanaceous and Brassicaceous plants have been extensively characterised, and there is now a substantial literature pertaining to TRV-induced VIGS in different plant species.

Tobacco Rattle Virus - TRV is a broad host range virus that is transmitted by nematodes. TRV can infect many species in the UK, but is not usually lethal to these plant species. In fact, while many plant species can be infected with TRV, few, if any, symptoms of viral infection are generally manifest. Hazards to the environment from natural isolates of virus are therefore very limited.

Poplar Mosaic Virus - PopMV is not a broad host range virus (like TV) and is transmitted manually, presumably by wounding brought about by insect feeding. As is the case with TRV, PopMV frequently does not even bring about viral symptoms on infected plants and is not lethal. The limited host range and low level of symptoms of PopMV means that there is likely to be a negligible risk to the environment from this virus.

K12 and B derivatives of Escherichia coli - disabled strains that cannot colonise the human gut and have a history of safe use.
In all instances viral genomic RNA are cloned as cDNAs in plasmid vectors. The plasmids are propagated in Escherichia coli. Viral RNA is unable to be expressed from the plasmid vectors in E.coli; therefore, viral RNA must be synthesised from purified plasmids in vitro. The plasmids function as templates for in vitro transcription reactions.

**Host/vector system**

The genes involved in transmission will be removed from TRV so that the virus can no longer be transmitted by nematodes. The PopMV coat protein gene is necessary for transmission of the virus from plant to plant and will be removed from the PopMV genome to prevent transmission. In both cases these genes will be replaced by a reporter gene (green fluorescent protein, GFP) which allows the virus to be detected in plants in which he virus is replicating.

To determine if TRV and PopMV can induce VIGS, the inserted gene encoding GFP as described above will be replaced by a portion of the gene encoding phytoene desaturase (PDS). In TRV three different RNA1 vectors will be made - one which contains the PDS sequence from tobacco, one which contains the PDS sequence from eucalyptus, and one which contains the PDS sequence for poplar. In PopMV two different vectors will be made - one that contains the PDS sequence from tobacco, and one that contains the PDS sequence for poplar. The PDS protein is an enzyme that catalyses a key step in carotenoid biosynthesis. Carotenoids are photoprotective pigments. Therefore, if the gene encoding PDS is silenced, no carotenoids are made and photobleaching occurs. Thus, photobleaching proves to be a simple means by which to test for whether TRV can cause VIGS of the PDS gene.

The PDS genes in TRV RNA2 and PopMV (described above) will be replaced by gene fragments corresponding to coding sequences for the following genes families:

i) Genes controlling flowering time, including LEAFY (which encodes a transcription factor) and TERMINL FLOWER-LIKE (which encodes a phosphatidyethanolamine-binding protein). Expression of these genes on viral vectors is hypothesised to alter flower time, either by overexpression or by VIGS.

ii) Genes involved in wood formation, including genes encoding MYB proteins, and lignin biosynthetic enzymes. Expression of these genes on viral vectors is hypothesised to alter wood quality or quantity, either by overexpression or by VIGS.

iii) Genes hypothesised to play a role in resistance to biotic or abiotic stress, including genes that encode leucine rich repeat (LLR) proteins. Expression of these genes on viral vectors is hypothesised to alter stress resistance, either by overexpression or by VIGS.

**Origin & function**

The insertion of foreign genes into the viruses is expected to decrease the fitness of the viruses as an infectious agent relative to the unmodified version of the virus. However in some cases the modified viruses may generate a wider range of symptoms on any plants that they do infect than does the unmodified virus. In particular:

i) VIGS induced loss of PDS activity results in photobleaching, this is likely to be deleterious to infected plants.

ii) Modifications resulting in alternations in flowering time and wood formation in infected plants result in changes in resource allocation that could be viewed as being deleterious to the plant; although, some of the changes in flowering time could be viewed as being beneficial to plant reproductive fitness. Overall the “health” of the plant (ie symptoms of disease) is likely to be unaffected by VIGS constructs designed to alter flowering time and wood formation.

iii) Constructs with modifications in genes hypothesised to play a role in resistance to biotic or abiotic stress, including genes that encode leucine rich repeat (LLR) proteins, are likely to increase the potential of the infected plants to succumb to abiotic or biotic stresses, the VIGS experiments would therefore have a deleterious effect on overall health or fitness of infected plants.

**Evaluation of foreseeable effects**

The genes involved in transmission will be removed from the TRV and PopMV such that in both cases the RNAs must physically applied to manually abraded plant leaves in order to be infectious.

The insertion of foreign genes into the viruses is expected to decrease the fitness of the viruses as an infectious agent relative to the unmodified version of the virus. However in some cases the modified viruses may generate a wider range of symptoms on any plants that they do infect than does the unmodified virus. In particular:

i) VIGS induced loss of PDS activity results in photobleaching, this is likely to be deleterious to infected plants.

ii) Modifications resulting in alternations in flowering time and wood formation in infected plants result in changes in resource allocation that could be viewed as being deleterious to the plant; although, some of the changes in flowering time could be viewed as being beneficial to plant reproductive fitness. Overall the “health” of the plant (ie symptoms of disease) is likely to be unaffected by VIGS constructs designed to alter flowering time and wood formation.

iii) Constructs with modifications in genes hypothesised to play a role in resistance to biotic or abiotic stress, including genes that encode leucine rich repeat (LLR) proteins, are likely to increase the potential of the infected plants to succumb to abiotic or biotic stresses, the VIGS experiments would therefore have a deleterious effect on overall health or fitness of infected plants.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for a least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 2, 1993 (either 121-125oC for at least 5 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Plants, plant material and soil - autoclave as specified in MAFF licence, discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Degree of kill
Autoclaving, effectively 100% kill (annual validation).
Incineration, effectively 100% kill (licensed incinerator).

The European badger (Meles meles) acts as a wildlife reservoir for the Mycobacterium bovis the causative agent of bovine tuberculosis. Badgers infected with M bovis similarly develop tuberculosis. The Department for Environment, Food and Rural Affairs, DEFRA (formerly MAFF) are funding the Veterinary Laboratories Agency (VLA) Weybridge to develop a vaccine for tuberculosis in the badger. The attenuated vaccine, M. bovis Bacille Calmette Guerin (BCG) is a candidate vaccine for badgers, given its safety record and reported efficacy against tuberculosis (of both human and bovine type) in a number of studies. The challenge associated with the use of BCG as a vaccine for wildlife species is one of vaccine delivery.

The preferred route of delivery is oral and work is ongoing to develop strategies and formulations for the oral delivery of BCG. This project is directed at understanding the local immunological events in the gastrointestinal tract following ingestion of live BCG and is fundamental to developing a successful oral BCG vaccine.

Alternative well-characterised reporter genes may be inserted into BCG studied in a similar way.

Recipient or parental organism
Mycobacterium bovis bacille Calmette Guerin (BCG)

Host/vector system
Bacterial host M bovis BCG with plasmid vector
Green fluorescent protein (GFP) - from jellyfish, fluoresces under UV light.
LacZ - from Escherichia coli, produces beta galactosidase which reacts with the chromogenic substrate x-gal to produce a blue colour.
LuxAB genes - from Vibrio harveyi (or the American firefly luc gene), produce luciferases which are enzymes that catalyze production of light from luciferin and ATP.

Evaluation of foreseeable effects

The reporter genes are all well-characterised reporter genes with no known associated health hazards. No modification of genes involved in pathogenicity, virulence, host specificity or tissue tropism are being undertaken and there is no reason to expect the resulting genetically modified organism will differ in pathogenicity from the unmodified BCG strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Purposes of the contained use**

The overall aims of this research programme are to understand the genetic basis of bacterial parasitism of plants and to understand at a mechanistic and evolutionary level how closely related bacteria have developed pathogenic or plant growth-promoting interactions with plants.

Plant pathogens and plant growth promoting Pseudomonas both enter into intimate interactions with plant hosts. The molecular basis of these interactions and of the different outcomes of these interactions, can only be described by comparing closely related model organisms. P. syringae and P. fluorescens are ideal organisms for this...
purpose: they share a high degree of similarity at a both genomic and physiological level; can be manipulated with the same molecular tools; the genomes of P. s. pv. 
tomato DC3000 and P. fluorescens SBW25 are being sequenced; and both P. s. pv. tomato and P. fluorescens enter into model interactions with the same host plant, the 
model plant Arabidopsis. Gene transfer between P. fluorescens SBW25, P. syringae pv. tomato and other relevant P. syringae strains, in conjunction with mutagenesis 
and complementation of genes involved in Pseudomonas-plant interactions, provided an extremely powerful explanatory tool for understanding the molecular basis of plant 
parasitism and plant-microbe interactions.

Recipient or parental organism

Pseudomonas savastanoi psv glycinea [pathogen of soybean (Glycine max)] and phaseolicola [pathogen of French bean (Phaseolus vulgaris)], P. syringae pathovars pisi 
[pathogen of pea (Pisum sativum)] syringae [pathogen of bean (P. vulgaris)], tabaci [pathogen of tobacco (Nicotiana tabacum) and N. clevelandii], and tomato [pathogens 
of tomato (Lycopersicon esculentum) and Arabidopsis thaliana] are all wild type strains.

P. s. pv. tomato mutant MXE is a kanamycin-resistant PT23 mutant with a transposon knockout of avrE.

Erwinia amylovora is a pathogen of most species of Maloidaea, such as apple and pear trees and the dspA/E-strain would be a kanamycin-resistant mutant with a 
transposon knockout of dspA/E.

Erwinia chrysanthemi is a pathogen of Chrysanthemum morifolium, but with a wide host range).

Escherichia coli strains (eg DH5, S17-1, Inv F’) and derivatives will be used for general cloning.

Host/vector system

Bacterial hosts identified above with plasmid vectors.

Origin & function

Various genes are known or are implicated to have a role in the complex interactions between micro-organisms and plants. These genes are instrumental in determining 
whether the outcome is a pathogenic or plant growth-promoting interaction with the plant. Such genes (including avirulence genes, regulatory genes from the type III 
secretion system and effector genes) will be transferred between different Pseudomonas and Erwinia. Mutagenesis and complementation of such genes will allow function 
to be elucidated.

Evaluation of foreseeable effects

The purpose of this work is to study the association between micro-organisms and plants and identify the genes and pathways that result in the association between either 
a pathogenic one or a plant growth promoting one. Transfer of such genes between pathogens and plant growth promoting bacteria is likely to result in a wide range of 
effects from reduced to enhanced virulence. In no case is the anticipated increased virulence expected to be significantly higher such as to warrant additional control 
measures compared to those required for wild type Pseudomonas pathogens. These are plant pathogens only and there is no reason to suspect that the modifications will 
result in any potential harm to humans or animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

Project Ref 553/02.4

02/03/2022
Investigation of the interaction between the nematode pathogen Microbacterium nematophilum and its host, Caenorhabditis elegans, will be carried out by conventional genetic methods and by attempting to introduce standard bacterial transposons, in order to disrupt and thereby clone bacterial genes that are involved in this interaction. Attempts will be made to introduce plasmids expressing Green Fluorescent Protein or other markers such as beta-galactosidase in order to facilitate examination of the bacteria during host infection.

Microbacterium nematophilum is a recently discovered bacterium that can act as a facultative pathogen of the soil nematode Caenorhabditis elegans. Infected worms become deformed and grow slowly, but are not killed by the infecting bacteria, so the pathogenic effects are minor.

A wild type strain of *M. nematophilum* will be modified using standard plasmid or phage vector systems.

Inserted DNA will carry selectable resistance markers and, in some cases, constructs encoding Green Fluorescent Protein or other standard histochemical staining markers. *E. coli* (disabled) and *Bacillus subtilis* will be used as sources of shuttle vectors for transformation. *E. coli* will also be the source of *lacZ*. Green Fluorescent Protein is a harmless protein isolated from jellyfish (*Aequoria victoria*).

Modification of *M. nematophilum* to create non-pathogenic, GFP-tagged or otherwise marked strains would, if anything, reduce the natural impact of this bacterium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) discharge to drains.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal waste (nematodes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill (Note - nematodes are only 1mm long and not recognisable following autoclaving).

Degree of kill
Autoclaving, effectively 100% kill (annual validation)

## Project Additional Information

### Purposes of the contained use

Bacteria in the species Salmonella are orally acquired bacteria causing diseases ranging from gastroenteritis to Typhoid fever.  *S. enterica* serovar Typhimurium (*Salmonella typhimurium*) is widely used in rodent models to study Typhoid fever pathogenesis. Oral infection models in rodents have greatly increased our understanding of mucosal and systemic immunity to orally acquired bacteria. As the oral infection route is a common way humans acquire many pathogens, and the potential to exploit oral immunisation in developing novel vaccine strategies or tolerance to orally-delivered antigens, understanding the mechanisms underlying generating immunity to orally acquired infections is vital.

Orally acquired bacteria must penetrate the gut epithelium to cause infection. Exactly how this occurs during Salmonella infection is not known. Furthermore, the cell(s) involved in transporting Salmonella from the gut mucosa into the body during oral infection mice is unknown.

**Aims:**

1. To identify the cell(s) transporting orally acquired Salmonella into draining lymph nodes
2. To determine the capacity of these cells to stimulate and modulate Salmonella-specific T cells.

*Salmonella typhimurium* will be genetically modified to carry the marker genes that will make the Salmonellas fluoresce under UV excitation, enabling the bacteria to be identified in the cells harvested from the lymph. Immunological techniques such as flow cytometry and immunofluorescence microscopy will then be used to identify and characterise the cell types harbouring the orally administered *Salmonella*. The influence of the isolated *Salmonella*-laden cells on other cells of the immune system, such as T lymphocytes, will also be evaluated. To assess the interaction with antigen-specific T cells the *S. typhimurium* will in addition be genetically modified to express albumin from chicken egg white. This approach is a unique means to study the interaction of orally administered bacteria, including pathogens as well as vaccine candidates, with the cells of the gastrointestinal tract responsible for delivering them into host tissues and also the activation of antigen-specific cells of the immune system. *Escherichia coli* genetically modified in the same way will be used for control purposes.

Genetically modified viruses expressing therapeutic genes have great potential for the treatment of a variety of human diseases including cancer. Replication deficient adenoviruses have been widely studied as potential vectors for many years, however as a delivery vehicle they are less than perfect. This work aims to address the limitations of systemic virus delivery.

In the treatment of cancer, extended circulation of the virus within the blood stream is crucial for gene delivery to secondary tumours which may have spread to sites distant from the primary tumour. However many people will have been exposed to naturally occurring wild type adenovirus type 5 (Ad5), consequently the administration of therapeutic adenoviruses will result in their recognition and neutralisation by pre-existing antibodies before they have a chance to reach their target. The use of avian based adenoviral vectors will be developed to circumvent this problem, as will chemical coating of human adenovirus.

Due to the problems of efficiently penetrating large tumour masses, it is virtually impossible for a replication-defective virus to deliver a therapeutic gene to every tumour cell. Viruses which are able to replicate and move to neighbouring cells adjacent to the site of initial infection, thus spreading throughout the tumour, are much more likely to achieve a therapeutic cure. Conditionally replicating mammalian adenoviral vectors will be developed to address this aspect of improved therapy.

Adenovirus will initially bind to cells via a receptor (CAR) that is present on a wide range of tissue types and so much of the vector is lost through infection of healthy cells, which reduces the amount of virus able to reach the target tissue. Part of this project aims to further develop the viral vectors described above and chemically alter them to produce non-infectious polymer coated virus which can them be retargeted by attaching individual ligands that recognise specific human cell surface receptors, which are restricted to certain tissue or overexpressed on tumours.

Recipient or parental organism

i) Chicken Embryo Lethal Orphan (CELO) Virus - an avian adenovirus.
ii) Human adenovirus.

The adenoviruses will be targeted by chemical treatment. This involves coating of the virus with a polymer which will abrogate the binding to cell surface receptors. The coated virus will then be retargeted using human ligands. The receptors for several of the ligands used are expressed on normal cells at very low levels but are up-regulated or over-expressed on tumour cells.

Host/vector system

CELO propagated in chicken eggs, human adenovirus propagated in human cell lines.

Origin & function

Two strategies have been developed to regulate the replication of the human adenoviruses. The first involves mutant adenoviruses that have been designed to replicate only in cells carrying genetic mutations typical of cancer cells; the second strategy uses cancer-selective promoters to regulate expression of virus genes that are essential in replication, thereby restricting virus proliferation to tumour cells.

Gene inserts are:

a) standard reporter genes:
   - luciferase, from firefly and sea pansy
   - B-galactosidase, from E.coli
   - green fluorescent protein (or similar), from jellyfish
b) therapeutic genes (prodrug activating enzymes):
- nitroreductase, from E. coli, a flavoenzyme, the natural function of which is unclear, though one possibility is a role in xenobiotic metabolism. It can reduce a variety of quinone and nitroaromatic substances, including prodrugs such as CB 1954.
- cytosine deaminase, from E. coli, activates 5-fluorocytosine to 5-fluorouracil (5-FU), a well established anticancer drug.
- uracil phosphoribosyl transferase, from E. coli; enhances the efficacy of the cytosine deaminase system by improving the conversion of 5-FU to 5-dUMP in the cell.
- ganciclovir is an acyclic analog of the natural nucleoside 2'-deoxyguanosine and has substrate specificity for the viral Herpes Simplex Virus Thymidine Kinase (HSV-TK) enzyme, that is three orders of magnitude more efficient at monophosphorylating GCV than any human nucleoside kinase. GCV monophosphate is converted into a toxic GCV-triphosphate nucleotide by cellular kinases. Since GCV monophosphate is converted into a toxic GCV-triphosphate nucleotide by cellular kinases. Since GCV-triphosphate resembles 2'-deoxyguanosine triphosphate it is a substrate for DNA polymerase, however because of its structure it is a poor substrate for continued chain elongation and chain termination occurs.

Some of the conditionally replicating adenoviruses will incorporate the therapeutic gene under an additional level of control in the form of a tissue specific promoter (for example telomerase and hypoxia responsive promoters). These are more active in particular tumour types than in the tissue from which they originate.

As described earlier some of the adenoviruses will be retargeted by chemical treatment (rather than by genetic modification).

Evaluation of foreseeable effects

In summary,
- therapeutic genes are active only in the presence of pro-drugs,
- chemical coating of the viruses will lead to improved ability to evade immune responses,
- retargeting will result in restricted tissue tropism,
- there is no reason to suspect alteration in host range,
- the human adenoviruses will replicate only in tumour cells.

More specifically:

i) CELO virus

Adenoviruses are extremely species specific in their replication capacity, as a result avian adenoviruses including CELO are unable to replicate in mammalian cells. The retargeting of CELO virus will restrict the tropism to cells that express the appropriate human cell surface receptors. Consequently the tissue tropism of the retargeted virus is restricted compared to that of the natural virus, which potentially could enter the extensive range of mammalian cells that express CAR. However the retargeted virus having gained entry to the cells via the appropriate receptor will still remain unable to replicate in mammalian cells. In the absence of prodrug, expression of the prodrug-activating transgenes is not expected to have any harmful consequences. The reporter genes are well established as non-harmful.

ii) Conditionally replicating human adenoviruses (CRAds)

Human adenoviruses including Ad5 are extremely species specific in their replication capacity. There is no evidence that human serotypes can naturally infect animals. The polymer coat of the retargeted viruses will help the virus to evade antibody neutralisation, however the virus will only gain entry to cells expressing an appropriate receptor and as such will have a restricted tissue tropism in comparison with the wild type Ad5 or non-polymer coated CRAd. The new targeting moiety would both enhance and restrict the entry of the virus to cells which would otherwise be entered via initial CAR binding. Since only human targeting ligands are being investigated the host range of the retargeted virus will not be altered. Non-tumour cells that express receptors recognised by the targeting ligand will not support virus replication. In the absence of prodrug, expression of the prodrug-activating transgenes is not expected to have any harmful consequences. The reporter genes are well established as non-harmful. The risks from CRAds expressing tissue specific promoter driven therapeutic genes would be no greater than CRAds expressing a CMV driven therapeutic gene.

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Genes encoding proteins likely to be important in controlling cell shape, motility, metabolism and nuclear organisation of the African trypanosome will be modified, expressed or manipulated in cultured insect or bloodstream forms of the parasite. Our aim is to study fundamental aspects of parasite molecular cell biology - in particular, cell differentiation, cell motility, mitosis and control of antigenic variation. Overall, we believe that these experiments will assist in providing insight to basic parasite biology and to pathogenicity mechanisms. Given the emerging T. brucei spp. sequence information, these experiments may identify strategies and targets important for future control measures for these parasites.

Recipient or parental organism

E. coli, Lambda phage, Crithidia fasciculate, Crithidia oncopelti, Crithidia deanei, Crithidia guillermei, Herpetomonas megaseliae, Herpetomonas roitmani, and Blastocrithidia culicis.

Leishmania major, Leishmania mexicana, Trypanosoma brucei brucei, Trypanosoma brucei gambiense and Trypanosoma congolense

Trypanosoma brucei rhodesiense.
Non-mobilisable shuttle vectors engineered to enable parasite gene expression or modulation in the parent organism using a tetracycline regulated inducible expression system.

**Origin & function**

The main focus of our work is genes that are likely to be important in controlling cell shape, motility, metabolism and nuclear organisation.

The main types of gene inserts to be used are:
- Cytoskeletal and other housekeeping genes involved in the construction of the cytoskeleton, mitotic spindle and flagellum of the protozoa. Usually these genes will be tagged to provide epitope or other marking of the expressed proteins.
- Portions of genes arranged to produce double stranded RNA copies that will down regulate endogenous gene expression by means of RNA interference.
- Flanking sequences will be used to engineer gene knockouts.

Most experiments will not involve cross species transfer. Some experiments will test putative homologous genes from other strains/species/genus for complementation of function or inactivation of function in the trypanosome. Given that the genes to be moved are involved in housekeeping functions are are not known (or likely to be) virulence genes the likely outcome of movement of genes is loss of virulence, and in the case of movement into a non-pathogenic strain will not result in a gain of virulence.

**Evaluation of foreseeable effects**

We expect to see phenotypes dependent upon the specific situation. These will range from paralysis (flagellum motility); abnormal shape/division defects (mitotic and cytoskeletal proteins); antigenic coat abnormalities (nuclear regulatory proteins); general growth phenotypes (metabolic proteins). Often, the outcome will be lethal phenotype particularly in initial gene experiments using RNA interference. In many cases, transgenic bloodstream and insect form parasites will be used and differentiation between these stages examined. However, it is not possible to differentiate parasites from the insect form back to the bloodstream form in the absence of the tsetse fly vector. Therefore, the lifecycle cannot be completed in the laboratory. These genes will be expressed using a tetracycline inducible expression system. Therefore, in the absence of tetracycline, the genes are effectively silenced.

Antibiotic resistance genes will be used for selection of transgenic parasites. These are not those used for clinical treatment of the parasite and will otherwise have no foreseeable effect.

Reporter genes (eg green fluorescent protein and epitope-tagged proteins) are for localisation and assay of expression pattern for particular parasite genes or sequences. There is no foreseeable adverse consequence of this.

In most instances the donor and recipient species are the same except during gene construction/manipulations in disabled E. coli. Usually genes transfer experiments will involve rescue of mutants to reveal shared functions or use of partial gene sequences (usually regulatory sequences) in order to control gene expression. This organism's pathogenicity is not based on toxins or other virulence factors whose genes could be inadvertently transferred between species. It is considered that no new or additional potential risks will be created through the movement of any cryptic gene to a new potentially pathogenic species background. The only known difference between T.b rhodesiense and the other trypanosomes is the possession of a human serum resistance gene. This is known and is not the focus of our studies.

The risks of the genetically modified organisms to human health and safety and to the environment are considered likely to be equivalent to, or usually lower than, that of the 'wild type' parental strain.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

These parasites do not produce spores and are fragile organisms. They are rapidly killed outside the culture vessel or blood by desiccation, osmotic shock, washing with water, detergents, and cannot penetrate unbroken skin. Tsetse flies are the vectors for trypanosomes and these are endemic only in the disease areas (Sub-Saharan regions).
Africa. We do not maintain insectories with these vectors. Thus these parasites are effectively deficient in mobilisation capacity.

The naturally occurring organism does not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes under the laboratory conditions. Once dehydrated such material would not be viable.

ACDP guidance on work with T.b. rhodesiense:
The Schedule to the certificate of exemption accompanying the Approved List specifies a number of parasites, including T.b. rhodesiense, for which full Containment Level 3 need not be used. ACDP state that work with such parasites does not generally require an inward flow of air to the laboratory or the use of a microbiological safety cabinet as none of these agents is normally infectious by the airborne route. ACDP recommends that for working with these agents in research a separate room should be used or a designated area in a larger laboratory. In ACDP's guidance list is the notation that the laboratory need not be sealable for fumigation.

In relation to the individual control measures to be omitted from both laboratory and animal facilities:

a) isolated laboratory suite
A dedicated room for will be used, however this will be used for all the work with parasites detailed in this risk assessment (ie in Classes 1, 2 and 3). The room will at all times be operated to Containment Level 3 working practices and have a documented Code of Practice. This room is within the suite of rooms allocated to the research group undertaking this work.

b) Laboratory not sealable for fumigation.
There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The area would be wiped down with disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.

c) No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination.
The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures.

d) Autoclave and some other equipment not within the laboratory.
Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment is in use, any equipment used is cleaned and disinfected immediately on completion of the work and any contaminated items wither returned to the dedicated laboratory:

i) Fluorescence microscopy: a fluorescent microscope is located within the same building.
ii) Storage: transfected parasite stocks are frozen and stored at -80 degrees C or in liquid nitrogen within the same building. The freezers are locked and accessed only by authorised personnel.
iii) Autoclaving: an autoclave validated for disposal of waste is located within the same building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Project Ref  553/03.1
This project is directed at understanding antigenic variation in trypanosomes and how the organism evades the complement system in mammalian hosts.

i) Antigenic variation
The trypanosome wears a dense Variant Surface Glycoprotein (VSG) coat which shields invariant molecules on the trypanosome surface from the immune system. The trypanosome evades the immune system of the mammalian host, by continuously changing its VSG coat. As trypanosomes multiply in the blood of an infected mammal, eventually an antibody response is raised against a given VSG coat, killing all trypanosomes wearing this coat. However, at the population level, trypanosomes are continuously generated that have switched to a new (and temporarily unrecognisable) coat. These switch variants are not recognised by host antibodies, and can form the next wave of infection. Antigenic variation allows trypanosomes to form chronic infections in large mammals which can last for many years.

An individual trypanosome has about 1000 genes encoding different VSG coats. The active VSG gene is located in a VSG expression site, which is invariably located at a telomere or chromosome end. Each trypanosome has 20 VSG expression sites, of which only one is active. An individual trypanosome transcribes only a single VSG at a time. Switching the active VSG involves DNA rearrangement events slotting a previously inactive VSG gene into the active VSG expression site. Alternatively, trypanosomes can switch between the twenty VSG expression sites. We would like to understand how trypanosomes coordinate expression of these 20 VSG expression sites.

ii) Evasion of the complement system
In addition to evading the antibody response using antigenic variation, trypanosomes are also able to evade the complement system of the mammalian host. The mechanism of complement evasion is unclear, and something that we would like to investigate. The complement system has different functions. One of these is the opsonisation or coating of microbes, making them targets for macrophages with complement protein receptors. In addition, complement proteins can assemble on the surface of a microbe resulting in the formation of a membrane attack complex.

We have performed an initial analysis of complement evasion by T. brucei incubated in bovine serum and obtained promising results. However, unfortunately we are hampered by the lack of reagents against components of the bovine complement system. We would therefore like to continue our analyses using T. brucei incubated in
human serum. There are a much larger range of reagents against human complement proteins. In addition, these studies will be more relevant for understanding complement evasion in the trypanosomes causing African trypanosomiasis.

The T. brucei brucei 427 strain that we currently work with (and which is sensitive to human serum) grown very well in vitro. In contrast, T. brucei rhodesiense field isolates that are resistant to human serum do not grow in vitro. We would therefore like to create a T. brucei brucei strain that can grow well in vitro in human serum. We would like to genetically modify nonhuman infective T. brucei brucei strains, and insert virulence genes like the Serum Resistance Antigen (SRA) gene into these trypanosomes so that they become resistant to human serum. This will make T. brucei brucei comparable to the T. brucei rhodesiense that we already currently hold. However, these genetically modified trypanosomes will have the advantage of being manipulable in vitro instead of requiring expansion in laboratory rodents. In addition, the virulence genes would be regulatable, greatly increasing the safety of the experiment. We would therefore be able to study the pathogenic aspects of human infectivity in a manipulable in vitro system, and could avoid amplification in laboratory animals.

Recipient or parental organism

E. coli K12 or B derivatives
Trypanosoma brucei brucei 427

Host/vector system

Bacterial or parasite host with plasmid vectors

Origin & function

i) Antigenic variation
Single copy marker genes will be inserted into the repetitive VSG expression sites in order to follow the transcriptional behaviour of single expression sites. Constructs containing fluorescent marker genes like Green Fluorescent Protein (GFP), Yellow Fluorescent Protein (YFP) and DsRed, and drug resistance marker genes like the hygromycin, neomycin, blasticidin, and puromycin resistance genes into various regions of the T. brucei genome including the VSG expression sites. Marker genes introduced into VSG expression sites will allow monitoring of their transcriptional behaviour.

VSG expression sites include multiple genes of unknown function, in addition to the telomeric VSG gene. RNAi (double stranded RNA inhibition) will be used to inactivate the transcripts from various Expression Site Associated Genes (ESAGs), in addition to transcripts from other candidate genes possibly playing a role in antigenic variation. This technique allows the researcher to investigate the essentiality of different gene families.

ii) Evasion of the complement system
Virulence genes like the Serum Resistance Antigen (SRA) gene will be inserted into nonhuman infective T. brucei brucei strains so that they become resistant to human serum. These virulence genes would be inserted behind a tetracyclin inducible promoter, allowing the researcher to turn expression on and off. This will make T. brucei brucei comparable to T. brucei rhodesiense and facilitate study of the pathogenic aspects of human infectivity in a manipulable in vitro system avoiding amplification in laboratory animals.

Evaluation of foreseeable effects

i) Antigenic variation
The genes used here are completely neutral markers encoding fluorescent proteins, or are drug resistance genes for drugs that are not therapeutically relevant for African trypanosomiasis. There is therefore no biochemical mechanism that could explain how these genetic modifications could change the host range or virulence of the genetically modified trypanosome. The genetic modifications proposed would not change T. brucei susceptibility to the therapeutic drug suramin and there is no reason to believe that these genetic modifications would change the tissue tropism of the parasite. The double-stranded RNA inhibition (RNA) experiments resulting in the ablation of T. brucei RNA transcripts will incapacitate the parasites if the transcripts that are being targeted are essential. Nonessential transcripts being targeted will not result in a change to the trypanosome phenotype. The genetic modifications resulting in the introduction of marker genes into the VSG expression site could result in damage to the active VSG expression site. This would lead to reduced efficiency of antigenic variation. None of these procedures would lead to increased risk to human health and safety.
Evasion of the complement system

These T. brucei genetic modifications could make a trypanosome strain that lyses in human serum into one that doesn't lyse in human serum, making it potentially human infective. These genetically modified strains would become similar to the human infective T. brucei rhodesiense strains. All published evidence indicates that the SRA gene product is a receptor that interferes with internalisation of the Trypanosome Lytic Factor (TLF) present in human serum. There is no published evidence indicating that expression of the SRA protein could affect the tissue tropism of the trypanosomes. The SRA protein is a receptor for the Trypanosome Lytic Factor, and there is no known biochemical mechanism that could mediate changed drug susceptibilities in an SRA transgenic trypanosome. There is no known biochemical pathway that would confer susceptibility to the drug suramin, currently used in treating human trypanosomiasis, to T. brucei SRA gene transgenics.

These genetic modifications could increase risk to human health and safety and consequently additional containment and control measures have been assigned. However, even though these genetically modified organisms would be less safe than the original trypanosome, they would be much more safe to work with than human infective T. brucei rhodesiense as the tetracyclin inducible nature of virulence gene expression means that the researcher can restrict expression of these genes to the shortest period of time.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

These parasites do not produce spores and are fragile organisms. They are rapidly killed outside the culture vessel or blood by desiccation, osmotic shock, washing with water, detergents, and cannot penetrate unbroken skin. Tsetse flies are the vectors for T. brucei and these are endemic only in the disease areas (subSaharan Africa).

The naturally occurring organism does not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes under the laboratory conditions. Once dehydrated such material would not be viable.

ACDP guidance on work with T. brucei sp.

The Schedule to the certificate of exemption accompanying the Approved List specifies a number of parasites, including T. brucei sp. for which full containment level 3 need not be used. ACDP state that work with such parasites does not generally require an inward flow of air to the laboratory or the use of a microbiological safety cabinet as none of these agents if normally infectious by the airborne route. ACDP recommends that for working with these agents in research a separate room should be used or a designated area in a larger laboratory. In ACDP's guidance list is the notation that the laboratory need not be sealable for fumigation.

In relation to the individual control measures to be omitted:

- Isolated laboratory suite
  A dedicated room will be used for working with T. brucei. The room will at all times be operated to derogated Containment Level 3 working practices and have a documented Code of Practice.

- Laboratory not sealable for fumigation
  There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels, then autoclaved, killing any parasites. The area would be wiped down with disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.

- No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination.
  The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for
sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures.

d) Equipment not within the laboratory
Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment is in use, any equipment used is cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities are undertaken outside the dedicated laboratory:

i) Storage: transfected parasite stocks are frozen and stored temporarily at -80 degrees C in the adjacent Containment Level 2 laboratory before long term storage in liquid nitrogen within the Containment Level 3 laboratory. The samples will be in Nunc ampules in closed and sealed freezing boxes that are clearly marked as biohazard. The -80 degrees C freezer will be locked during use and accessed only by authorised personnel.

ii) Autoclaving: an autoclave validated for disposal of waste is located within the same building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (121-125 degrees C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646 Part 3, 1993 (121-125 degrees C for at least 15 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (121-125 degrees C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - Dispose via clinical waste stream for incineration.

Degree of Kill

Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

### Project Ref 553/03.10

- **Date Ackn'd**: 10/12/2003
- **CU2 Project Title**: USING RETROVIRAL VECTORS FOR THE CHARACTERISATION OF THE HYPOXIA-INDUCIBLE FACTORS (HIF) PATHWAY IN CANCER CELLS; AMPHOTROPIC VISUS.
- **Class**: Class 2
- **CultureVolClass2**: < 1 litre
- **Non-GMM Consent Granted**: N

**Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

### Project Additional Information

**Purposes of the contained use**

Replication defective amphotropic retroviruses will be used to assess the downstream biological effects of HIF-1, HIF-2 and degradation resistant HIF-1 in Renal cell carcinoma and other similar cell lines.

**Recipient or parental organism**

02/03/2022
For construction of retroviral vectors:
K12 or B derivatives of E. coli will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ACDP hazard group 1.

For packaging recombinant retroviral particles.
The packaging cell lines are of human origin, which are well characterised and authenticated and are obtained from commercial sources. Examples of packaging cell lines likely to be used are Phoenix 293 ampho cells, which generate amphotropic retroviruses. They can be regarded as low ghazard for GM activities and as hosts are suitable for Containment Level 1 precaution. However due to the presence of the E1a gene of Ad5 these cells will be handled at Containment Level 2 under COSHH.

For recombinant retroviral infection
Human renal cancer cell lines (and other similar cancer cell lines), eg 786-0 and RCC4 can be considered as especially disabled hosts and as such may be considered to be equivalent to ACDP hazard group 1.

Host/vector system
Genes of interest will initially be obtained from plasmids based on pcDNA1 Neo and pcDNA3. They will then be inserted into disabled retroviral expression vectors LZRS-IRES-GFP and/or pBMN-1-GFP. Vectors are based on pUC backbone and are non-mobilisable.

pBMN-1-GFP contains 5' and 3' LTR and IRES-GFP into which the gene of interest is inserted.

LZRS-IRES-GFP contains 5' and 3' LTR and IRES-GFP into which the gene of interest is inserted and also EBV nuclear antigen and origin of replication.

To generate amphotropic retroviruses the expression plasmids are transfected into Phoenix-Ampho cells, derived from HEK293 cells which have already undergone subsequent stable transfections with plasmids containing moloney packaging functions gag-pol and env genes. Non-moloney promoters are used to drive the gag-pol and env genes to minimise their inter-recombination potential. Stable integration of gag-pol and env genes into different sites of the 293 genome means that none of these genes are included in the viral particle thus generating a replication deficient virus.

Transfection with pBMN-1-GFP plasmid generates transient production of virus particles.

Transfection with LZmartin.wale@hpa.org.uk plasmid generates medium term production of virus particles over 20-3 months due to episomal nature of the plasmids.

Origin & function
Wild type HIF-1
Wild type HIF-2
HIF-1 double prole mutant resistant to degradation.

In normal cells HIF-1 and HIF-2 expression is regulated by degradation, the mutant would be constitutively expressed. In VHL defective renal cells HIF-1, HIF-2 and the mutant would be constitutively expressed.

HIF-1 and HIF-2 over-expression (constitutive or mutant forms) have been shown to have varying effects on tumourigenesis. Indeed, HIF-1 seems to retard tumour growth in certain models, while in normal mice mutant HIF-1 has promoted angiogenesis and thus hypervascularity without tumour formation. HIF-2 seems to have a possible role in the progression of Renal Cell Carcinoma; however, no specific genes to date have been assigned to this transcription factor that are not already also controlled by HIF-1, thus uncertainty remains in the field as to its role in tumour progression. It is not able to transform cells.

Standard markers such as enhanced green fluorescent protein (EGFP) from jellyfish will also be used. These are not known to have any harmful physiological or pharmacological properties or to affect pathogenicity of the micro-organisms.
**Evaluation of foreseeable effects**

No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are based on the pUC backbone and are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at Containment Level 1.

Transfection of the Phoenix-Ampho cell line is expected to result in the generation of a Retrovirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As the virus is replication defective there is no risk of transmission within the environment. ACDP states that replication defective amphotropic viruses contain functional oncogenes should be handled at Containment Level 2. Due to the uncertain role of HIF-1 in the progression of tumourigenesis they will be handled at Containment Level 2.

Calls infected with virus will be handled at Containment Levels 2. Once the original supernatant is removed, the viruses inside the cells integrate their DNA into the host genome within 24-36 hours, and thus the viruses themselves disassemble during this period. After this period, the cells can be handled at Containment Level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| Not applicable. |

We aim to isolate putative cellular receptor(s) for Hepatitis B Virus. We propose to develop a modified HIV1 minimal vector system for this purpose. Using the modified HIV1 minimal vector system, we would like to isolate cDNA corresponding to the putative receptor(s) from a human liver cDNA library expressed in 293T cells.

<td><strong>Origin &amp; function</strong></td>
<td>A modified HIV minimal vector carrying a reporter gene and pseudotyped with HBV envelope will be produced. These vector particles will be used to transduce 293T cells (human kidney derived) expressing human liver cDNA library. Successfully transduced cells will be selected and cDNA(s) corresponding to HBV receptor(s) isolated from these cells.</td>
<td></td>
</tr>
<tr>
<td><strong>Evaluation of foreseeable effects</strong></td>
<td>The vector particles are non-replication competent and self-limiting. The further modification of the minimal vector particles brings about only a change in the intracellular location of packaging and release of the vector particles, and such vector particles will be very much restricted in their host range (compared to standard HIV1 minimal vector particles). Hence they may be considered to be safer than the standard HIV1 minimal vector particles. The modified HIV1 minimal vector particles are therefore considered to present low risk to human health. However, since the envelope from a level 3 virus (HBV) is used, containment level 2 is considered appropriate.</td>

Project Additional Information

Purposes of the contained use

The overall aim of this research programme is to understand the genetic basis of the co-evolution of a bacterial host and a virulent RNA bacteriophage. This research will investigate how host and phage mutants diversify and adapt to one another and, by specific molecular analysis of phage attachment processes, to identify host and phage mutations which give rise to resistance or increased virulence.

This proposal therefore seeks to examine how a bacterial host, P. aeruginosa PA01, and its bacteriophage, PP7, co-evolve when incubated for long periods together. During this time, mutations may occur in the host which make it more resistant to the bacteriophage, and similarly, mutations may occur in PP7 allowing it to overcome the host defences.

In order to interpret the significance of mutations in both host and bacteriophage at a population level, bacteria and bacteriophage isolated at different time points will need to be compared against standard references. These references are essentially the original PA01 and PP7 strains used to inoculate the experimental microcosms. However, in order to determine relative fitness between PA01 and evolved PA01 strains, the reference PA01 strains needs to be distinguishable from the evolved PA01 mutants to allow competition experiments (microcosm trials in which the two strains are grown together). In order to do this, we will utilise a PA01 derivative (PA01 panB) in which panB, a gene involved in the synthesis of pantothenate, has been deleted.

PP7 infects PA01 by binding to Type IV pili on the outer surface of the bacterium, and these pili are known to be involved in bacterial attachment to solid surfaces (biofilm formation). In order to determine how PA01 may acquire resistance to PP7 infection, it would be logical to look at possible mutations in Type IV pili expression, biofilm formation and regulation. We will therefore need to make use of a number of specific PA01 mutants for this purpose.

Recipient or parental organism

Pseudomonas aeruginosa PA01

Host/vector system

The GM mutants are all mini-transposon mutants, mini-transposon-derived mutants, or allelic replacement mutants.

Origin & function

Mutant strains

PA01 panB   Not-viable mutant in which panB, an essential gene in the biosynthesis of pantothenate has been deleted from the chromosome. Will not grow in minimal media without pantothenate; grows poorly in rich media without pantothenate; requires pantothenate in rich media for normal, wild type levels of growth;

pilA       Viable mutant which does not express Type IV pili (natural mutant);

wsp         Viable mutant in which the regulatory operon controlling bacterial attachment and biofilm formation has been lost (specific operon deletion with no marker inserted);

PA0164*     Viable mutant in which autolysis is up-regulated (no chromosomal marker as the Tet of the mini-transposon has been deleted);

PA0197       Viable mutant in which the mini-transposon (Tet ) has inserted into pilU; does not express Type IV pili;

PA01 162     Viable mutant in which the mini-transposon (Tet ) has inserted into pilT; does not express Type IV pili;

PA01*        Different isolate of PA01 which differs from PA01 and shows no autolysis;
Evaluation of foreseeable effects

The fitness of PA01 panB relative to the wild type PA01 strain is significantly reduced in media lacking exogenous pantothenate. The requirement for exogenous pantothenate means that PA01 panB would not be capable of colonising human surface wounds and subsequent infection. Therefore, PA01 panB is most unlikely to represent a significant risk to human health.

The fitness of the other GM PA01 strains is lower than that of PA01. The GM strains have mutations that destroy various virulence functions - such as PQS signalling, pili expression, attachment and biofilm formation. Although these functions are not important for the growth in laboratory situations, these are critical for survival in natural environments and in human infection.

The GM Ps. aeruginosa are not expected to be any more harmful than the parent wild type strain. In most cases the fitness and virulence will be reduce. No risks to the environment have been identified.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes). Any excess liquids discharged into drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

</table>

Mycobacteria have long been proposed as candidates for use as live vaccine vehicles, one of the main reasons being their outstanding adjuvant properties. Mycobacterium bovis BCG, an avirulent strain of M. bovis, has received tremendous attention in recent years in this regard. BCG has been used as a vaccine against tuberculosis since 1948. In 1991, it was estimated to have been given to 2.5 billion people, with few serious cases of complications having been reported, and thus it has a long-standing safety record. Other properties that have made BCG an outstanding candidate for live vaccine development include the fact that it can be given at birth or at...
anytime thereafter, a single inoculum can produce long-lasting immunity, it is also inexpensive which makes it an ideal candidate for developing countries.

Various foreign genes have indeed been expressed in BCG over the past decade, including bacterial and viral genes, and in some cases protective immunity to the antigens of interest has been reported in animal models. Extra-chromosomal and integrative vectors that are able to transform mycobacteria have been developed, and different mycobacterial promoters have been used to drive the expression of foreign genes in BCG. The most widely used promoter in these studies is the hsp60 promoter, however it has been reported that though it may be adequate for some antigens, its high activity is detrimental to the expression of others. We therefore undertook this study to try and develop mycobacterial promoters with a wide range of activities to drive the expression of foreign genes in BCG.

### Recipient or parental organism

**Mycobacterium bovis bacille Calmette Guerin (BCG)**

### Host/vector system

**Bacterial host M. bovis BCG with plasmid vector.**

### Origin & function

- **Reporter genes:**
  - Green fluorescent protein (GFP) - from jellyfish, fluoresces under UV light.
  - LacZ - from Escherichia coli, produces beta galactosidase which reacts with the chromogenic substrate X-gal to produce a blue colour.
  - LuxAB genes - from Vibrio harveyi (or the American firefly luc gene), produce luciferases which are enzymes that catalyze production of light from luciferin and ATP.

- **Promoter sequences from M. tuberculosis, M. smegmatis, and M. avium (shuffled by DNase digestion to yield a library of chimeric sequences).**

### Evaluation of foreseeable effects

The reporter genes are all well-characterised reporter genes with no known associated health hazards. The DNA fragments that will be inserted into the vectors are regulatory sequences required for initiating transcription of the reporter genes. No modification of genes involved in pathogenicity, virulence, host specificity or tissue tropism are being undertaken and there is no reason to expect the resulting genetically modified organism will differ in pathogenicity from the unmodified BCG strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to generate single cycle Env-pseudotyped luciferase reporter virus expressing the envelope protein from clinical and laboratory-adapted virus stocks in order to answer questions concerning the interplay between the Env protein and target cell components at a clonal level.

The resultant virus will be used for in vitro assays to assess inhibition of viral entry for polyanionic compounds used in topical microbicidal formulations, HIV-1 fusion inhibitors and also for assays assessing the neutralising activity of gp140 antibodies from mouse sera.

#### Host/vector system

- **Recipient or parental organism**: Initial transfection of 293T cells and resultant pseudovirus will then be used to transduce human glial cell lines (eg U87-CD4-CXCR4, U87-CD4-CCR5).

- **Origin & function**: The purpose of the modification is to produce HIV virus capable of mimicking the natural interactions under investigation but incapable of replication and therefore representing a significantly reduced hazard. The retrovirus (HIV-1) from which the pNL4-3 Env (-) Luc (+) construct was derived can cause disease in its natural host. HIV-1 is a human retrovirus, which causes severe immunodeficiency in humans (AIDS). Both plasmids have the potential to incorporate their genetic information into the genome of the target cells used for transfection. However, the design of the HIV -1 construct (containing a frameshift in the 5’ end of env) prevents production of infectious, replication-competent virions. Co-transfection with the env-carrying pcDNA3. 1/Zeo (+) plasmid allows rescue of infectious virus for env in the viral RNA (vRNA) and as such are only capable of a single round of replication, as no infectious viral progeny will be produced.

- **Evaluation of foreseeable effects**: The reporter gene (Luc) is all well-characterised with no known associated health hazards.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **Not applicable**.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - treated with 2% Virkon final concentration, left overnight and then discharged to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Disinfection, effectively 100% kill - Virkon has been tested by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS)

**Date of Significant Change** 21/11/2005

**Project Additional Information**

**Purposes of the contained use**

To rescue recombinant, third-generation (self-inactivating), replication-defective lentivirus based on human immunodeficiency virus type 1 (HIV-1) virus, VSV-G/lentiviral replication-incompetent lentiviral and recombinant replication-defective amphotropic murine retroviruses all expressing various transcription factors, cytokine receptors, growth factors or other regulatory molecules. Use said recombinant viruses to transduce a range of human and murine haemopoietic cell lines and primary cells to identify and characterise the molecules and processes controlling the self-renewal, lineage commitment and differentiation of haematopoietic stem and progenitor cells. Murine and human cells infected with genes of interesting phenotype will be transplanted into NOD/SCID mice for further analysis.

**Recipient or parental organism**

For construction of retroviral vectors:

E. coli K12 and B derivatives (disabled)

For packaging recombinant retroviral particles:

293FT (Human embryonic kidney cell line 293F constitutively expressing SV40 T antigen from pUC-based plasmid pCMVSPORT6TAg.eno)

293T (similar to 293FT)

GP+envAM12 (murine cell line NIH3T3 + one plasmid containing the Moloney murine leukaemia virus gag and pol genes and a second plasmid containing the 4070A amphotropic env gene)

For recombinant retroviral infection:

human cell lines (such as established human leukaemic cell lines, eg MALM-6, KG1, HL-60, U937)

murine FDCPmix cell line (a multipotential haematopoietic cell line)

primary human cell cultures (from screened samples)

primary murine haematopoietic cell cultures.
The recombinant viruses are able to efficiently infect human and murine dividing and non-dividing cells but are replication defective. They contain transgenes driven by viral LTR or an internal eukaryotic promoter (such as CMV). There is also the facility for dual expression from RNA transcripts via an internal ribosome entry site to allow expression of a selectable marker. None of the selectable markers are considered to be hazardous to human health or the environment however the transgenes are likely to affect cell cycling and have the potential to be oncogenic. As such they could present a significant hazard to human health however the effect on the environment is likely to be less significant due to the inability of the virus to replicate and the instability of the virus outside of the laboratory environment. Human and murine cell lines and murine primary cell lines are not considered to be hazardous to human health or the environment due to the immune response and stringent nutritional requirements. Human primary cells although screened could still potentially harbour adventitious agents and as such could pose a threat to human health but would not be hazardous to the environment due to stringent nutritional requirements. Mice injected with mammalian cells previously infected pose no risk to the environment as the virus is unable to replicate and NOD/SCID mice are unable to survive outside of the labloratory environment.

Host/vector system

The ViraPower Lentiviral Expression System (Invitrogen)
Expression vector pLent6/V5 containing the gene of interest under the control of the human CMV immediate/early enhancer/promoter and elements that allow packaging of the construct into virions.

pLP1, pLP2 and pLP/VSV-G supply the helper functions as well as the structural and replication proteins in trans required to produce the replication-incompetent lentiviral particle.

VSV-G/lentiviral expression system
A lentiviral vector with viral genes deleted containing the Spleen Focus Forming Virus promoter driving expression of the gene of interest. (2) A lentiviral packaging plasmid encoding gag/pol, tat, rev and HIV-1 rev-response element (RRE), with virulence genes vif, vpr, vpu and nef deleted. (3) An envelope plasmid expressing only the VSV-G gene from Vesicular Stomatitis virus. The three plasmids are co-transfected into human 293T cells to produce the replication-incompetent lentiviral particles.

Amphotropic murine retroviral vectors.
Derived from the Murine Moloney Leukaemia Virus (eg p50-M-X-neo) and Murine Stem Cell Virus (eg MSCV-ires-GFP), recombinant murine retroviral vectors carrying the gene of interest.

All plasmids carry the ampicillin resistance gene driven by a bacterial promoter with the ColE1 origin of replication.

Viruses can only be generated in certain packaging cell lines which when transfected with a selection of vectors (2-4) provide all the genes necessary for efficient viral production. This allows the production of replication-defective viruses by expression of genes in trans and reduces the risk of replication competent viruses being generated. Infected cells will be checked for the absence of replication-competent helper virus.

Origin & function

Human genomic DNA and cDNA inserts, wild-type and mutated.
-- Wild-type transcription factors such as GATA family, Hhex, Pax5. Forced expression of these molecules is likely to influence the self-renewal and differentiation of haematopoietic cells, based on what is known about their normal function. The factors are not known to be transforming or oncogenic, although point mutations in GATA-1, have recently been reported in Down's syndrome-related acute megakaryoblastic leukaemia and Pax5 expression is deregulated in human medullablastomas.

-- Other regulatory molecules such as components of the notch pathway, cytokine receptors and growth factors. Modulation of the expression of these factors is expected to result in a transcriptional response within the nucleus and to alter the balance between self-renewal and lineage differentiation in stem and progenitor cells and perhaps also to alter the lineage output of apparently committed cells.

-- Other candidate regulatory molecules from differential expression analysis, expected to function in a similar manner to the genes described above. The function of these is currently unknown but is expected to have some impact on controlling haematopoietic cell self-renewal, growth and differentiation.
Known products of chromosomal translocations, their normal counterparts, or mutated versions with deletions, insertions and/or point mutations. These genes will include, but not necessarily be limited to, TEL-AML1, PML-RARa, PLZF-RARa, bcr-abl. These genes are suspected oncogenes by virtue of their expression as a result of specific translocations associated with different forms of human leukaemia.

Selective modifications of any/all of the above. Most of the modified versions of the proteins under study would be expected to display essentially the same biological activity in an experimentally inducible manner or to display a subset of the activities of their wild-type counterparts. However, the possibility of inadvertently generating novel biological activities cannot be excluded.

Standard reporter genes: such as neomycin resistance (neoR), beta-galactosidase (lacZ), jellyfish green fluorescent protein (GFP and derivatives) will not increase the level of risk to human health and the environment.

Viruses are either human or murine and the viruses have the capacity to infect, but not replicate in most mammalian cells. The transgenes are a variety of factors which are expected to influence self-renewal and differentiation of haematopoietic cells including but not limited to cytokine receptors and growth factors. Standard reporter genes may also be included into the virus such as neomycin resistance (neoR), beta-galactosidase (lacZ), jellyfish green fluorescent protein (GRP and derivatives).

Evaluation of foreseeable effects

E. coli K-12 and B derivates are disabled hosts, which cannot colonise the human gut, cannot survive outside of the alboratory and have a history of safe use. The vectors used for cloning are non-mobilisable, are based on pUC vectors and the genes are not expressed in bacteria. Therefore the risk from the cloning stage is negligible with respect to both human health and the environment. Cell lines and primary mouse cells could also be considered disabled hosts due to their inability to survive outside of the laboratory environment and the risks are negligible to both human health and the environment. Human primary cells pose a risk to human health due to possible adventitious agents. The risk from work with cells after infection is likely to be negligible to both human health, due to the immune system recognising the cells as non-self, and the environment, due to their inability to survive outside of the laboratory. The viruses are able to infect most mammalian cells but are unable to replicate. There are a number of safety features in the lentiviral vector systems that minimise the relation to wild type HIV-1 and the generation of replication competent virus. The major risk come from expression of the transgenes some of which have unknown effects but are likely to be oncogenic in nature.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose fo solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, ((either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.
Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1994 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Is an emergency plan required according to regulation 20? N

CU2 Project Title TO OBSERVE THE EFFECT ON MAMMALIAN HEART DEVELOPMENT OF BOTH, SHORT HAIRPIN RNA (SHRNA) TO KNOCK DOWN OR SILENCE GENE FUNCTION, AND CDNA TO OVER EXPRESS GENES, DELIVERED BY SELF-INACTIVATING...

Date Project Ceased 02/03/2022

Class 2

CultureVolClass2 < 1 litre

Non-GMM

Consent Granted not applicable
We propose to develop and optimise a lentivirus-based system as a tool to modulate candidate target genes in mouse tissues, cells (eg cardiac myocytes, embryonic stem cells) and embryos, in order to study their role in heart development. In the long term we will be able to combine this with high-throughput magnetic resonance imaging of embryos, enabling us to rapidly understand the functions of genes that contribute to heart development. Gene transfer using Lentiviruses will also enable us to study the function of gene promoters fused to appropriate reporters (eg lacZ - encoding b-galactosidase, or GFP encoding green fluorescent protein). Once gene transfer is achieved embryos and cells will be phenotyped using MRI, microscopy, or enzyme assays (eg lacZ) or epifluorescence (GFP).

For construction of retroviral vectors:
K12 or B derivatives of Escherichia coli, such as DB3.1, TOP10 and DH5α, will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within HEK293 derived packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ACDP hazard group 1.

For packaging recombinant retroviral particles:
The HEK293 derived packaging cell line 293FT is of human origin, is obtained from commercial sources and is well characterised and authenticated. It contains the SV40 large T antigen driven by a CMV promoter, and is to be used for the packaging and expression of the viral vectors. They can be regarded as low hazard for GM activities and, as hosts are suitable for Containment level 1 precaution.

For recombinant retroviral infection:
Primary mouse cells (eg cardiomyocytes, skeletal myocytes, embryonic cells, stem cells) and embryos will be obtained from mice that are bred in a specific pathogen free unit, and have previously been obtained from approved commercial sources (eg Harlan) will be used for infections as target cells. None of these cells will be deemed high risk for blood borne pathogens. For the purposes of this assessment they can all be regarded as low hazard for GM activities and, as hosts are suitable for containment level 1 precautions. No human cells will be infected.

Host/vector system

pLenti-DEST Gateway Vector System (used for transgene expression)
pLENTILOX Vector (used for shRNA expression)
Both these plasmids are HIV-1 derived lentiviral vectors.

These lentivirus expression vectors are self-inactivating as they carry a deletion in the U3 region of the 3'LTR. Upon integration into the host genome, the 3'LTR is copied to the 5'LTR, rendering it transcriptionally inactive and therefore unable to generate a functional retrovirus. The HIV-1 Lentivirus based expression vectors lack any of the
packaging genes (gag, pro, pol, vif, vpr, tat, rev, nef, env) and require the use of a packaging cell line based on HEK293 (ie HEK293FT) and 3 other plasmids which provide gag, pol, rev and VSVG. The HIV-1 derived elements in these lentivirus expression vectors (ie 5’ and 3’ LTR’s and the psi packaging signal) allow packaging of the transgene itself. Importantly the tat gene, which is a crucial factor for HIV replication, is removed and replaced with a strong constitutive promoters, such as the RSV or CMV promoters in pLenti-DEST (invitrogen) and pLENTILOX respectively. Therefore the number of genes from HIV-1 has been reduced to 3, ie gag, pol, and rev. Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

These packaging genes are provided by co-transfection of packaging vectors pLP1 (provides gag/pol), pLP2 (provides rev), pLP/VSVG (provides VSV envelope) into the HEK293FT cell line along with the expression vector. By using this enhanced 4-plasmid system, virus particles can be produced that can infect human and mouse cells, but are replication deficient and cannot be transmitted from one cell to another. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, eng) in the 293FT producer cell line, none of them contain LTRs or the psi packaging sequence. This means that one of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced. The expression of gag/pol from pLP1 has been rendered rev dependent by the introduction of a rev-response element, and so only expresses with co-transfection of pLP2, which provides rev. Addition of the RRE prevents gag and pol expression in the absence of Rev. The HIV-1 env gene is replaced with a Vesicular Stomatitis Vierus envelope.

We are only infecting mouse cells/embryos from mice bred in a specific pathogen free unit, obtained originally from commercial suppliers. Therefore there is no chance that an endogenous mouse HIV-1 would recombine with the replication defective lentivirus as ordinary mice do not carry HIV-1 (it requires CD4 and a co-receptor (CXCR4/fusin or CCR-5) for infection - this is only present on human cells).

Overall then, only Lentiviral particles, which are unable to replicate, but which can deliver the gene of interest, are produced. Therefore the main risk is in their ability to deliver genetic material into a host genome and as described above, this is unlikely to pose any significant risk.

Origin & function

Standard reporter genes such as Lac Z (beta-galactosidase) from E. coli, GFP (Green fluorescent protein) from Jellyfish and Liciferase from Firefly have a history of safe use and are of no or negligible hazard to human health or the environment.

Murine transcription factors and other genes which have been indicted to play a role in heart development will be depleted or knock down using shRNA or over expressed using cDNA. These included:

1. Transcription factors that control heart development - for instance.

(a) Cited family members, (Cited2, Cited1, Cited4)
(b) TFAP2 isoforms, A, B, C, D, E
(c) FKBP family members (eg FKBP12, FKBP25)
(d) Aip1
(e) Hox genes
(f) polycomb group genes (eg Bmi1, Mel18, Mph1, Rae28; Nspc1,2)
(g) Nkx2.5
(h) Pax3
(i) retinoic acid receptors
(j) eHAND, dHAND
(k) Tbx isoforms
(l) Gata isoforms
2. Other genes that have been identified in human, zebrafish, or mouse genetic studies as affecting heart development:
For example, EVC1, EVC2, reptin, pontin, Jekyll, heart and soul, miles apart, gridlock, heartstrings, looptail, Gnas, Cyclin D isoforms, PTPN11, jagged, notch, lefty1, lefty2, nodal, inversin; and other genes identified in ENU mutagenesis screens.

Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Importantly, in no case will we knock down genes that are known to function as tumour suppressors (eg RB, p53, BRCA1, BRCA2, INK4A etc) or overexpress genes that are known to promote tumour formation.

Evaluation of foreseeable effects
No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are based on the pUC backbone and are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at containment level 1.

Transfection of the HEK 293FT cell line with the 4 plasmids is expected to result in the generation of a Lentivirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As stated above none of the inserted DNA is expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Therefore all work, which involves the handling of the virus, or cell lines and tissues infected with the virus, will be done at containment level 2, with the use of a microbiological safety cabinet for procedures which generate aerosols.

Infected embryos will be implanted into recipient pseudopregnant mice using standard methods. The embryos should only contain integrated virus, as the virus containing supernatant will have been washed away by several (at least 5) changes of medium. Although embryonic transfer is via mouth pipetting the risks of exposure are minimal, due to the length, complexity of tubing and cotton plug used in these procedures. However as a precaution two 0.2um filters will be placed in series along the length of the tubing.

The glass capillary tubes used to implant the embryos are potential sharps. As stated above the embryos posed a minimal risk as the virus should be integrated. Nevertheless, disposable gloves will be worn when handling all potential sharps that have come into contact with these embryos.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes) discharge to drains.
Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Animal bedding - dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Sharps - (eg Glass capillary tubes) - collect in a suitable Sharps Containers for disposal. Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via clinical waste stream for incineration.

Routine Disinfection - (eg Hard surfaces, work benches, sinks etc) - Spray or wipe surface with 1% VIRKON, leave for 10 minutes and dry with paper towel to remove any remaining white deposit. Collect tissues and dispose of as above for consumables.

Embryos - are fixed in 4% paraformaldehyde for >2 weeks before embedding in agarose for MRI examination or in paraffin wax for histology, and subsequently disposed of in clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incineration)

IDENTIFICATION OF PROTEINS REQUIRED FOR SECRETION IN LYMPHOCYTES

Retroviral and lentiviral delivery of a selection of human genes to cytotoxic T lymphocytes (CTLs) to assess their role in regulating secretion of stored proteins required for the immune effector functions.

FOR CONSTRUCTION OF RETROVIRAL VECTORS
K12 or B derivatives of E. coli will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ADCP hazard group 1.

FOR PACKAGING RECOMBINANT RETROVIRAL PARTICLES
The packaging cell lines are of human or murine origin, which are well characterised and authenticated and are obtained from commercial sources. Examples of packaging cell lines likely to be used are HEK293T cells (amphotropic) to generate lentivirus or PT67 to produce retrovirus. They can be regarded as low hazard for GM activities and as hosts are suitable for containment level 1 precaution.

FOR RECOMBINANT RETROVIRAL INFECTION:
Human primary lymphoid cells (eg CD8+ blasts or CTL) can be considered as especially disabled hosts and as such may be considered to be equivalent to ADCP hazard group 1 however the cells have the potential to contain adventitious agents and as such must be handled at containment level 2 under COSHH.

Lentiviral expression plasmid pHR-SINcPPT-SGVC containing 5' and 3' LTRs, packaging signal and Rev response element from HIV-1
p8.91 packaging plasmid containing Gag, pol, rev, tat from HIV-1
pMD-G envelope plasmid containing VSV-G envelope protein.

These three vectors are co-transfected into a packaging cell line to generate replication defective lentivirus.
This lentivirus expression vector is self-activating as it carries a deletion in the U3 region of the 3'-LTR. Upon integration into the host genome, the 3'-LTR is copied to the 5'LTR, rendering it transcriptionally inactive and therefore unable to generate a functional retrovirus. The HIV-1 Lentivirus based expression vector lacks any of the packaging genes (gag, pro, pol, vif, vpr, tat, rev, nef, eng), and requires the use of a packaging cell line based on HEK293 (ie HEK293T) and 2 other plasmids which provide gag, pol, rev, tat and VSVG. The HIV-1 elements in the lentivirus expression vectors (ie 5' and 3' LTRs and the psi packaging signal) allow packaging of the transgene itself. Therefore the number of genes from HIV-1 has been reduced to 4, ie gag, pol, rev and tat. Genes encoding the structural and other components required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology and each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

The packaging genes are provided by co-transfection of packaging vectors p8.91 (provides gag/pol, rev and tat) and pMD-G (provides VSV-G envelope) into the HEK293T cell line along with the expression vector. By using this enhanced 3-plasmid system, virus particles are produced that can infect human and mouse cells, but are replication deficient and therefore cannot be transmitted from one cell to another. Although the two packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, env) in the 293T producer cell line, none of them contain LTRs or the psi packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced. The rev response element allows for rev-dependant nuclear export of unspliced viral mRNA. The HIV-1 env gene is replaced with a Vesicular Stomatitis Virus envelope.

Overall then, only Lentiviral particles, which are unable to replicate, but which can deliver the gene of interest, are produced. Therefore the main risk is in their ability to deliver genetic material into a host genome and as described above, this is unlikely to pose any significant risk.

Retroviral expression plasmid pMSCV containing 5' and 3' LTR and packaging signals. The LTR is from murine stem cell viral and prevents transcriptional suppression in embryonic stem and embryonal carcinoma cells. Therefore driving high levels of constitutive expression. Retroviral expression plasmid pLEGFP-C1 containing 5' and 3' LTR and packaging signals from Moloney murine leukemia virus.

Either of the above 2 plasmids will be transfected into PT67 packaging cells to generate replication defective retrovirus. PT67 packaging cell line is derived from NIH3T3 cells, which have subsequently been stably transfected with 2 plasmids that contain the gag/pol and env gene. This cell line produces viruses, which are dualtropic and have a broad mammalian host range. Split genome design lowers the possibility of generating replication-competent virus. Only the expression plasmids contain the LTRs and the packaging signals and therefore the generated virus contains one of the structural genes rendering it replication defective.

As with the lentivirus the main risk with retroviruses is their ability to deliver genetic material into the host genome. This is unlikely to pose any significant risk.

**Origin & function**

Mammalian proteins implicated in a specialised lymphoid secretory pathway such as:
- **Rab27a** (studies have shown that transgenic mice expressing Rab27aGFP are healthy)
- Rab geranylgeranyltransferase: a rab modifying enzyme that adds a geranyl geranyl group to Rab27a and 4 other Rab proteins.
- Rab7 and RILP: Both involved in moving lysosomes along microtubules.
- Tubulin-GFP: forms microtubules along which lysosome move
- Actin-GFP: forms the sub-cortical cytoskeleton.
- LYST: a protein required for the final step of secretion of secretory lysosome.
- AP-3: a clathrin binding adaptor protein involved in sorting proteins to the lysosome.
- Perforin: a pore forming protein used by lymphocytes to form pores in target cells.

Other good candidate genes such as the microtubule motors kinesins or clp proteins that attach lysosomes to microtubules.
All of the above and other candidate proteins will be involved in the secretion of lysosomes in immune cells. None of the available literature indicates any oncogenic or harmful effect of these proteins.

Standard reporter genes such as GFP (Green fluorescent protein) from jelly fish, luciferase from firefly, and B-galactosidase from E. coli. None of the above proteins are known to have harmful properties.

Standard antibiotic resistance genes such as Neomycin, hygromycin, puromycin and ampicilin.

**Evaluation of foreseeable effects**

No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are based on the pUC backbone and are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at containment level 1.

Transfection of the HEK 293T cell line with the 3 plasmids is expected to result in the generation of a Lentivirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As stated above none of the inserted DNA is expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Therefore all work, which involves the handling of the virus, or cell lines and tissues infected with the virus, will be done at containment level 2, with the use of a microbiological safety cabinet for procedures which generate aerosols.

Transfection of the pT67 cell line with the retroviral expression plasmids is expected to result in the generation of a retrovirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As stated above none of the inserted DNA is expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Therefore all work, which involves the handling of the virus, or cell lines and tissues infected with the virus, will be done at containment level 2, with the use of a microbiological safety cabinet for procedures which generate aerosols.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Historical Significant Changes

Historical Date of Additional Info
We plan to develop recombinant Calmette-Guerin BCG (rBCG) as a candidate pediatric HIV vaccine. The avirulent strain of Mycobacterium bovis BCG offers as a vaccine vector some unique advantages and has a long record of safe use in more than two billion humans as a vaccine against tuberculosis. It is an excellent candidate vector for a pediatric HIV vaccine as it can be given safely at, or any time after birth, and indeed in many countries is given to newborns. Moreover, it can be delivered orally, the natural route of HIV infection of breast-fed babies born to HIV positive mothers, and is a potent adjuvant for Th1 responses able of inducing long-lasting immunological memory. Here, candidate rBCG constructed elsewhere will be used to vaccinate animals alone or in a prime-boost combination with other vectors expressing common HIV-derived immunogens.

The critical issues to be considered in developing rBCG technology include antigen localisation and long-term in vivo plasmid stability, both of which will be addressed in this work.

Recipient or parental organism

Mycobacterium bovis bacilli calmette-guerin (BCG)

Host/vector system

Vaccine strain BCG Pasteur,
lysine A (-) BCG strain (auxotrophic selection of plasmids pJH222 and pJH223)
Three E. coli-mycobacterial shuttle plasmids with kanamycin resistance gene as selectable marker will be constructed:
1) pMV261 - expression of foreign genes will be regulated by BCG hsp60 promoter, transfection will result in a multicopy and extrachromosomal plasmid.
2) pJH222 - expression of foreign genes will be regulated by alpha antigen promoter from Mycobacterium spp., transfection will result in a multicopy and extrachromosomal plasmid, plasmids harbor the complementing lysine gene regulated by BCG hsp60 promoter.
3) pJH223 - expression of foreign genes will be regulated by alpha antigen promoter from Mycobacterium spp., transfection will result in an integrated construct, plasmids harbor the complementing lysine gene regulated by BCG hsp60 promoter.

Origin & function

1. Multi-CTL epitopes. CTL recognize and kill cells displaying on their surface 8- to 10- amino acid-long peptides derived from microbial proteins. One way to minimise the amount of protein administered during vaccination is to engineer artificial proteins consisting of CTL epitopes. Compared to whole proteins, the use of CTL epitopes overcomes the potential risk of undesired biological activities of whole proteins and makes the possibility of reversion to virulence non-existent. The genes coding for short peptide epitope are derived from HIV, SIV, influenza or melanoma-associated antigens.

   gag group specific antigens - structural capsid proteins, RNA nuclear transport
   pol enzymes - protease, reverse transcriptase
   env envelope (gp41+ gp120=gp160) - external viral glycoprotein
   nef many functions - e.g. down regulation or up regulation of some specific cellular proteins
   tat viral transcription transactivator
   rev RNA transport and stability
   vif promotes virion maturation and infectivity
vpr promotes nuclear localisation, inhibits cell division
vpu promotes release of virions, degrades some specific cell proteins
vpx SIV homologue of vpr

3. Chimeric fusion proteins of the above Genes coding for SIV or HIV proteins or parts joint into one open-reading frame.

HIVA is derived from consensus HIV-1 clade A gag p24/p17 sequences and a string of clade A CTL epitopes. It does not contain the envelope gene and focuses solely on the induction of cell-mediated immune responses. Inserted in plasmid DNA and Modified Vaccinia Virus Ankara, HIVA was shown to be safe in normal BALB/c mice, severe combine immunodeficiency (SCID) mice, SIV-infected (immunocompromised) rhesus monkey and in over one hundred healthy human volunteers vaccinated with these constructs.

RENTA complements the HIVA immunogen and will join the present vaccine in a four-component DNA/HIVA-RENTA prime-MVA/HIVA-RENTA boost formulation in year 2004. RENTA is a fusion protein derived from consensus HIV-1 clade A sequences of tat, reverse transcriptase, nef and gp41. The natural biological activities of the HIV components have been inactivated.

4. reporter genes. Harmless commonly used marker genes such as GFP or beta-galatosidase may be inserted alone or in a combination with the above genes.

Evaluation of foreseeable effects

Mycobacterium bovis bacille calmette Guerin (BCG) is an attenuated strain of M.bovis. Wild type M. bovis is closely related to Mycobacterium tuberculosis (probably a subspecies) but is generally more pathogenic for animals than M.tb primarily causing tuberculosis in cattle. The BCG strain was attenuated by several hundred serial subcultures and named after the French scientists Calmette and Guerin. Wild type M. bovis is classified as an ACDP hazard group 3 agent with the BCG strain classified as hazard group 2 even though it has used since the 1920s to immunise humans against tuberculosis and currently is the most frequently administered vaccine in the world.

The inserted reporter genes are all well-characterised with no known associated health hazards.

Most of the foreign genes inserted into BCG will encode for epitopes derived from HIV, SIV, influenza and melanoma associated antigens. These sequences are unlikely to be hazardous to human health and pose no greater threat than BCG itself. Genes encoding for whole HIV or SIV proteins are likely to have some biological activity but as they only code for a small percentage of the overall HIV/SIV virus their risk to humans and the environment is likely to be insignificant.

No modification of genes involved in pathogenicity, virulence, host specificity or tissue tropism are being undertaken and so there is no reason to expect the resulting genetically modified organisms will differ in pathogenicity from the unmodified BCG strain.

Accidental inoculation is likely to result in priming of the immune system to HIV, SIV, influenza or melanoma which is unlikely to have any detrimental effects.

The greatest environmental hazard associated with exposure of animals to BCG is that cattle infected with BCG become positive for the tuberculin skin test. Although BCG does not persist in cattle and causes no disease, animals that become tuberculin positive through exposure to BCG would be deemed tuberculosis by the current TB screening measures in Great Britain and would be slaughtered as a result. This hazard is therefore an economical one.

Containment Level 2 will be sufficient to control the risk of exposure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a makesafe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126 - 130C for at least 10 minutes or 134 - 138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126 - 130C for at least 10 minutes or 134 - 138C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121 - 125C for at least 15 minutes or 126 - 130C for at least 10 minutes or 134 - 138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126 - 130C for at least 10 minutes or 134 - 138C for at least 3 minutes), discharge to drains OR dispose via clinical waste stream for incineration.

Animal carcasses - disposal via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form Y
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

**Project Additional Information**

**Purposes of the contained use**

The project proposes to unravel the contribution made by the fungus, Magnaporthe grisea, to the management of host imposed oxidative stress, that is, to understand how the pathogen survives in the hostile environment of the host, during successful infection. Also the role of fungal cutinase in penetration of the plant epidermis will be investigated.

The aim is to evaluate the contribution of catalase and cutinase activity in pathogenicity and virulence by "knocking out" the resident M. grisea catalase or cutinase gene(s) and replacing them with selectable markers. The knockouts will then be assessed for attenuated pathogenicity.

**Recipient or parental organism**

Escherichia coli strain DH5alpha is disabled and not harmful to animals or plants.

Agrobacterium tumefaciens strain LBA1126 is disarmed, having had the tumour-forming genes removed. It is considered to pose minimal risk to the environment. Magnaporthe grisea is the telemorph (sexually reproducing form) of the imperfect fungus Pyricularia grisea, the casual agent of rice blast. The telemorph is rarely encountered in nature. The strain to be used is Guy-11, which is widely used as a model plant pathogen. In the absence of a strain opposite mating type, guy-11 is not able to produce sexual (resting) spores. The asexual conidia that are produced are very limited viability and will not survive more than 24 hours or produce mature infection structures in the absence of host tissue. It is therefore considered unlikely to pose any risk to the environment in the UK.

**Host/vector system**

a) construct made from pBSC from stratagene

b) construct made from pGeenII (carries kanamycin resistance and R and LT-DNA border repeats and will express in fungal cells using donor vector pGPS3-Hyg (carries AmpR, HygR and an Aspergillus promoter and terminator)
Vectors have no harmful properties.

**Origin & function**

Two catalase genes (A and B) will be knocked out, and replaced by common selectable markers either as single or double knockouts. Neither of these genes has an implication for control of Magnaporthe as extra-cellular catalase activity is believed to allow the fungus to combat host-imposed oxidative stress, in fact this is expected to result in attenuated pathogenicity.

Two cutinase genes will be knocked out and replaced by common selectable markers either as single or double knockouts. Neither of these genes has an implication for control of Magnaporthe as cutinase is an enzyme which breaks ester linkages between cutin molecules. It is believed that Magnaporthe penetrates the host solely by mechanical means however as it carries 2 genes the group wish to investigate their function.

The standard marker genes used e.g. hygromycin B (an antibiotic) and Bialophos (a herbicide), will not be selected by those used to control this fungus commercially and are not expected to have harmful or physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Gene transfer is possible but unlikely to be hazardous.

**Evaluation of foreseeable effects**

The E. coli and Agrobacterium strains used are not capable of causing disease in animals or plants and do not present any risk to the environment.

The transgenic fungus will be compromised in its ability to produce extra-cellular catalase or cutinase and is likely to have impaired host penetration function. These individual alterations are expected to result in attenuated pathogenicity, as extra-cellular catalase activity is believed to allow the fungus to combat host-imposed oxidative stress and loss of cutinase may impair host penetration, which will reduce the fungus ability to infect.

The transgenes introduced, as selectable markers will alter the sensitivity of the GMO to hygromycin B, and the herbicide Bialophus - neither of which is used to control this fungus commercially. The products of gene expression are not toxic. No fungicide resistance genes will be introduced.

It is not expected that loss of catalase or cutinase will have any significant effect on the fungus, other than attenuated pathogenicity. While it is possible that minor morphological changes that might result, there is no reason whatsoever to expect that the modified pathogen will be more virulent than the wild type.

The fungus is not a native species of the UK and in the absence of strains of fertile strains of the opposite mating type, the strain used for this work can produce only asexual spores of very limited viability. There is no known mechanism of genetic transfer between the GMO and other organisms.

The risk assessment indicated that modified fungus is no more hazardous than the wild type. However, since the work involves genetic modification of a pathogen with the potential to cause significant crop disease and serious economic losses, it is considered appropriate to work under containment level 2 conditions as a precautionary measure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Project Ref** 553/04.3

**Date Ackn’d** 06/05/2004  **CU2 Project Title** Using retroviral vectors for the characterisation of the hypoxia-inducible factors (HIF)  **Class** Class 2  **CultureVolClass2** < 1 Litre  **CultureVolumeClass3-4**
Replication defective amphotrophic retroviruses will be used to assess the biological effects of murine and human HIF, related hydroxylases, their respective substrates, selected fusions between these genes, activating and inactivating mutations thereof and inhibitory RNA to knock down expression of these genes in primary cells and mammalian cell lines.

For Construction of retroviral vectors:
K12 or B derivatives of E. coli will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ADCP hazard group 1.

For packaging recombinant retroviral particles:
The packaging cells are of human origin, which are well characterised and authenticated and are obtained from commercial sources. Examples of packaging cell lines likely to be used are Phoenix 293 ampo cells, which generate amphotropic retroviruses. They can be regarded as low hazard for GM activities and as hosts are suitable for handling at Containment Level 1. However due to the presence of the E1a gene of Ad5 these cells will be handled at Containment Level 2 under COSHH.

For recombinant retroviral infection:
Primary cells and cell lines of murine and human origin can be considered as especially disabled hosts and as such are suitable for handling at Containment Level 1. However due to the possible presence of adventitious agents primary cells and uncharacterised cell lines will be handled at Containment Level 2 under COSHH.

Host/vector system
enes of interest will initially be obtained from plasmids generally derived from IMAGE clones. They will then be inserted into disabled retroviral vectors, which are based on pUC and are non-mobilisable. Vectors include LZRS-IRES-GFP, Pbmn-1-GFP and pRetroSuper.

pBMN-1-GFP contains 5’ and 3’ LTR and IRES-GFP into which the gene of interest is inserted.

LZRS-IRES-GFP contains 5’ and 3’ LTR and IRES-GFP into which the gene of interest is inserted and also EBV nuclear antigen and origin of replication.
pRetroSuper contains the H1 RNA promoter driving transcription of siRNA and 5 Thymidine residues as a termination signal which has been inserted into the pRetro system. pRetro is a self inactivation pMSCV retroviral vector.

To generate amphotropic retroviruses the expression plasmids are transfected into Phoenix-Ampho cells, derived from HEK293 cells which have already undergone subsequent stable transfections with plasmids containing moloney packaging functions gag-pol and env genes. Non-moloney promoters are used to drive the gag-pol and env genes to minimise their inter-recombination potential. Stable integration of gag-pol and env genes into different sites of the 293 genome, means that none of these genes are included in the viral particle thus generating a replication deficient virus.

Transfection with pBMN-1-GFP and pRetrosuper plasmids generates transient production of virus particles.

Transfection with LZRS-IRES-GFP plasmid generates medium term production of virus particles over 2-3 months due to the episomal nature of the plasmid.

**Origin & function**

Inserts are designed to result in increased or decreased activity of normal mammalian genes and/or are standard marker genes to identify or select infected cells. Marker genes include EGFP and standard drug resistance markers such as those for puromycin. Inserts are not expected to affect pathogenicity of the cloning hosts or normal human defence mechanisms. The interventions planned are likely to produce variations in HIF activity that are, no bigger than those encountered in normal health.

Inserts code for either normal mammalian genes, or selective alterations of those genes, or for short inhibitory RNAs designed to knockdown expression of the endogenous genes, and/or standard marker genes to identify or select infected cells.

These genes include mouse and human HIF and related hydroxylases (eg PHD1-3 and FIH) and their respective substrates eg mouse and human HIF-1 alpha, human HIF-2alpha, human HIF-3 alpha, selected fusions between these genes and activating and inactivating mutations thereof (eg of the specific HIF prolyl and asparaginyl residues targeted by the hydroxylases, or of residues affecting the active site of the hydroxylases).

Based on previous published research, HIFs play a role in hypoxic gene regulation, especially pathways involving metabolism and angiogenesis (Harris 2002). Wild type HIF-1 and HIF-2 should be constitutively expressed in VHL defective renal cell lines and up-regulate or down-regulate a variety of consensus hypoxia responsive genes. HIF itself would be normally regulated and degraded in all other cell lines and tissue types using this system. The HIF-1 mutant would be constitutively expressed. HIF-1 and HIF-2 over-expression (constitutively or mutant forms) have been shown to have varying effects on tumourigenesis (Semenza 2002). Indeed, HIF-1 seems to retard tumour growth in certain models, while in normal mice mutant HIF-1 has promoted angiogenesis and thus hypervascularity without tumour formation (Elson et al., 2001). HIF-2 seems to have a possible role in the progression of Renal Cell Carcinoma; however, no specific genes to date have been assigned to this transcription factor that are not already also controlled by HIF-1, thus uncertainty remains in the field as to its role in tumour progression but it is not able to transform cells. The HIF hydroxylases module HIF activity. They are not equilibrium enzymes and so activity does depend on the amount of enzyme expressed. This is under dynamic control in normal physiology. HIF activity is also dynamically regulated over a very wide range in response to commonly encountered physiology stimuli.

Inserts code for either normal mammalian genes, or selective alterations of those genes, or for short inhibitory RNA designed to knockdown expression of the endogenous genes, and/or standard marker genes to identify or select infected cells.

These genes include mouse and human HIF and related hydroxylases (eg PHD1-3 and FIH) and their respective substrates eg mouse and human HIF-1 alpha, human HIF-2 alpha, human HIF-3 alpha, selected fusions between these genes and activating and inactivating mutations thereof (eg of the specific HIF prolyl and asparaginyl residues targeted by the hydroxylases, or of residues affecting the active site of the hydroxylases).

Based on previous published research, HIFs play a role in hypoxic gene regulation, especially pathways involving metabolism and angiogenesis (Harris 2002). Wild type HIF-1 and HIF-2 should be constitutively expressed in VHL defective renal cell lines and up-regulate or down-regulate a variety of consensus hypoxia responsive genes. HIF itself would be normally regulated and degraded in all other cell lines and tissue types using this system. The HIF-1 mutant would be constitutively expressed. HIF-1 and HIF-2 over-expression (constitutively or mutant forms) have been shown to have varying effects on tumourigenesis (Semenza 2002; Elson et al., 2001).
No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are based on the pUC backbone and are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at Containment Level 1.

Transfection of the Phoenix-Ampho cell line is expected to result in the generation of a retrovirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As the virus is replication defective there is no risk of transmission within the environment. ADCP states that replication defective amphotropic retroviruses expressing innocuous genes may be handled at Containment Level 1. However due to the uncertain nature of the genes involved in the HIF pathways as a precautionary measure these viruses will be handled at Containment Level 2.

Cell lines infected with the virus will initially be handled at Containment Level 2. Once the viral supernatant is removed, the viruses inside the cells integrate their DNA into the host genome within 24-36 hours, and thus the viruses themselves disassemble during this period. After this period there will be no infectious virus and cells can be handled at Containment Level 1.

Evaluation of foreseeable effects

Project Additional Information

Purposes of the contained use

Replication defective E1/E3 deleted adenoviruses will be utilised to induce auto-antibodies to voltage gated potassium channels (VGKC) in mice to demonstrate a role for auto-antibodies in central nervous system (CNS) disorders.

Recipient or parental organism

For construction of adenoviral vectors:
E.coli K12 or B derivatives will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history for safe use. These hosts may be considered equivalent to ACDP hazard group 1.

For packaging of recombinant adenoviral particles:
The packaging cell lines are of human origin (HEK293), which are well characterised and authenticated and are obtained from commercial sources. HeLa cells will be used to confirm that wild type virus is not present in the viral stocks. HEK293 and HeLa cells can be regarded as low hazard for GM activities and as hosts are suitable for Containment Level 1 precaution.

The recombinant replication defective adenoviral particles will then be used to inoculate mice in an attempt to provoke an immune response.

Host/vector system

Genes of interest, such as HBK5 (gene for voltage gated potassium channel), NIK (NF kappaB inducing kinase) and reporter genes, will be cloned into standard plasmid vectors. These vectors (pAdKS216 and pAdKS217) are versions of pAdTrack-CMV with alterations to the multiple cloning site.

pAdTrack-CMV is a shuttle vector containing a poly linker site, which is flanked by adenoviral sequences allowing homologous recombination with the pAdEasy vectors to occur in E. coli. The vector also contains a CMV promoter and a polyadenylation site flanking a polylinker site and also the sequence for enhanced GFP. This vector contains the origin of replication from pBR322.

pAdEasy contains all the adenoviral genes except E1 and E3. The version to be used also contains a chimeric CMV promoter, which drives 5-10 fold higher expression than normal CMV. This can lead to expression levels up to 30% of the cellular protein.

Homologous recombination takes place in E. coli BJ5183 cells and large scale amplification take place in E. coli DH10B cells.

Production of replication defective virus particles takes place in HEK293 cells.

Viruses expressing a variety of transgenes will be generated which include:
CMV driving EGFP
CMV driving HBK5
CMV driving HIK
CMV-EGFP and CMV-HBK5
CMV-EGFP and CMV-NIK
CMV-HBK5 and CMV-NIK

Origin & function

The voltage gated potassium channel protein (VGKC) is encoded by the HBK gene. This gene is expressed in several different endogenous cell types particularly in the
nervous system. It is a trans-membrane protein located in the plasma membrane and it is known to be expressed at high levels in neurons, in the hippocampus and in the molecular layer of the dentate gyrus in the mammalian brain. VGKCs control repolarisation and frequency of action potential in neurons, muscles and other excitable cells.

KF-kappaB inducing kinase (NIK) gene induces expression of NF kappa, which activates the immune system. NIK is also an endogenously expressed protein.

Standard marker reporter genes such as Lac Z, GFP etc will be used. These inserts have a history of safe use and are not expected to have harmful physiological or pharmacological properties or affect the pathogenicity of the host.

None of the genes are oncogenic nor will they be integrated into the host genome.

**Evaluation of foreseeable effects**

No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at Containment Level 1.

Transfection of HEK293 cells is expected to result in the generation of an adenovirus that is capable of infecting mammalian cells but cannot propagate any further. As the virus is replication defective there is no risk of transmission within the environment. BHK5 and NIK are both constitutively expressed in several mammalian cells, especially neurons. Over expression of HBK5 is not expected to have harmful properties. Over-expression of NIK could possibly activate the immune system. Therefore the risk of these viruses is increased, because the genetic inserts could give rise to an immune response, which could be deemed harmful. Therefore as a precautionary measure these viruses will be handled at Containment Level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993. (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.
Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

This project aims at analysing the role of macrophage pattern recognition receptors (PRR), in particular class A scavenger receptor (SR-A), in recognition and phagocytosis of pathogenic bacteria using two important Gram-positive pathogens Streptococcus pyogenes and Streptococcus agalactiae.

When streptococcal candidate surface protein ligands have been identified, the corresponding genes will be cloned in disabled E. coli and the proteins will be expressed and purified as glutathione-S-transferase (GST) fusions or as His-Tag proteins. Streptococcal mutants negative for expression of candidate surface protein ligands will be constructed by replacing the structural gene with a kanamycin resistance cassette (Km-2) or a chloramphenicol resistance cassette (cat). The streptococcal mutants negative for expression of candidate surface protein ligands and the wildtype (WT) strains will be used in experiments with purified WT and SR-A deficient murine macrophages to analyse the role of these streptococcal surface proteins in recognition and phagocytosis of streptococci by SR-A on macrophages. Moreover, the streptococcal mutants and WT strains will be inoculated into WT and SR-A deficient mice to analyse the role of streptococcal surface proteins in SR-A phagocytosis in vivo. In addition, streptococcal mutants defective in D-alanylation of LTA and surface capsular polysaccharide may also be used for analysis of interaction with SR-A both in vitro and in vivo. Alongside and subsequent to the analysis of SR-A interactions with streptococcal ligands, the roles of other macrophage PRR and cytokines may also be examined (for example, mannose receptor).

**Recipient or parental organism**

Attenuated E. coli strains such as DH5a, XL-1Blue, JM103, BL21 and KJ622.

Streptococcus pyogenes (group A streptococcus): Wildtype isolates of several serotypes, including M1, M3, M4, M5, M6, M22 and M28.

Streptococcus agalactiae (GBS - group B streptococcus): Wildtype isolates of several capsular serotypes, including Ia, III and V.

**Host/vector system**

Standard plasmid vectors will be used such as pJRS233, pLZ12Spec, pGEX, pET and pBR322.

pJRS233: Temperature-sensitive E. coli/streptococcal shuttle vector. This vector contains a temperature sensitive ori from plasmid pVE6004 that renders it unable to replicate at temperatures above 35 degrees C. It also contains the low-copy replicon pSC101 to allow work in E. coli at 37 degrees C. Further, pJRS233 also contains the erythromycin resistance gene (erm) and the polylinker of the plasmid pBluescript SK+ (Stratagene).
plZ12Spec: This plasmid is an E. coli/streptococcal shuttle vector that is not temperature sensitive in streptococci, and it contains the repA replicon and the spectinomycin resistance gene specR.

pGEX vectors (Amersham Biosciences): Non-mobilisable expression vectors for generation of GST fusion proteins. Expression is under the control of the tac promoter, which is induced by IPTG. Also contains an internal laq1 gene. The laq1 gene product is a repressor protein preventing expression until induction by IPTG.

pET vectors (Novagen): Mobilisable defective expression vectors based on the T7 promoter-driven system. Can be used to generate recombinant streptococcal surface proteins with N- or C-terminal His-Tags.

pBR322 vectors: Mobilisable defective expression vectors containing the origin of replication from pMB1. They contain a low-copy number regulatory region (rop) and also the amp® and tet® selectable marker regions.

Origin & function
Streptococcal surface proteins are likely to be virulence factors acting as adhesions, invasins and/or antiphagocytic factors, or may perform functions important for the survival of the bacteria. For example, members of the M protein family in S. pyogenes have been shown to possess antiphagocytic properties, allowing the bacterium to grow in whole human blood. Deletion of the gene(s) encoding M protein(s) renders S. pyogenes highly sensitive to phagocytosis in human blood. Members of the Alp protein family in S. pyogenes and GBS are also likely to affect virulence, possibly by acting as epithelial cell adhesins/invasins. It has been reported that the Alp family member protein enhances the virulence of GBS in a mouse model. Also, capsule negative mutants and mutants defective in D-alanyl LTA have been shown to be significantly less virulent than the parental strains in the mouse model.

In addition, streptococcal surface proteins may also perform functions important for survival of the bacteria. Thus, mutations in genes encoding surface proteins may be lethal or lead to bacteria that are less viable than the parental strain.

Evaluation of foreseeable effects

In E. coli:
Cloning and expression of genes encoding streptococcal surface proteins in attenuated E. coli is unlikely to give rise to harm. Surface proteins from streptococci are not expected to be exposed in the surface of E. coli, due to different mechanisms of surface protein attachment between Gram-positive and Gram-negative bacteria. The two major groups of surface proteins that have been identified in group A and group B streptococci are LPXTG proteins and lipoproteins. The LPXTG proteins are covalently attached to the streptococcal cell wall. When genes encoding LPXTG proteins are expressed in E. coli, the processed form of the protein is normally found in the periplasmic space, as shown for M proteins of S. pyogenes (Frithz et al., Mol Microbiol, 1989, 3:1111-9). Streptococcal lipoproteins are attached to the outer leaflet of the cellular membrane. Lipoproteins from Gram-positive bacteria are often toxic in E. coli (Sutcliffe and Russell, J Bacteriol, 1995, 177:1123-8), and it has been shown the N-terminal signal sequence of the lipoprotein is responsible for the toxicity. Therefore, genes encoding streptococcal lipoproteins will probably have to be cloned without the region encoding the N-terminal signal sequence. The resulting gene products are therefore expected to be found in the E. coli cytosol.

There are no reports in the literature indicating that isolated streptococcal surface proteins may act as toxins or that they in any other way may have harmful effects in humans. Therefore they are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer as described above is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients.

In Streptococci:
Isogenic mutants of S. pyogenes, and GBS negative for expression of candidate surface proteins will be generated by homologous recombination employing the temperature-sensitive E. coli/streptococcal shuttle vector pJR3233. The streptococcal gene will be replaced with either the kanamycin or the chloramphenicol resistance cassette. Deletion of genes encoding surface proteins in S. pyogenes and GBS will most probably decrease the virulence of these two organisms.
Transcomplementation if isogenic streptococcal mutants negative for surface protein expression will be performed with pLZ12Spec containing genes encoding surface proteins, including the promoter region and transcription termination signals. These derivatives are expected to restore the wildtype properties of the strain.

Revertants of isogenic streptococcal mutants may also be constructed. In this case, the streptococcal gene of interest and its flanking regions is cloned in pJRS233. The resulting pJRS233 construct is transformed into the isogenic mutant by electroporation and a revertant is recovered after homologous recombination between the plasmid and the bacterial chromosome, replacing the kanamycin or the chloramphenicol resistance cassette with the structural gene. Revertants of isogenic streptococcal mutants are also expected to obtain the wildtype properties.

The streptococcal WT strains, isogenic mutants, revertants and the transcomplemented strains may be used in experiments with purified WT and SR-A deficient mice to analyse the role of streptococcal surface proteins in recognition and phagocytosis of streptococci by SR-A on macrophages in vitro and in vivo.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

Purposes of the contained use

The aim of the project is to develop candidate HIV-1 vaccines using engineered recombinant influenza viruses expressing HIV-1-derived immunogens. The focus is on induction of T cell responses and using prime-boost regimens heterologous vectors delivering a common immunogen. While the immunogen defines
vaccine specificity and provides a basic level of intrinsic immunogenicity, the choice of a vaccine vector and route of administration in great part determines the quality,
strength and longevity of elicited immune responses. Furthermore, functional properties of T cells primed by one vector can be further enhanced and/or developed by
heterologous boost administration.

Recipient or parental organism

E. coli K12 are disabled hosts that cannot colonise the human gut and will be used to manipulate plasmids containing sections of the influenza virus and transgenes.
Recombinant influenza virus based on influenza A/PR/8/34. Influenza A/PR/8/34 was isolated in 1934, is a laboratory-adapted strain which is non-virulent to people. When
given to human volunteers it caused no measurable disease symptoms.
HEK293T cells and MDCK cells will be used for rescue and amplification of the virus respectively. Cell lines have very strict nutritional requirements and are unlikely to
survive outside of these.
The recombinant influenza virus will be used to elicit an immune response to HIV.

Host/vector system

The 12 plasmid rescue method will be used to generate recombinant influenza viruses (Fodor et al., 1999). This involves the transfection into 293T cells of 8 plasmids,
encoding the 8 vRNA segments of the influenza genome and further 4 plasmids expressing the three influenza virus RNA polymerase subunits and the nucleoprotein.
Virus is expected to be generated by 24-48 hr post transfection. Recombinant viruses will be amplified on MDCK cells. The growth properties of the viruses will be
assessed on MDCK cells.
Advances in our understanding of the packaging of the influenza virus RNA genome together with technological innovations in reverse genetics allow the development of a
new generation of influenza virus vectors. The vector systems proposed by Horimoto et al. (2004) relies on a chimeric segment containing both the HA and NA genes,
joined via a promoter sequence. Since both HA and NA are encoded by a single segment with HA packaging signals, a foreign gene can be inserted into a NA-like
segment containing NA packaging signals.
The pPOLI-PR8 plasmid (Subbarao et al., 2003) will be modified by inserting the 3' end promoter sequence downstream of the HA stop codon followed by the insertion of
the NA ORF (Machado et al., 2003; Horimoto et al., 2004). After the NA stop codon 80 nucleotides of the |Haa coding region will be repeated followed by the HA
non-coding region (Watanabe et al., 2003). This construct, when transfected into 293T cells, will be transcribed by the cellular RNA polymerase 1 into an HA-like vRNA
with the capacity to encode both HA and NA proteins, after transcription by the influenza RNA-dependent RNA polymerase. Because the NA is expressed from the
chimeric construct, the NA segment is available for the expression of foreign genes. Transgenes will be inserted into pPOLINA-PR8, after removing most of the NA ORF,
maintaining 183 and 157 coding nucleotides at the 3' and 5' ends, respectively. These coding regions are required to ensure that the transgene vRA will be packaged into
viral particles.

Origin & function

Hiva Immunogen is derived from consensus HIV-1 clade A gag p24/p17 sequences and a string of CTL epitopes (Hanke and McMichael, 2000). The gene was made
synthetically to humanize the codons. In studies conforming to good laboratory practice requirements, the HIVA-expressing vaccines vectored by MVAand pTHr plasmid
DNA were shown to be non-toxic in BALB/c mice. Furthermore, acute toxicity and biodistribution of MVA HIV A were carried out in mice with severe combined
immunodeficiency (SCID) and SIV-infected rhesus macaques which again demonstrated that the MVA.HIVA vaccine was non-toxic and non-persistent. We have now
completed small phase I/II clinical trials approved by GTAC employing MVA.HIVA alone and in pTHRHIVA DNA prime-MVA.HIVA boost regimens in healthy HIV-1-uninfected
human and showed that the vaccine was safe. A number of other phase I/II trials are currently under way in Europe and Africa. In addition, a small safety/immunogenicity
trial in HIV-1-infected human subjects on highly active antiretroviral treatment in Oxford is underway, in which the vaccine has been so far safe. Thus, HIVA has been safe
in several hundred healthy HIV-1 uninfected and HIV-1-infected vaccinees.

Renta immunogen is a fusion protein derived from consensus HIV clade A sequences of Tat, reverse transcriptase, Nef and gp41. We inactivated the natural biological
activities of the HIV components and confirmed this formally in appropriate assays (Nkolola et al., 2004).

Reporter genes such as GFP, beta-galactosidase and luciferase are commonly used and have been shown to be harmless.
Multiple CTL epitopes - CTL recognize and kill cells displaying on their surface 8 - 10 - amino acid-long peptides derived from microbial proteins. One way to minimize the amount of protein administered during vaccination is to engineer artificial proteins consisting of CTL epitopes. Compared to whole proteins, the use of CTL epitopes overcomes the potential risk of undesired biological activities of whole proteins and makes the possibility of reversion to virulence non-existent. The genes encoding for short peptide epitope are derived from HIV, SIV, influenza, plasmodium or melanoma-associated antigens.

Individual whole SIV or HIV genes and their truncations - individual whole SIV or HIV proteins possess certain biological activities. However, the proteins on their own represent only an insignificant risk to people and or environment. In many instances, the protein biological activities are genetically inhibited.

gag group specific antigens - structural capsid proteins, RNA nuclear transport
pol enzymes - protease, reverse transcriptase
tat viral transcriptional transactivator
rev RNA transport and stability
vif promotes virion maturation and infectivity
vpr promotes nuclear localization, inhibits cell division
vpu promotes release of virions, degrades some specific cell proteins
vpx SIV homologue of vpr

Evaluation of foreseeable effects

Influenza virus is classified as a Hazard Group 2 organism by ACDP. The recombinant influenza virus is based on influenza A/PR/8/34, which was isolated in 1934 and has been passaged successively over 100 passages in ferrets, over 100 passages in mice and many times in embryonated chicken eggs. When given to human volunteers, it caused no measurable disease symptoms.

The inserted reporter genes are all well-characterised with no known associated health hazards.

Most of the foreign genes inserted into influenza A/PR.8/34 virus will encode for epitopes derived from HIV or SIV. These sequences are unlikely to be hazardous to human health and pose no greater threat than influenza itself. Genes encoding for whole HIV or SIV proteins are likely to have some biological activity but as they only code for a small percentage of the overall HIV/SIV virus their risk to people and the environment is likely to be insignificant. No modification of genes involved in pathogenicity, virulence, host specificity or tissue tropism are being undertaken and so there is no reason to expect the resulting genetically modified organisms will differ in pathogenicity from the unmodified influenza strain.

Accidental inoculation is likely to result in priming of the immune system to HIV, SIV and certain strains of influenza, which is unlikely to have any detrimental effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
The aim of this project is to use replication defective amphotropic retrovirus to enable the conditional immortalisation of primary and cultured human cells from both normal subjects and cells isolated mainly from patients with metabolic or genetic bone diseases. Primary cells from patients with metabolic or genetic bone diseases and normal subjects. Primary cells may contain adventitious agents and under CoSHH will be handled at Containment Level 2. These cells will be screened prior to infection for endogenous helper virus using either the his-D reporter system or RT assay.

Retrovirus virions will be generated by employing the TE-Fly cell lines. TE-Fly cells are derived from TE 671 (human medulloblastoma) cells by transfection with CEB, a MLV gag-pol gene expression plasmid.

Further transfection has been performed to generate cell lines that also express env glycoproteins.

A - env 4070A amphotropic MLV
RD - env RD 114
GA - env from Gibbon Ape Leukemia virus

Finally cell lines will be transfected with expression vectors containing hTERT and telomerase. These cell lines will produce virions containing hTERT and Telomerase, which are capable of infection but are replication defective.

Temperature sensitive SV40 large T antigen (TsA58-U19) with mutation abrogating DNA binding; inactivates p53 and RB pathways, extends cell lifespan. hTERT catalytic subunit of human telomerase; extends cell life span by reconstituting telomerase activity.

Reporter genes confer neo- and hygro-mycin-resistance to transfected cells.
Cells infected with virions containing SV40 tag and hTERT are expected to be immortalised. Once the DNA has integrated, the cells may be considered as posing minimal risk of oncogenicity and they can normally be handled at Containment Level 1. Immortalised cell lines will be tested for the presence of retroviral virions both immediately after transduction and during long-term culture of the transduced cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Purposes of the contained use

The aim of this project is to use self-inactivating lentiviral vectors to deliver genes, which have been implicated in immune regulation, to cells which are typically resistant to normal transfection methods. The cells to be transduced will include primary murine T cells or clones, embryonic stem cells and murine bone marrow dendritic cells.

Recipient or parental organism

Viral packaging cell line, such as 293T cell lines
These cells will be used for the production of virus

Murine cell lines, primary murine cells and established murine clones
These cells will be infected with the virus to enable efficient transfer of genes

Host/vector system

02/03/2022
The inserted genetic material will be cloned into one of the following self-inactivating lentiviral plasmid systems.
- pWPXL-GFP, pWPI-GFP (sourced from Trono Lab, Geneva)
- LentLox 3.7 (pLL3.7) (sourced from Van Parijs Lab, Cambridgeshire MA)
- pLVTH, pLVTH-siGFP, pLV-tTR-KRAB, pLV-tTR/KRAB-Red (sourced from Trono Lab, Geneva)

### Origin & function

Inserted genetic material will be mammalian (murine) origin of shRNA silencing constructs, derived from genes implicated by gene expression profiling and/or supportive literature in immune regulation. These genes include transcription factors such as FoxP3, T-bet, ROG and GATA-3, known to influence development of regulatory versus TH1 and TH2 effector cells; signalling molecules such as calcineurin and PLC-γ targetting pathways, implicated in T cell anergy and Smad 2/3/4 and 7 and Arkadia implicated in TGF-beta signalling; and ubiquitin ligases such as Cblb, GRAIL and Itch, and the molecule Carma-1 that appear to have opposing effects on the ability of T cells to signal for tolerance or immunity. Other examples include inhibitory receptor molecules implicated in mediating the effect of tolerogenic dendritic cells, such as PDL-1 and PDL-2, gp49B, PIRB and Pilr(alpha), and adhesion receptors CD147 and embikin. Standard reporter genes (eg GFP, EGFP, luciferase) and standard antibiotic resistance and mammalian marker genes will be used.

### Evaluation of foreseeable effects

Each of the lentiviral plasmid systems contain a feature where upon integration into the host genome, the 3'-LTR is copied to the 5'-LTR, rendering it transcriptionally inactive and therefore unable to generate a functional retrovirus, or mediate transcription of a host gene at the integration site.

The lentiviral particles are replication defective and therefore cannot disseminate in the environment. All non-essential genes have been removed from the system.

Genes encoding the structural and other components required for packaging have been separated into different plasmids and the chance of recombination has been minimised by the removal of any regions of homology between those plasmids.

The infectious virus particles will have a broad tropism due to the VSV-G envelope protein and therefore have the potential to infect laboratory workers. However as the vectors are replication defective and unable to disseminate beyond initial target cell, it is very unlikely that there would be any deleterious effect.

The inserts have been selected based on their implied relevance to immune regulation and as such could represent a risk to animal and human health. However, only murine sequences not known to interact with human receptors and ligands will be utilized minimising the hazard posed to human health. The constructs remain potentially hazardous for rodents but work will only be undertaken on cell cultures not on animals. As a precautionary approach for human health considerations ant to protect the environment, Containment level 2 will be applied while handling infectious viral particles.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate using a final concentration of 2% Virkon for at least 1 hour following manufacturers guidelines, discharge liquid to drains.
Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpals) - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% (manufacturers validation)

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Project Ref 553/05.3

Date Ackn'd  15/04/2005
CU2 Project Title  Boosting Immunity with recombinant listeria monocytogens.

Date Project Ceased  02/03/2022
Class  Class 2
CultureVolClass2  < 1 Litre
Consent Granted  Not Applicable

02/03/2022  Page 8932 of 15326
### Project Additional Information

#### Purposes of the contained use

Attenuated (actA/inB double deficient) listeria monocytogenes expressing various T cell epitopes will be used to immunise mice with the aim of generating a T cell responses that will be evaluated in terms of vaccine-induced protective immunity against challenge infection.

#### Recipient or parental organism

Attenuated Listeria monocytogenes carrying in frame deletions of two bacterial virulence factor genes. ActA gene is required for cell-cell spread and inlB gene is required for liver infection.

#### Host/vector system

Standard bacterial vectors introduced by electroporation followed by selection for homologous integration into the L. monocytogenes chromosome between two divergent transcription unit.

#### Origin & function

Defined T cell epitopes derived from plasmodium berghei, plasmodium yoelii and mycobacterium tuberculosis will be less than 20 amino acids in length. Such as, CD8 epitopes from Plasmodium berghei CSP, Plasmodium yoelii MSP1, Plasmodium yoelii CS58-67 and CD4 and CD8 epitopes from mycobacterium tuberculosis 85A.

Hen ovalibumin lacking amino terminal 80 residues and also containing CD8+ T cell epitopes in the middle of the ovalbumin.

#### Evaluation of foreseeable effects

Virulent Listeria monocytogenes may cause gastroenteritis in healthy adults and more severe disease in immunocompromised individuals including abortion in pregnant women and is classified as a Hazard Group 2 organism by ACDP.

The attenuated strains which will be used in this project have been altered to carry deletions of the DNA encoding two important virulence factors. Due to the large deletions of two genes reversion to virulence is unlikely. Removal of these virulence factors attenuates the organism by more than 1000 fold in murine models of infection.

Although it is likely that the attenuated Listeria monocytogenes will be less virulent in humans than the parental form, due to the lack of clinical data in humans to support reduced virulence work will be performed at Containment Level 2.

Secretion of fusion proteins from the attenuated Listeria monocytogenes is unlikely to increase the virulence of the organism or have any other deleterious affects. The likelihood of developing an allergy to naturally occurring ovalbumin is small as the recombinant ovalbumin will not assume a native conformation due to the deletion and
addition mentioned above. In addition allergic reactions tend to be initiated upon exposure to protein antigens in the absence of infection.

The epitopes are less than 20 a mino acids in length and represent only a small portion of a single gene. Therefore it is highly unlikely that these epitopes will confer any of the pathogenic properties of Plasmodium or mycobacterium species to the recombinant Listeria.

Animals will be anaethetised prior to inoculation and all inoculations will be carried out in a Class II microbiological safety cabinet. Inoculations will be carried out with a 1ml syringe and the inoculation volume is 0.2ml, thus, up to five animals will be injected with the same needle. The needle will not be re-sheathed between inoculations and the attached syringe/needle will be disposed of into an appropriate sharps container after the syringe is empty. The needle will not be re-sheathed prior to disposal. Listeria will be shed at low levels for four to five days post inoculation therefore all bedding will be autoclaved prior to disposal. Animals are housed in individually ventilated cages and all handling will be done in a class II Microbiological Safety cabinet. Cages containing inoculated animals will be clearly labelled and husbandry staff made aware of the risks.

Contents and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquid (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge to drains, or inactivate using 1% Virkon following manufacturers instructions.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively, 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (manufacturers validation using Virkon)
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Date of Significant Change: 17/10/2008
### Purposes of the contained use

The aim of the project is to assess the immunogenicity of candidate HIV-1 vaccines vectored by recombinant viruses expressing HIV-1-derived immunogens.

### Recipient or parental organism

Development of vaccines against HIV-1

### Host/vector system

Not applicable

### Origin & function

1. HIV-1 and SIV Chimeric genes

   HIVA Immunogen HIVA is derived from consensus HIV-1 clade A gag p24/p17 sequences and a string of CTL epitopes (Hanke and McMichael, 2000). The gene was made synthetically to humanize the codons.

   RENTA Immunogen RENTA is a fusion protein derived from consensus HIV clade A sequences of Tat, reverse transcriptase, Nef and gp41. We inactivated the natural biological activities of the HIV components and confirmed this formally in appropriate assays (Nkolola et al., 2004).

2. Reporter genes. Harmless commonly used marker genes such as GFP or beta-galatosidase may be inserted alone or in a combination with other transgenes.

3. Multi-CTL epitopes. CTL recognise and kill cells displaying on their surface 8- to 10-amino acid-long peptides derived from microbial proteins. One way to minimise the amount of protein administered during vaccination is to engineer artificial proteins consisting of CTL epitopes.

4. Individual whole SIV or HIV proteins and their truncations: Individual whole SIV or HIV proteins possess certain biological activities. However, the proteins on their own represent only an insignificant risk to people and or environment. In many instances, the protein biological activities are genetically inhibited.

   - **gag**: group specific antigens - structural capsid proteins, RNA nuclear transport
   - **pol**: enzymes - protease, reverse transcriptase
   - **tat**: viral transcriptional transactivator
   - **rev**: RNA transport and stability
   - **vif**: promotes nuclear localisation, inhibits cell division
   - **vpu**: promotes release of virions, degrades some specific cell proteins
   - **vpx**: SIV homologue of vpr

### Evaluation of foreseeable effects

HIVA vectored by DNA and modified vaccinia virus Ankara (MVA) was safe and non-persistent in healthy and immunocompromized mice, healthy and SIV-infected rhesus macaques and in over 200 healthy and HIV-infected humans (Hanke et al., 2000, 2002, in press; Mwau et al., 2004). We have now completed small phase I/II clinical trials approved by GTAC employing MVA.HIVA alone and in pTHr.HIVA DNA prime-MVA.HIVA boost regimens in healthy HIV-1-uninfected humans and showed that the vaccine was safe. A number of other phase I/II trials are currently under way in Europe and Africa. In addition, a small safety/immunogenicity trial in HIV-1-infected human subjects on highly active antiretroviral treatment in Oxford is underway, in which the vaccine has been so far safe. Thus, HIVA has been safe in several hundred healthy HIV-1 uninfected and HIV-1-infected vaccinees.

Biological activities of RENTA components were inactivated and when vectored by DNA and MVA was safe in healthy mouse and monkeys (Nkolola et al., 2004). None of
The viral proteins are modified, therefore there is no possibility of change of virulence, invasiveness, host range, tropism or the ability to stimulate host defence mechanisms by the recombinant virus. Whole HIV-1/SIV envelope will not be used in these experiments.

Reporter genes such as GFP and luciferase have a history of safe use.

Compared to whole proteins, the use of CTL epitopes overcomes the potential risk of undesired biological activities of whole proteins and makes the possibility of reversion to virulence non-existent. The genes coding for short peptide epitope are derived from HIV, SIV, influenza, plasmodium or melanoma-associated antigens.

The HIV-1-derived transgene products are taken out of the HIV-1 virus context and/or are modified or biologically inactivated and are therefore harmless.

### Project Additional Information

**Purposes of the contained use**

| Construction of several Vibrio Harveyi mutants |

**Recipient or parental organism**

| Vibrio Harveyi is non-pathogenic to humans but has severe pathogenic activity in a variety of shell fish, including prawns, shrimp and oysters. Infection causes vibriosis, resulting in tissue necrosis (due to production of exotoxin by the bacteria) and death. Shell fish are farmed in aquaculture and although treatment is possible using broad spectrum antibiotics, Vibrio Harveyi has the potential to cause environmental harm. By analogy with other Vibrio species, we have assigned Vibrio Harveyi to Containment Level 2. Vibrio Harveyi is ubiquitously found in the environment and infections are often linked to stressful environmental conditions of the hosts. |

**Host/vector system**

| Disabled E.Coli K12 and B derivatives - Class 1 |
| Wild type Vibrio Harveyi - Class 2 |
| Standard DNA Cosmids, P1 or lambda Phage |

**Origin & function**

| Mutations in the lux luminescence regulatory pathway will be obtained by gene replacement using Tn5 or Tn5lac transposons, conjugation of recombinant cosmids and other standard microbiological manipulation using disabled E.coli as an intermediate. |
| DNA transposons encodes a kanamycin resistance gene and transposase. |

**Evaluation of foreseeable effects**

| The inserts code for a transposase enzyme and resistance to the antibiotic kanamycin and/or standard marker genes such as Lac Z, GFP etc. None of the inserts nor any of the mutations in the lux luminescence regulatory pathway are expected to alter the pathogenicity of Vibrio Harveyi. Kanamycin is not the antibiotic of choice for treatment of this disease. |

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Project Additional Information**

**Purposes of the contained use**

The overall aims of this research programme are to understand the genetic basis of bacterial parasitism of plants and to understand at a mechanistic and evolutionary level how closely related bacteria have developed pathogenic or plant growth-promoting interactions with plants and other soil eukaryotes.

**Recipient or parental organism**

- *Pseudomonas syringae* (various strains of)
- *Pseudomonas fluorescens* (various strains of)
- *Pseudomonas aeruginosa* (various strains of)

**Host/vector system**

- E. coli (such as)
- E. coli DH5α pir - cloning
- E. coli TOP10 (Invitrogen) - cloning
- E. coli BL21 DE3 - cloning, protein expression
- E. coli ROSETTA (DES3) (Novagen) - cloning, protein expression

- *Pseudomonas* (such as)
  - *P. syringae* pv. *Tomato* DC3000 - plant pathogen (tomato, Arabidopsis)
  - *P. syringae* pv. *Syringae* B728a - plant pathogen (bean)
  - *P. syringae* (savastanoi) pv. *Phaseolicola* 1448a - plant pathogen (bean)
  - *P. fluorescens* SBW25 - non pathogen
  - *P. fluorescens* Pf5 - non pathogen
  - *P. fluorescens* Pf01 - non pathogen
  - *Pseudomonas* sp. NZ17 - muchroom pathogen
  - *P. aeruginosa* PA01 - opportunistic pathogen - clinical isolate
  - *P. aeruginosa* PA14 - opportunistic pathogen - clinical isolate

- Mutant banks (such as)
  - *P. aeruginosa* PA01: ISphoAhah, ISlacZhah.
  - [Http://rod.brinkman.mbb.sfu.ca/glbrowse/uwgc_insertions/Mutant_Info.pdf](http://rod.brinkman.mbb.sfu.ca/glbrowse/uwgc_insertions/Mutant_Info.pdf)
  - *P. aeruginosa* PA01: miniTn5:lux
P. aeruginosa PA14: miniTn5::phoA, MAR2xT7. P. syringae pv. Tomato DC3000 regulatory mutants. Available from Arun Chatterjee Carol Bender and Alan Collmer (GacS, RpoN, HrpL, HrpS, RpoS, HrpV). Most mutants available from secondary sources contain a kanamycin resistant transposon insertion or are clean deletions created by homologous recombination.

Vectors: (such as)
pBBR1MCS and derivatives: (Labes et al. 1990)
pRU1156, pRU1144: (Karunakaran et al. 2005)
PET vectors (www.novagen.com)
pCR2.1 (www.invitrogen.com)

Fluorescent protein vectors: pMP4642/4655 (gfp), pMP4641 (cfp), pMP4658 (yfp) pME6010 (vector control), pMP4662 (rfp) (all Bloemberg et al. 2000)
miniTn5::uidA (miniTn::Km with promoterless uidA)
miniTn5::gfp::luxCDABE (miniTn::Km with promoterless gfp::luxCDABE)
miniTn5::ptac (miniTn::Km with outreading tac promoter)
pCre. The pCre plasmid encodes the enzyme Cre-recombinase and can be used to remove antibiotic resistance inserts from transposons such as Ispho Ahah and ISlacZhah when introduced into the same strain (Bailey and Manoil, 2002).

Complementation constructs will be constructed by amplifying and cloning the target genes into pCR2.1, followed by transfer to pUIC-I or pBBR1MCS. Protein expression constructs will be constructed by amplifying the coding region of the target gene and cloning into an appropriate pET vector. Epitope-tagged pET constructs may subsequently be cloned into pBBR1MCS for expression and characterisation in Pseudomonas.

We will obtain some complementing and epitope-tagged clones from existing clone collections. A FLEXgene collection of all P. aeruginosa PA01 ORFs, including a set of clones in bacterial protein expression vectors that add polypeptide tags including N-terminal 6xHis-(pDEST17), C-terminal 6xHis-(pDEST42), and N-terminal GST-(pDEST-GST), has been constructed using high-throughput methods, as described in LaBaer et al. (2005).

Origin & function

Candidate genes that are likely to have a key role in bacteria-plant interactions will be selected on the basis of comparative genomic and functional genomic analyses of model Pseudomonas strains. Seven criteria have been used to select genes.

1) Plant-induced - expression of genes is up-regulated during plant colonisation (Gas et al. 2003; Boch et al. 2002; Lindow et al. 2005)
2) Over-represented - certain protein domains are over-represented in Pseudomonas genomes. Genes containing these domains are likely to encode functions that have adaptively diversified. (Studholme et al 2005).
3) Under-represented - certain protein domains are under-represented in Pseudomonas genomes. Genes containing these domains may have been lost through negative selection. Remaining domains are likely to be under positive selection. (Studholme et al. 2005).
4) Novel architectures - one way bacteria evolve new functions is through the creation of novel domain architectures in which existing protein domains are recombined to give a new or altered function. (Studholme et al. 2005)
5) Secretion - proteins or protein products that have a direct role in plant-interactions are likely to be secreted. Secreted proteins can be identified through bioinformatic and functional analyses. (Preston et al. 2005).
6) Co-regulation - many genes involved in plant-bacteria interactions are coregulated through conserved global regulators such as GacS and RpoN, which in turn are subject to regulation by modification and modulation by proteins such as Lon protease and hydroxylases. These co-regulated genes can be identified on the basis of conserved promoter elements and regulation confirmed by examining expression in a regulatory mutant background.
7) Lateral gene transfer - some of the most interesting candidates for proteins involved in plant-interactions display features characteristic of laterally transferred genes and are most similar to genes present in phylogenetically distant organisms.

As genome sequence databases and the results of bioinformatic analyses are continually under review the list of inserts under consideration for further analysis is also...
under regular review. We have therefore assessed the risks associated with this project on an equivalent basis to the risks associated with a transposon mutagenesis approach to studying virulence in P. aeruginosa or P. syringae, followed by subsequent complementation and characterisation of disrupted genes.

Mutants will routinely be constructed by amplifying and cloning 2kb of flanking sequence from either side into pCR2.1, which will be assembled into a linear 4kb deletion construct before transfer to the suicide vector pUIC-M, and recombination into the target genome.

**Evaluation of foreseeable effects**

**For E. coli work (Class 1)**

The E. coli are K12 or B derivatives. These are disabled hosts that cannot colonise the human gut, have a history of safe use and cannot survive in the environment. Although BL21 has been shown to have slightly higher colonisation potential than K12 strains, it lacks pathogenicity determinants, and is not believed to present any risk to healthy adults.

Cloning vectors (pCR2.1, pET) are non-mobilisable pUIC and pME6010 vectors used are only mobilisable with the addition of a strain containing a helper plasmid for triparental mating.

Inserted genetic material will consist of 1-10kb of DNA from the pathogenic Pseudomonas strain. Although some cloned DNA will encode adaptive traits such as nutrient transport, secreted proteins or regulatory proteins, they will not increase the level of risk for these disabled GMMs.

**For Pseudomonas work (Class 2)**

P. fluorescens are not pathogenic to plants or animals.

P. syringae strains are plant pathogens that have never been isolated from human hosts, they are unable to grow at 37 degrees C. Gene inserts will be used to excise target genes and to restore function to mutants with deletions in target genes by complementation. Mutations are likely to reduce plant pathogenesis where they have any observable effect.

P. aeruginosa is an opportunistic pathogen of immuno-compromised patients. It is able to grow at 37 degrees C. It is occasionally associated with infections of epidermal surfaces, corneal surfaces, burns and wounds. It is highly unlikely to pose any risk to normally healthy laboratory workers using good laboratory technique. Gene inserts will be used to excise target genes and to restore function to mutants with deletions in target genes by complementation. Mutations are likely to reduce pathogenicity where they have any observable effect.

Fluorescent plasmids will be used to observe and track strains using microscopic techniques. The fluorescent proteins cloned in these vectors will not alter or enhance the pathogenesis of these organisms. Vectors used contain antibiotic resistance genes, giving marginal risk of transfer to other strains, this is not likely to increase risk above background levels. The antibiotic genes introduced in this study would be unlikely to increase resistance to antibiotics commonly used in clinical treatment. A worst case scenario would be that modifications or random mutations in cultured bacteria cause a minor increase in infectivity or antibiotic resistance and that a worker subsequently exposes themselves to the altered strain through an uncovered wound or burn, or through contact of contaminated fluids or surfaces with eyes. This is unlikely to pose a significantly increased risk to healthy laboratory workers for the reasons outlined above.

P. aeruginosa pathogenicity assays.

The model nematode Caenorhabditis elegans can be used to test organism to assess P. aeruginosa pathogenesis in simple laboratory test. C. elegans is a bacteriovorous soil microorganism that poses no risk to human health (the standard strain C. elegans N2 was isolated from mushroom compost).

P. aeruginosa strains have been shown to be infectious in various laboratory models, including mouse, nematodes (Caenorhabditis elegans, Panagrellus redivivus), insect (Drosophila melanogaster, Greater Wax Moth Galleria mellonella), amoebae and plant (Arabidopsis, alfalpfa). It should be noted that most of these are artificial models of infection that use large doses of bacteria, and unnatural inoculation methods, facilitating biofilm formation by this bacterium. P. aeruginosa and P. syringae are not typically regarded as vector-borne diseases, although they can be dispersed in a non-persistent, non-circulative manner by insects, soil micro-organisms and on seeds. The most frequent forms of transmission for P. syringae are through aerosols, rain-splash and seeds.

The consequence of the hazards being manifest are considered to be to be low and the likelihood of manifestation is negligible when containment assigned above is taken into account. In all cases, taking into account the control measures assigned above, the overall risks to the environment from the genetically modified micro-organisms produced in this work is low. Therefore additional containment or control measures are considered necessary to protect the environment other than those described to
protect human health and safety. These include containment of infected plants in growth chambers and measures to prevent insect transmission from infected plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125 degrees C for at least 15 minutes or 126-130 degrees C for at least 10 minutes or 134-138 degrees C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Plants, plant material and soil - autoclave as specified in Defra Plant Health Licence, discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

For waste items that are both radioactive and contain GMMs.

Consumables (mainly plasticware eg pipettes, flasks, tubes) - disinfect with 2% Virkon for at least 30 minutes, discharge any excess liquids to drains as aqueous liquid radioactive waste subject to limits contained in an authorisation granted under the Radioactive Substances Act 1993, dispose of solids as solid low level radioactive waste under an authorisation granted under the Radioactive Substances Act 1993.

Liquids (eg samples, culture supernatants, tissue culture media) - disinfect with 2% Virkon for at least 30 minutes, discharge to drains as aqueous liquid radioactive waste subject to limits contained in an authorisation granted under the Radioactive Substances Act 1993.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines).

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to modulate (overexpress or down-regulate) expression of critical transcription factors and other molecules such as cell cycle or gene expression.
regulators, which are thought to be involved in lineage commitment and differentiation of haematopoietic cells. Analysis of the effects on proliferation, differentiation and survival of the cells will be conducted at molecular and cellular levels.

**Recipient or parental organism**

Replication defective amphotropic Retrovirus - The recombinant pseudo-typed vectors expressing the gene of interest are amphotropic and can therefore infect human cells, however they are replication incompetent and do not express viral genes.

Replication defective Lentivirus - A number of features are designed to enhance biosafety. (i) The 3'LTR of the lentiviral vector has been deleted that results in self-inactivation of the lentivirus after transduction of the target cells without altering the vector titers. (ii) The current, third generation packaging unit of HIV-a based vectors conserves only three of the nine genes present in the genome of the parental virus: gag, pol, and rev, expressed from split genomes. This eliminates the possibility that a wild-type virus will be reconstituted through recombination. (iii) The VSV-G gene from Vesicular Stomatitis is used in place of the HIV-1 envelope protein. (iv) The lentiviral particles are replication incompetent and only carry the gene of interest.

The viruses are replication defective and pose no environmental danger. They are unstable, inactivated by detergent, UV light and ethanol and would not survive outside the laboratory environment.

Mouse and human primary cells and cell lines - The infected human and mouse cells will be recognised as non-self by the immune system and rapidly lysed by the complement and therefore are unlikely to be pathogenic. Moreover, once integrated into the transduced target cells, the retroviral and lentiviral genomes are no longer capable of producing packageable viral genomes. Cells are unable to survive outside tissue culture conditions and therefore pose no risk to the environment.

**Host/vector system**

Packaging cell lines, such as 293-GPG and 293T and Retroviral and Lentiviral vector systems. Packaging cell lines when transfected with vectors containing the genes of interest produce infectious viral particles, however these particles are only capable of one round of infection, as they do not contain the relevant viral genes necessary for replication. The viral particles are therefore replication defective.

As separate entities the packaging cell lines and the vectors pose no hazard to human health or the environment.

**Origin & function**

Human and mouse genomic wt DNA and cDNA inserts (coding for transcription factors such as SCL, GATA family members, Gfi1b, ETO-2, E2A, HEB, E2-2, Pax5, LEF1, Pu.1, CEBPa) will be overexpressed in the cells. We expect an alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or their progeny. In the course of the study, the above list could be extended to molecules identified as partners or targets of some of the transcription factors mentioned above. These could involve other transcription factors, co-factors, chromatin remodelling factors, cell cycle regulators, apoptotic factors, structural proteins, members of the general transcriptional machinery and other regulators of gene expression. They are all expected to modify the proliferation/differentiation balance or induce apoptosis.

Short-interfering RNA (siRNA) will be expressed to knock-down expression of some or all of the proteins mentioned above. We expect an alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or their progeny.

Modified forms (including truncations and point mutations) of some or all of the proteins mentioned above will be expressed. They are expected to display a subset of the activities of their wild-type counterparts. However, the possibility of inadvertently generating novel biological activities cannot be excluded. Inducible forms of chosen genes of siRNAs may also be used in the course of the study.

The bacterial Cre recombinase will be expressed in murine cells to specifically excise sequences flanked by loxP sites. Standard selection markers (GFP, antibiotic resistance, lacZ) will allow purification of the transduced cells and won't have any biological actions.

Of the transcription factors mentioned above, SCL is an oncogene. When ectopically expressed in T cells, it contributes to leukaemogenesis. Gfi-1b is a potential...
oncogene, as it was found to be the target of proviral integrations. Mutations in GATA1 have recently been reported in Down's syndrome-related acute megakaryoblastic leukaemia. The other molecules we propose to study have no known transforming or oncogenic properties.

The GFP (and derivatives) and LacZ DNA inserts and the Cre recombinase code for prokaryotic genes that have not been associated with harmful properties in humans. Outside a viral construct, none of this material is active as they lack promoter sequences.

**Evaluation of foreseeable effects**

Although retroviruses and lentiviruses can integrate into the genome of a cell they are generally considered to be of minimal risk to human health and the environment. However in this case a number of the genes being expressed have the potential to be involved in oncogenesis. For this reason it is felt that Containment Level 2 is necessary when working with the infectious viruses to protect human health. Use of sharps will be avoided while working with the viruses.

Infected cell lines pose minimal hazard once the virus has integrated into the host genome as no further viral particles can be produced. Therefore infected cell lines can be handled at Containment Level 1 48 hours post transfection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Historical Significant Changes

Project Additional Information

Purposes of the contained use

The primary aim of the project is to explore the genetic basis of biochemical pathways that determine physiological responses to environmental and innate stimuli. This involves an integrated programme to target candidate genes by adenoviral, lentiviral and retroviral techniques and assess responses to a range of external stimuli including...
**Recipient or parental organism**

E. Coli - The E.coli are K12 or B derivatives e.g. DH5a will be used as cloning hosts to generate plasmid expression clones in readiness for transfection into packaging cell line. These are disabled hosts that cannot colonise the human gut and have a history of safe use.

Retrovirus – The virus carrying the inserts is replication defective and is therefore only capable of one round of infection. The viruses generated will be either ecotropic, amphotropic or pantropic depending on the envelope protein. The packaging cell lines used are second generation where the gag / pol and env genes are provided on separate vectors. The gene of interest is provided on a third vector. The possibility of producing replication competent virus using this system is minimal.

Lentivirus – The virus carrying the inserts is replication defective and is therefore only capable of one round of infection. The necessary genes are carried on four separate plasmids thus minimising the possibility of producing replication competent virus.

Adenovirus – The E1 deleted adenovirus carrying the genes of interest is replication defective and is only capable of one round of infection. CMV – Wild type and various mutants of Cytomegalovirus (CMV) will be used. The deletion of genes is not expected to increase the pathogenicity of the virus.

**Host/vector system**

Packaging cell lines and viral vectors systems - Cell lines are considered to be specially disabled hosts however the packaging cell lines will be used to generate viruses that are replication defective but capable of one round of infection.

Cell lines that have been exposed to infectious virus will still contain infectious viruses for a certain period of time (36 hours post transfection). However post 36 hours the viruses will have integrated their DNA into the host cell and the virus can then be deemed non infectious.

**Origin & function**

Inserts are designed to result in increased or decreased activity of normal mammalian genes. They either code for normal mammalian genes or selective alterations of those genes or for short inhibitory RNAs designed to knockdown expression of the endogenous genes. Standard marker genes to identify or select infected cells will also be used. These genes include mouse and human ligands for immune cells and receptors for immune cells and transcription factors involved in the regulation of immune ligands. Genes deleted from CMV - US2-US11, US6-US11, US2-US3 and pp65. The genes are believed to have a role in immune subversive functions of CMV by interfering with expression of MHC class I and/or MHC class II, rendering the target cell less immunogenic to circulating virus-specific T cells. Marker genes include EGFP and standard drug resistance markers such as those for puromycin. Inserts are not expected to affect pathogenicity of the cloning hosts or normal human defence mechanisms.

**Evaluation of foreseeable effects**

Retroviruses - Work, which involves handling of the infectious virus, such as the transfected packaging cell line or infecting mammalian cells, could pose a risk if there is free virus. Amphotropic retroviruses can infect human cells and integrate into the genome. Although these viruses would not be able to replicate, they might encode for oncogenes or cause oncogenic mutations during their integration. Both risks are small, particularly the latter, though this would increase with the number of infected cells.

However, known oncogenes should not be encoded in amphotropic or pantropic retroviruses capable of infecting human cells, and caution should be exercised with genes of unknown function and others like HIF genes where there are some indications that they could have a synergistic role in tumour progression. Lentivirus - The safety features make the chance of generating a replication competent retrovirus unlikely. However, there is a very small risk, which is difficult to quantify, that we might inadvertently produce an oncogenic inhibitory RNA into human cells by a single infection event. This risk exists because of the unknown function of the genes we would be investigating, and because some inhibitory RNAs have effects on multiple genes. Similar effects might apply to a transgene of unknown function and there is also a small risk that the integration site of the virus could trigger oncogenic potential.

Adenovirus - The viruses cannot replicate outside complementary cells and do not insert their DNA into the host genome. However, known oncogenes should not be encoded in these viruses, and caution should be exercised with genes of unknown function and others like HIF genes wherever there is some indication that they could have a synergistic role in tumour progression. The level of risk is small.

CMV - is a lymphotropic/epitheliotropic beta-herpesvirus that is carried as an asymptomatic life-long infection by the majority of individuals in all communities. Control of CMV infection is attributed to the potent cellular immune response that is detected in healthy immunocompetent virus carriers. CMV causes disease in severely immunocompromised individuals (e.g. end-stage HIV infection, Transplant recipients on immunosuppressant drugs). CMV is also associated with intrauterine infection and foetal developmental defects which may be severe and life threatening to the foetus/neonate. Those associated with the project who are pregnant or may intend to become pregnant should discuss this with the occupational health physician. The deleted genes are believed to have a role in immune subversive functions of CMV by interfering with expression of...
MHC class I and /or MHC class II, rendering the target cell less immunogenic to circulating virus-specific T cells. This property is diminished significantly for the RV798 strain and also in the RV35 and RV47 strains although to a lesser degree. The replacement of these genes with a prokaryotic reporter gene does not appear to alter the host range or pathogenicity of the recombinant virus. The loss of the pp65 gene appears to alter certain phenotypic traits of recombinant CMV (RVAd65) in human fibroblasts. This is manifest in delayed maturation although replication is at similar levels as wild type CMV (Schmolke et al. J Virol. 1995 Oct;69(10):5959-68), suggesting that this gene may be dispensable for growth in vitro. It is possible that these viruses will be more immunogenic and provoke a more vigorous immune response than parent CMV due to the less hindered presentation of a variety of antigens. One possibility to be considered is that an enhanced immune response may also result in greater inflammation at the site of infection. Embryos infected with Retrovirus or Lentivirus may generate transgenic animals, however once the virus has integrated into the host genome it is non-infectious and therefore the risks to humans and the environment are minimal and the work is assigned to Class 1. Ecotropic Retrovirus and Adenovirus work is assigned to Class 1. Cell lines, tissues and animal work is assigned to Class 1 36 hours post transfection. Amphotropic and pantropic Retrovirus, lentivirus and CMV work is assigned to Class 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. Liquids (e.g. samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains. Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
Project Additional Information

Purposes of the contained use

The aim of this project is to identify HIV CTL escape mutations and their impact in viral attenuation. For these purposes we need to express HIV recombinant virus containing specific CTL escape mutations. Escape mutations will be located in different conserved regions of the HIV proteome (Gag, Pol, Env and accessory proteins), depending on CTL responses of the patients. The construction of CTL escapes viral variants and the replication capacity assays will enable us to:

1. Identify epitopes and escape mutations within them that induce viral attenuation.
2. To associate viral attenuation for the CTL escape mutants with a better immune control for the remaining CTL responses.

Recipient or parental organism

E. coli K12 & B derivatives, such as DH5alfa, will be used as cloning host to generate plasmid expression clones. K-12, B strains are disabled hosts that cannot colonise the...
human gut. These E.coli strains are defective in cell wall components relevant to the ability to recognize and adhere to the mucosal surface of colonic cells (Curtiss, 1978), and have a history of safe use. These hosts may be considered equivalent to ADCP hazard group 1.

Packaging cells lines are of human origin, which are well characterised and authenticated and are obtained from commercial sources. They can be regarded as low hazard for GM activities.

Primary cells, such as Peripheral Blood Mononuclear cells (PBMCs), CD4 T cells and CD8 T cell clones from healthy donors will occasionally be used. These can be considered as especially disabled hosts and as such may be considered to be equivalent to ADCP hazard group 1. However Human Primary Cells and cell lines such as HEK293 have the potential to contain adventitious agents and as such must be handled at Containment Level 2 under COSHH.

Host/vector system

Vectors listed are derivatives from pUC non-mobilisable vectors. The inserted genetic material will be cloned into pNL4-3, p83-2 or pJM series vectors.

pNL4-3 - Full-length, replication- and infection-competent chimeric DNA derived from NY5 (5’) and LAV (3’) provirus strains.

p83-2 - Derived from pNL4-3. Contains a 5747 bp fragment with 155 bp of cellular flanking DNA and 5592 bp of DNA from HIV-1NY5 containing the 5’ LTR, complete gag, pol, and vif coding regions, and part of the vpr gene cloned into pDR8 (a derivative of pUC19).

p83-10 - Derived from pNL4-3. Contains a 4002 bp fragment with the LAV vpr (partial), tat, rev, vpu, env, and nef coding regions, 3’ LTR, and 34 bp of cellular DNA cloned into pDR8 (a derivative of pUC19).

p83-10GFP – Derived from p83-10 with Green fluorescent protein (GFP) cloned in frame.

pJM series - Derived from p83-2. Plasmids with specific HIV-1 deletions:
  - pJM11 with a deletion of gag PR,
  - pJM13 with a deletion of gag PR-RT,
  - pJM14 with a deletion in RT
  - pJM31 derived from pNL43 with a deletion in PRRT.

Transfection of plasmids and recombinant constructions derived from pNL43, p83-2 or pJM derivatives plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293 or MT4 producer cell lines containing LTR packaging sequence. Replication-competent virus will be produced after transfection. Therefore, the risk associated is their ability to deliver genetic material into susceptible cell lines genomes only through specific techniques, such as electroporation or lipofectamine transfection and produce fully infectious particles, as described above.

MT4 - Human T cells isolated from a patient with adult T-cell leukemia. HTLV-I-transformed. RT production is negative or sufficiently low to assay for production of RT. Very useful for cytotoxicity inhibition assays for antiviral drugs. OKT4+, OKT4A+, and IL-2 receptor+.

MT2 - Human T-cell leukemia cells isolated from cord blood lymphocytes and co-cultured with cells from patients with adult T-cell leukemia. Transformed with and continuous producer of HTLV-I virions and should be handled accordingly. Line cloned for maximal cytopathic effects with LAV-1 and cured of mycoplasma.

HEK 293 - Primary human embryonic kidney cells transformed by sheared human adenovirus type 5 DNA. Cells grow as a monolayer. These cells express the transforming genes of Ad5, and are particularly well suited for titration of human adenoviruses, as they are susceptible to human adenovirus and highly permissive for adenovirus DNA.

JURKAT - Derived from Jurkat FHCRC. An IL-2 producing cell line, derived by incubating the cells at 41°C for 48 hours followed by a limiting dilution cloning over
macrophages.

JURKAT CypA -/- - cells show decreased HIV-1 replication with the onset of virus exponential growth delayed 4-5 days.

GHOSTX4 - Derived from HOS cells. Stably transduced with MV7neo-T4 retroviral vector, and stably co-transfected with the HIV-2 LTR driving hGFP construct and the CMV IE driving hygromycin-resistance construct. Co-receptor genes were introduced via retroviral infection. Indicator cells for HIV-1, HIV-2, or SIV infection with un-cloned, primary isolates, molecular clones, or pseudotyped virus. The puromycin-resistant cells are pools rather than clones for co-receptor expression.

Peripheral Blood Mononuclear cells (PBMCs), CD4 T cells and CD8 T cell clones from healthy donors will be used occasionally.

Origin & function

DNA or RNA extracted from blood samples from HIV seropositive patients.

Inserted material codes for escape mutations which are located in different conserved regions of the HIV proteome (such as Gag, Pol, Env and accessory proteins), structural viral proteins (eg. p24, p17) or viral enzymes (eg. protease, reverse transcriptase or integrase).

When expressed in E.coli, this is not expected to pose any significant risk, as there will be no protein expression due to the lack of inducer promoters.

Gene transfer is possible, significantly from the transfected producer cell lines, as the resulting production of infectious viral particles will be able to infect human cells. Accidental exposure could lead to the infection of human cells.

Evaluation of foreseeable effects

For E.coli work. No significant hazards have been identified above. The resulting GMO’s are not expected to carry any additional risks compared to the un-modified recipients. The insertion of the foreign sequences is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer as described above is possible, but unlikely to be hazardous. Assignment to provisional containment: Containment level 1 with Good Microbiological Practice and Good Occupational Health and Safety.

For viral work. The production of infectious viral particles from transfected cell lines (eg. MT4, MT2, HEK293) does pose a risk. Transfected plasmids will be integrated into host cell line genomes producing infectious HIV viral particles. The produced HIV CTL escape variants will contain mutations in highly conserved region of the HIV proteome, mainly structural and enzymatic proteins with an important role in the HIV life cycle. It has been described that amino acid changes in conserved regions of the HIV genome produce reduction in the replicative capacity of the mutant virus (Prado et al AIDS 2002). Our previous studies have shown that CTL escape mutants in highly conserved regions of the HIV proteome, such as p24 capsid (a protein that forms the viral core and is essential for the maintenance of the structure of the HIV particle) revert after transmission (Leslie et al Nat med 2004). In vivo reversion from mutant to wild type in the absence of immune pressure can be associated with a fitness cost to the mutant virus. Moreover, we have shown an in vitro fitness cost of the same p24 CTL escape mutants (Martinez-Picado JV 2006).

Thus, based in our previous results our hypothesis is that CTL escape mutations in conserved regions of the viral genome drive HIV variants into a state of viral attenuation. All CTL escape mutants to be tested are naturally occurring mutations in highly conserved proteins and the likelihood of increasing the risk of producing novel HIV particles by inadvertent recombination is low and has not been described in the literature so far. Additionally, HIV is already a highly variable RNA virus.

In conclusion, the resulting GMOs are not expected to pose any additional risks compared to the wild type and may therefore be handled at the same Containment Level. In the event of any adverse results the risk assessment will be reviewed. Assignment to provisional containment: Containment level 3 with Good Microbiological Practice and Good Occupational Health and Safety.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes).

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill: Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N

**Project Additional Information**

**Purposes of the contained use**

1. **HBV:** To study the effects on the cell lines HepG2, Huh7, and HepaRG of (a) the transfection of plasmids expressing different regions of the HBV genome and (b) infection with HBV - the differential expression of various proteins in the cell line will be studied in the absence or presence of inhibitors, using a proteomics approach.

2. **HCV:** To study the morphogenesis and full infectious cycle of hepatitis C virus (HCV) in vitro, in the absence and presence of putative antiviral compounds.

**Recipient or parental organism**

1. **HBV:** The cell line HepG2.2.15, produces infectious HBV viral particles. HepG2.2.15 is a hepatoblastoma cell line (HepG2) transfected with a plasmid carrying the gene that confers resistance to G418, and four 5’ to 3’ tandem copies of the HBV genome positioned in such a way that two dimers of the genomic DNA are 3’ to 3’ with respect to one another. The isolated clone produces high levels of HBV e antigen and HBV surface antigen. HBV DNA is carried by these cells as chromosomally integrated sequences and episomally as relaxed circular, covalently closed DNA (cccDNA) and incomplete copies of the HBV genome.

2. **HCV:** Subgenomic replicons of the JFH1 genotype 2a strain cloned from an individual with fulminant HCV hepatitis replicate efficiently in cell culture. Huh 7.5.1 cells will be used to express wild type or modified infectious HCV viral particles derived from the pJFH1 plasmid.

**Host/vector system**

1. **HBV:** Host = HepG2.2.15 is a hepatoblastoma cell line (HepG2). Vector = The basic plasmid for use in the HBV studies is the 2XHBV plasmid. This plasmid contains two head to tail copies of HBV full-length DNA (sub-type adw) ligated into the pGEM3Z plasmid vector. Further we would use the 1.3X HBV DNA construct containing an over-length HBV genome of 4.2Kb. The individual genes encoding core, surface, polymerase, and the X protein will be subcloned into vectors for transfection studies.
2. HCV: Host = Huh 7.5.1 is a human hepatoma cell line. Vector = plasmids based upon pJFH1, a plasmid containing full length JFH1 cDNA

Origin & function

Gfp is a harmless fluorescing protein expressed in the jellyfish Aquoria victoria and is widely used as a reporter gene

Luciferase is a harmless enzyme that breaks down luciferin to produce visible light expressed by the firefly Photinus pyralis and is widely used as a reporter gene

HA tag is a widely used epitope tag derived from the influenza haemagglutinin gene for use in antibody studies

All other constructs will be modifications (mutations, deletions, over- or under-expression) to HBV or HCV genes not involved in pathogenesis.

Evaluation of foreseeable effects

HBV: Infectious HBV particles will be expressed in HepG2.2.15 (Human hepatoblastoma) cells. Modifications to the HBV construct will include expression of reporter genes such as luciferase, structural genes, such as core and surface proteins, and polymerase. None of these modifications are expected to increase pathogenicity or to alter tropism.

HCV: Infectious HCV particles will be expressed in Huh 7.5.1 (Human hepatoma) cells. Recombinants of the HCV include expression of marker genes such as gfp and luciferase, mutation of the GDD motif (abolishes RNA polymerase activity), overexpression and knockout of structural viral genes such as those coding for glycoproteins E1 and E2, NS5B, and expression of siRNA specific for inhibition of HBV and HCV viral genes. None of these modifications are expected to increase pathogenicity or to alter tropism.

Purposes of the contained use

The aim of this research is to determine the steps at which specific gene products influence metastasis. Our lab has established a series of steps for both pulmonary and liver metastasis including arrest in the organ, survival, proliferation and vascular remodelling. We now seek to understand how the tumour cells effect these functions in mouse models for metastasis by modifying the gene expression of tumour cells in tissue culture with adenoviral vectors and then injecting the tumour cells into mice to note how the altered expression impacts on metastasis. We will alter the expression of genes affecting survival, angiogenesis, and some proteases that we have previously shown to alter metastatic behaviour by tumour cells. We will also use adenoviral vectors to label tumour cells in order to track them in mice.

Recipient or parental organism

HEK 293 - Human embryonic Kidney cell line used for generating replication defective adenovirus

Human, rat or murine tumour or normal cells - infecting with Adenovirus

Cell lines can be considered as disabled hosts due to their strict environmental and nutritional requirements. Furthermore they are unable to colonise the lab worker due to host-cell line histocompatibility differences that would lead to rejection by the host's immune system.

Host/vector system

Replication defective adenovirus expressing reporter genes, mammalian genes and shRNA. Adenovirus 5 with deleted E1 and E3 genes is unable to replicate except within cells which provide the missing E1 and E3 genes, such as HEK 293 cells. The harvest of the Adenovirus from the replicative competent cells (HEK293) and its subsequent use in the infection of cells is the main point at which a risk might arise as this is the time when the largest titres are obtained and when an accident might have the greatest risk to a lab worker. This single point of infection posing a hazard puts some of the work into Containment Class 2 due to the possible tumour enhancing nature of some of the inserts. After this point no further infection can occur and no additional hazard is expected. Once the cell lines are infected they cannot support adenoviral replication and hence become minimal risk.

Origin & function

Reporter Genes

- Green fluorescent protein is a naturally fluorescent protein from the jellyfish, several variants of the natural gene have been produced that encode a protein with modified adsorption/emission characteristics and which have been optimised for higher level expression or better fluorescent properties for imaging, e.g. the "EGFP" or fluorescent properties such as mPlum or mCherry. FPs are widely used and no hazardous properties have been reported.

- Luciferase from firefly and sea pansy are widely used as reporter genes are not considered to have harmful properties.

Mammalian expression

Genes that are part of the inherent apoptosis pathways in cells such as DR4, DR5, caspas 3,8,9,10, FADD, GLIP,Bcls etc. The augmentation or elimination of expression of these genes in a tumour cell can enhance (or retard) their growth rate when transplanted into a murine host. They can lead to more metastatic tumours. These vectors will be handled under containment level 2 conditions.

Genes that affect angiogenesis such as ang 1 or 2, VEGF, Tiel or Tie2, VEGFR, TF, or HIF1a or b, for example. These genes in themselves are not oncogenic, but when expressed in tumour cells can lead to tumours with a more rapid growth rate.
Genes for protease expression especially of the matrix metalloproteinase family. Overexpression of some genes in this family in tumour cells can lead to more rapid tumour growth or more metastatic tumours.

Genes for the expression of tissue factor, an endogenous molecule involved in clotting initiation and angiogenesis. Overexpression of this gene product due to infection of the adenovirus in a host would be unlikely to be at sufficient high levels to result in any clotting disorders since this is widely expressed throughout the body. Expression in a tumour cell that lacked this gene might alter its ability to metastasize. Other consequences would not be apparent from the literature.

Induction of short hairpin RNAs to specifically downregulate gene expression of genes with homologous sequences. Unexpected effects often appear to be due to homology with microRNAs and hence in recent design of these vectors this lack of specificity is being eliminated by screening for this type of homology. There are some instances in which RNAi lacks specificity in that interferon may be induced, but there is no recognized hazard here.

All the above types of manipulations have been widely used and are not known to have resulted in any harmful effects. However expression of some of these genes while not oncogenic in themselves have been noted to alter tumour growth parameters. Antiapoptotic gene expression can enhance tumour growth and progression. HIF1 overexpression has been shown to lead to more rapid tumour growth. Overexpression of VEGF or ang2 can have a similar effect. Overexpression of some proteases can enhance metastasis and hence any vectors in this category will also be used under containment level 2 conditions.

Evaluation of foreseeable effects

The Adenovirus used has been disabled by deletion of the E1 and E3 genes and cannot replicate unless the E1 and E3 genes are provided in trans (as in the HEK293 cells). Therefore the possibility of the virus disseminating within the environment is minimal. However as with all viral delivery systems there is a single round of infectivity with viruses generated from HEK293 cells. Although none of the genes to be expressed are oncogenic by themselves, a number of them are involved in the apoptosis pathway and expression may affect growth and metastasis of the tumours. For this reason the genes listed in the appendix will be handled at Containment level 2.

**Project Additional Information**

**Purposes of the contained use**

Salmonella enterica serovar Typhimurium strains in which genes involved in the flagellar export apparatus have been mutated or deleted.

**Recipient or parental organism**

Salmonella enterica serovar Typhimurium strains are Hazard Group 2 bacteria, which can cause acute gastroenteritis and infect many mammalian species. Salmonella enterica serovar Typhimurium can only cause harm to animals in large doses (10^6 or higher). The control measures necessary to protect humans are adequate to protect the environment.

**Host/vector system**

**Origin & function**

flh, fli, and flg operon regions of Salmonella enterica serovar Typhimurium are involved in the flagellar export apparatus system.

**Evaluation of foreseeable effects**

The mutations will adversely affect the assembly of the flagellum, which should lead to a decreased or absent motility. Motility is not essential for virulence but it does enhance pathogenicity. Therefore it is expected that the mutants will have reduced pathogenicity compared to the wild type. As flagellin is an activator of the innate immune response it is possible that the mutant strains will be less immunogenic, however there are a number of other bacterial products that can activate the innate immune response. Therefore the mutant strains are not expected to be more hazardous than the wild type strains. Master flagellar regulator genes flhDC will be overexpressed from an inducible plasmid which should lead to the overexpression of the flagellar IM domain. In mutant strains lacking flgB this will lead to non-motile
strains with flagellar IM domain at enriched levels

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Purposes of the contained use

The overall aim is to functionally characterise known and candidate tumour growth control genes using viral transfection systems.

### Recipient or parental organism

- **E.Coli K12 and B derivatives (disabled)**: will be used to generate the plasmids and the genes are unlikely to be expressed due to the presence of a mammalian promoter sequence.
- **Yeasts (s.cerevisiae, S.pombe, S.pastoris) and BL21**: in these non-pathogenic systems soluble proteins will be expressed.
- **Mammalian cell lines**: for protein expression and analysis
- **Insert cell lines (Sf21, SF9, D-Mel2)**
- **Packaging cell lines such as Phoenix 293T**: provide additional viral sequences necessary to generate replication deficient pseudoviruses.

### Host/vector system

- A variety of modern multi-vectored (9ie3 plasmid or 4 plasmid) systems will be used. These systems all feature split components to ensure there is no generation of replication competent virus.
- **Murine Stem cell based vectors**: high level expression in embryonic stem cells.
- **pRev TRE based vectors**: gene expression can be controlled by various concentrations of tetracycline or derivatives such as doxycycline.
- **pSUPER RNAi vectors**: expression of synthetic short RNAs can lead to specific suppression of gene expression.
Cancer promoting and cancer suppression (that antagonise tumour promoting genes) genes such as IGF2r, IGF2, IGFbps, Pten, PDK, Akt, MTOR, Raptor, Grb2,IRS1, Pat and amino acid transporters, IGFr, Hub genes, Foxo transcription factors, Akt phosphorylation substrates.

Selected modifications of any or all of the above.
Reporter genes such as lac Z, GFP etc

siRNA - validation of target and off target effects will be sought in transient systems using PCR and Western blots prior to using stable expression systems.

Origin & function

The pseudo-retroviruses are replication deficient by the nature of their design and as such cannot spread from one cell to another. However they are capable of one round of infection of mammalian cells, including human and insertion of the viral DNA into the host genome. There is a potential for adverse effects due to insertional mutagensis however this is expected to be minimal.

The genes to be analysed do not one their own initial cancer as a result of mutation or abnormal expression. However they can significantly promote or inhibit phenotypic consequences of cancer initiating genes (oncogenes or loss tumour suppressor genes).

Cell lines and primary cells (other than packaging cells) which have been exposed to the psudovirus pose a minimal risk once the virus has integrated into the genome due to its inability to replicate.

Evaluation of foreseeable effects

The pseudo-retroviruses are replication deficient by the nature of their design and as such cannot spread from one cell to another. However they are capable of one round of infection of mammalian cells, including human and insertion of the viral DNA into the host genome. There is a potential for adverse effects due to insertional mutagensis however this is expected to be minimal.

The genes to be analysed do not one their own initial cancer as a result of mutation or abnormal expression. However they can significantly promote or inhibit phenotypic consequences of cancer initiating genes (oncogenes or loss tumour suppressor genes).

Cell lines and primary cells (other than packaging cells) which have been exposed to the psudovirus pose a minimal risk once the virus has integrated into the genome due to its inability to replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Generation of germline genetic manipulations will be done by collaborators at their institutions.

There is minimal risk from the transgenics as the replication deficient virus will be integrated into the genome.

Therefore animal containment level 1

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Withdrawn N
Tick if notifying a connected programme of work N

**Historical Significant Changes**
The overall aim of the project is to identify and characterise the molecules and processes controlling the safe-renewal, lineage commitment and differentiation of haematopoietic stem and progenitor cells. Regulatory genes, such as transcription factors. Growth factors, cytokine receptors and signalling molecules will be delivered to human and murine blood cells by using retroviruses and the effects on the survival, growth and differentiation of the recipient cells will be monitored. The genes may be either wild-type or in the form of the point mutants or chimeric factors generated by chromosomal translocations associated with human leukaemias, or selectively altered variants of any/all of these genes designed to modify and dissect their function.

Recipient or parental organism

E.coli K12 and B derivatives (disabled) - will be used to generate plasmids containing reporter genes, antibiotic resistance genes, regulatory genes of interest and certain retroviral genes.

293FT (human embryonic kidney cell line 293F constitutively expressing SV40 T antigen from pUC based plasmid pCMVSPORT6TAg.neo) and 293T (similar to 293F, T antigen increases viral particle yield). - used to generate pseudovirus.

GP+envAm12 (murine cell line NIH3T3 + one plasmid containing the Moloney murine leukaemia virus gag and pol genes and as second plasmid containing the 4070A amphotropic env gene)

Human cell lines (such as established human leukaemic cell lines, eg, MALM-6, KG1, HL-60, U937)

Murine cell lines (multipotential haematopoietic cell lines)

primary human cell cultures (from screened samples) and primary murine haematopoietic cell cultures

FACS sorted human and murine cells in culture. Cells may also be transplanted to recipient wild type and transgenic mice (transgenics covered by a separate risk assessment).

Host/vector system

The ViraPower Lentiviral Expression System (Invitrogen) generates recombinant, replication-defective lentivirus.

293FT cells transiently transfected with an expression vector (pLenti6/V5) containing the gene of interest under the control of the human CMV immediate/early enhancer/promoter and elements that allow packaging of the construct into virions. A mixture of three packaging plasmids (pL,P1, pLP2 and pLP/VSV-G) are co-transfected to supply the helper functions as well as the structural and replication proteins in trans required to produce the replication-incompetent lentiviral particle.

VSV - g/lentiviral expression system. Will be used for the expression of transcription factors PU.1, HoxB4 and GATA-1. Similar to that described above, it also incorporates a number of safety features. There is SIN factor in the vector and it utilises three plasmids rather than a four plasmid system: (1) A lentiviral vector with viral genes deleted containing the Spleen Focus Forming Virus promoter driving expression of the gene of interest. (2) A lentiviral packaging plasmid encoding gag/pol, tat, rev and HIV-1 rev-response element (RRE), with virulence genes vif,vpr, vpu and nef deleted. (3) An envelope plasmid expressing only the VSV-G gene from Vesicular Stomatitis virus. The three plasmids are co-transfected into human 293T cells to produce the replication-incompetent lentiviral particles.

Amphotropic murine retroviral vectors. Derived from the Murine Moloney Leukaemia Virus (eg p50-M-X-neo) and Murine Stem Cell Virus (eg MSCV-ires-GFP), recombinant murine retroviral vectors carrying the gene of interest will be transfected into murine GP+envAm12 packaging cell line to produce replication-defective
amphototropic retroviral particles.

For retroviral expression systems above, the resulting disabled particles are able to infect most mammalian cells including human, mouse and rat.

**Origin & function**

Mice and human genomic DNA and cDNA inserts, wild-type and mutated (see below, section 2 in appendix for details):

Wild Type transcription factors, such as GATA family, Pu.1, HoxB4

These factors exert their function within the nucleus and are expected to alter the balance between self-renewal and lineage differentiation in stem and progenitor cells.

Other regulatory molecules, such as components of the notch pathway, adaptor proteins (e.g. LNK), cyrokinw receptors and growth factors.

Acting primary outside the nucleus, modulation of the expression of these factors is expected to result in a transcriptional response within the nucleus and to alter the balance between self-renewal and lineage differentiation in stem and progenitor cells.

LNK has been shown to be involved in several intracellular signalling pathways that all regulate the survival and proliferation of hematopoietic cells.

Members of the Notch family may be involved in mediating cell-fate decisions during hematopoiesis.

Other candidate regulatory molecules from differential expression analysis, expected to function in a similar manner to the genes described above.

Known products of chromosomal translocations, their normal counterparts, or mutated versions with deletions, insertions and/or point mutations. These genes will include, but not necessarily be limited to, TEL~AML1, JAK2 and FLT3-1TD. These are suspected oncogenes by virtue of their expression as a result of specific translocations associated with different forms of human leukaemia or point mutations resulting in constitutively activated signalling pathways.

Selective modifications of any/all of the above.

Standard reporter genes: such as neomycin resistance (neoR), beta-galactosidase (lacZ), jellyfish green fluorescent protein (GFP and derivatives), and nerve growth factor (NGF)

**Evaluation of foreseeable effects**

The psuedo-retroviruses are replication deficient by the nature of their design and as such cannot spread from one cell to another. However they are capable of one round of infection of mammalian cells, including human, and insertion of the DNA into the cell genome. There is the potential for adverse effects due to insertional mutagenesis however this is expected to be minimal.

The majority of the genes to be analysed are likely to affect self renewal and lineage differentiation and as such are likely to affect survival and proliferation of cells. Other genes are suspected oncogenes. The potential for harm due to accidental exposure is therefore greater than a psuedo-retrovirus expressing a reporter gene.

Cell lines and primary cells (other than HEK 293 and GP+ env AM 12) which have been exposed to the psuedovirus pose a minimal risk once the virus has integrated into the genome due to its inability to replicate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15
minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquid to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg sample, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalps) - dispose via clinical waste stream for incineration.

Animal bedding - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
Use of viral vectors and lentiviruses to study growth control of cells in tissue culture.

purposes of the contained use

The use of amphotropic retrovirus, lentivirus and adenovirus vectors to help study the functions of cellular and viral genes that affect the regulation of cell proliferation and cell survival.

Recipient or parental organism

E. coli - disabled hosts such as HB101, DH1, DH 5, JM101 and derivatives cannot colonise the human gut and have a history of safe use.

Mammalian cells - these are considered to be especially disabled hosts as they have specific nutritional requirements and the immune system should recognise the cells as foreign.

Packaging cell lines- Variants of HEK cells lines and other well characterised cell lines complement the missing genes to enable the viruses to be effectively packaged. Prior to transfection these cell can be considered to be especially disabled hosts, however once transfected they will be handled according to classification of the virus package.

host/vector system

Retrovirus (amphotropic) - replication defective but can infect and integrate into the genome.

Lentivirus - a variety of different systems may be used to generate the replication defective virus. Some contain the SIN function otheres contain the WPRE function. These viruses can infect and integrate into the human genome but are unable to replicate.

Adenovirus - E1 or E2 / E3 deletion. These viruses can infect cells but they do not integrate into the genome and they cannot replicate.
**Origin & function**

cellualle and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis.
cellualle and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis.
siRNAs directed against cellualle and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis.
siRNAs directed against cellualle and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis.

Only single growth-promoting (for example ras, myc, or E1A) and anti-apoptotic genes (such as mdm2, iASPP, mutant p53) will be transduced in this programme of work. The work will not include viral oncogenes which have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of genes such as HPV16 E6-E7. Expression of siRNA limited to a single siRNA directed against this class of genes, or the expression of multiple siRNAs which affect the same regulatory pathway.

Ecotropic virus receptor enables entry of ecotropic viruses into cells expressing this receptor.

Also included are standard reporter genes such as GFP, luciferase and B-gal, and standard antibiotic selection genes.

The Cre and Cre recombinase gene may also be used for control of expression of the gene of interest (eg switching genes on and off).

**Evaluation of foreseeable effects**

The inserts to be used are involved in cell cycling and as such many act as oncogenes or tumour suppressor genes. Viruses provide an efficient means of transducing cells. In particular both amphotropic retroviruses and lentiviruses can integrate into the genome of infected cells. There is therefore the potential, should accidental exposure occur, to affect cell cycling (either to suppress or to proliferate) of infected cells. However as cancer is a multi step process and only individual oncogenes will be integrated the likelihood of adverse effects is low, especially when considering the exposure titre and the likelihood of stem cells being transduced.

Also included in this work is the transfection of human cell lines with a virus containing the ecotropic virus receptor. Should accidental exposure with this virus occur it would render those cells infected susceptible the infection by ecotropic viruses which cannot normally enter a cell.

Project Ref 553/07.4

Date Ackn'd  05/07/2007
CU2 Project Title Use of Chimeric HIV for assessment of candidate vaccine efficiency in mice.

Class 2
CultureVolClass2 < 1 Litre
Consent Granted Not Applicable

Project notified under transitional arrangements  N

Tick if notifying a connected programme of work  N

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

In chimeric HIV-1 the gp120 envelope is substituted with pg80 envelope of ecotropic murine leukaemia virus (MLV), therefore allowing chimeric HIVs to infect mouse cells through the cationic amino acid transporter, the MLV receptor. They do not enter/replicate in human cells. Their replication in mice overtime declines to zero. Thus, chimeric HIVs can serve as a challenge for mice immunized with candidate vaccines, which employ non-env HIV-1-derived genes as a source of immunogens.

**Recipient or parental organism**

HIV-1 with gp120 envelope gene deleted. A number of different HIV-1 clades will be used including B and D termed EcoHIV and EcoNDK respectively.

**Host/vector system**

HEK 293T cell line – used as a producer cell line for generating the chimeric viruses
E. coli – used for constructing the pseudoviruses and producing DNA

**Origin & function**

gp80 envelope gene from murine leukaemia virus - Envelope gp80 of ecotropic murine leukaemia virus facilitates entry of the chimeric HIV viruses into mouse cells expressing the cationic amino acid transporter, the MLV receptor.

**Evaluation of foreseeable effects**

HIV is a hazard group 3 virus for which the eventual prognosis following infection is generally fatal. The replacement of HIV-1 gp120 envelope with the envelope gene from murine leukaemia virus creates a chimeric viruses, such as EcoHIV-1 and EcoNDK, which can no longer enter human cells. Instead the chimeric virus can only gain entry into murine cells. The chimeric virus has been shown not to replicate in human lymphocytes in culture (ref A mouse model for study of systemic HIV-1 infection, antiviral immune responses and neuroinvasiveness. Potash et al. PNAS 2005; 102:3760-3766).

However as we are creating a novel animal virus with only one recombination step required to generate the parental organism which would be pathogenic to humans we believe Containment Level 2 to be appropriate for this work.

The likelihood of recombination is minimised by control measures both within the lab and within the cells being used.

Recombination in E.coli is unlikely as a) HIV-1 does not naturally infect E.coli, b) other constructs used within the laboratory only contain partial env genes and there are no
regions of homology between the sequences flanking partial env and the chimeric molecular clones.

Recombination in human 293 cells is unlikely because c) HIV-1 does not infect 293 cells; d) only partial HIV-1 env genes are used in the laboratory.

Recombination in the mouse is unlikely because e) HIV-1 does not infect mice efficiently if at all; f) there will be no HIV-1 present in Animal Facility, unless the personnel were infected with HIV-1, which would cause greater risk of HIV-1 infection itself than theoretical recombination; g) the EcoHIV and wt HIV would have to infect the same cells in the mouse body for a recombination to occur.

Recombination in humans accidentally exposed to EcoHIV h) EcoHIV does not replicate in human cells; and i) if the wt HIV-1 were present in humans, it would cause the disease without the need for recombination.

Possibility of cross-contamination of EcoHIV with wt HIV-1.
EcoHIV stocks will be grown exclusively in LEVEL-2 laboratory, in a dedicated incubator, in which the risk of accidental exposure to HIV-1 is zero. Purified plasmid DNA will be transfected into 293 cells. Contaminating wt HIV-1 does not infect 293 cells and thus would not be amplified. Theoretically, plasmid EcoHIV DNA might also be contaminated by plasmid carrying a molecular clone of wt HIV-1, but the likelihood is very small and even if this happened, the EcoHIV virus stock will only be used for injections into mice in which wt HIV-1 cannot replicate.

Therefore the greatest risk is due to the unknown nature of creating a novel animal virus, however research has been carried out in the USA with this virus with no unexpected side effects.

Historical Significant Changes

02/03/2022
The aim of the project is to develop aptamers (synthetic nucleic acid ligands) that are able to neutralize HSV-2 infection. The addition of reporter genes to the virus will enable accurate quantitative analyses of the virus neutralisation activity of the aptamers.

Herpes Simplex Virus type 2 (HSV-2)

Virus will be constructed by collaborators outside of the University.

Standard Reporter genes such as fluorescent proteins, β-galactosidase (Lac Z) and luciferase

HSV-2 is a human pathogen transmitted by sexual contact and is assigned to Hazard Group 2 by ADCP. Infections are asymptomatic in the majority of cases but can cause life threatening complications in immuno-compromised hosts.

The standard reporter genes are all well established and in common use. No known detrimental effects have been observed through their use.

Therefore the addition of reporter genes are expected to have no effect on HSV-2, which will remain in the same classification as the wild type organism.

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15
minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

</table>
The use of self-inactivating, replication Incompetent lentivirus based expression vectors to generate stable cell lines expressing T-cell receptor signalling components or protein arginine methyltransferases (PRMT5) (wild type and null mutants that abolish methylation activity), and reporter gene as part of a bi-cistronic RNA. Future plans include the stable inactivation of these genes using lentiviruses expressing small interfering RNA (siRNA) and short hairpin RNA (ShRNA).

Replication defective Lentivirus — The lentiviral systems to be used are replication defective and self-inactivating. The number of genes used from HIV-1 has been reduced to either three or four (gag, pol, rev and tat). The env gene is VSV, which allows for amphotrophic infection. Genes have been separated on to three or four plasmids, which have minimal regions of homology, minimising the likelihood of recombination events. The main risk from these vectors is the possibility of gene knockout upon integration into the genome.

The viruses pose no environmental danger. They are unstable, inactivated by detergent, UV light and ethanol and would not survive outside the laboratory environment Mammalian cell lines — are especially disabled hosts and once the virus has integrated in the host genome pose minimal risk. The infected cells will be recognised as non-self by the immune system and rapidly lysed by the complement and therefore are unlikely to be pathogenic. Cells are unable to survive outside tissue culture conditions and therefore pose no risk to the environment Primary lymphoid cells (human) — are especially disabled hosts and once the virus has integrated in the host genome pose minimal risk. However, they may harbour adventitious agents and as such will be handled at Containment Level 2 under COSHH.

Host/vector system
Packaging cell lines, such as 293T and Lentiviral vector systems
Packaging cell lines when transfected with vectors containing the genes of interest produce infectious viral particles, however these particles are only capable of one round of infection, as they do not contain the relevant viral genes necessary for replication. The viral particles are therefore replication defective. As separate entities the packaging cell lines and the vectors pose no hazard to human health or the environment. The WPRE sequence is present in some of the vectors and in line with guidance Containment Level 2 will be used.

Origin & function
Inserts code for mammalian proteins implicated in specialised lymphocyte antigen receptor activation pathway. Examples include TCR signalling adapters (human SLP-76,
LAT, ADAP), protein tyrosine kinase (Lck), protein arginine methyltransferases (PRMT 1-8). Mice lacking expression of SLP-76 or LAT do not develop T cells. Mice lacking expression of ADAP develop T cells which are defective in adhesion pathways. Lck controls the activity of SLP-76, LAT and ADAP and mice lacking expression do not develop T cells. Mice lacking PRMT1 and PRMT 4 cause embryonic and perinatal lethality respectively.

Inserts code for siRNA and shRNA to knock out expression of the genes of interest mentioned above.

Standard reporter genes — such as, eGFP, Luciferase, B-galactosidase.

These are regularly used reporter genes that have a history of safe use.

Standard antibiotic resistance genes — such as, neomycin, hygromycin, puromycin and ampicillin.

**Evaluation of foreseeable effects**

The viral vectors are capable of one round of infection but are unable to replicate. Therefore, in the unlikely event of exposure there is the potential for the virus to integrate into the host genome at a point where they disrupt the function of a gene. As the vectors are self-inactivating they are unlikely to activate gene transcription at the site of integration.

The genes to be expressed are not expected to be toxic or oncogenic, however as they are involved in survival, proliferation, differentiation and death signalling pathways a cautious approach is being taken.

Inactivation of these genes using silshRNA is also not expected to be toxic or oncogenic, however as above a cautious approach is being taken.

### Project Ref  553/08.1

**Date Ackn’d**: 22/01/2008  
**CU2 Project Title**: Immortalisation of human and mouse cells using an Adenoviral-expressed temperature-sensitive SV40 mutant.  
**Class**: Class 2  
**Culture Volume Class 2**: < 1 Litre  
**Non-GMM Consent Granted**: Not Applicable  
**Withdrawn**: N  
**Project notified under transitional arrangements**: N  

---

### Purposes of the contained use

Replication defective (Ei or EiIE3 deleted) adenovirus will be used to deliver a temperature sensitive mutant of the A gene of SV40.
### Recipient or parental organism

Primary mammalian cells from various tissues. Mammalian cells are considered to be especially disabled hosts and unlikely to survive within the environment.

### Host/vector system

Replication defective adenovirus 5 cause transient transfections of human cells. They are unable to disseminate within the environment.

### Origin & function

Temperature sensitive mutant of the A gene from the 3V40 virus. The normal A gene from SV4O is involved in the viruses ability to transform cells. The temperature sensitive version conditionally transforms cells growing at 33°C. At 37°C the cells differentiate.

### Evaluation of foreseeable effects

The adenovirus is replication defective and therefore cannot disseminate, however the initial virus is capable of a single round of infection. Although at 37°C the insert has a much decreased ability to transform cells a precautionary approach is being taken due to the fluctuating temperatures within the airways (the natural infection route for adenovirus).

**Project Ref 553/08.2**

- **Date Ackn’d**: 28/04/2008
- **CU2 Project Title**: Genetic modification of human embryonic stem cells and primary blood-derived leukocytes using retroviral and lentiviral vectors to study macrophage function and HIV infection.
- **Class CultureVolClass2 CultureVolumeClass3-4**: Class 2 < 1 Litre
- **Non-GMM Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

**Project Additional Information**

- **Purposes of the contained use**: The aim of this project is to use replication defective retrovirus and lentivirus to deliver genes, or selected mutants of those genes, or to knock down genes, which are implicated in the entry and exit pathways of HIV-1.
Viral packaging cell lines, such as HEK293, will be used for the production of virus capable of infecting human cells but incapable of replicating. Mammalian cells, such as primary human embryonic stem cells and blood derived macrophages.

**Host/vector system**

- Constitutive expression of the transgene-of-interest using Self-Inactivating lentivirus (pi-IR-SIN) vectors, including LentiLox
- Tetracycline-responsive, titratable control of expression of the transgene, using a commercially available retrovirus (Murine Moloney Leukaemia Virus)-based system (Clontech 632104);
- Inducible individual gene-knockdown, using a commercially-available retroviral (MLV), Tet-inducible RNAi system (Clontech 630926);
- Library gene-knockdown, using commercially available lentiviral shRNA libraries (Sigma MISSION RNAi)

**Origin & function**

The genes to be studied are primarily those involved in the entry and exit pathways of HIV-1 in monocytes and macrophages, such as:
- Receptors CD4, CCR5, CXCR4,
- Restriction factors, including APOBECs, especially APOBEC3G,
- Cytoskeletal transport, including Actin-GFP, Tubulin-GFP, motor proteins, which are implicated in HIV transport into the cell,
- Proteins involved in the budding/retention of the virus in intracellular vesicles, including tetraspanins CD9, CD81, CD53 and tetherin (CD317),
- Defined mutants of the above.
- shRNAs to downregulate expression of these genes individually or in groups.
- Possible future work may include a genome-wide shRNA screen.
- standard reporter genes (e.g. GFP, Luciferase, 6-galactosidase)
- standard antibiotic resistance genes (e.g. Neomycin, Hygromycin, Puromycin and ampicillin).

**Evaluation of foreseeable effects**

All the retroviruses and lentiviruses used in this project are replication defective due to the deletion of numerous genes and essential genes being separated on to plasmids with minimal homology. Therefore the viruses are capable of a single round of infection and integration into the genome but they are unable to replicate and disseminate within the environment.

Inserts code for mammalian proteins implicated in HIV entry/transport/exit. The proteins products of the genes to be studied are not expected to be toxic or cancer inducing in any way. However, the HIV receptors are also receptors for chemokines and as such the genes could modulate immune function, especially chemotaxis, in target cells. This could provide a growth/invasion advantage to cells.

ShRNA against mammalian proteins implicated in HIV entry/transport/exit. Initially, the shRNAs to be used are not targeting known tumour suppressors. However, there is potential for off-target effects with shRNAs, which could potentially have tumour-suppressive effects. This will be minimised by designing shRNAs with as little sequence homology as possible to off-target genes, including BLAST searches against genome databases.

In the immediate future our experiments will target individual genes. It is possible however that we may later want to perform a genome-wide screen using shRNA technology with our hES-derived macrophage system. In this case the risk of the shRNAs will be greater, as shRNAs against all possible genes would be employed, and may include unknown tumour suppressors.

Gene transfer is possible, significantly from the transfected producer cell lines, as the resulting Lentivirus/Retrovirus will be able to infect a wide range of cells, including human cells, as the VSV-G envelope enables amphotropic infection. However dissemination in the environment is limited due to the viruses being replication defective. Gene transfer from the individual packaging and expression plasmids is unlikely because they are based on the pUC series of plasmids and can be described as non-mobilisable.

Most of the genetic inserts are not likely to cause significant effect on an individual. However the WPRE represents a potential oncogenic risk, and some of the
genes-of-interest may modulate immune function. It is theoretically possible for these Lentiviruses to integrate into the genome of an individual on exposure. As they are self- inactivating they are not capable of activating gene transcription from the inactivated viral LTR. However they could in theory disrupt the function of a gene at the site of insertion. The worst-case scenarios could be 1) the WPRE exerting an oncogenic effect; or 2) the chance integration of the virus into a tumour suppressor, thus disrupting that gene’s function; or in the long-term 3) the potential interruption/knock down of a tumour suppressor gene. Even so this single event is unlikely to cause any tumour formation and so the overall risk is still considered low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by the ACGM.
The aim of this project is to generate single-cycle Env-pseudotyped virus expressing the envelope protein from clinical and laboratory-adapted HIV in order to answer questions concerning the interplay between the Env protein and target cell components at a clonal level. Resultant virus will be used in neutralisation (antibody) and viral inhibitory assays (e.g. gp41 inhibitory peptides).

Initial transfection of 293T cells and resultant pseudovirus will then be used to transduce human cell lines expressing CD4, CCR5 and/or CXCR4, such as PBMC5, U87.CD4.CCR5, U87.CD4.CXCR4, TZM-bl cells.
## Host/vector system

- **pNL4-3.Luc.R-E-** (developed by Dr Nathaniel Landau, Aaron Diamond AIDS research Center NY, USA) and pSG3deltaEnv backbone plasmid (available through the NIH AIDS Research & Reference Reagent Program) and mammalian expression plasmids encoding HIV Env (e.g. the Standard Reference Panel of Subtype B HIV-1 Env Clones available through the NIH AIDS Research & Reference Reagent Program).

## Origin & function

HIV-1 env insert is derived from primary and patient isolates. It encode the envelope protein of HIV-1.

- **pNL4-3.Luc.R-E-** Backbone plasmids encode full-length HIV virus with mutations in the env gene (e.g. insertion mutations, frameshift mutations, and/or stop codon mutations) that prevent viral progeny from producing and expressing Env protein. Additional HIV genes have been disabled in backbone plasmids (e.g. vpr and nef in pNL4-3.Luc.R-E-).

- **pSG3deltaEnv** - Backbone plasmids encode full-length HIV virus with mutations in the env gene (e.g. insertion mutations, frameshift mutations, and/or stop codon mutations) that prevent viral progeny from producing and expressing Env protein. Additional HIV genes have been disabled in backbone plasmids (e.g. vpu in pSG3deltaenv).

## Evaluation of foreseeable effects

The purpose of the modification is to produce HIV virus capable of mimicking the natural interactions under investigation but incapable of replication and therefore representing a significantly reduced hazard. The retrovirus (HIV-1) from which the backbone constructs were derived can cause disease in humans. However the design of these plasmids prevents production of infectious, replication-competent virions. Co-transfection with the env-carrying plasmid allows rescue of infectious virus for env in the viral RNA and as such are only capable of a single round of replication, as no infectious viral progeny will be produced.

Reporter genes (such as luciferase) are well characterised with no known associated health hazards.

02/03/2022
The researchers propose to use replication defective lentivirus delivered transgenes (cDNA) to overexpress genes or short-hairpin RNA (shRNA) to knockdown expression of genes involved in cardiac energetics both in vitro and in vivo.

E. coli K12 or B derivatives will be used as bacterial cloning hosts (e.g. DH5a, XL-10, JM-109) to generate plasmids. These are disabled hosts, they cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ACDP hazard group 1.

Established cell lines (e.g. HL-1 mouse atrium, 3T3 fibroblasts, C2C12 myoblasts) have a history of safe use and can be considered as disabled hosts and therefore may be considered to be equivalent to ACDP hazard group 1.

Primary mouse and rat cells (e.g. cardiomyocytes, skeletal myocytes) will used as target cells for viral transduction and will be obtained from rats and mice that are bred in a specific pathogen free unit or from approved commercial sources (e.g. Harlan). None of these cells are deemed high risk for blood borne pathogens. These hosts may be considered equivalent to ACDP hazard group 1.

HEK 293 cells (or derivatives of) are of human origin and used for the production of replication deficient, infectious lentiviral particles. Untransfected cells may be considered equivalent to ADCP Hazard Group 1 as GM hosts, however they will be handled at Containment Level 2 due to the potential presence of adventitious agents, as required under the COSHH Regulations. Once transfected the cells will be considered equivalent to ADCP Hazard Group 2 due to the infectious viral particles.

Standard lentiviral systems will be used that generate amphotropic replication deficient viral particles, such as Open Biosystems packaging system. These systems have standard feature to maximise safety, such as:

- The expression vectors contain a deletion in the 3' LTR that results in “self-inactivation” of the lentivirus after transduction of the target cell.
- The number of genes from HIV-1 that are used in the system has been reduced (i.e. gag, pol, rev, tat and vpr).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto a number of plasmids minimizing the threat of recombinant replication competent virus production.
- None of the structural genes are actually present in the packaged viral genome, therefore no new replication-competent virus can be produced.
- The VSV-G gene from Vesicular Stomatitis Virus is used to pseudotype the vector particles. The HIV-1 envelope has been completely removed from the vector.
- Although the packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gag, pol, rev, env) in the TLA-HEK293T producer cell line, none of them contain LTRs or the \( \Psi \) packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- The reverse transcriptase (RT) and integrase (IN) proteins are provided in trans producing a class of vectors that contain split gag-pol components on separate vectors.

Viral post-transcriptional regulatory elements – The lentiviral plasmid pGIPZ contains the woodchuck hepatitis B virus (WHV) regulatory element (WPRE) which increases transgene expression. The form of WPRE present in pGIPZ has been modified and is not capable of expressing part of the X protein from WHV.
The transducing vector will contain inserts including mammalian cDNA, shRNA oligonucleotide constructs, standard reporter genes (e.g. eGFP, Luciferase, β-galactosidase) and standard antibiotic resistance genes. The inserts have a role primarily in regulating energy metabolism within the cell and have no known role in tumour growth/suppression. Examples include Creatine Transporter, Creatine Kinase Isoenzymes (MM-CK, mito-CK, BB-CK), Adenylate Kinase, AMPK, PGC-1α and ANT The shRNA constructs will be used to deplete the target endogenous mRNA and therefore restrict gene function. However no shRNA will be used that depletes a known tumour suppressor. The products of the inserted genes are not considered to be inherently toxic. However, their expression by the GMM may result in an altered cardiac phenotype in murine hosts. Gene products are not expected to have harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms.

Evaluation of foreseeable effects

Insertion of the foreign sequences into E. coli is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the host or normal human defence mechanisms. The resulting GMO's are not expected to carry any additional risks compared to that of the un-modified recipients. This work is assigned to Class 1.

Primary and continuous cell culture exposed to infectious virus poses minimal risk after the initial media change as once the virus has integrated into the genome it poses minimal risk due to the replication defective nature of the virus. There may be an alteration in the cellular energetics due to the inserted transgene however that is unlikely to overcome the strict biological requirements of the cell culture nor affect the response of the immune system. This work is assigned to Class 1.

HEK 293 cells producing infectious replication defective viral particles and work with the infectious viral particles poses the greatest risk within this project. The lentiviruses being generated have a wide tropism and will be able to infect human cells. It is theoretically possible for the lentivirus to integrate into the genome of the infected cells of an individual on exposure. In the unlikely event that normal human defence mechanisms were evaded upon accidental exposure to lentivirus (eg following needlestick injury), any potential effect of inserts on cellular metabolism is unlikely to be harmful and would remain localised. Infection cannot spread as the viruses are replication defective and self-inactivating making the integrated lentivirus incapable of activating nearby genes or producing a packageable viral genome. However in theory the function of a gene at the site of insertion could be disrupted. Even so this single event is unlikely to cause any tumour formation in humans and so the overall risk is still low. Further, the theoretical risk of oncogenesis resulting from the X protein of WHV has been eliminated in the pGIPZ vector with a modified WPRE element.

Assignment to provisional containment for virus work: Class 2.

Animals inoculated with lentivirus are not likely to exhibit different behavioural characteristics compared to uninfected animals nor do they pose any greater risk to human health from biting or scratching. There is effectively no risk of transfer from infected animal to open wounds as the virus is self-inactivating and cannot propagate once integrated into the genome of a host cell. The greatest risk to humans will be from any percutaneous injury sustained during the inoculation procedure. This risk will be reduced due to the animal being anaesthetized. Needles and syringes are restricted for use only when there is no alternative, ie for intramyocardial injection. Scalpels will only be used for the surgery preceding the inoculation via injection and will therefore not be exposed to virus. Appropriate control measures include wearing gloves and safe disposal of the intact needle-syringe assembly in a Sharps Waste Container placed adjacent to the animal. Post inoculation the animals will be held in Containment Level 1 facilities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15
minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)

Social traits, such as co-ordinated behaviour, anticompetitor toxins and iron-scavenging, can be important for the success of pathogenic bacteria. We are addressing under which conditions these traits are beneficial to the bacteria, and how the expression of these traits affects their pathogenicity in animal (caterpillar) hosts. Mutation rates can affect the evolution of these traits, and we are also investigating this question.

Pseudomonas aeruginosa is a hazard group 2 pathogen which can cause infection of immunocompromised individuals, people with cystic fibrosis, and can potentially establish an infection through burns and cuts. Infections can be fatal if untreated.

Recipient or parental organism
Pseudomoas aeruginosa is a hazard group 2 pathogen which can cause infection of immunocompromised individuals, people with cystic fibrosis, and can potentially establish an infection through burns and cuts. Infections can be fatal if untreated.

Host/vector system
All genetically modified strains of Pseudomonas aeruginosa to be used are knockouts. The majority of which are transposon-insert mutants (with associated tetracycline resistance cassettes from Escherichia coli) obtained from external sources.

mutS knockout was made by digesting the wildtype allele, liberating an internal fragment, and then ligating. This non-functional allele, and an associated kanamycin resistance cassette from E. coli, was then inserted back into the wild type background by conjugation from an E. coli donor.

Origin & function
bacteriocin (pyocin) mutant (pys2 knockout) - Bacteriocins cause cell lysis of susceptible P. aeruginosa strains.
pyoverdin mutant (pvdF knockout) - pyoverdin is the primary iron-scavenging siderophore of P. aeruginosa.
Quorum sensing (QS) mutants (lasR, rhlR knockouts) and knockouts of genes under the control of QS expression (lasB, rhlA; which encode elastase and rhamnolipid, respectively) - QS describes changes in gene expression in a wide range of genes (such as those coding for proteases (eg elastase) and surfactants (rhamnolipids)) in response to high concentrations of diffusible signal.

Type IV pili mutant (pilA knockout) - type IV pili are involved with social motility.

mutS knockout - results in less efficient DNA repair, and hence an approximately 100-fold higher mutation rate. strain.

Evaluation of foreseeable effects

Pyoverdin mutants have reduced ability to obtain iron, hence are likely to grow less well, and are expected to be less virulent, in humans. There is no reason to suspect the growth or virulence of the pyocin mutant would be altered in human hosts. Quorum sensing mutants do not express a range of traits, including many traits crucial for successful growth of bacteria in vivo, such as proteases (elastase), polysaccharides for biofilm formation and surfactants (rhamnolipid). They will therefore be less virulent. The type IV pili mutants have reduced motility and attachment, so would be less efficient at colonising human hosts. The mutS mutant typically shows reduced virulence in published in vivo studies using mouse models.

The antibiotic cassettes are not the antibiotics typically used for treatment of P. aeruginosa, hence they will not increase risks to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Caterpillar carcasses - Autoclave using a make safe cycle as specified n BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 10% kill (licensed incinerator)
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

### Project Additional Information

#### Purposes of the contained use

We propose to utilise the HSV-1 amplicon vector pHSV-ips to deliver a strong, but short lived, expression "pulse" of the key genes required for the induction of human iPSC cells from primary human fibroblasts.

#### Recipient or parental organism

- Disabled E. coli and yeasts, such as K12 derivatives and S. cerevisiae
- Mammalian cell lines, such as MRC5V2, HEK293, CHO, African Green Monkey cells (Vero 2-2, which also constitutively express ICP27) for generating amplicons glioma cells (G16-9) for amplicon titration
- Primary cells, such as human fibroblasts

#### Host/vector system

Fully defective, non-replicating viral system based on herpes simplex virus type 1 (HSV-1) amplicon vector.

The HSV genome lacking the packaging signal and ICP27 is inserted into a BAC. The packaging signal and the HSV origin of replication is inserted into a plasmid vector containing the transgenes of interest, selectable antibiotic markers and reporter genes to create an amplicon. Transducing amplicon particles are then generated by co-transfecting the amplicon with the helper plasmid containing the packaging gene ICP27 and the BAC containing the deleted HSV genome into Vero 2-2, which also constitutively express ICP27. As the BAC and the helper plasmid do not contain a packaging signal they cannot be incorporated into the transducing amplicon particles which are therefore non replicating.

This results in no detectable helper virus contamination (< 1 helper virus/10⁹ amplicon particles).

#### Origin & function

Genes known to generate induced pluripotent stem (iPS) cells by "reprogramming" primary cell types. A range of such genes have been described, including the transcription factors OCT4, SOX2, KLF4, C-MYC, NANOG and LIN28. These genes have been identified as potentially oncogenic.

Standard reporter genes, such as GFP, EFP and Lac Z etc

Standard antibiotic resistance genes, such as Neomycin and Hygromycin etc

TA-Advanced is a tetracycline controlled transactivator protein.

Cre, is a type I topoisomerase which catalyses site specific recombination between loxP sites.

HSV-TK (Herpes simplex virus thymidine kinase), phosphorylates gancyclovir enabling it to be incorporated into the cellular DNA.

### Evaluation of foreseeable effects

When expressed in combination the genes are expected to reprogram somatic cells to pluripotent cells. As the genes are suspected oncogenes accidental exposure could pose a problem, however a number of safety features have been incorporated into this work to minimise the risks.
The genes have been synthetically sequenced to have approximately 70% homology with the wild type sequence while maintaining protein homology. This will reduce the likelihood of homologous recombination with the wild type variants.

It is possible to excise the four transgenes from their promoter by cre recombinase as they are flanked by lox-P sites. This excision is verified by the expression of M-cherry. The cre recombinase used to excise the genes is under the control of a tet responsive element (pTight). TA-Advanced is a tetracycline controlled transactivator protein, which works in conjunction with a tet responsive element. In the presence of doxycycline the TA-Advanced binds to the TRE and activates expression of the Cre recombinase. In the absence of doxycycline the rtTA-Advanced is unable to bind the TRE and gene expression is blocked.

This vector also contains the HSV-TK (Herpes simplex virus thymidine kinase) suicide gene which allows any cells containing the plasmid to be selectively killed by the addition of gancyclovir.

Expression of Cre recombinase and TA-Advance is unlikely to have any deleterious effect.

Project Additional Information

Purposes of the contained use

The objective of this work is to identify and define the multiple individual receptor-ligand interactions involved in the interaction of fungi with the immune system. *Candida albicans* will be modified such that they have deficiencies in selected genes, including those for cell wall synthesis. The strains are, therefore, deficient in components of...
the cell wall. This will allow us to determine which components interact with each specific immune receptor that we are studying. Some deleted strains will have the gene re-integrated to allow the experiments to be controlled with precision.

**Recipient or parental organism**

Saccharomyces cerevisiae is assigned to Hazard Group 1.

Wild type Candida albicans is assigned to Hazard Group 2.

**Host/vector system**

Standard integrative plasmids such as Clp10

**Origin & function**

URA3 selection to allow growth in medium deficient in uracil

Knock out and/or reintroductions of genes encoding cell wall components

GFP or derivatives a fluorescent standard marker protein

10 or16 amino acid epitopes derived from chicken ovalbumin

**Evaluation of foreseeable effects**

The C. albicans strains CAI4 (ura3), CAI8 (ura3, ade2), RM1000 (his1, ura3) and BWP17 (arg4, his1, ura3) are the standard hosts for DNA transformation world-wide. These auxotrophies makes C. albicans avirulent. Transformation with URA3 plasmids partially restores the virulence of CAI4, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to attenuate virulence partially but not completely. By necessity, some of the transformants are not genetically disabled, although their virulence is slightly lower than the wild type strains of C. albicans carried by most individuals. It is important to note that although a large number of C. albicans mutants have been analysed, including virulence attributes, metabolic and cell wall genes, there is NO report of a mutation that increases the virulence of this yeast. This is unsurprising, since all evidence to date indicates that virulence in C. albicans is a multi-factorial process at the molecular level, with no single virulence factor of over-riding importance. While one might imagine that inactivating a repressor might increase virulence this is NOT the case. Therefore, mutations in wild isolates are expected to have a neutral or negative effect upon virulence. Furthermore, none of the genetic modifications are expected to affect the effectiveness of current therapies (nystatin, fluconazole, amphotericin)

Inserts knock down the expression of genes encoding yeast cell wall components, or encode wild-type copies of these genes for re-introduction into mutant strains. Also selection marker genes such as URA3, allowing growth in medium deficient in uracil, have been introduced into these strains. Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. No harmful properties of these strains have been identified over the years that they have been used in various laboratories around the world.

Most of the C. albicans transformations have inactivated a specific target gene to create a null mutant. In none of the cases we are studying is this likely to increase virulence. As described above, it has been shown in numerous cases that C. albicans virulence is either decreased or remains unaffected by gene knockouts. No null mutations have been described that increase the virulence of C. albicans.

All the mutants have been generated by gene disruption with the URA3 gene marker and recycling of this in selective medium. Therefore, the original open reading frame has gone and is replaced with hisGdp1200 sequence scar. For the construction of the re-integrant control and to put back the URA3 gene, mutants are transformed with a StuI-digested plasmid, which is inserted in the RPS1 locus. This will remove the RPS1 open reading frame from one allele.

The ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth. The key point is that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds [1994] ASM News, 60, 313).

We propose to grow and use mostly strains that already exist and that have been used safely in a number of laboratories elsewhere. These strains have been in use in
other laboratories without problems developing. The strains that will be generated in our lab contain GFP with either 10 or with 16 amino acid extension sequences derived from a non pathogenic protein (chicken ovalbumin). These are not expected to present any changes in the properties of expressed GFP protein and thus the new strain is unlikely to behave any differently from the one that has been used safely in other laboratories.

Inoculation of mice – the use of needles may increase the risk of percutaneous injury occur. Systemic infection is rare in healthy individuals however any accident will be reported immediately to Occupational Health to assess whether antifungal treatment is required.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

Vaccinia Virus will be used to express selected genes from Foot and Mouth Disease Virus (FMDV) to enable crystallisation studies of the capsids.

**Recipient or parental organism**
**Host/vector system**

Standard plasmid vectors will be used to transfer the genes to the Vaccinia Virus by homologous recombination with the TK gene.

**Origin & function**

5' and 3' UTRs, coding sequence for the viral capsid and selected non-structural proteins of Foot and Mouth Disease Virus. Also specific mutations in the FMDV capsid with the intention of stabilizing its structure. Expression should generate virus-like particles of FMDV which lack genes essential for replication and are not infectious.

T7 RNA polymerase will be expressed in a separate Vaccinia virus to the FMDV genes. This is a bacterial promoter and will provide the polymerase necessary for the transcription of the FMDV genes.

Standard antibiotic resistance genes

**Evaluation of foreseeable effects**

Humans are not a natural host of Vaccinia Virus. Vaccinia infection is typically asymptomatic in healthy individuals but may cause a mild rash and fever. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous infection. Substantial safety data has been obtained in human subjects as the Wyeth strain was used as a vaccine for smallpox. Serious complications occurred mainly in immunosuppressed and extremely young individuals. Rare complications include eczema vaccinatum, disseminated vaccinia rash, progressive vaccinia and encephalitis.

Vaccinia virus can infect a broad range of cell types.

Inserts are placed into the TK region of the Vaccinia Virus thus knocking out the gene. This slightly attenuates the virus and the GM versions therefore pose a reduced risk when compared to the wild type.

Foot and Mouth disease virus does not infect humans and therefore poses minimal risk to workers, however FMDV is a DEFRA category 4 pathogen which infects livestock. At no point will full length FMDV RNA or cDNA be used. The sequences are all derived from synthetic genes. Only the genes required for capsid production will be expressed, no viable FMDV will be generated.

Expression of the FMDV capsid is unlikely to alter the envelope of the Vaccinia virus because although both viruses are enveloped vaccinia has a complex structure while FMDV has a simple icosahedral structure.

The FMDV genes are driven by bacterial T7 promoter and therefore are unlikely to be expressed in mammalian cells unless a second vaccinia virus expressing the T7 polymerase is present in the same cell.

In the unlikely event of recombination between the two GM Vaccinia viruses generating a single Vaccinia Virus expressing FMDV genes and T7 polymerase the resulting virus is likely to be less virulent as constitutive expression of FMDV proteins as toxic to the infective cell.

If the Vaccinia Virus expressing FMDV was accidentally released and subsequently infected cattle there is a remote possibility of the animals generating antibodies against FMDV but only if they were infected with the Vaccinia Virus expressing T7 polymerase as well. The animals would not be infectious for FMDV but would test positive in an antibody test.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
Use of Viruses to Deliver Transgenes for Cancer Therapy

Purposes of the contained use

Use of Hazard Group 2 viruses for delivery of transgenes to cells with the ultimate aim of using the viruses as cancer gene therapy.

Recipient or parental organism

Pox viruses, such as Vaccinia Virus Western Reserve and Wyeth – Hazard Group 2
Modified Vaccinia Ankara and Fowlpox may also be used to help boost immune responses – Hazard Group 1
Alpha viruses, such as Sindbis Virus – Hazard Group 2

Host/vector system

Homologous recombination between shuttle plasmids and the viral genome.

Origin & function

Antigen molecules and/or costimulatory molecules under transcriptional control of endogenous or synthetic promoters such as, but not limited to L6 tumour antigen, carcinoembryonic antigen (CEA), B7-1, intercellular adhesion molecule-1 (ICAM-1), and leukocyte function associated antigen-3 (LFA-3).
Cytokines such as, but not limited to granulocyte-macrophage colony-stimulating factor (GM-CSF), IL10 and IL2.
Prodrug-activating enzymes genes (PAE) (or variants of) will include genes such as, but not limited to nitroreductase, cytosine deaminase or uracil phosphoribosyl transferase (UPRT) under transcriptional control of endogenous or synthetic promoters.
Hyaluronidase or DNase expression will involve encoding human PH-20 (spam1), Hyal1, Hyal2, or DNase under the control of P7.5 vaccinia or PSE/L synthetic promoter.
within the TK site of attenuated vaccinia. MicroRNA (mir) binding sites will be used to target RNA for accelerated degradation within cells expressing the appropriate mirs. Anti angiogenic factors such as but not limited to Endostatin, soluble Ftl1 and delta4. Standard reporter genes such as β-galactosidase, luciferase, green fluorescent protein. Antibiotic resistance genes for selection purposes.

Evaluation of foreseeable effects

Humans are not a natural host of Vaccinia Virus. Vaccinia infection is typically asymptomatic in healthy individuals but may cause a mild rash and fever. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous infection. Substantial safety data has been obtained in human subjects as the Wyeth strain was used as a vaccine for smallpox. Serious complications occurred mainly in immunosuppressed and extremely young individuals. Rare complications include eczema vaccinatum, disseminated vaccinia rash, progressive vaccinia and encephalitis. Vaccinia virus shows an inherent selectivity for cancerous tissues relative to normal tissues and is therefore a good candidate for cancer therapy. The foreign genes are inserted into the thymidine kinase region of the virus. They are under the control of the P7.5, PSE/L or synthetic promoter which results in the disruption of the thymidine kinase gene reducing the virulence.

TK gene-deleted vaccinia viruses, including JX-594, are significantly attenuated in normal tissues in vivo and are, therefore, less toxic whilst maintaining anti-tumoural activity. This increased therapeutic index is thought to be due to over-expression of cellular TK in cancer cells, supplying TK in trans to the deletion mutant virus. JX-594 is a replication-competent, transgene-armed therapeutic vaccinia virus derived from the commonly used Wyeth vaccine strain (Dryvax®, Wyeth laboratories). It is designed to selectively replicate in and destroy cancer cells, while at the same time stimulating a systemic anti-tumoural immune response through the expression of its transgene, hGM-CSF, in the context of tumour lysis. Three genetic modifications are included in JX-594: (1) thymidine kinase (TK) gene deletion, (2) GM-CSF gene insertion under the control of the synthetic early-late promoter, and (3) lac-Z gene insertion.

Western Reserve strain has had the TK gene and the Vaccinia Growth Factor (VGF) gene deleted. While removal of just TK or VGF decrease viral pathogenicity to some extent, the double deletion has a dramatic effect on decreasing pathogenicity. vvDD has been shown to be non-toxic to nude mice. Accordingly this agent is a relatively safe starting point for introducing transgenes with additional anticancer function.

Sindbis virus is mildly pathogenic to humans causing poly-arthritis, mild fever and skin rash. Infection is self limiting. Other symptoms include headache and myalgia. There is no evidence for person to person transmission. The virus is normally transmitted via arthropod organisms.

Sindbis virus can localise to tumour tissues via interactions with the laminin-1 high affinity cell surface receptor. Increased expression of the high affinity Laminin receptor in tumours, coupled with a lack of free laminin in the tumour environment should allow differential localisation between the tumour and other sites of infection. microRNA binding sites should accelerate viral transcript degradation in cells expressing the appropriate microRNAs. Two significant toxicities observed in Sindbis infection are toxicity to macrophages in the synovium of the joints and toxicity to skeletal muscle. These two sites of toxicity show tissue-specific expression of microRNA molecules (Macrophages – Mir-142, Muscle – Mir-133 and Mir-206) Binding sites specific for these (and other) microRNA molecules will be incorporated into the virus genome to prevent replication at these sites and consequently to limit virus induced toxicity. The transgene will also be suppressed, by the same microRNA mechanism.

Antigen molecules and/or costimulatory molecules – certain self antigens (such as CEA and L6) are overexpressed in cancers and are consequently used as markers for certain cancers. Expression of these genes in vaccinia should boost immunity. It is not expected that immunity against these self antigens will be harmful. GM-CSF (granulocyte-macrophage colony-stimulating factor) is widely used in the clinics to rescue patients after chemotherapy-mediated suppression of their immune systems. It is reportedly the most effective cytokine for stimulating tumour-specific anti-tumoural immunity. It is not expected to be hazardous when expressed in vaccinia or Sindbis. Prodrug-activating enzymes genes convert non toxic prodrugs into active cytotoxic ones. In the absence of the prodrug moderate levels of the activating enzymes are not expected to be harmful. Some studies have indicated that high levels of nitro-reductase enzyme could have limited cytotoxicity in some cells.

DNase cleaves DNA and will be used to break down extracellular DNA within tumour nodules and improve virus spread. A recombinant DNase protein has been licensed for use to treat cystic fibrosis by reducing lung secretion viscosity. PH-20 (spam1) has endoglycosidase activity. It can cleave hyaluronic acid in the Extracellular Matrix resulting in a decrease in interstitial fluid pressure (Breken et al 1998). A recombinant protein has been developed by Halozyome http://www.halozyome.com/ and has been approved for use in the clinic to increase dispersion of sub-cutaneous injections.

Inclusion of hyaluronidase or DNase should allow the virus to spread more effectively through interstitial connective tissue, but replication will be mainly restricted to cycling cancer cells and pathology in normal tissues is expected to be lower than the wild type (class II) virus.

Anti angiogenic factors interfere with pathological angiogenesis and can be expressed without overt toxicity to existing tissues. Cytokines regulate the immune response towards the tumour. Some cytokines will stimulate an anti-tumour response (for example by promoting engraftment of T cells)
while others will suppress the immune response in order to allow the infected virus to spread more effectively through the tumour.

Standard reporter genes and antibiotic resistance genes are widely used and no hazardous properties have been reported.

In vivo experiments pose the greatest risk of accidental exposure due to percutaneous injury. Standard working practices such as immediate disposal of needles and not resheathing should minimise the risks.

Tissues from treated animals will be handled at the same level as the virus stocks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM

02/03/2022
Project Additional Information

Purposes of the contained use

Mutants of intercellular signalling genes in a number of Hazard Group 2 bacteria will be assessed for their effect on quorum signalling

Recipient or parental organism

Helicobacter pylori. This is a hazard group 2 microaerophilic bacterium that inhabits various areas of the stomach and duodenum. It causes a chronic low-level inflammation of the stomach lining and is strongly linked to the development of duodenal and gastric ulcers and stomach cancer. Over 80% of individuals infected with the bacterium are asymptomatic.
Pseudomonas aeruginosa. This is a hazard group 2 pathogen that can cause infection of immunocompromised individuals, people with cystic fibrosis, and can potentially establish an infection through burns and cuts. Infections can be fatal if untreated.

Actinomyces naeslundii T14V. This is a hazard level 2 bacteria that occupies the oral cavity. They have been implicated in periodontal disease and root cavities. These bacteria are also associated with good oral health.

Streptococcus oralis A hazard level 2 bacteria that is numerous in the mouth and throat. It is a common cause of endocarditis, which may be fatal if untreated, and is also implicated in dental plaque formation.

Salmonella typhimurium. A hazard level 2 bacteria that occupies the gut. It is a major cause of gastroenteritis, which may require hospitalisation, and may be fatal if untreated. Infection is established through ingestion.

Enterococcus faecalis A hazard level 2 opportunistic pathogen. It is a normal inhabitant of the intestinal tract and female genital tract but can develop virulence through a fluid gene transmission system whereby it can acquire virulence factors and antibiotic resistance.

Porphyromonas gingivalis A hazard level 2 anaerobic pathogen. It is commonly found in the human body and especially in the oral cavity, and is associated with periodontal lesions, infections, and adult periodontal disease. Approximately 70-90% of people pubescent and older have gingivitis, a possible precursor to adult periodontal disease, which is associated with Porphyromonas gingivalis and allows it to further infect the areas near the root of the teeth causing tooth decay and infection.

Staphylococcus aureus. A hazard level 2 bacterium that is a common coloniser of human skin and mucosa. Infection may develop through cuts and sores, and skin and wound infections, urinary tract infections, pneumonia and bacteraemia (blood stream infection) may then develop. In immunocompromised individuals infection can be severe, and antibiotic resistant S. aureus (MRSA) is a major cause of hospital secondary infections.

Host/vector system

Individual genes from the various Hazard Group 2 bacteria will be knocked out and replaced by the kanomycin resistance gene using standard DNA plasmids or cosmids.

Origin & function

Genes which have been identified as having a possible role in interspecies communication will be knocked-out by the insertion of the gene for kanamycin resistance using transposons. Examples of such genes are homologues of the luxS or luxP genes of Vibrio harveyi. The luxS gene produces the protein autoinducer 2, which is a quorum sensing signal protein and the luxP gene produces a protein which detects and transduces the quorum sensing signal.

Evaluation of foreseeable effects

Quorum signalling results in changes of gene expression in a wide variety of genes, including many which code for traits crucial for successful growth of bacteria in vivo, such as proteases (elastase), polysaccharides for biofilm formation and surfactants (rhamnolipid). The knock-out strains are expected to show some alteration to the changes in gene expression and are expected to be less virulent than the wild type strains as a result.

Project Ref 553/09.5
**Project Additional Information**

**Purposes of the contained use**

Lentiviruses and amphotrophic retroviruses will be used to deliver genes or short hair pin RNAs to investigate their roles in the insulin like growth factor signalling pathway.

**Recipient or parental organism**

- E. coli K12 or B derivatives - E.coli strains are disabled and cannot colonise the human gut.
- Mammalian cell lines - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.
- Primary cell cultures - Primary human cells and human cell lines that are not fully authenticated and characterised may carry contaminating infectious agents. Primary cells from non primate sources are deemed to be of low hazard.
- Packaging cell lines - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.

**Host/vector system**

Replication defective amphotrophic retroviruses and lentiviruses

Both these systems have the required viral genes (gag and pol, env) split onto separate plasmids. These have either been separately integrated into the genome of the packaging cell line (such as 293T) or will be transfected at the same time as the plasmid containing the transgene.

These systems produce infectious viral particles, which cannot replicate and are designed so to minimise the likelihood of generating replication competent virus through recombination.
Human and mouse genomic DNA and cDNA inserts encoding proteins in the IGF signalling pathway, and other proteins that regulate cellular processes including proliferation, cell survival and DNA repair. Also included are inserts encoding fusion proteins that regulate the subcellular localisation of the transgene product, such as the HA-ER-I-PpoI system in which the DNA binding domain of the estrogen receptor (ER) is fused to, and directs nuclear import of, the I-Ppo1 endonuclease (Berkovich et al Nat Cell Biol, 9: 683-690, 2007). In the course of the study, this list may be extended to molecules identified as partners or targets of components of the IGF axis. These could involve other cell surface receptors, co-factors, repair proteins, chromatin remodelling factors, cell cycle regulators, apoptotic factors, structural proteins, members of the general transcriptional machinery and other regulators of gene expression.

Short hairpin RNA (shRNA) will be expressed to silence expression of signalling proteins including components of the IGF axis, and or proteins involved in DNA repair. This is likely to influence cellular proliferation, apoptosis induction, and cell survival following DNA damage.

Standard selection markers (GFP, antibiotic resistance, lacZ) will allow identification of the transduced cells, but is unlikely to have any significant biological effect.

**Evaluation of foreseeable effects**

The Lentiviruses and Retroviruses are amphotrophic and can therefore infect human cells however the design of these systems is such that the viral particles are replication defective and are only capable of one round of infection.

The genes to be expressed or knocked down have the potential to affect proliferation, apoptosis and survival of cells and could therefore in some instances have detrimental effects should they be integrated into genomic DNA of a workers cells.

Once incorporated into the genomic DNA of the experimental cell lines the inserts pose minimal risk due to the replication defective nature of the viruses. The cells would be recognised as non-self by the immune system and rapidly lysed by complement.

Experimental procedures will minimise the likelihood of exposure to the infectious virus, such as the use of a micro-biological safety cabinet and sealed centrifuge tubes and rotors, however the use of needles will be required for inoculations and this poses a risk. Staff are trained in appropriate handling procedures and syringe-needle assemblies are disposed of immediately after use.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Date Project Ceased

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The use of replication defective Lentiviral vectors to modulate expression of candidate genes to assess their role in tumourigenesis.

**Recipient or parental organism**

E.coli K12 or B derivatives

Mammalian cell cultures - especially disabled hosts which should be recognised as foreign by the human immune system. Due to the presence of adentitious agents certain cell lines will be handled at Containment level 2.

**Host/vector system**

Standard Lentiviral vector systems, which produce replication defective virions.

The system to be used is a third generation one. The expression vectors have a deletion in the 3’ LTR which results in self inactivation. The number of HIV genes have been reduced to gag, pol, rev, tat and vpr. The envelope protein is VSV-G which allows amphotrophic infection. The genes are split onto four different plasmids. No replication competent virus can be produced.

**Origin & function**

Mammalian genes thought to be involved in Hereditary Leiomyomatosis renal cell cancer (HLRCC) such as Fumerate Hydratase, succinate dehydrogenase and G-protein coupled receptors.

Fumerate Hydratase is a nuclear-encoded protein that catalyses a step of the Krebs cycle, converting fumarate to malate. It is also thought to be a tumor suppressor as inactivated protein is seen in tumours from patients suffering from Hereditary Leiomyomatosis renal cell cancer.

Succinate dehydrogenase is an enzyme also involved in the Krebs cycle catalysing the oxidation of succinate to fumarate.

G-protein coupled receptors are transmembrane signalling receptors, which pass signals across cellular membranes to activate internal pathways.

Other genes identified during the course of the project may also be expressed/knocked down.

shRNA constructs to knock down expression of the above genes.
Standard reporter genes and antibiotic resistance genes

**Evaluation of foreseeable effects**

E. coli K12 or B derivatives are disabled hosts which cannot colonise the human gut and have a history of safe use. Genes are not expected to be expressed in these systems due to the lack of bacterial promoter.

Mammalian cell cultures are especially disabled hosts which should be recognised as foreign by the human immune system. Due to the presence of adventitious agents certain cell lines will be handled at Containment Level 2. As lentivirus integrates into the host DNA and lacks essential genes for replication, mammalian cells, which have been infected pose minimal risk.

293 cells (and various derivatives) are used to produce viral particles which are capable of one round of infection. These cells will be handled at Containment Level 2 with the use of sharps minimised.

Lentiviral particles are infectious but replication defective however they are capable of integrating into the host genome where they may cause insertional mutagenesis. Control measures are in place to minimise the likelihood of exposure however needles are required for inoculations.

Inoculations using transduced cells pose minimal risk to the worker as the lentivirus will be integrated into the host genome and replication defective. The cells should be recognised as foreign by the human immune system.

Inoculations using lentivirus capable of one round of infection poses the greatest risk due to the use of needles. Workers are trained in these procedures including the policy of not re-sheathing needles and disposing of intact needle-syringe assembly into sharps bins immediately after use.

Accidental exposure to a single gene is considered to be low risk.

The genes themselves are involved in individual steps of the Krebs cycle and cellular signalling. Although the loss of fumarate hydratase is seen in HLRCC patients it is likely that other gene mutations are required for the progression of the disease.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Ref 553/09.7

Date Ackn'd 08/10/2009

CU2 Project Title
The use of retroviral and lentiviral vectors to facilitate transgene expression and/or gene silencing by RNA interference in mammalian cell and tissue culture systems

Date Project 02/03/2022

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 < 1 Litre

Non-GMM Consent Granted
**Project Additional Information**

**Purposes of the contained use**

Replication defective retroviral and lentiviral gene transfer vectors will be used to introduce transgene and/or RNA interference expression cassettes into mammalian cells to investigate the role. A variety of transgenes / RNAi targets associated with cell growth and survival, cell growth properties, apoptosis, key regulatory pathways, and fluid transport processes will be investigated.

**Recipient or parental organism**

E. coli K12 or B derivatives - E.coli strains are disabled and cannot colonise the human gut.

Mammalian cell lines - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.

Adult mice - no hazard to human health

Fertilized mouse eggs prior to re-implantation to create transgenic mouse lines - no hazard to human health

**Host/vector system**

Replication defective ecotropic and amphotrophic retroviruses and lentiviruses

Third or later generation retro- and lentiviral systems (based on viruses from various species) incorporating self-inactivating 3' LTR (SIN) U3 deletion. Both these systems have the required viral genes (gag and pol, env) split onto separate plasmids. These have either been separately integrated into the genome of the packaging cell line (such as 293T) or will be transfected at the same time as the plasmid containing the transgene. These systems produce infectious viral particles, which cannot replicate and are designed so to minimise the likelihood of generating replication competent virus through recombination.

**Origin & function**

Mammalian and reporter gene sequences:

1) FOXP Forkhead Transcription Factors and associated interacting genes / proteins

FOXP Forkhead transcription factors have key roles in development and in human malignancy. Best studied in terms of cancer is FOXP1 which in its full length form is believed to act as a tumour suppressor and in an N-terminally truncated form has been shown to have oncogenic activity in a model of avian nephroblastoma.
2) HSP90 Heat Shock Proteins
HSP90 heat shock proteins are highly conserved molecular chaperones that have key roles in signal transduction, protein folding, protein degradation, and morphologic evolution. HSP90 proteins play important roles in folding newly synthesized proteins or stabilizing and refolding denatured proteins after stress.

3) Lymphoma Associated miRNA Factors
Several miRNA families are over or under expressed in lymphoma. Best studies examples include the miR-155 and miR-199 families.

4) Lymphoma Associated Antigens
Lymphoma-associated antigens have been identified through their humoral recognition by patients' the immune system and/or their presence in lymphomas despite restricted normal tissue expression.

5) Modulators Of Epithelial Ion Transport
Modulators of epithelial ion transport have a key role in regulating fluid balance across epithelia. Best studies examples of such modulators include ENaC the epithelial sodium channel, CFTR an epithelial chloride channel and members of the CLC family of calcium activated chloride channels and protein and RNA factors that activate or repress their activity.

6) Common causes of blindness
Mutations in a variety of genes result in retinal dysfunction and inherited blindness.

7) Commonly Used Reporter Transgenes
Commonly used, simple to measure reporter genes will be utilised to assist in vector development, and as experimental controls. Examples include firefly luciferase and similar transgenes, jellyfish green fluorescent protein and similar transgenes, E.coli LacZ, mammalian serum, blood clotting and red cell production factors such as alpha-fetoprotein, FIX and EPO.

**Evaluation of foreseeable effects**

The inserted mammalian and reporter gene sequences are normal or selective alterations of characterised mammalian genes or miRNAs and/or standard reporter genes. The inserted sequences are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the packaging cell lines.

The majority of the sequences are expected to pose little or no risks in humans. However, some inserted sequences may have harmful properties in humans via the ability to act as tumour suppressor and/or oncogenes eg truncated FOXP1, or by their ability to affect normal human defence mechanisms by mediating immunotolerance eg FOXP3. Consequently, gene transfer of some of the sequences to humans may be hazardous.

The retroviral and lentiviral particles produced will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see below) into the host genome. This is an anticipated risk associated with the use of retroviral and lentiviral gene transfer vectors.

The viral particles have however been rendered non-replicable by a number of safety features:

1) The viral genomes are self-inactivating, carrying a deletion in the U3 region of 3’LTR. During integration into the host cell genome, the viral 3’ LTR is copied to the 5’ of viral genome rendering it transcriptionally inactive and unable to function as a replicative retroviral genome.

2) The viral genome does not contain any of the viral packaging or structural genes necessary for viral replication.

3) The viral packaging and structural genes factors necessary for viral particle production are supplied in the producer cell line in trans, either by the producer cell line itself or by co-transfection with packaging plasmids. Regions of homology (eg LTRs or packaging sequences) between these viral elements and the viral particle genome have been minimised to eliminate undesirable recombination events that could lead to the generation of replication competent virus (RCV).
4) In the case of lentiviral vectors, the viral particle genomes contain exogenous promoter sequences to permit transgene/RNAi factor expression. This allows viral tat gene, essential to wildtype lentiviral replication, to be completely eliminated from the packaging system. Thus no RCV can be produced.

Consequently, only retroviral and lentiviral particles which are unable to replicate, but which can deliver the transgene/RNAi insert of choice will be produced. These viral particles cannot contain additional viral genes as their sequences lack the LTR or packaging sequences necessary for their sequences to be incorporated into the viral particles.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

Accidental human exposure to viral particles could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences into the host genome. Importantly, in the context of human gene therapy clinical studies, high doses of retroviral and lentiviral vector particles have been administered in vivo with no observed complications. However, in the worst case scenario, integration within a tumour suppressor gene or the biological activity of the integrated sequences could lead to the generation of a tumour. Indeed, leukaemia like tumours have been observed in a small number (~10%) of individuals infused with bone marrow stem cells that had previously been treated ex vivo with retroviral vectors. Despite these observations it is considered highly unlikely that accidental human exposure to the viral particles described in this risk assessment would lead to the generation of a tumour. Major differences between the described worse case scenario and any accidental exposure exist including large differences in transgene/host interactions, likely exposed viral particle numbers, in vivo rather than ex vivo delivery route, consequent exposure of viral particles to complement/immune system, likely access to relevant precursor stem cells and immune status of individuals involved.

Consequently, it is not anticipated that accidental human exposure to viral particles is associated with significant risk. However, given the nature of some of the mammalian gene sequences (discussed above), gene transfer could be hazardous.

Retroviral and Lentiviral Transduction

Retroviral and lentiviral particles will be purified from packaging cell cultures and used to transduce mammalian cells to facilitate the production of new mammalian cell lines permanently expressing the desired transgene and/or RNAi inducing molecule. Gene transfer from viral particle to mammalian cell line is expected.

The inserted sequences are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the transduced mammalian cell line. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

Accidental human exposure to viral particles during mammalian cell transduction could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences into the host genome. These risk are discussed in detail above.

In some cases new transgenic lines will be created using viral particles. Due to the replication defective nature of the particles once integrated into the host genome the virus poses minimal risk to humans.

Where viral particles are used in vivo the greatest risk is from the use of needles however as detailed above it is not anticipated that accidental exposure would be linked to significant risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Transgenic mice will be housed and handled at Animal Containment Level 1.

Where no viral particles are present, standard practices will be employed. No further controls are required for safe handling.

In the presence of viral particles, animals will be housed in IVCs marked as biohazardous and handled at Containment Level 2. At first cage change, IVCs and contents will
be autoclaved. Thereafter standard practices only will be required due to the replication defective nature of the particles.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or via the industrial (black bag) waste stream for landfill.

Liquids (eg bacterial and mammalian culture media, culture supernatants, viral samples) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or disinfect with 2% Virkon for at least 30 minutes, discharge to drains.

Consumables (mainly plasticware eg pipettes, flasks, tubes) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or disinfect with 2% Virkon for at least 30 minutes, discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for sharps.

Animal bedding – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes). Dispose of solids via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Virkon, used according to manufacturers instructions under standard conditions, manufacturers validation [eg4.79] log reduction ([eg99.998]% kill).

Purposes of the contained use

Ubiquitin processing enzymes play an important role in host-pathogen interactions and some pathogen genomes encode for unique deubiquitinating enzymes (DUBs).

1. The Paramyxoviruses human respiratory syncytial virus and human parainfluenza virus as representatives of the Pneumoviridae and Paramyxovirinae subfamilies, respectively, will be analysed for their potential to induce enhanced deubiquitinating activity in infected cells. Small active site modifiers specific for deubiquitinating enzymes will be used to monitor and analyse DUB activity in infected cells

2. The Yersinia Enterocolitica and Pseudotuberculosis as representatives of Enterobacteria will be analysed for their potential to induce or block deubiquitinating activity in infected cells. Small activity-based modifiers specific for deubiquitinating enzymes will be used to monitor and analyse DUB activity in infected cells. Active proteins will then be identified using tandem mass spectrometry. The discovery of novel mechanisms of how Yersinia enteropathogens exploit cellular functions will shed light on the biological role of Yersinia infection and provide a window for potential antiviral pharmaceutical intervention.
### Recipient or parental organism

**For Part 1:**
- Disabled E. coli, K12 and B derivatives and BL21
- Mammalian cell lines: Vero, LLCMK2, HEp2, 293T
- Parainfluenza Virus (PIV) Type I, II, III;
- Respiratory Syncytial Virus (RSV)

**For Part 2:**
- Disabled E. coli, K12 and B derivatives and BL21
- Mammalian cell lines: U937, THP-1 293T
- Yersinia Enterocolitica
- Yersinia Pseudotuberculosis

### Host/vector system

Standard bacterial cloning of E.coli strains using non-mobilisable plasmid vector systems

T7 or PolI expression vectors carrying whole cDNA clones of the viral genomes, respectively, will be transfected into mammalian cell lines in addition to eukaryotic expression plasmids coding for proteins required for transcription of viral mRNAs and replication of the viral genome. Additionally, expression vectors carrying whole open reading frames of the deubiquitylating enzymes or other mammalian proteins under study will be transfected into mammalian cell lines.

### Origin & function

**Part 1:**
- Bacterial and viral constructs may either include additional genes coding for nonhazardous reporter genes or tags (i.e. green fluorescent protein) or contain single or multiple sequence deletions.

**Part 2:**
- Bacterial constructs will encode human genes encoding for the deubiquitylating enzyme OTUB1 and C91S, a catalytically inactive form. These constructs may either include additional genes coding for nonhazardous reporter genes or tags (i.e. green fluorescent protein) or contain single or multiple sequence deletions.

- Mammalian constructs will include eukaryotic expression vectors carrying whole open reading frames of the deubiquitylating enzymes or other mammalian proteins under study

### Evaluation of foreseeable effects

**Part 1:**
- E. coli K12 or B derivatives are disabled hosts which cannot colonise the human gut and have a history of safe use. Genes are not expected to be expressed.

- Mammalian cell cultures are especially disabled hosts which should be recognised as foreign by the human immune system. These will be used for production and amplification of recombinant Paramyxoviruses as below. This will increase the level of containment to the degree of the resulting virus.

- Human Paramyxoviruses (PIV-I-III, RSV) infect the upper and lower respiratory tract epithelia causing common cold symptoms like sore throat, coughing and running nose and are often accompanied by malaise and fever. Recombinant viruses will either have single or multiple gene deletions within their genome, or additionally code for a nonhazardous, characterized reporter gene like green fluorescent protein (GFP). An analogous recombinant virus was produced in the USA, University of Utah, using reverse genetics technology (Roth et al. 2009, Antiviral Research) and was shown to be less infective than the wild type strain in cell culture systems. Therefore, the
inserted genetic material should not increase the level of risk for the GMMOs

Part2:  
E. coli K12 or B derivatives are disabled hosts which cannot colonise the human gut and have a history of safe use. Genes are not expected to be expressed

Mammalian cell cultures are especially disabled hosts which should be recognised as foreign by the human immune system. These will be used for infection studies increasing the required containment appropriate for the infecting organism as below.

Yersinia pseudotuberculosis mutant strains YPIII (pIB44) ΔypkA (Km-R), YPIII (pIB47) YpkA D270A (Tc-R) and the contact A mutant strain of Yersinia pseudotuberculosis (IP2777) containing Y591A, N595A and E599A mutations will be used for infection assays. The mutant strains have a lower level of virulence and are generally less viable as compared to wildtype.

**Project Ref** 553/10.1

- **Date Ackn’d**: 12/01/2010
- **CU2 Project Title**: Generation of HIV Virus-Like Particles (VLP)
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **CultureVolumeClass3-4**: Non-GMM Consent Granted

**Date Project Ceased**: 12/01/2010

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

**Historical Significant Changes**: N

**Historical Date of Additional Info**: 12/01/2010
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to generate single-cycle envelope-pseudotyped virus expressing the envelope protein from clinical and laboratory-adapted strains of HIV in order to answer questions relating to the development of broadly neutralizing antibodies. The level of production as well as the potency will be assessed by various different techniques.

**Recipient or parental organism**

Producer cell lines, such as HEK 293 cells
- Mammalian cells including primary human cells
- E. coli K-12 and B derivatives

**Host/vector system**

pNL 4.3.luc.R-E- is a plasmid which encodes HIV backbone however it has a number of mutations which render the resulting viral particles replication defective. There is a frameshift mutation in the envelope gene and also the Vpr gene which knocks out production of both of these proteins. In addition the luciferase gene has been inserted in the place of the Nef gene. Nef is a protein that co-ordinates host cellular activities to enable viral replication and it has been demonstrated that viruses without functional Nef cannot replicate. Therefore three of the genes are missing from the backbone plasmid.

Different HIV envelope proteins are supplied on separate plasmids which are co-transfected into the producer cell lines to generate replication defective virus like particles

**Origin & function**

Luciferase is a standard reporter gene with a history of safe use. Other standard reporter genes such as GFP may be used.

The envelope genes are all from strains of HIV.

The rest of the alterations to the virus knock out genes necessary for viral replication.

**Evaluation of foreseeable effects**

The purpose of the modification is to produce HIV virus capable of mimicking the natural interactions under investigation but incapable of replicaton and therefore representing a significantly reduced hazard. The retrovirus (HIV-1) from which the backbone constructs were derived can cause disease in humans. However the design of these plasmids prevents production of infectious, replication-competent virions. Co-transfection with the env-carrying plasmid allows rescue of infectious virus for env in the viral RNA and as such are only capable of a single round of replication, as no infectious viral progeny will be produced.

As there are two mutations and the Nef gene missing, the virus would have to undergo multiple successful recombination event in order to revert to a replication competent virus. The two plasmids have minimal regions of homology to minimise the risk from recombination. The viruses are not repeatedly passaged and therefore any mutations will not be maintained within the population. The Nef gene is not present in either plasmid and therefore the possibility of the virus like particles obtaining Nef is remote.

Reporter genes such as (luciferase) are well characterised with no known associated health hazards.
The main risk of exposure would be due to a percutaneous injury however as the virus is replication defective no disease can form but individuals may mount an immune response and as such may test positive for HIV. All individuals are trained in the handling and disposal of sharps to reduce to risk of exposure.

02/03/2022
Project Additional Information

Purposes of the contained use

Replication defective Lentiviruses have become a standard research tool for genetically modifying mammalian cells. They are especially useful where the cells to be modified are difficult to transfect using conventional methods. These cells include non-dividing cells, cells that are not active or growing, and difficult to transfect cells such as neurons, primary cells and stem cells.

Recipient or parental organism

Mammalian cells both primary and standard cell lines

Host/vector system

Standard commercially available replication defective lentiviral systems based on viruses such as MoMLV, HIV and EIAV. These systems have had non-essential genes removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to each other.
For example, those viral vectors based on HIV are lacking tat, vif, vpu, vpr, nef and the envelope genes has been replaced with VSVG-env. The remaining genes gag, pol, rev, VSVG-env, gene of interest (with cis-acting signal required for reverse transcription and integration) are generally divide onto a number of plasmids depending on the system used.

Due to the fact that none of the plasmids carrying gag, pol, rev and env have the cis-acting signal they are unlikely to be present in the packaged virus and the risk of generating replication competent viruses minimal.

Some of the vectors will also include a self-inactivating feature which results in the inactivation of the LTR upon integration and reduces the risk of transactivation of host genes.

Some of the viruses will contain WPRE as it is frequently included in lentiviral systems. Current HSE guidance will be followed in relation to the hazard posed by WPRE.

**Origin & function**

The genes to be expressed are potential oncogenes such as human telomerase reverse transcriptase (hTERT) and human papilloma virus 16 E7 (HPV16-E7) or other genes that potentially pose an increase in hazard.

hTERT is a ribonucleoprotein polymerase that maintains the length of telomeres. Telomerase expression plays a role in cellular senescence and is normally suppressed in postnatal somatic cells.

HPVs have been found in 90% of cervical cancers as well as other carcinomas. Viral early proteins E6 and E7 induce immortalization and transformation in a variety of rodent and human cell types.

**Evaluation of foreseeable effects**

The viral vectors are replication defective and therefore cannot disseminate should exposure occur. However the nature of these vectors is to integrate into the host cell genome where there is a potential for disruption of the host genes. In addition, the genes to be expressed effect the cell cycling and may lead to immortalization of the cell.

To minimise the risk sharps will be excluded from this work and all work with the virus will be performed in a Class II micro-biological safety cabinet.

Once the virus is integrated into the mammalian cells they poses no greater risk than other immortalised cell lines as the virus cannot replicate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Ref  553/11.1

Date Ackn'd  25/01/2011

Date Project Ceased  

CU2 Project Title  To develop a protective vaccine against Staphylococcus aureus infections

Consent Granted

Class Consent Granted

CultureVol L2 < 1 litre

Project notified under transitional arrangements [N]
This project aims to measure
1) The immune responses elicited by irradiated Staphylococcus aureus strain Newman, and an isogenic spa mutant, which has been previously described. Briefly, isogenic spa::Tcr mutants were constructed by the insertion of a tetracycline resistance cassette into spa using allelic replacement. The mutant exhibits reduced virulence in mouse models. Immune responses elicited by spa mutant organisms are of interest in view of the possibility that Spa is an immune subversion protein.
2) The virulence of S. aureus strain Newman and bioluminescent strain Xen8.1 will in murine challenge models. S. aureus spa::Tcr will be (i) studied as an radiation inactivated vaccine (ii) used in immunological assays of vaccine efficacy.

Recipient or parental organism
S. aureus is a facultatively anaerobic, Gram-positive coccus that is able to cause a variety of skin and soft tissue infections (boils, wound infections) as well as invasive disease (septic arthritis, osteomyelitis, septicemia, endocarditis). Additionally, some strains carry heat stable enterotoxins mediating food poisoning. Rates of invasive infection in healthy adults without hospital exposure are low, invasive infection occurs most frequently following exposure of wounds and burns to S. aureus. It also commonly results following injection of the organism, as occurs commonly with intravenous drug users.

Origin & function
SPA is an exoprotein that is considered to be a virulence factor, as it:

- Binds the Fc region of immunoglobulins of most mammalian species.
- Binds Fab fragments of immunoglobulins independent of the heavy-chain isotype via an alternative site, conferring superantigen-like function.
- activates complement.
- spa deletion reduces the virulence of S. aureus in mice.

The Lux operon (derived from Vibrio fischeri) encodes the bacterial luciferase (light emitting) system enabling various in vitro and in vivo assays to be undertaken. It is a widely used and safe standard reporter gene system.
SPA mutations:

Since spa is involved in pathogenicity and virulence, and its deletion reduces virulence in mice, the genetic modification is expected to reduce virulence of the organism in humans relative to unmodified Staphylococcus aureus strain Newman.

Lux operon

Expression of the lux operon in the form of bioluminescent luciferase will have no harmful effects nor will it increase virulence of the host pathogen. It will help to:

A) Develop in vitro assays for inhibition of Staphylococcal growth by sera from vaccinated animals.
B) Track systemic spread of S. aureus infection in unimmunised and immunised mice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

Project Additional Information

Purposes of the contained use

In this project we will assess macrophage and T cell infection by chronic and transmitter/founder (T/F) viruses as well as cell-to-cell spread by chronic and T/F viruses and the role of the accessory genes Vpu and Nef on cell-to-cell spread. These viruses will be capable of establishing a spreading infection.

The aims of the project will be able to produce the HIV-1 strains expressing reporter genes Luciferase, GFP, RFP or mCherry, or the strains deleted in vpu or nef by transduction of E. coli with a plasmid containing the HIV-1 genes as well as one of the reporter genes, or a plasmid deleted in vpu or nef. Selection will be with either ampicillin or kanamycin, depending on the plasmid. The resulting plasmid will then be transfected into HEK-293T cells and the resulting virus-containing supernatant harvested and used in macrophage and T cell infections. The level of infection will be established by assessing the expression of the relevant reporter genes or the level of HIV-1 Gag p24 protein or HIV-1 DNA where no reporter genes are present. The HIV-1 genes will either consist of wild-type patient-derived sequences or lab-adapted, chronic strains and in relation to the T/F infections viruses consisting of a patient-derived env gene cloned into the backbone of the lab-adapted NL4-3 strain will also be used.

Recipient or parental organism

E. coli strains are disabled and cannot colonise the human gut.

Packaging cell line HEK293T - Minimum hazard for human cell lines obtained from commercial sources that are well characterised and authenticated.

Primary human cells that are not fully authenticated and characterised from commercial sources that are well characterised and authenticated.

Primary human cells that are not fully authenticated and characterised may carry contaminating infectious agents.

Host/vector system

Standard plasmid vector systems are non hazardous.

Replication-competent HIV-1 vector capable of establishing a spreading infection in cells expressing CD4 and CCR5 or CXCR4 (ACDP Class 3). Infection, through exposure of blood and body fluids is terminal although controllable with lifetime antiretroviral therapy.

Origin & function

Mammalian and reporter genes.

Insertion of the reporter genes luciferase, GFP, RFP and mCherry into the HIV-1 plasmid and deletion of vpu and nef from the HIV-1 plasmid will have no effect on virus production.

Expression of Luciferase, GFP, RFP and mCherry in infected cells will have no effect on HIV-1 virulence.

Lack of expression of Nef from HIV-1 results in decreased virulence.

Lack of expression of Vpu from HIV-1 results in decreased virulence.
E.coli transformed with HIV-1 plasmids. No HIV-1 proteins will be expressed at this stage and the E.coli strain is disabled therefore the risk is minimal. The risks will be minimized by performing all work under good microbiology practices with PPE including lab coat, gloves and goggles. The use of sharps is prohibited.

HEK-293T cells transfected with HIV-1 plasmids. These cells produce the HIV-1 virus for use in future experiments. There is a recognised hazard at this stage of the work which is the possibility of human infection. The risk will be minimised by following good microbiology practices, performing all work in a Class 2 safety cabinet with PPE including lab coat, disposable apron, double gloves and goggles. The use of sharps is prohibited.

Primary cells and cell lines infected with replication-competent genetically-modified HIV-1. These cells produce HIV-1 virus and therefore there is a recognised hazard at this stage of the work which is the possibility of human infection. This risk will be minimised by following good microbiology practices, performing all work in a containment level 2 safety cabinet with PPE including lab coat, disposable apron, double gloves and goggles. The use of sharps is prohibited.

Contains and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes ) - soaked in 5% Trigene before autoclaving using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least three minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) wate stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - treated with 1% Trigene and autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least three minutes) before discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least three minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Any equipment, surfaces that may come into contact with the virus will be treated with 5% Trigene followed by 70% ethanol which inactivates the virus.

Degree of kill

Autoclaving, effectively 100% kill (annual validation)

Chemical disinfection with Trigene, used according to manufacturers’ instructions under standard conditions (effectively 99.998% kill)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

**Purposes of the contained use**

Murine cytomegalovirus induces a high frequency of antigen specific T cells, many of which can be triggered by proinflammatory cytokines in the absence of cognate antigen. We theorise that these "innate-like" T cells may impact on the development of the other infections. Listeria monocytogenes DPL-1942 carries a genetically modified epitope from chicken ovalbumin which can be recognised by CD8 T cells. This is the standard bacterial infection model used to study CD8 T cell responses because it is well characterized and many experimental reagents are available to track the ovalbumin-specific T cells. Tracking T cells specific for unmodified Listeria would be technically difficult. The ovalbumin modification is necessary since natural Listeria epitopes have not yet been identified for H-2b mice. Homogenisation and culture of
organs from infected mice can inform if MCMV enhances protection. This work will involve the study the immune response by infecting C57Bl/6, IL18 ko and IL 18ra ko mice with Listeria DPL-1942. Outcomes will be measured using culture of L.monocytogenes and cellular immune responses.

Recipient or parental organism

Listeria monocytogenes (attenuated)

Host/vector system

The L. monocytogenes DPL-1942 (ova) was constructed and described by Pope, C, et al in 2001. “A rLM (rLM-ova) was constructed that expresses a secreted form of OVA and an erythromycin-resistance marker. An Ag expression cassette was constructed that consists of the entire coding sequence of OVA fused to the signal sequence and promoter of the hly gene and an erythromycin resistance gene for selection. The Ag expression cassette was introduced into the Listeria, and double-crossed into the Listeria chromosome by homologous recombination. Integration of the Ag cassette into the LM genome and secretion of the OVA fusion protein by rLM-ova were confirmed by PCR and Western blot analyses, respectively.” Pope, C, et al. 2001. "Organ-specific regulation of the CD8 T cell response to Listeria monocytogenes infection". J. Immunol. 166, 3402-9.

Origin & function

The OVA ovalbumin sequence is derived from chicken and functions as a specific marker antigen. It is not expected to have any biological activity.

Evaluation of foreseeable effects

LM DPL 1942 is act A deficientThe attenuated actA mutant of Listeria monocytogenes can enter and multiplu in the cytosol of the infected host cell but is deficient in actin-dependent cell-to-cell spread. It has been found to be of attenuated virulence for inbred C3H mice: the LD50 after I.v injection is 1000-fold higher than that of the wild-type strain. Thus the GMO is significantly less pathogenic than wild type Listeria. There is no risk posed by transfer of OVA to this strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Innoculated mice will be held at the Animal Containment Level 2.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121- 1250c for at least 15 mins or 126-130oc for at least 10 mins or 134-138oc for at least 3mins) discharge any excess liquids to drains, dispose of solids via clinical waste stream for incinerator/ dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, part3, 1993 (either 121-1250c for at least 15 mins or 126-130oc for at least 10 mins or 134-138oc for at least 3mins), or inactivate by chemical means (following manufactures guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 646, part 3, 1993 (either 121-125oc for 15 mins or 126-130oc for at least 10 mins or 134-138oc for at least 3mins), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/ dispose of solids vis the industrial(black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose vis clinical waste stream for incineration.

Animal bedding - Either autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125oc for at least 15 mins or 126-130oc for at least 10 mins, or 134-138oc for at least 3mins), dispose via the industrial (black bag) waste stream for landfill OR dispose vis clinical waste stream for incineration.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
### Purposes of the contained use

Replication defective retroviral and lentiviral gene transfer vectors will be used to introduce transgenes into human and murine primary cells and cell lines.

### Recipient or parental organism

- **E. coli K12 or B derivatives** - E. coli strains are disabled and cannot colonise the human gut.
- **Mammalian cell lines including primary cells** - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.
- **Packaging cell lines** - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.
- **Adult mice** - No hazard to human health.

### Host/vector system

Replication defective ecotropic and amphotropic retroviruses and lentiviruses

Third or later generation retro- and lentiviral systems (based on viruses from various species) incorporating self-inactivating 3' LTR (SIN) U3 deletion which is transferred to the 5' LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIV and EIAV. However non-essential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses, being created is minimal.

**Baculvirus system** - baculviruses have a restricted host range and are not generally known to infect vertebrate cells and replication incompetent in vertebrate cells

### Origin & function

Mammalian and reporter genes.

- Human and mouse genomic DNA and cDNA inserts coding for transcription factors such as MAZ, GATA family members, TFII-I or MLL-fusion proteins, HOXAS, Meis1.
- MLL-fusion proteins and HOX9/Meis1 are known oncogenes.
- MAZ, GATA family members and TFII-I have no transforming or oncogenic properties.
- ETV6-AML1 and bcr-abl - suspected oncogenes.
- MAZ, GATA family members and TFII-I have no transforming or oncogenic properties.
Short interfering RNA (siRNA) will be expressed to knockdown expression of some or all of the proteins mentioned above. An alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or their progeny is expected.

Standard selection markers (GFP, antibiotic resistance, lacZ) will allow identification of the transduced cells, but is unlikely to have any significant biological effect.

**Evaluation of foreseeable effects**

The lentiviruses and retroviruses are amphotropic and can therefore infect human cells however the design of these systems is such that the viral particles are replication defective and are only capable of one round of infection.

The genes to be expressed or knocked down have the potential to affect proliferation, apoptosis and survival of cells and could therefore in some instances have detrimental effects should they be integrated into genomic DNA of a workers cells. Once incorporated into the genomic DNA of the experimental cell lines the inserts pose minimal risk due to the replication defective nature of the viruses. The cells would be recognised as non-self by the immune system and rapidly lysed by complement.

The lentiviral particles produced will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see above) into the host genome. This is an anticipated risk associated with the use of lentiviral gene transfer vectors. The viral particles have however been rendered non-replicative by a number of safety features.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

Accidental human exposure to viral particles could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences into the host genome. Importantly, in the context of human gene therapy clinical studies, high doses of retroviral and lentiviral vector particles have been administered in vivo with no observed complications. It is considered highly unlikely that accidental human exposure to the viral particles described in this risk assessment would lead to the generation of a tumour.

**Retroviral and Lentiviral Transduction**

Retroviral and lentiviral particles will be purified from packaging cell cultures and used to transduce mammalian cells to facilitate the production of new mammalian cell lines permanently expressing the desired transgene and/or shRNA inducing molecule. Gene transfer from viral particle to mammalian cell line is expected.

In some cases new transgenic lines will be created using viral particles. Due to the replication defective nature of the particles once integrated into the host genome the virus poses minimal risk to humans.

Where viral particles are used in vivo the greatest risk is from the use of needles however it is not anticipated that accidental exposure would be linked to significant risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified I BS2646, Part 3. 1993 (either 121-125°C for at least 14 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) wastestream for landfill.
Liquids (e.g., samples, culture supernatants, tissue culture media) - autoclave using a makesafe cycle as specified in BS2646, Part 3 1993 (either 121-125°C for at least 14 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (e.g., needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Project Ref 553/11.3

Date Ackn’d CU2 Project Title Class Culture Vol
03/03/2011 Infection of Human And Murine Cells with Recombinant Replication Defective Class 2 < 1 Litre
Purposes of the contained use

Replication defective lentiviral gene transfer vectors will be used to introduce transgenes and short hair pin RNA into different mammalian cells.

Recipient or parental organism

E. coli K12 or B derivatives - E.coli strains are disabled and cannot colonise the human gut.
Mammalian cell lines - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.
Primary cell cultures - Primary human and mice cells and human and mice cell lines that are not fully authenticated and characterised may carry contaminating infectious agents. Primary cells from non primate sources are deemed to be of low hazard.
Packaging cell lines - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.
Adult mice - No hazard to human health

Host/vector system

Replication defective lentivirus
The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIVand EIAV. However nonessential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal. In addition, some of the later generation viral vectors also include a self inactivating feature, a deletion within the 3' L TR, which is transferred to the 5' LTR after reverse transcription and integration in infected cells. This results in the
Transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

**Origin & function**

**Mammalian and reporter genes**

Human and mouse genomic DNA and eDNA inserts encoding JmjC-domain-containing protein.

JmjC is a histone demethylase that specifically demethylates Lys-27 of histone H3 and plays a central role in regulation of posterior development, by controlling HOX gene expression. The expression of JmjC is induced upon activation of the RAS-RAF signalling pathway. JmjC recruits to the INK4A-ARF locus and contributes to the transcriptional activation of p16INK4A in human diploid fibroblasts. Inhibition of JmjC expression in mouse embryonic fibroblasts results in suppression of p16INK4A and p19Arf expression and in cell immortalization.

JmjC2d is also a histone demethylase that specifically demethylates Lys-9 of histone H3. The majority of histone lysine methyltransferases contain a SET domain, which catalyzes the addition of methyl groups to the specific lysine residues. No oncogenic or tumourigenic properties have been associated with JmjC2d.

Jmjd2d is also a histone demethylase that specifically demethylates Lys-9 of histone H3. The majority of histone lysine methyltransferases contain a SET domain, which catalyzes the addition of methyl groups to the specific lysine residues. No oncogenic or tumourigenic properties have been associated with Jmjd2d.

MLL2 is a histone methyltransferase that methylates Lys-4 of histone H3. H3 lys-4 methylation represents a specific tag for epigenetic transcriptional activation. These genes are expressed on all cell types. Elevated levels of MLL2 in the breast and colon cells may be associated with malignancy.

**Tyrosine kinase 2 (TYK2) gene and variants of.** TYK2 is a member of the Janus-activated kinase family and plays a key role in the signal transduction pathway of many cytokines, including type I interferons, IL-6, IL-10 and IL-22.

TYK2-Pro1 104Ala that is protective for multiple sclerosis (MS). The germline allele encoding TYK2-Ala104 has been potentially linked to cancer. Given that the allele encoding TYK2-Ala1 104 is expressed in healthy individuals it seems unlikely that this variant has oncogenic properties per se but instead requires additional genetic variants or environmental factors to contribute to carcinogenesis.

**Regulator of G protein signalling 1 (RGS1) gene -** RGS1 may be involved in regulating B cell activation and proliferation, although it is expressed in various cell types and tissues. RGS1 over-expression has been correlated with melanoma progression and is a prognostic marker for primary cutaneous melanoma. RGS1 over-expression has not been directly associated with oncogenesis.

**Chemokine (C-X-C motif) receptor 4 (CXCR4) gene -** The CXCR4 protein has 7 transmembrane regions and binds stromal cell-derived factor-1 (SDF-1/CXCL12). The interaction with its ligand leads to an increase in intracellular calcium. CXCR4 plays a role in haematopoiesis, vascularisation and possibly cerebellar development and hippocampal-neuron survival. CXCR4 over-expression has been associated with the ability of the receptor to mediate metastasis of various cancers including prostate cancer, and it has been found 10 be a prognostic marker for leukaemia and breast cancer.

**Interleukin-12A (IL12A) gene -** IL-12A is a subunit of a cytokine that acts on T cells and NK cells and plays an important role in Th1 and Th2 cell differentiation. Polymorphisms in the non-Coding region of IL12A have been associated with the risk of cervical cancer and hepatocellular carcinoma. IL-12A overexpression or knockdown using the lentiviral system is unlikely to be oncogenic.

**Prostaglandin E receptor 4 (PTGER4) gene -** PTGER4 is a member of the G-protein coupled receptor family and binds prostaglandin E2 (PGE2). PTGER4 has been implicated in T cell factor signalling, skin immune responses and development of the circulatory system. The knockdown of PTGER4 accelerates B cell/lymphoma spreading in mice and a role for PTGER4 in inflammatory breast cancer cell invasiveness has been described.

**Interleukin-7 receptor alpha-chain (IL7RA) gene -** IL-7RA plays an important role during VDJ recombination during the development of lymphocytes and is important in T-cell differentiation and activation. The precise function of sIL-7RA remains to be elucidated. Genetic variation potentially leading to changes in IL-7RA expression has been linked with non-small cell lung carcinoma, however overexpression or knockdown of IL-7RA using the lentiviral system is unlikely.
to be oncogenic.
Cytochrome P450, family 27, subfamily B, polypeptide 1 (CYP27B1) gene - CYP27B1 is a member of the cytochrome
P450 superfamily that localizes to the inner mitochondrial membrane where it catalyzes the hydroxylation of 25-
hydroxyvitamin D3 to give rise to the active form of vitamin D3 that in turn regulates calcium homeostasis. Changes in
CYP27B1 expression has been linked with prognosis of prostate cancer.
M-phase phosphoprotein 9 (MPHOSPH9) gene - MPHOSPH9 over-expression has been observed in neuroblastoma
cell lines.
Tumour necrosis factor, alpha-induced protein 3 (TNFAIP3) gene - TNFAIP3 expression is upregulated by TNF and it
functions to inhibit NF-KB activation and TNF-mediated apoptosis. TNFAIP3 is a tumour suppressor gene and its
inactivation has been observed in several B-celllymphomas and in chronic lymphocytic leukaemia, leading to
constitutive NF-KB activation that is thought to be pathogenic.
Interferon regulatory factor 8 (IRF8) gene - IRF8 expression is a transcription factor involved in regulating responses
to type I interferons by binding to the interferon-stimulated response element. While the expression or knockdown of
IRF8 variants using the lentiviral system is unlikely to be oncogenic, changes in IRF8 expression have been observed
in human multiple myeloma.
Signal transducer and activator of transcription (STAT3) gene - STAT3 is a transcription factor that becomes activated
and translocates to the cell nucleus once it is phosphorylated by receptor associated kinases that themselves become
activated upon the binding of cytokines to their transmembrane receptors. STAT3 has been described to be involved
in the development and progression of head and neck cancers.
Ectopic viral integration site 5 (EVI5) gene - EVI5 is a regulator of cell cycle progression and plays a role during
interphase and cytokinesis. Expression of EVI5 variants using the lentiviral system is unlikely to be oncogenic. a
 genetic region including EVI5 has been associated with melanoma.
VAV1 gene - VAV1 is a guanine nucleotide exchange factor for the Rho family of GTP binding proteins and is involved
in haematopoiesis and T- and 8-cell development and activation. Expression of VAV1 variants using the lentiviral
system is unlikely to be oncogenic, studies in mice suggest that VAV1 may be implicated in lumphomagenesis and
metastasis.
Suppressor of cytokine signalling 1 (SOCS1) gene - SOCS1 is a negative regulator of cytokines that signal through
the JAKISTAT3 pathway. for example. The expression of SOCS1 variants using the lentiviral system is unlikely to be
oncogenic. SOCS1 expression has been suggested as a biomarker of aggressive laryngeal carcinoma.
Standard selection markers (GFP, antibiotic resistance, lacZ) will allow identification of the transduced celis, but is
unlikely to have any significant biological effect.

**Evaluation of foreseeable effects**

The inserted mammalian and reporter gene sequences are normal or selective alterations of characterised
mammalian genes or shRNAs and/or standard reporter genes. Most of the genetic inserts are not likely to cause
significant effect on an individual. However, since some of the genes to be expressed in these vectors are potential
oncogenes, they may cause host cells to proliferate.

The lentiviral particles produced will have a broad tropism and be capable of infecting and transducing human and
other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see above) into the host
genome. This is an anticipated risk associated with the use lentiviral gene transfer vectors. The viral particles have
however been rendered non-replicative by a number of safety features.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected
to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the
complement/immune system of any exposed individual.

Accidental human exposure to viral particles could lead to viral infection and the insertion of viral and mammalian
and/or reporter gene sequences into the host genome. Importantly, in the context of human gene therapy clinical
studies, high doses of retroviral and lentiviral vector particles have been administered in vivo with no observed complications. It is considered highly unlikely that accidental human exposure to the viral particles described in this risk assessment would lead to the generation of a tumour.

Retroviral and Lentiviral Transduction

Retroviral and lentiviral particles will be purified from packaging cell cultures and used to transduce mammalian cells to facilitate the production of new mammalian cell lines permanently expressing the desired transgene and/or shRNA inducing molecule. Gene transfer from viral particle to mammalian cell line is expected in some cases new transgenic lines will be created using viral particles. Due to the replication defective nature of the particles once integrated into the host genome the virus poses minimal risk to humans. Where viral particles are used in vivo the greatest risk is from the use of needles however it is not anticipated that accidental exposure would be linked to significant risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transgenic mice will be used and handled at Animal Containment Level 1.

Where no viral particles are present, standard practices will be employed. No further controls are required for safe handling.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Purposes of the contained use

Replication defective lentiviral gene transfer vectors will be used to introduce transgenes and RNA into cancer cell lines.

### Recipient or parental organism

- **E. coli K12 or B derivatives** - E. coli strains are disabled and cannot colonise the human gut.
- **Mammalian cell lines** - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.
- **Primary cell cultures** - Primary human and human cell lines obtained from commercial sources that are well characterised and authenticated.
- **Packaging cell lines** - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.
- **Adult mice** - No hazard to human health.

Replication defective virus from numerous wild type viruses, such as MoMLV, HIV and EIAV. However non-essential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr, nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.

In addition, some of the later generation viral vectors also include a self inactivating feature, a deletion within the 3' LTR, which is transferred to the 5' LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

### Host/vector system

Replication defective lentivirus

The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIV and EIAV. However non-essential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr, nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.

In addition, some of the later generation viral vectors also include a self inactivating feature, a deletion within the 3' LTR, which is transferred to the 5' LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

### Origin & function

A range of genes including those known or thought to control growth and differentiation (e.g. CDX1, KRT20, BMI1, ALDH1 etc) will be transfected into human cancer cell
lines and cells isolated from fresh tumour material. Similarly, genes which are known or thought to be involved in the development and progression of cancer will also be studied.

**CDX1**
This gene is a member of the caudal-related homeobox transcription factor gene family. The encoded DNA-binding protein regulates intestine-specific gene expression and enterocyte differentiation. It has been shown to induce expression of the intestinal alkaline phosphatase gene, and inhibit beta-catenin/T-cell factor transcriptional activity.

**KRT20**
The protein encoded by this gene is a member of the keratin family. The keratins are intermediate filament proteins responsible for the structural integrity of epithelial cells. This cytokeratin is a major cellular protein of mature enterocytes and goblet cells and is specifically expressed in the gastric and intestinal mucosa. It is perhaps the most commonly used diagnostic marker of colorectal epithelial cell differentiation.

**BMI1**
Component of the Polycomb group (PcG) multiprotein PRC1 complex, a complex required to maintain the transcriptionally repressive state of many genes throughout development. PcG PRC1 complex acts via chromatin remodelling and modification of histones; it mediates monoubiquitination of histone H2A 'Lys-119'. Rendering chromatin heritably changed in its expressibility.

**ALDH1**
Aldehyde dehydrogenase (ALDH) is an enzyme involved in intracellular retinoic acid production. ALDH1A is an important member of the ALDH family that includes 17 genes encoding different substrate specificities, of which ALDH1A1 catalyses the oxidation of retinal to retinoic acid. Retinoic acid signalling is linked to cellular differentiation during development and has important function in stem cell self-protection throughout an organism's lifespan. This gene has been used as a marker of cancer stem cells in breast, prostate and colorectal cancers.

Short-interfering RNA (siRNA) may be expressed to knock-down expression of some or all of the genes studied. We expect an alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or their progeny.

**Evaluation of foreseeable effects**

Modified forms (including truncations and point mutations) of some or all of the proteins mentioned above will be expressed. They are expected to display a subset of the activities of their wild-type counterparts. By definition, some of these genes will be considered as oncogenic and could be expected to have effects on proliferation, differentiation and survival of host cells.

The lentiviral particles produce will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see above) into the host genome. This is an anticipated risk associated with the use of lentiviral gene transfer vectors. The viral particles have however been rendered non-replicative by a number of safety features.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

Accidental human exposure to viral particles could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences (see above) into the host genome. ### Purposes of the contained use

Replication defective lentiviral gene transfer vectors will be used to introduce transgenes and RNA into human cells in order to generate iPS cells. Cellular signalling pathways, epigenetics, and senescence will be investigated in the produced iPS cells.

### Recipient or parental organism

- **E. coli K12 or B derivatives** - E. coli strains are disabled and cannot colonise the human gut.
- **Mammalian cell lines** - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.
- **Primary cell cultures** - Primary human and mice cells and human and mice cell lines that are not fully authenticated and characterised may carry contaminating infectious agents. Primary cells from non primate sources are deemed to be of low hazard.
- **Packaging cell lines** - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.

### Host/vector system

#### Replication defective lentivirus

Genes encoding the structural and other components required for packaging the viral genome are separated onto two plasmids. The packaging genes for lentiviral vectors are provided by co-transfection of packaging vectors and viral vector into a packaging cell line such as HEK293. By using this enhanced 3-plasmid system, virus particles can be produced that can infect human and mouse cells, but are replication deficient therefore cannot be transmitted from one cell to another. Although the two packaging plasmids allow expression of proteins required to produce viral progeny (e.g. gag, pol, env) in the HEK293 producer cell line, none of them contain LTRs or the psi packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. Therefore, no new replication-competent virus can be produced. The HIV-1 env gene is replaced with a Vesicular Stomatitis Virus G (VSV-G) envelope.

Because the number of HIV-1 genes are reduced to minimum (gag and pol) and that none of the 2 packaging plasmids contain LTRs or psi sequences, the number of recombination events required to generate a wild-type virus capable of infecting & replicating ensures that no replication competent virus can be produced.

Different transcription genes are supplied in separate plasmids which are co-transfected into the producer cell lines to express protein.

### Origin & function

**Mammalian and reporter gene sequences:**

- **hTER** - The ectopic expression of the telomerase catalytic subunit (human telomerase reverse transcriptase of hTERT) and subsequent activation of telomerase can allow cells to proliferate so that they can stay in a stem cell like state and divide repeatedly.

- **SV40LT** - encodes for a protein (Tag) that is a proto-oncogene derived from the polyomavirus SV40 which is capable of transforming a variety of cell types. The transforming activity of Tag is due in part to its perturbation of the retinoblastoma (pRB) and p53 tumour suppressor proteins, an activity that also helps to maintain a pluripotent state of cells and prevent cell apoptosis.

- **P-MIG** - The pMIG vector includes a sequence for an internal ribosome entry site, abbreviated IRES. This is a nucleotide sequence that allows for translation initiation in the middle of a messenger RNA (mRNA) sequence as part of the greater process of protein synthesis. IRES are often used by viruses as a means of shutting down translation.
hOCT4 - OCT4 is a homeodomain transcription factor of the POU family. It is expressed in mammalian early embryo and germ cells and can both stimulate and repress target gene transcription. OCT4 is critically involved in the self-renewal of undifferentiated embryonic stem cells and regulates the expression of multiple genes via interaction with other transcription factors present in pluripotent cells, e.g. SOX2.

hSOX2 - SOX2, also known as SRY (sex determining region Y)-box 2, maintains or preserves developmental potential.

hKLF4 - The Kruppel-like family of transcription factors (Klfs) has been extensively studied for their roles in cell proliferation, differentiation and survival. KLF4 promotes self-renewal in ES cells as well as inhibiting cell differentiation.

Standard selection markers (GFP, antibiotic resistance, lacZ) will allow identification of the transduced cells, but is unlikely to have any significant biological effect.

Evaluation of foreseeable effects

The inserted mammalian and reporter gene sequences are normal or selective alterations of characterised mammalian genes or miRNAs and/or standard reporter genes. Most of the genetic inserts are not likely to cause significant effect on an individual. However, some inserted sequences may have harmful properties in humans via the ability to act as a tumour suppressor and/or oncogenes eg SV 40 LT - encodes for a protein (Tag) that is proto-oncogene derived from the polyomavirus SV40 which is capable of transforming a variety of cell types. The transforming actiity of TAg is due in large part to its perturbation of the retinoblastoma (pRB) and p53 tumour suppressor proteins, an activity that also helps to maintain a pluripotent state of cells and prevent cell apoptosis.

The lentiviral particle produced will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see below) into the host genome. This is an anticipated risk associated with the use of lentiviral gene transfer vectors. The viral particles have however been rendered non-replicative by a number of safety features.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences into the host genome. It is considered highly unlikely that accidental human exposure to the viral particles described in the risk assessment would lead to the generation of a tumour.

Retroviral and Lentiviral Transduction

Retroviral and lentiviral particles will be purified from packaging cell cultures and used to transduce mammalian cells to facilitate the production of new mammalian cell lines permanently expressing the desired transgene and/or RNAi inducing molecule. Gene transfer from viral particle to mammalian cell lines is expected.

In some cases new transgenic lines will be created using viral particles. Due to the replication defective nature of the particles once integrated into the host genome the virus poses minimal risk to humans

Project Ref 553/11.6

Date Ackn'd | CU2 Project Title | Class | CultureVolClass2 | CultureVolumeClass3-4 |
-------------|------------------|-------|-----------------|-----------------------|
20/06/2011   | Investigation of copine protein function and trafficking in neuronal cells using delivery | Class 2 | < 1 Litre |
Purposes of the contained use

Sindbis virus constructs will be used to express mutant versions of copine proteins in different cell lines and primary cultures of neurones, and study the consequences of the mutations on the cells.

Recipient or parental organism

E.coli strains that are disabled and cannot colonise human gut.

Mammalian cell lines (BHK, HEK 293, COS-7). Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised.

Primary cell culture - Primary rat cell lines can only survive in cell culture facility conditions.

Host/vector system

The Sindbis virus expression system was commercially available from Invitrogen and has been used worldwide to produce viruses for use in dissociated neuronal cultures and slices.

The system consists of two plasmids, pSinRep5 (used to express the gene of interest) and pDH(26S), a helper plasmid (produces structural proteins (capsid, p62, 6K and E1) required for viral encapsidation and release from the produced cell line). The E1 and E2 glycoprotein sequences from pDH(26S) that are required for viral infection of host cells, are derived from a neurovirulent strain of Sindbis virus cDNA (TE12), thus allowing for efficient infection of neurons in culture. RNA transcripts of these plasmids (capped and poly-adenylated) are generated in vitro and transfected into BHK cells, where they are translated as mRNA to produce encapsulated viral particles. Particles produced by these transfections have little or no plaque forming unit (pfu) capability associated with them.

In addition, we also plan to use the pSinRep5nsP2ser plasmid (with pDH(26S) as a helper), which has reduced cytotoxic effects of sindbis viral expression on cultured cells. In the Sindbis Expression System, the structural genes in the viral genome have been replaced by a cassette into which the gene of interest is cloned. The structural genes are provided on the helper plasmid and are not incorporated into the final Sindbis viral particles. Rather, the gene of interest is packaged, along with the replicase sequences. This is designed to render those particles non-infectious following a single round of infection. The risk of replication competent virus being created is minimal.

Origin & function
Mammalian and reporter genes.
The genetic material to be introduced into the virus will be derived from normal mammalian genes. None of the inserts, or mutations are expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms.

Copine protein family - Copines are Ca2+-dependent phospholipid-binding proteins that are thought to be involved in membrane-trafficking, and may also be involved in cell division and growth.

Standard selection markers and polypeptide tags (GFP, antibiotic resistance, lacZ) will allow identification of the transduced cells, but is unlikely to have any significant biological effect.

Evaluation of foreseeable effects

The inserted mammalian and reporter gene sequences are normal or selective alterations of characterised mammalian genes. The genetic inserts are not likely to cause significant effect on an individual.

Native Sindbis virus is endemic in Northern and Eastern Europe and is maintained in the avian population. Human infection, caused by mosquito bites, is rare even in the countries of origin, and causes mild fever with a rash, and may predispose to the development of arthritis. The virus is unstable and can survive for only a limited time outside the laboratory. However the Sindbis virus to be used here can only undergo one round of replication when co-expressed with the appropriate helper vector and in a suitable cell line. It is not anticipated that accidental human exposure would be linked to significant risk.

Consequently, considering the non-replicative nature of virus type to be used and complexity of the life cycle of sindbis virus, its accidental release into the environment would not cause any significant impact.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - treated with 1% virkon and discharge to drains or autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 - (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes).

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Any equipment surfaces that may come into contact with the virus will be treated with 1% Virkon or 70% ethanol which inactivates the virus.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Chemical disinfection with Virkon, used according to manufacturers' instructions under standard conditions (effectively 99.998% kill)

**Project Additional Information**

**Purposes of the contained use**

Sinbis virus constructs will be used to express proteins in order to investigate the mechanisms that regulate synaptic inhibition in the brain.

**Recipient or parental organism**

E.coli strains that are disabled and cannot colonise human gut.

Mammalian cell lines (BHK, HEK 293, COS-7). Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised.

Primary cell culture - Primary rat neuronal cell lines and slice cultures can only survive in cell culture facility conditions.

**Host/vector system**

The Sindbis virus expression system was commercially available from Invitrogen and has been used worldwide to produce viruses for use in dissociated neuronal cultures and slices.

The system consists of two plasmids, pSinRep5 (used to express the gene of interest) and pDH(26S), a helper plasmid (produces structural proteins (capsid, p62, 6K and E1) required for viral encapsidation and release from the produced cell line). The E1 and E2 glycoprotein sequences from pDH(26S) that are required for viral infection of host cells, are derived from a neurovirulent strain of Sindbis virus cDNA (TE12), thus allowing for efficient infection of neurons in culture. RNA transcripts of these plasmids (capped and poly-adenylated) are generated in vitro and transfected into BHK cells, where they are translated as mRNA to produce encapsulated viral particles. Particles produced by these transfections have little or no plaque forming unit (pfu) capability associated with them.

In addition, we also plan to use the pSinRep5nsP2ser plasmid (with pDH(26S) as a helper), which has reduced cytotoxic effects of sindbis viral expression on cultured cells. In the Sindbis Expression System, the structural genes in the viral genome have been replaced by a cassette into which the gene of interest is cloned. The structural genes are provided on the helper plasmid and are not incorporated into the final Sindbis viral particles. Rather, the gene of interest is packaged, along with the replicase sequences. This is designed to render those particles non-infectious following a single round of infection. The risk of replication competent virus being created is minimal.

**Origin & function**

Mammalian and reporter genes.

The genetic material to be introduced into the virus will be derived from normal mammalian genes. None of the inserts are expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms.

GABA receptors (e.g. GABA-A, GABA-B): Activation of these receptors results in the opening of channels in the cell's membrane that allow specific ions to flow, such as potassium and chloride.

Ion transporter proteins (e.g. NKCC1, KCC2): establish the relevant ionic gradients.

Standard selection markers and polypeptide tags (GFP < antibiotic resistance, lacZ) will allow identification of the transduced cells, but is unlikely to have any significant biological effect.

**Evaluation of foreseeable effects**

The inserted mammalian and reporter gene sequence are normal or selective alterations of characterised mammalian genes. The genetic inserts are not likely to cause...
Native Sindbis virus is endemic in Northern and Eastern Europe and is maintained in the avian population. Human infection, caused by mosquito bites, is rare even in the countries of origin, and causes mild fever with a rash, and may predispose to the development of arthritis. The virus is unstable and can survive for only a limited time outside the laboratory. However the Sindbis virus to be used here can only undergo one round of replication when co-expressed with the appropriate helper vector and in a suitable cell line. It is not anticipated that accidental human exposure would be linked to significant risk.

Consequently, considering the non-replicative nature of virus type to be used and complexity of the life cycle of sindbis virus, its accidental release into the environment would not cause any significant impact.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - treated with 1% virkon and discharge to drains or autoclaved using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes).

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Any equipment surfaces that may come into contact with the virus will be treated with 1% Vinikon or 70% ethanol which inactivates the virus.

### Degree of kill

**Autoclaving**, effectively 100% kill (annual validation)

Chemical disinfection with Vinikon, used according to manufacturers' instructions under standard conditions (effectively 99.998% kill)

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Herpes simplex type 1 amplicon technology will be used to deliver the iPS and pluripotency genes in order to improve iPS formation efficiency.

**Recipient or parental organism**

E. coli strains that are disabled and cannot colonise the human gut.
Mammalian cell lines including primary cells: Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised.

Host/vector system

The vector pEP4EO2SET2K, (carrying the iPS inducing genes and the SV40 large T antigen) will be ligated by standard enzyme digestion and ligation and/or LoxP-Cre recombined with pHGPuro (carrying the HSV-1 origin of replication and packaging signal), to generate an HSV-1-iPS inducing construct. The HSV-1-iPS construct DNA will be extracted and transfected into the packaging cell line Vero 2-2 along with the fHSVpac270 DNA and pEBHICP27 vectors. The fHSVpac270 DNA, which contains a modified HSV-1 genome, will furnish all the necessary genes to assemble infectious virions, apart from ICP27, which is encoded by pEBHICP27. However, fHSVpac270 cannot itself be packaged since it lacks the HSV-1 iPS vector can be replicated and packaged. The infectious particles thus generated will be released from the cells by sonication, using a dedicated instrument, and concentrated by ultracentrifugation on sucrose gradients. The HSV-1 iPS vector will be stably maintained as an episome, as it possesses the oriP and EBNA1 genes as a part of the pEP4EO2SET2K vector, and it will drive the expression of the iPS genes Oct4, KLF4, Sox2 and the SV40 large T antigen.

The HSV-1 iPS vector on its own cannot generate infectious particles and hence the system is safe.

Origin & function

Mammalian and reporter genes.

The SV40 large T antigen is an oncogene, capable of conferring transforming properties to primary cells (immortalisation).

The iPS inducing genes HLF4, Oct4 and Sox2 are transcription factors, able to alter the cellular gene expression pattern, to reprogram differentiated cells to a stem cell-like status.

Evaluation of foreseeable effects

The resulting GMOs (HSV-1 iPS transduced fibroblast cells are not expected to carry any additional risks to that of the un-modified recipients and could not survive outside the lab environment. However, secondary infection of the transduced cell with a wild type HSV-1 virus, could in theory generate infectious particles carrying the iPS and T antigen genes. Even in this event, the HSV-1 iPS particles would only be able to infect cells once, but would not be able to further spread, as they would lack the HSV-1 proteins necessary to replicate their genome, and assemble a functional viral capsid.

## Project Additional Information

**Purposes of the contained use**

Lentivirus expressing a defined protein will be injected into mouse articular cartilage in order to understand what maintains homeostasis.

**Recipient or parental organism**

Mammalian cell lines including primary cells - Minimal hazard for mammalian cell lines obtained from commercial sources that are well characterised and authenticated.

Packaging cell lines - produce infectious replication defective viral particles after they have been transfected with multiple viral plasmids.

Adult mice - No hazard to human health.

**Host/vector system**

Replication defective lentiviruses

Third generation lentiviral systems (based on viruses from various species) incorporating self-inactivating 3' LTR (SIN) U3 deletion which is transferred to the 5' LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIV and EIAV. However non-essential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr, nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence non of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.

Some of the vectors contain the woodchuck hepatitis virus PRE (WPRE) either in the mutate or wild type form. The wild type WPRE contains the gene X promoter and encodes a truncated X protein. Theses have the potential to have oncogenic effects.

**Origin & function**

Mammalian and reporter genes
Tissue inhibitors of metalloproteinases (TIMPs) are widely distributed in the animal kingdom. Four genes encoding TIMPs (1 to 4) were identified into human and mouse genomes. Was originally thought that TIMPs exert their regulatory activity on other classes of enzymes such as ADAMs (a disintegrin and metalloproteinases) and ADAM-TSs (a disintegrin and metalloproteinases with thrombospondin domains). These enzymes are important for ECM turnover during embryonic development, as well as during remodeling into adult tissues. Some enzymes are also necessary for the shedding of molecules anchored to the cell surface. Imbalance into the physiological crosstalk between enzymes and inhibitors may result in diseases associated with uncontrolled ECM turnover, inflammation, cell growth and migration, such as arthritis, cardiovascular disease or cancer.

Members of the Toll-like receptors (TLRs) family - TLRs were initially identified based on their sequence similarity with Drosophila Toll receptors. These receptors form part of the innate immune response. In general TLRs are thought to be involved in host defence against infection with different microbial products and the reason why we wish to use it is that it recycles TIMPs. Dominant negative versions would be expressed to stop internalisation of TIMPs.

Human TNF (Tumour Necrosis Factor) a multifunctional proinflammatory cytokine that belongs to the TNF superfamily.

CCN family proteins are involved in a number of biological processes in development, tissue repair, and tumor suppression; but their exact functions are still unspecified. The CCN family consists of 6 distinct proteins (i.e. cysteine-rich 61; Cyr61/CCN1, CTGF/CCN2, nephroblastoma overexpressed; Nov/CCN3, Wnt-inducible secreted proteins 1, 2, and 3; Wisp1-3/CCN4-6 with similar structures as described above, except for Wisp2/CCN5, which lacks the CT module. Connective tissue growth factor (CTGF) is the second member of the CCN family of proteins (CCN2) and its structure is characterized by 4 distinct modules, i.e. insulin-like growth factor binding protein-like (IGFBP), von Willebrand factor type C (VWC), thrombospondin type 1 repeat (TSP1), and a carboxyl terminal cysteine knot (CT).

Tenascin family members are also matricellular proteins and TNC has been shown to protect cartilage from degradation. We wish to understand these proteins and their role in the maintenance of articular cartilage.

Luciferase reporter constructs - Luciferase firefly gene is located downstream of promoter region. Used to monitor signalling in cells by assaying for luciferase activity.

Evaluation of foreseeable effects

The lentivirus amphotrophic and can therefore infect human cells however the design of these systems is such that the viral particles are replication defective and are only capable of one round of infection.

Some of the vectors contain the woodchuck hepatitis virus PRE (WPRE) either in the mutate or wild type form. The wild type WPRE contains the gene X promoter and encodes a truncated X protein. These have the potential to have oncogenic effects.

The lentiviral particles produced will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see above) into the host genome. This is an anticipated risk associated with the use of lentiviral gene transfer vectors. The viral particles have however been rendered non-replicative by a number of safety features.

Lentiviral Transduction

Lentiviral particles will be purified from packaging cell cultures and used to transduce mammalian cells to facilitate the production of new mammalian cell lines permanently expressing the desired transgene inducing molecule. Gene transfer from viral particle to mammalian cell line is expected.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

There is a risk of accidental human exposure to viral particles due to the use of needles to inject the mice and could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences into the host genome. To minimise the risk all staff are trained in the use of needles and the injections will only be performed...
Once. Importantly, in the context of human gene therapy clinical studies, high doses of lentiviral vector particles have been administered in vivo with no observed complications. It is considered highly unlikely that accidental human exposure to the viral particles described in this risk assessment would lead to the generation of a tumour.

Where viral particles are used in vivo the greatest risk is from the use of needles however it is not anticipated that accidental exposure would be linked to significant risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Mice will be injected and held at containment level 2 facilities.

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Use of Adeno-associated virus and replication defective lentivirus to selectively eliminate or activate specific neural circuits in a reversible fashion

**Recipient or parental organism**

E. coli K12 or B derivatives - E. coli strains are disabled and cannot colonise the human gut

Mammalian cells lines - Packaging cell lines such as HEK293 cells are especially disabled hosts and are of minimal hazard.

**Host/vector system**

Vectors containing essential genes (gag, pol and env) will be transfected into packaging cells (generally HEK293 derivatives) to generate lentiviral particles which are capable of infecting cells but are self-limiting due to their replication defective nature.
Adeno associated vectors appear to be defective and require co infection with a helper virus (such as Adeno virus or Herpes simplex virus) in order to replicate.

**Origin & function**

Microbial opsin genes encode light-activated channels which will be used to selectively eliminate or activate specific circuits in a reversible fashion. An example of such genes is ArchT from Halorubrum sp which encodes a light-driven proton pump. The vectors also contain the WPRE genes used to enhance expression of the transgenes.

Standard reporter genes and antibiotic resistance genes

**Evaluation of foreseeable effects**

The lentiviral particles produced will have a broad tropism and will be capable of infecting and transducing human and other mammalian cells, inserting viral and transgene sequences into the host genome. There is an anticipated risk associated with lentiviral gene transfer vectors however the viral particles have been rendered non-replicative by a number of safety features.

Adeno associated viruses are naturally replication defective requiring a helper virus for replication. Although wild type AAV can integrate into the host cell chromosome the gutless nature of the vectors means that integration is unlikely to occur. Long term expression is mainly due to the maintenance of episomes.

Both vectors contain the Woodchuck post regulatory element to enhance viral titre and expression. Some concern has been raised with regards to the oncogenic potential of this element.

These light activated channels are not expected to make the replication defective viruses more hazardous.

Standard reporter genes and antibiotic resistance genes are widely used and no hazardous properties have been reported.

Accidental exposure to the viral particles could lead to the insertion of viral and/or transgenes into the host DNA which in the worst case could lead to integration knocking out a tumour suppressor gene or the oncogenic expression of WPRE.

Exposure will be minimise by control measures however such as using MSC and minimising the use of sharps.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Project Ref 553/12.11

Date Ackn’d 13/08/2012  

CU2 Project Title Interactions of myxoma viral proteins with host receptors

Class 2  

Culture Vol  

Class CultureVolClass2 CultureVolumeClass3-4

Non-GMM  

Consent Granted
Immunity against pathogens is maintained with a complex network of interactions between various cellular and humoral components of the immune system. Cell surface receptors play a major role in this process. They are not only involved in sensing the pathogen threat and turning on the immune system against it but also limiting the immune response from going out of control. Inhibitory cell surface receptors are expressed on many immune system cells to slow down the immune response when necessary and so to avoid self-destruction. However, these fine tuners of the immune system can occasionally be hi-jacked by microorganisms which down-regulate the immune response for their benefit. Common strategies used by pathogens involve inducing expression of host ligands for inhibitory receptors or using decoy ligands that are encoded in their genome to pair with the host receptor.

Myxoma virus - is a pox virus responsible for myxamotosis in the rabbit and hare population and has been used in Australia as a biological control for their alien rabbit population. It is endemic in the rabbit population of this country and sporadic outbreaks occur regularly. It is typically a fatal disease that is mainly spread by direct contact and it is recommended that pet rabbits are vaccinated against this disease. It is not pathogenic to humans and therefore doesn't have an ADCP grouping.

mammalian cell lines used for the production of the virus, such as BGMK and RK13, are especially disabled hosts and cannot survive outside the strict conditions of laboratory culture. They are unlikely to pose a hazard to the worker.

Host/vector system
Genetically modified viruses have been created elsewhere by homologus recombination.

Origin & function
Green Flourescent protein or other non hazardous marker genes.
M141R open reading frame deletion. M141 shares sequence homology to host CD200 which is involved in mediating the host immune response by binding to CD200 receptor.
M128R open reading frame deletion. M128 has a similar phenotype and is thought to bind to a similar inhibitory receptor.

Evaluation of foreseeable effects
No adverse effect is expected from GFP or other non hazardous marker genes as they have a history of safe use.
M141 and M128 are thought to be involved in the pathogenicity of the virus by binding to a receptor in the host that is involved in mediating the innate immune response. Interactions between other viral CD200 homologues and the CD200 receptor lead to a down regulation of the immune response in the host. Therefore knocking out these
genes may lead to a virus that will be less able to down regulate the immune response.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Containment

Laboratory Activities  Glass Houses  Growth Rooms
Purified virions will be used for biophysical characterisation using electron and fluorescence microscopy.

Recipient or parental organism

Bunyamwera Virus is an ACDP hazard group 2 agent whose natural host is the Aedes genus. The natural route of transmission to humans is via an insect bite.

Host/vector system

These viruses have been created elsewhere and are simply being produced from a variety of mammalian cell lines.

Origin & function

Fluorescent proteins, such as GFP or RFP have a history of safe use.

Truncation of the Gc protein, which is responsible for catalyzing the fusion of the viral envelope and the host membrane.
Bunyamwera virus has been found to be pathogenic to mice and occasionally humans, transmission is via an insect bite and may lead to a mild febrile illness with headache, joint and back pains but most infections are unrecognised.

Bunuamwera virus is not known to exist in the UK environment.

In the lab the main route of transmission would be via a percutaneous injury and as such the use of sharps will be minimised.

Truncation of the Gc gene will not impair the virus's ability to replicate and as such will behave similar to a wild type virus.

Addition of fluorescent proteins is not expected to alter the hazards associated with the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM
The overall aim of the project is to investigate the therapeutic potential of inhibiting kinases and/or oncogenes in ovarian cancer cells. Our aim is to modify the expression of such genes in human and murine tumour cell lines and monitor the effects on the survival, apoptosis and microtubule dynamics of the recipient cells.

Recipient or parental organism

Human cell lines (such as SKOV3, Hey, A2780, OC316 cell lines)
Murine cell lines (MUKA) generated from a mouse model of low grade ovarian cancer following the deletion of PTEN and activation of KRAS.
Human and murine lymphocytes, including T cell, B cell and dendritic cell (DC)
### Host/vector system

For construction of retroviral vectors:

The pLZRS, pQCXIH and pLPC are self-inactivating retroviral vector containing an inactive 3' Long terminal repeat sequence (LTR) which becomes duplicated into the 5' LTR upon integration into the host genome. This ensures that the virus generated from this vector self inactivates and becomes replication-incompetent after integration into the host genome.

Lentiviruses, pHr-SIN-GFP, including 3rd generation VSV-G pseudotyped lentiviruses, similar to available commercial systems, such as sold by e.g. invitrogen. Commercially available adenoviruses expressing Cre will be used for recombination experiments in vivo. For packaging recombinant retroviral particles: 293FT (human embryonic kidney cell line 293F constitutively expressing SV40 T antigen from pUC-based plasmid pCMVSPORT6TAg.neo) and 293T (similar to 293FT). T antigen increases viral particle yield. GP+envAm12 (murine cell line NIH3T3 + one plasmid containing the Moloney murine leukaemia virus gag and pol genes and a second plasmid containing the 4070A amphotropic env gene)

### Origin & function

Wild-type and mutated murine and human genomic DNA and cDNA inserts:

- Wild-type kinase genes such as FER, FES, PTEN, SIK2 and CRMP2 or oncogenes such as TP53
- Mutated versions with deletions, insertions and/or point mutations. Selective modifications of any/all of the above.

- Standard reporter genes such as puromycin and neomycin resistance (puroR, neoR), beta-galactosidase (lacZ), jellyfish green fluorescent protein (GFP and derivatives), truncated hCD4, hCD25, tdTomato and nerve growth factor (NGF)

Short hairpin RNA interference sequences against the above mentioned genes (or other genes).

### Evaluation of foreseeable effects

Expression of the genes of interest, their mutants and inhibition of expression is likely to result in eukaryotic cell proliferation, quiescence, and apoptosis.

### Evaluation of foreseeable effects

Evaluate the effects of the activity on the environment, including potential impacts on human health and the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

In vivo growth of transplanted modified human and murine cells will be undertaken at Animal Containment Level 1

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

02/03/2022 Page 9069 of 15326
### Project Additional Information

#### Purposes of the contained use

The aim of the project is to identify molecules and associated mechanisms that regulate tissue stem cell function. Of particular interest in the transcriptional and extrinsic control of hematopoietic and epithelial (principally mammary and thymic) stem cells by transcription factors and signalling molecules, as well as the interaction of these mechanisms and the resulting changes in stem cell self-renewal, lineage priming, chromatin states and differentiation potential.

#### Recipient or parental organism

- **E. coli - K12 and B derivatives**
- Mammalian cells and primary murine stem cells
- Occasionally avian cell lines
- Packaging cells lines such as Phenix E and 293 T to generate retro and lentiviruses

#### Host/vector system

Standard second and third generation lentiviral plasmids using HIV-1–based packaging systems, including separate, non-homologous cistrons for envelope (typically VSV-G) and other viral proteins, and self-inactivating LTRs. WPRE elements will be included in the viral backbone to enhance protein expression.

#### Origin & function

- Genes involved in hematopoietic lineage specification (e.g. C/EBPs, PU.1, GATA-1/2, Klf1)
- Genes involved in lineage-specific progenitor proliferation (e.g. Epo/Epor, GM-CSF/GM-CSFR, M-CSF/M-CSFR)
- Genes involved in stem cell maintenance (e.g. Mpl/Thpo, Kit/Kitl, Imp1)
- RNAi-based constructs to effect knockdown of genes of interest above.
- Standard reporter genes such as GFP, Luciferase and beta-galactosidase
- Standard antibiotic resistance genes such as puromycin and neomycin

#### Evaluation of foreseeable effects

- No hazard expected from the expression of the genes in E. coli K12 and B derivatives
- No hazard expected from the over expression or knock down of genes in mammalian or avian cells
Potential hazard from the replication defective but infectious viral particles (for one round) due to the presence of WPRE and the potential for insertional mutagenesis. Viral particles are designed in such a way that they do not have the mechanisms for replication and as such no viral particles can be produced after the first round of infection.

Use of sharps is limited when working with virus particles.

Mammalian cell lines exposed to viral particles are not expected to pose any hazard after the initial infection. Infectious particles would have integrated into the host genome and any free viral particles removed in the washing stages.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)

**Project Ref** 553/12.15

- Date Ackn'd: 26/11/2012
- CU2 Project Title: Transfection of eukaryotic (human and mouse) cells by replication defective lentivirus vectors
- Class: Class 2
- Culture: < 1 Litre
- Consent: Granted

**Project Additional Information**

- Purposes of the contained use: Use of lentiviral vectors to over-express and knock down genes involved in transplant rejection
**Recipients or parental organism**

| Human and murine primary T cells |
| 293 packaging cells |

**Host/vector system**

| second generation lentiviral vectors |

**Origin & function**

Inserted mammalian DNA will comprise non-oncogenic transgenes such as siRNA genes, suicide genes and marker genes.

**Evaluation of foreseeable effects**

The potential for generation of replication-competent lentivirus is addressed by the design of the vectors. The second and higher generations of lentiviral systems separate transfer, envelope and packaging components of the virus onto different vectors. In this system the transfer vector encodes the gene of interest and contains the sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors. It is not possible for viruses normally produced from these systems to replicate and produce more viruses after the initial infection. Importantly, the inability to replicate reduces the likelihood of unintended spread and mutagenic or oncogene-activating or tumor suppressor gene-inactivating insertion, and thus greatly improves the safety of these vectors.

Negligible risk and effects of recombination or complementation.

The WPRE sequence is present in these vectors which has been shown to have potential oncogenic activity.

Primary cells exposed to the replication defective lentivirus will be used in vivo. There is low risk from this activity since any virus will have either integrated in to the host genome or have been washed free of the media.

Lentiviral particles may be used in vivo.

- [ ] Date of Significant Change

### Project Additional Information

**Purposes of the contained use**

Using mouse and human lentiviral shRNA in pooled or arrayed screens to conduct cell based loss of function screening as well as gain of function screening using cDNA.

**Recipient or parental organism**

Mouse and human cell types including primary cells, iPS cells, immortalized cells and secondary cells.
Host/vector system

HEK293 cells
GIPZ shRNA vector or other lentiviral expression vectors. These lentivirus expression vectors are self-inactivating as they carry a deletion in the U3 region of the 3'-LTR. Upon integration into the host genome, the 3'-LTR is copied to the 5'LTR, rendering it transcriptionally inactive and therefore unable to generate a functional retrovirus. Packaging vectors such as Gag-Pol and env. Other systems available may include additional vectors such as TetOn/Off and Tat-Rev

Origin & function

Genetic material from mouse and human. The shRNA and cDNA libraries we employ will naturally contain known human tumour suppressor and oncogenes and will be under the control of constitutively active mammalian promoters. As such it could pose the risk of cell transformation if it is accidentally administered.

As the TDI facility provides a service for all University Departments projects the facility will participate in should span very diverse fields of diseases, cell processes and tissue types.

As this is high throughput screening a large proportion of the work will be done by robotics.

Evaluation of foreseeable effects

The shRNA and cDNA libraries we employ will naturally contain known human tumour suppressor and oncogenes and will be under the control of constitutively active mammalian promoters. As such it poses the risk of cell transformation if it is accidentally administered. However, these risks are strongly mitigated by the biosafety features of the vectors as well as the risk reduction for lentiviral transductions.

Overall then, only lentiviral particles, which are unable to replicate, but which can deliver the gene of interest, are produced. They cannot contain any other genes (e.g. gag, pol, rev & env) because none of the vectors used to supply these elements contain LTR’s or the psi packaging signal required for these genes to be delivered. Therefore, the main risk is in their ability to deliver genetic material into a host genome and as described above, this is unlikely to pose any significant risk.

One further consideration, however, is that the Woodchuck hepatitis B virus regulatory element (WPRE), used to enhance stability of the transcript, is present in some lentivectors. This element may have oncogenic properties so virus produced using these vectors should be considered to have an accordingly higher level of risk. We might buy/use other libraries and packaging systems in future but they will incorporate at least the same biosafety features as the aforementioned libraries and packaging plasmids.

Once the viral particles are integrated into the genome of the cells they pose minimal risk due to the replication defective nature of the viral systems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

Purposes of the contained use

Inflammatory bowel diseases (IBD) are chronic diseases of the gastrointestinal tract that are thought to arise from a dysregulated immune response to the intestinal microflora. A growing number of genes are identified to be linked to human IBD including cytokines, genes involved in pathogen recognition or autophagy.

We will use self-inactivating, replication incompetent viruses (e.g. lentivirus or retrovirus) based expression vectors containing the genes of interest or sh/siRNA against them.

Recipient or parental organism

mammalian cell lines and primary cells

Host/vector system

Standard packaging cell lines such as HEK293
Standard commercially available replication defective retro and lentiviral systems

Origin & function

Genes known or suspected to be linked to inflammatory bowel disease such as cytokines, genes involved in pathogen recognition and autophagy, and sh/siRNA against those genes.

Evaluation of foreseeable effects

Viruses to be used are replication defective and have a number of safety features such as packaging genes divided onto different plasmids, self inactivation of the 3'UTR etc

The woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) sequence is present within many of the lentivirus vectors to be used. This sequence has been linked to liver tumours in mice.

Overexpression or knocking down genes suspected to be involved in IBD is unlikely to have any adverse effects.
Once the replication defective virus has integrated into the host genome it presents minimal risk and the cells can be used in subsequent experiments at class 1. Infectious virus will not be inoculated.

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
Project Additional Information

Purposes of the contained use

1) to investigate whether particular genetic sequences (either single genes, genetic mutations, or combinations of genes) observed by whole genome sequencing are responsible for drug resistance. This will be used to characterise novel mutations in known resistance genes in several bacterial species of major clinical relevance (S. aureus and members of the Enterobacteriaceae family).

2) to characterise gene transfer systems permitting exchange of resistance genes amongst clinically relevant Enterobacteriaceae.
Enterobacteriaceae - clinical isolates such as E. coli, Klebsiella spp, Enterobacter spp. Some isolates will be multidrug resistant but effective treatments remain available
Staphylococcus aureus - clinical isolates which may have multiple drug resistance but effective treatments remain available
Staphylococcus - Newman strain
E. coli K12 derivatives such as DH5alpha and DC10B - hazard group 1 lab strain

Host/vector system

The vectors to be used (such as pRMC2, pIMAYZ) are derivatives of those used in laboratories to study virulence and resistance genes. No attenuating effect on laboratory strains has been reported.

Origin & function

Gene inserts will be obtained from clinical isolates of Staphylococcus aureus. The genes to be inserted will be either housekeeping genes, chromosomal genes or genes on mobile genetic elements which have been incorporated into the host genome. Only the gene and ~150bp flanking regions will be inserted. These genes will be capable of causing resistance to a single class of antibiotics and are not known to cause any alteration in transmissibility or pathogenicity.

For the Enterobacteriaceae work
i) naturally occurring plasmids. These are frequently large plasmids which can include multiple resistance genes, as well as virulence factors and mechanisms for plasmid transfer.

ii) recombinant plasmid vectors including one or more genes conferring antimicrobial resistance to a single antibiotic, obtained as described in the overview above.

Evaluation of foreseeable effects

For the Staphylococcus aureus work:
The final GMM organism will be S. aureus Newman with resistance to a single class of antimicrobial. As this strain is fully susceptible, a broad range of antimicrobial treatment is still available. No increased transmissibility or virulence is anticipated.

For the Enterobacteriaceae work:
The recipient E.coli are K12 or B derivatives, such as DH5alpha and DH10B strains. These are disabled hosts that cannot colonise the human gut and have a history of safe use, and are assigned to ADCP hazard group 1. Insertion of the genetic content should (in the case of recombinant plasmid vectors) result in resistance to a single antibiotic class. In the case of naturally occurring plasmids from Enterobacteriaceae, several resistance genes may be transferred and possibly virulence factors. Although the isolates from which these plasmids will be obtained will be multiply drug-resistant, the susceptibility phenotype will be known prior to manipulation, and we can ensure that any transformant strains generated will be susceptible to some clinically useful anti-microbials. As an additional precaution, resultant modified strains will be handled as hazard group 2 organisms.

In vivo testing may be required when the results of the in vitro work are inconclusive. The challenges will be carried out intravenously in a class II micro biological safety cabinet. Dissemination of the organism is not expected in the short time scale of the experiments.

Evaluation of foreseeable effects

N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15
minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Liquids (e.g., samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Sharps (e.g., needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes) disposition via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N

Gene therapy involves the treatment of disease through the delivery of exogenous nucleotides which interact with the host transcriptional or translational machinery to correct specific deficits in gene function. Genetic material can be delivered with high efficiency using viral vectors. We propose to utilize standard lentiviral and adeno-associated virus (AAV) vector technology for the production of lentiviral vectors and AAV vectors. These vectors will be used to deliver therapeutic genes and common reporter genes to mammalian cells in culture and to tissues in vivo.

The inserted genes will fall broadly into two categories:

a) Reporter genes, the product of which are non-toxic, typically fluorescent, and used to easily identify and evaluate the success of gene transfer. These genes are derived from a variety of organisms but have a long history of safe use.

b) Mammalian genes with important roles in phototransduction and/or a potential influence on retinal degeneration process.
derived from a variety of organisms but have a long history of safe use

b) Mammalian genes with important roles in phototransduction and/or a potential influence on retinal degeneration process.

**Host/vector system**

Lentiviral vectors – Vectors are attenuated, non-pathogenic, replication deficient, and bare little genetic homology with wild type virus. Additionally, vectors are self inactivating (SIN), so following integration any vector would be unable to be packaged by a latent wild type lentivirus if one were present. Viral genes required for vector packaging are coded on three separate plasmids during production, all but eliminating the possibility of recombination, and are provided in trans (i.e. not packaged). Virus genes which are not essential for packaging are not present. Vectors are integrating, and thus pose a theoretical risk of causing insertional mutagenesis following administration. No harmful chemicals or compounds are used during production or purification.

AAV vectors – AAV vectors are non-pathogenic, replication deficient and bare little genetic homology with wild type virus. AAV viruses do not contain genes required for independent replication. AAV genes required for packaging (rep and cap) and helper genes are provided in trans (i.e. not packaged) and on separate plasmids. No harmful chemicals or compounds are used during production or purification.

Both lentivirus vectors and AAV vectors may contain the WPRE sequence which has been linked to tumour growth in rodents. However the sequence used in these vectors has been modified from the wild type so that the X-protein is not produced and it is therefore not tumourogenic.

**Origin & function**

Inserts code for normal mammalian genes or selective alterations of those genes. Also standard marker genes such as lac Z, GFP, etc. Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms.

**Evaluation of foreseeable effects**

Resulting GMOs will express mammalian genes or marker proteins to investigate their use as gene therapy agents but will carry no additional hazards. Any transfer of genetic material to other organisms would be of minimal hazard. GMOs would not survive outside laboratory conditions. E.coli strains do not colonise the human gut; mammalian cells will not survive outside laboratory conditions. Vectors are non pathogenic and replication deficient.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The inoculation of experimental models is assigned to Class 2 due to the combined use of syringe needles and lentiviral vector as indicated in the SACGM Compendium of Guidance. Workers will receive specific instructions and training in the safe use and disposal of contaminated syringes and syringe needles. All other work may be undertaken safely at Class 1.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or
134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

The assessment was originally assigned to Class 2 on the basis of the vector alone. This element was re-assigned to Class 1 as the system has intrinsic biological safety features but the inoculation stage was identified as requiring assignment to Class 2 due to the combination of a lentiviral system and the use of syringe needles.

Appropriate containment and control measures have therefore been assigned in accordance with the latest guidance issued by SACGM.

Use of viral vectors to deliver the appropriate factors to create iPS cells by reprogramming and induced neurons (iN) by direct differentiation of donor cells originating from genetically diverse mice. The effect of genetic variations on the characteristics and properties of the reprogrammed/differentiated cells will then be assessed.

Recipient or parental organism

Primary murine cells are low risk

Primary human cells are low risk but may contain adventitious agents and will be handled at containment level 2 due to CoSHH

Origin & function

Transcription factors which are known or suspected to reprogram somatic cells into embryonic stem-like pluripotent cells include:-

Myc - a known human oncogene that will be under the control of constitutively active mammalian promotors.

Klf4 - also associated with cellular transformation in some scenarios, so should be assigned a similar level of risk to Myc.

Klf2 is a newly reported reprogramming gene, which helps to reprogramme cells to a naive hES cell-like state, which is more closely related to mouse ES cells than normal.
hES cells. Sox2 - has been suggested to act by maintaining or preserving development potential. Oct4 - is a homeodomain transcription factor of the POU family. It is expressed in mammalian early embryo and germ cells and can both stimulate and repress target gene transcription. Oct4 regulates the expression of multiple genes via interaction with other transcription factors present in pluripotent cells. Together c-Myc, Klf4, Sox2 and Oct4 are capable of reprogramming cells to become pluripotent.

In addition other transcription factors may be used to achieve direct differentiation of somatic cells to neurons such as:-
- Neurons (iNs): Ascl1, Brn2 and Myt1l (10)
- Motor neurons (iMNs): Ascl1, Brn2, Myt1l, Lhx3, Hb9, Isl1 and Ngn2 (11)
- Dopaminergic neurons (iDAs): Ascl1, Nurr1 and Lmx1a (17)

Other reprogramming genes which could have oncogenic potential may be used in the future.

Evaluation of foreseeable effects

Together c-Myc, Klf4, Sox2 and Oct4 are capable of reprogramming cells to become pluripotent. As such they pose a greater risk in combination than individually. The risk of induction of pluripotency in the event of ingestion, inhalation or injection is very low, as even if the genetic material is successfully introduced into the genome of cells within the body, reprogramming is an inherently very inefficient process (~0.01% efficiency) even in defined tissue culture conditions, and the environment in which a reprogramming cell would find itself would not be conducive to the reprogramming process (other signalling events induced by the local environment would be likely to override the reprogramming process). In addition the genes are in four separate vectors decreasing the likelihood of all four entering the same cell in the event of accidental exposure. If, despite this low level of risk, reprogramming does occur within a laboratory worker, then it is possible that a teratoma could result, as is the case when iPS cells are injected into immunosuppressed mice. Other reprogramming genes which also have oncogenic potential may be used in the future.

EBV-episomal systems do not integrate into the host DNA and replicate once per cell cycle in the presence of drug selection. Once drug selection is removed episomes are lost at approx 5% per cell generation. As this is a plasmid based system the likelihood of the vector gaining entry into cells without very specific transfection methods is unlikely.

PiggyBac is also a plasmid based delivery system and the likelihood of the vector gaining entry into cells without very specific transfection methods is unlikely.

Replication defective adenovirus retains the ability to enter human cells and will express the foreign genes for a limited period of time, however it will be less pathogenic than the wild type due to the inability to replicate.

Replication defective retroviruses and lentiviruses have a number of modifications to decrease the risks such as separation of the gag, pol and env genes onto different plasmids (or stable expression in the packaging cell line), self-inactivating nature of the LTR’s and deletion of non-essential genes. However the vectors can integrate into the host genome and this potentially could inactivate a tumour suppressor gene. The WPRE element is also present in some of these vectors which may have an oncogenic property.

The inserts are not expected to increase the hazard from E. coli cells.

Murine and human somatic cells once tranduced with the vectors are not expected to present a risk as the vectors lack elements essential for replication and packaging.

Project Ref  553/12.4
Experimental evolution of antibiotic resistance in pseudomonas aeruginosa

The evolution of antibiotic resistance poses an important threat to human health and welfare and the overall goal of this project is to study the underlying evolutionary processes that drive the spread of resistance in pathogen populations. To achieve this goal, we will carry out experiments in which we will challenge genetically modified populations of the pathogenic bacterium P.aeruginosa with evolving antibiotic resistance in controlled lab experiments. Specifically looking at costs and benefits of resistance mutations, compensatory adaptation, physiological interactions between antibiotics and mutation rate and resistance.

**Recipient or parental organism**

PSEUDOMONAS AERUGINOSA

**Host/vector system**

Standard E.coli (K12 and B derivatives) and vectors will be used to generate the plasmids for transfecting into the Pseudomonas. Also oligo-mediated recombineering to introduce mutations into the Pseudomonas.

**Origin & function**

- Reporter genes (such as eFPs and Lux) that have no known toxicity
- Antibiotic resistance marker (such as aac1 and amp)
- rpoB alleles containing rifampicin resistance mutations.
- A null mutation in a stress response gene (LexA).
- Knockout mutations of DNA repair genes.

**Evaluation of foreseeable effects**

Pseudomonas aeruginosa is a hazard group 2 micro-organisms that is an opportunistic pathogen of humans. This organism is primarily a danger to individual who suffer from cystic fibrosis or who have compromised immunity. This organism can be readily isolated from environmental samples, and healthy adults are considered to be at
negligible risk from infection from this organism.

Reporter genes (such as eFPs and Lux) have no known toxicity and are not expected to alter the pathogenicity of the Pseudomonas.

The antibiotic resistance marker (such as aac1 and amp) does not provide resistance to antibiotics that are currently used to treat Pseudomonas infections.

rpoB alleles containing rifampicin resistance mutations. Rifampicin is not used to treat Pseudomonas infections and rifampicin resistance mutations tend carry a fitness cost implying that Pseudomonas carrying engineered rifampicin resistance alleles will tend to be at a competitive disadvantage.

A null mutation in a stress response gene (LexA). This mutation disables a highly conserved stress response gene that helps to protect bacteria against antibiotics and oxidative stress.

Knockout mutations of DNA repair genes. There is no evidence that increasing mutation rates directly results in an increase in the virulence of bacterial pathogens.

We do not expect that any of these manipulations will increase the toxicity or pathogenicity of Pseudomonas. If anything, we expect that these manipulations will attenuate the virulence of this organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information
### Purposes of the contained use

Deregulation of cell controls affecting proliferation and/or apoptosis is a common event during host pathogen interactions. This program of work is to study the molecular mechanisms used by Helicobacter pylori to hijack and alter host defense mechanisms, cell cycle and apoptotic responses. Using strains of Helicobacter pylori deficient for genes that potentially target the host response (mainly contained within the cag-pathogenicity island of the bacterium) as well as strains that transgenically express the fluorescent marker enhanced green fluorescent protein (to follow the localization of the bacterium during infection), we will be able to pinpoint the molecular mechanisms used by this bacterium to modulate proliferation and apoptosis of the host cell.

### Recipient or parental organism

*Helicobacter pylori* - hazard group 2 micro-organism

### Host/vector system

Mammalian cell lines and primary cell cultures, multicellular gastric organoids, and animals will be inoculated with the genetically modified Hp to test the cellular interactions between host and pathogens.

### Origin & function

The strains generated will be knock-out or knock-in mutants of genes which are potentially involved in targeting the host response such as cagA, virb10, and VacA.

Inserted genetic material will encode non-infectious, non-hazardous proteins, such as standard marker proteins to allow for visualising localization during infection.

### Evaluation of foreseeable effects

Insertion of non-infectious, non-hazardous genes (e.g. standard reporter genes) is not expected to alter the pathogenicity of the bacteria.

Helicobacter strains mutated in the cag (deltaCags) and/or vacA gene products lack some of the components that enable the bacterium to produce the major virulence factors used to establish the infection. Therefore they have an attenuated virulence as compared to the wild type strain. None of the genetically modified Helicobacter strains are expected to present an increase in hazard to humans compared to the parental strains.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Carcasses will be sent for incineration via a licenced contractor

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Consumables (mainly plasticware eg pipettes, flasks, tubes)** - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

**Liquids** (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

**Agar plates** - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Purposes of the contained use

The purpose of the contained use is for the handling of gram negative bacteria which have genetic modifications in their polysaccharide translocation machinery.

Recipient or parental organism

Hazard Group 2 gram negative bacteria, such as E. coli E69.

Host/vector system

Mutants created elsewhere.

Origin & function

Genes to be knocked out or mutated are involved in the polysaccharide translocation machinery and are expected to lead to a reduction in capsule formation.

Possible inclusion of standard antibiotic resistance genes or reporter genes.

Evaluation of foreseeable effects

Mutations of proteins involved in the polysaccharide translocation machinery are expected to prevent the formation of capsular polysaccharide on the cell surface. The hypothesis is that this will increase the antigenicity of the affected bacteria, allowing them to be more rapidly detected and cleared by the host immune system. The mutants act as a positive control for the chemical compounds to be tested.

In some cases the gene will be disrupted by the insertion of a standard molecular biology antibiotic resistance gene. These antibiotics are not routinely used to treat disease.

The inclusion of standard reporter genes would not be expected to increase the hazard of the bacteria.

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

### Project Additional Information

**Purposes of the contained use**

Use of replication defective Retrovirus and Lentivirus containing WPRE.

**Recipient or parental organism**

*E. coli* K12 or B derivatives - *E. coli* strains are disabled and cannot colonise the human gut

Mammalian cells lines - Packaging cell lines such as HEK293 cells are especially disabled hosts and are of minimal hazard.

**In vivo work**

**Host/vector system**

Vectors containing essential genes (gag, pol and env) will be transfected in to packaging cells (generally HEK293 derivatives) to generate lentiviral particles which are capable of infecting cells but are self limiting due to their replication defective nature.

**Origin & function**

Inserts will be standard reporter genes, such as GFP, standard antibiotic resistance genes, structural proteins and other non-functional harmless genes.

The vectors may also contain the WPRE genes used to enhance expression of the transgenes.
The lentiviral particles produced will have a broad tropism and will be capable of infecting and transducing human and other mammalian cells, inserting viral and transgene sequences into the host genome. There is an anticipated risk associated with lentiviral gene transfer vectors however the viral particles have been rendered non-replicative by a number of safety features.

The vectors may contain the Woodchuck post regulatory element to enhance viral titre and expression. Some concern has been raised with regards to the oncogenic potential of this element. Where possible the vectors will contain versions that have mutated start codons.

Standard reporter genes and antibiotic resistance genes are widely used and no hazardous properties have been reported.

Accidental exposure to the viral particles could lead to the insertion of viral and /or transgenes into the host DNA which in the worst case could lead to integration knocking out a tumour suppressor gene or the oncogenic expression of WPRE.

Exposure will be minimise by control measures however such as using MSC and minimising the use of sharps for in vitro work. Needles may be required for in vivo work.

Project Ref  553/12.8

Assessment of the protective efficacy of candidate vaccines against human malaria (Plasmodium falciparum or P. vivax) using transgenic parasites

Date Ackn’d  20/06/2012

Class  Class 3
CultureVolClass2  < 1 Litre
CultureVolumeClass3-4  Non-GMM
Consent Granted  Yes

Project notified under transitional arrangements  N

Tick if notifying a connected programme of work  N

Historical Significant Changes
**Project Additional Information**

### Purposes of the contained use

The aim of this project is to assess the protective efficacy of candidate vaccines against *P. falciparum* or *P. vivax* antigens, using parasites that express fluorescent or bioluminescence reporter genes. These transgenic parasites enable easy visualisation within the mosquito vector. This research will assess the protective efficacy of these vaccines and look for immune correlates of protection against liver-stage, blood-stage and mosquito-stage malaria infection.

### Recipient or parental organism

*Plasmodium falciparum* is a hazard group 3 micro-organism and is the causative agent of malaria in human. It's life cycle is split between the human host and an insect vector. Transmission to human occurs via a bite by the infected mosquito vector and only female Anophele mosquitoes are involved as the males do not feed on blood.

### Host/vector system

The transgenic parasites have been made elsewhere using homologous recombination.

### Origin & function

Standard marker proteins, such as EGFP and Luciferase.

### Evaluation of foreseeable effects

*Plasmodium falciparum* is the causative agent for malaria and is assigned to hazard group 3 by ACDP.

Falciparum malaria symptoms include: complain of headached, fever and aches and pains all over the body, and diarrhoea and abdominal pain are sometimes present. Spleen and liver are often palpable on clinical examination. This may be misdiagnosed as influenza in non endemic areas, and, unless treated promptly, the clinical picture can deteriorate rapidly. Can progress to cerebral malaria: confusion, delirium, loss of consciousness. Incubation period: at least 7 days.

Standard marker proteins, such as luciferase and GFP have a history of safe use and are not expected to alter the pathogenicity of the parasites and therefore have no additional risks compared to the wild types.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

*P. falciparum* gametocytes will be cultured in human erythrocytes either in the insectary or in the blood-stage CL3 laboratory in the Jenner Institute. For dissections,
mosquitoes will be killed by drowning in 70% ethanol and then decapitation.

The GM parasites will be used to infect mosquitoes, but the mosquitoes are not in themselves genetically modified. Infected mosquitoes are maintained in a secure insectary at a containment level appropriate to the pathogenic nature of the parasites. Access to the insectary is through a sealed anteroom and all doors have rubber seals and brushes to prevent mosquitoes escaping from the insectary area.

Mature plasmodium gametocytes will be fed to mosquitoes in sealed pots using standard membrane-feeding techniques. Infected mosquitoes will be maintained for up to 16 days at 26°C before dissection. Mosquitoes must be kept in a pot within a sealed plastic container which is then placed in an enclosed mosquito cage (i.e triple contained). The cage itself will be kept in a locked incubator.

For dissections, mosquitoes will be killed by drowning in 70% ethanol and then decapitation.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Justification for containment level 3

Plasmodium falciparum is a hazard group 3 pathogen, normally requiring containment level 3. However, the HSE advisory committee on dangerous pathogens, annex 1 lists biological agents which may be used at less than the minimum containment conditions required by COSHH. Plasmodium falciparum is listed as an agent to which the derogation may apply.

For work with genetically modified Plasmodium falciparum parasite-infected mosquitoes the following derogations from full Class 3 containment are requested (the insect facility is classified as an animal facility)

1. The laboratory is not sealable for fumigation
2. Entry to lab via airlock is not required.
3. There is no negative pressure relative to the immediate surroundings
4. Extract and input air are not HEPA filtered
5. Autoclave is not required in the laboratory suite
6. Inactivation of GMMs in effluent from handwashing sinks and showers and similar effluents is not required
7. Incinerator for disposal of animal carcasses is not required (mosquitoes)

Justification: A 14-day developmental period is required within the mosquito post-infection before parasites are capable of infecting humans. At this point direct inoculation of the parasites into the human blood is required, through the bite of the insect. There is no air-borne route of infection. There is no aerosol formation. Parasites are inactivated by bleach, detergent, disinfectant, or desiccation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

1. Please can you confirm whether this notification is solely for P. falciparum or is it to include vivax as well.
2. If it is to include vivax we will need some more information on the micro-organism.
3. P. falciparum 3D7 has been sequenced but could you please provide any other information such as has it been in continuous blood culture for a number of years, has no resistance to major anti-malarial drugs, any other relevant information

response
1. Just for P. falciparum, not for P. vivax
2. N/A
3. 3D7 is not drug-resistant and infections are treatable with standard anti-malarials such as riamet and chloroquine (3D7 is the strain which is used for challenge and subsequent drug-cure of human volunteers in vaccine trials). It is a totally laboratory-adapted strain, having been in continuous culture under lab conditions for many years.

Project Ref 553/12.9
Use of viruses to determine the mechanisms that regulate interferon production

Purposes of the contained use
Use of recombinant replication-defective lentiviruses in overexpression and knockdown of genes thought to be involved in regulating interferon. As interferons play an important role in coordinating the mammalian host defence against viruses we will also be using wild type and genetically modified versions of viruses to challenge the mammalian immune response.

Recipient or parental organism
Replication defective retro and lentiviruses
encephalomyocarditis virus (EMCV),
herpes simplex virus 1 (HSV-1) - hazard group 2,
influenza A virus (flu, PR8 strain and derivatives thereof) - hazard group 1,
Sendai virus (SeV, cantell strain),
moloney murine leukaemia virus (MLV),
vaccinia virus (VV) - hazard group 2 and
varicella zoster virus (VZV) - hazard group 2
Mice (wild type and genetically modified)

Host/vector system
E. coli K12 or derivatives of
Mammalian cell lines
Standard plasmid vectors

Origin & function
encephalomycarditis virus (EMCV) can infect rodents and pigs that are the natural hosts of this picornavirus, which infects multiple body systems. It causes a variety of gastrointestinal, respiratory and systemic signs, as well as mortality. It is not known to infect humans.

Herpes simplex virus 1 (HSV-1) is a hazard group 2 micro-organism that can cause infection predominantly of mucosal surfaces (mouth, lips, etc.) in humans. In the majority of cases, infection (often acquired in early childhood) is not life threatening and passes asymptomatically. HSV-1 is susceptible to treatment with anti-viral drugs (nucleoside analoges). Primary infection can lead to persistent infection of the central nervous system without overt symptoms (latency). HSV is ubiquitous and it is estimated that one out of two people experience recurrent infection.

Influenza A virus (flu, PR8 strain and derivatives thereof) is a hazard group 1 micro-organism which infects birds and mammals and transmission occurs through aerosolised particles and close contact with infected animals. Symptoms are minor including chills, fever, sore throat, muscle pain, headaches, coughing but can develop into more severe and life threatening disease (pneumonia), especially in immune-compromised, old or very young individuals.

Sendai virus (SeV, cantell strain) induces lesions within the respiratory tract and naturally infects rodents and pigs.

Moloney murine leukaemia virus (MLV), naturally infects mice and causes leukemia.

Vaccinia virus (VV) is a hazard group 2 micro-organism and is relatively safe for humans as testified by its use as a vaccine against smallpox. Transmission could occur through inhalation of airborne virus in droplets or through skin injuries.

Varicella zoster virus (VZV) is a hazard group 2 micro-organism where primary infection occurs this results in chicken pox and very rarely lung or CNS involvement. Most UK adults are immune (from childhood infection) and all individuals working on the project have been confirmed to be immune by antibody titre. Transmission can occur via direct inoculation or direct contact with vesicle fluid from chicken pox patients.

Mammalian genes known or suspected to control the production of IFN, including genes linked to Aicardi-Goutieres-Syndrome (AGS) in humans, such as RIG-I, MDA5, MAVS, TREX1 and SAMHD1. These genes may be modified, for example by truncation or point mutation.

DNA and RNA viruses (listed above) genetically modified to lack one or multiple genes and to express reporter genes such green fluorescent protein, luciferase or beta-galactosidase, or strains expressing tags such as the FLAG-tag.

Reporter genes, such as GFP, luciferase and B-galactosidase

**Evaluation of foreseeable effects**

Genes known or suspected to control the production of IFN, including genes linked to AGS in humans are expressed in healthy individuals and none of them (including variants of them) is known as either an oncogene or a tumour suppressor gene. Therefore, overexpression and knockdown are highly unlikely to have oncogenic potential or pose any additional risks.

DNA and RNA viruses lacking one or more genes are typically non-infectious or attenuated when compared to the wild-type versions, therefore these recombinant viruses are not expected to pose any additional risks.

Standard reporter genes have a history of safe use and are not expected to pose any additional risks.

Animals challenged with cells transduced with replication defective viruses pose minimal risk. When challenged with replication defective retro/lentiviruses there is a potential hazard posed by the presence of WPRE and or insertional mutagenesis. When challenged with the genetically modified DNA / RNA viruses listed there are potential risks however these viruses are expected to be attenuated compared to the wild type and control measures and training should reduce the risks.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Additional Information

Purposes of the contained use

The process of DNA replication is crucial for all dividing cells as the genetic material must be accurately copied before partition into two new daughter cells. Errors that occur during the process of DNA replication underlie the development of cancer, other diseases and genetic diversity. Identification of pleotropic mutations in replication genes that permit cellular viability while manifesting as altered cellular phenotypes are crucial for understanding this complex and vitally important process.

Recipient or parental organism

Packaging cell lines such as HEK293 cells (and derivatives of) are especially disabled hosts and require strict nutritional requirements for survival. They do however contain fragments of viral sequences.

Human primary cells, such as fibroblasts are especially disabled hosts and require strict nutritional requirements for survival.

Mammalian cell lines, such as retinal pigment epithelial cells are especially disabled hosts and require strict nutritional requirements for survival.
E.coli K12 and B-derivatives are disabled hosts and cannot colonise the human gut

**Host/vector system**

- 3rd generation replication defective lentiviral vectors expressing gag, pol, tat and VSV-G
- Adeno- associated virus

**Origin & function**

- Genes encoding DNA replication proteins such as the PCNA gene.
- Genes encoding proteins thought to interact with DNA replication proteins such as Fen-1, DNA2, PolD1, PolD2, MSH6, Lig1, Caf-1 p150, DNMT1
- Standard reporter genes, such as GFP and antibiotic resistance genes
- shRNA to inhibit genes transcription from DNA replication genes and genes which are thought to interact with DNA replication proteins

**Evaluation of foreseeable effects**

In the lentiviral vector systems essential genes are split onto multiple plasmids which have limited sequence homology. In addition none essential genes are removed from the vectors. As such it is highly unlikely that a recombination event could generate a replication competent virus. However the replication defective virus is infectious for one cycle and has the potential to integrate into the host genome.

Adeno associated virus also has its essential genes split onto a number of plasmids to reduce the likelihood of recombination generating replication competent virus. However the replication defective virus is infectious for one cycle.

Packaging cells lines once transfected with viral vectors produce infectious but replication defective viral particles.

PCNA is normally highly expressed in proliferating cells, but there are no reports that it has oncogenic potential

Vectors contain WPRE but it has the ATG and promoter sequence mutated so that it does not express any fragment of the potentially oncogenic protein X ORF. However it may be necessary to use vectors in the future where the WPRE is the standard gene commonly found in vector systems.

shRNA against some of the PCNA interacting proteins may potentially be more hazardous as there is some evidence that these proteins may have tumour surpressing funtions and thus their inactivation could increase the potential for the transduced cell to become transformed.

Once primary cells and cells lines have been transduced they do not pose any greater risk than the unmodified versions due to the replication defective nature of the viruses.

02/03/2022
### Project Additional Information

#### Purposes of the contained use

The purpose of this study is to look at how HCV stimulates innate immunity, how it inhibits the activation of innate antiviral mechanisms, and how innate antiviral mechanisms control HCV infection. As part of this project we will also study how HCV causes mixed cryoglobulinemia. Finally, we seek to understand at the molecular level how B cells and antibodies recognise HCV and HCV-infected cells.

#### Recipient or parental organism

Hepatitis C virus - Hazard group 3
mammalian cell lines, such as hepatome Huh-7 and primary human cells
293 cells for lentiviral production

#### Host/vector system

Plasmid encoding HCV RNA
Plasmids encoding the sequences necessary for replication defective lentiviral production.

#### Origin & function

Anti viral genes such as genes involved in pathogen detection, interferon induction and antiviral pathways
shRNA to genes such as those involved in pathogen detection, interferon induction and antiviral pathways
Immunoglobulin genes
reporter genes such as GFP, RFP, YPET, VENUS and Luciferase
WPRE in the lentiviral constructs

#### Evaluation of foreseeable effects

Growth of HCV in plasmids is used to conserve a consistent genetic make up of the virus as it rapidly mutates in mammalian cells. This also allows for selective alteration of the genetic structure using sequences found in patient samples. These samples can be considered to be of the same harm as the wild type virus. Addition of marker
proteins such as GFP or luciferase is not expected to increase the harm, in fact it causes a reduction in viral replication.

As part of the project the group will be looking at mammalian genes which are active or interact with the virus during infection. Lentivirus will be used as an agent to transfect mammalian cells to either overexress or knock down such genes. These genes may also be selectively mutated using site directed mutagenesis.

Lentiviral vectors are replication defective and as such are only infectious for a single round of infection. There is the potential presence of WPRE in the vectors which may have oncogenic potential and as such this work will require containment level 2. Knock down or overexpression of individual genes is not expected to increase the potential harm from the lentivirus. Expression of reporter genes has a history of safe use.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. |
| Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), inactivate by chemical means (following manufacturers guidelines, discharge to drains. |
| HCV - will be inactivated by virkon. |
| Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill. |
| Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration - NO SHARPS WILL BE USED IN CL3 |

### Degree of kill:

- **Autoclaving**: effectively 100% kill (annual validation)
- **Incineration**: effectively 100% kill (licensed incinerator)
- **Chemical**: effectively 100% kill (following manufacturer's guidelines)

### Project Additional Information

**Purposes of the contained use**

Use of lentiviral vectors to over express or knock down genes predicted to be involved with general tumour and immune biology.

**Recipient or parental organism**

E. coli K-12
**Mammalian cell lines and primary cells**

Lentiviral production cells based on HEK 293 cells

**Host/vector system**

Standard second and third generation replication defective lentiviral vector systems such as pLENTI

**Origin & function**

The transcribed gene product will either be a non-coding gene (e.g. microRNAs), protein-coding gene or the corresponding knockdown sequence.

Some of the genes could potentially be tumour suppressors and/or oncogenes and therefore an overexpression or knock-down may result in a decrease or increase in the malignant capability of the cell lines, particularly in their ability to proliferate, migrate and secretion of growth factors.

Other genes being looked at are involved in the innate immune system such as receptor genes including members of the killer cell immunoglobulin-like and leukocyte immunoglobulin-like receptor family (KIR and LILR) and HLA-molecules and genes which regulate their function into natural killer cell and T cell lines and antigen presenting cells (APC).

Commonly used reporter genes such as GFP, luciferase, etc.

Standard antibiotic resistance genes such as puromycin, hygromycin, etc

WPRE which is known to enhance shRNA function by stabilizing and promoting nuclear export of the shRNA transcripts and also increases lentiviral titres by facilitating packaging of the virus. However, there have been concerns about the use of WPRE, as it has been reported that it may lead to tumourigenesis, especially if it encodes the X protein.

**Evaluation of foreseeable effects**

Due to the nature of the project a number of the genes could either be tumour suppressors or oncogenes when they are over-expressed or if the gene sequence is used to knock out the corresponding gene. Therefore there is a potential increase in hazard when these genes are used in combination with lentivirus which is infectious for a single round after exposure. However working practices are such that exposure is unlikely to occur.

Once the virus has integrated into the cells it is incapable of generating more viral particles and as such these cells can be handled at containment level 1 (class 1) after 48 hours and a change of media.

Overexpression or knocking down of innate immune receptor genes is unlikely to have a harmful effect should accidental exposure occur, the greater risk is from the presence of the WPRE.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Project Ref** 553/13.2
Use of replication defective viruses to assess the role of genes thought to be involved in neurodegenerative diseases

### Purposes of the contained use

Replication defective lentiviruses will be used to alter the expression of genes involved in the process of neurodegeneration. Directed differentiation of transfected stem cells and subsequent in vitro methods will be used to functionally characterise both molecularly and electrophysiologically the effect of these genes.

### Recipient or parental organism

Packaging cell lines such as HEK293 cells (and derivatives of) are especially disabled hosts and require strict nutritional requirements for survival. They do however contain fragments of viral sequences.

Mammalian primary cells, such as murine embryonic stem cells and progenitor cells are especially disabled hosts and require strict nutritional requirements for survival.

Mammalian cell lines are especially disabled hosts and require strict nutritional requirements for survival.

E. coli K12, B-derivatives and Saccharomyces cerevisiae are disabled hosts and cannot colonise humans - ADCP 1

### Host/vector system

3rd generation replication defective retro / lentiviral vectors which contain WPRE

### Origin & function

All the DNAs/gene products are well characterised and are either associated with neurodegeneration or neurotrophin receptor signalling. Plasmids generally encode fragments of known cDNAs, intact cDNAs for expression in mammalian cell lines, or mammalian genomic DNA. Where full cDNAs are used, none are predicted to alter pathogenicity of host organisms or to cause adverse effects in humans.
Standard reporter genes and antibiotic resistance genes such as GFP, luciferase, beta galactosidase, kanamycin, neomycin and ampicillin.

Wild type and mutated genes coding transcription factors potentially involved in the striatal lineage commitment/differentiation process. The expected action will be the modification of these processes.

ShRNAs that prohibits translation of specific mRNAs, reducing target protein levels in particular of the products of previously mentioned genes.

**Evaluation of foreseeable effects**

In the lentiviral vector systems essential genes are split onto multiple plasmids which have limited sequence homology. In addition non essential genes are removed from the vectors. As such it is highly unlikely that a recombination event could generate a replication competent virus. However the replication defective virus is infectious for one cycle and has the potential to integrate into the host genome.

Packaging cells lines once transfected with viral vectors produce infectious but replication defective viral particles.

Vectors contain WPRE which may have oncogenic potential.

ShRNA against the genes may affect the differentiation of neuronal cells and is not expected to pose any risk to the worker. Over expression or mutation of the genes is not expected to pose a risk to the worker.

Once primary cells and cells lines have been transduced they do not pose any greater risk than the unmodified versions due to the replication defective nature of the viruses

Risks posed by in vivo work are limited to the use of needles and the presence of the WPRE gene. All workers will have attended the home office course and suitably trained. Minimal risk posed to husbandary staff.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Date Project Ceased: 02/03/2022
Innate immunity is the first line host defence present in all metazoans. Given the extensive evolutionary conservation of innate immunity between fruit flies and mammals, we have established the fruit fly Drosophila melanogaster as a model to study gastrointestinal infection by the human fungal pathogen Candida albicans (C. albicans). The model can be used as a platform to explore virulence and pathogenicity of C. albicans at a level of detail unavailable in mammalian experimental models (see below). We want therefore, to use a library of C. albicans deletion mutants to discover the fungal attributes that contribute to pathogenicity in the gut and participate in the shift from a gastrointestinal (GI) infection to a systemic one during immunosuppression of the host.

Recipient or parental organism
C. albicans wild type reference strain SN152 and derived mutants with auxotrophies for histidine, leucine, and arginine.

Host/vector system
The two deletion mutant libraries have already been constructed elsewhere. Fusion PCR was used to synthesize gene disruption cassettes containing either C. dubliniensis HIS1 or C. maltosa LEU2 flanked by ~350 nucleotides matching sequences upstream and downstream of the target gene. The knock out therefore was performed as a homologous recombination event without using transposable elements. One of 48 20-nucleotide barcodes was included adjacent to the selectable markers. Heterozygous gene disruption strains were constructed by transformation of SN152 with a HIS1-marked gene disruption cassette; His+ transformants were screened by colony PCR for the presence of expected 5’ and 3’ junctions of the integrated DNA. Homozygous gene disruption strains were constructed by transforming the heterozygous knockout strain with a LEU2-marked gene disruption cassette; His+Leu+ transformants were screened for expected 5’ and 3’ junctions of the second disrupted allele and for absence of the original target ORF. At least two homozygous knockout isolates were obtained for each target gene.

Origin & function
Mutations are all deletions of normally expressed genes. Genes identified as contributing to pathogenicity via loss of immune response in the D. melanogaster model upon deletion will be re-integrated into genome to demonstrate restoration of response.

Evaluation of foreseeable effects
The mutations that were introduced do not affect the organism's fitness but they do not increase it, since they are either neutral or lead to loss of a normal function6,7. Recent paradigms using these libraries of C. albicans mutants did not indicate any incident of hyper-virulence20, 21. Hence, there is no indication to date suggesting any increase in pathogen fitness or virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes, vials with Drosophila larvae-pupae) - autolave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130° for at least 10 minutes or 134-138° for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - optionally pre-treat using 2% Virkon then always autolave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130° for at least 10 minutes or 134-138° for at least 3 minutes), discharge to drains.

Agar plates - autolave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130° for at least 10 minutes or 134-138° for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpeks) - dispose via clinical waste stream for incineration.

Degree of kill -
- autoclaving, effectively 100% kill annual validation;
- incineration, effectively 100% (licensed incinerator).

Project Additional Information

Purposes of the contained use

Use of EnvA-pseudotyped, glycoprotein (G)-deleted mutant of the SADB19 strain of rhabdovirus expressing genes to help elucidate neural circuit function.

Recipient or parental organism

SADB19 is a naturally attenuated strain of Rhabdovirus used as an oral vaccine for wild animals throughout Europe. The attenuated strain has not been derogated be ADCP and therefore remains in the same hazard group at the wild type - Hazard group 3

Host/vector system

pcDNA-SAD-deltaG- transgene plasmids

Origin & function

EnvA envelope protein of avian sarcoma and leukemia virus.

Fluorescent reporter proteins, e.g. GFP, mCherry or tdTomato and other standard reporter genes.

Light-activated ion channels/pumps (and their reporter protein fusions), e.g. Channelrhodopsin-2 (ChR2) or the Archaerhodopsins (Arch and ArchT).

Enzymes (e.g. Cre or Flp recombinases, horse radish peroxidase).

‘Designer Receptors Exclusively Activated by Designer Drugs’ (DREADDs), e.g. hM4D(Gi), will be inserted into the plasma membrane of cells. DREADDs are only active in...
the presence of their synthetic ‘designer’ ligands.

Other receptors/ligands, e.g. TVA, the highly-specific cognate receptor for the avian sarcoma and leukosis virus envelope protein EnvA.

**Evaluation of foreseeable effects**

SADB19 is a naturally attenuated strain of Rhabdovirus and has been used as an oral vaccine strain throughout Europe since the 1970's with no known adverse effects. Research has shown that of the 16 species tested all remained free of clinical signs except a small percentage (5.7) of murine species and a high percentage of immunocompromised mice (nude and scid) when inoculated intramuscularly. Importantly in these animals the virus was not detected in the salivary glands and was not passed on to untreated controls in the same cage. In addition the vector to be used has the glycoprotein G deleted this renders the virus unable to spread from the initially-infected ‘primary’ cells. The Env gene is replaced with the EnvA gene from avian sarcoma and leukosis virus and mammals do not naturally express any known receptor for EnvA therefore pseudotyping the virus with this envelope will decreasing the risk to humans and other mammals.

Fluorescent reporter proteins, e.g. GFP, mCherry or tdTomato, or other standard reporter genes will accumulate intracellularly and/or be inserted into the plasma membrane, thereby labelling the transduced cells. These proteins have a history of safe use.

Light-activated ion channels/pumps (and their reporter protein fusions), e.g. Channelrhodopsin-2 (ChR2) or the Archaerhodopsins (Arch and ArchT), will accumulate intracellularly and be inserted into the plasma membrane.

Enzymes (e.g. Cre or Flp recombinases, horse radish peroxidase) will accumulate intracellularly.

‘Designer Receptors Exclusively Activated by Designer Drugs’ (DREADDs), e.g. hM4D(Gi), will be inserted into the plasma membrane of cells. DREADDs are only active in the presence of their synthetic ‘designer’ ligands.

Other receptors/ligands, e.g. TVA, the highly-specific cognate receptor for the avian sarcoma and leukosis virus envelope protein EnvA, will accumulate intracellularly and be inserted into the plasma membrane of cells.

None of the inserts are expected to increase the hazard of the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

### Project Additional Information

**Purposes of the contained use**

Replicating and conditionally replicating (so called 'oncolytic') adenoviruses and Herpes simplex virus 1 expressing agents capable of further potentiating its anticancer effects.

**Recipient or parental organism**

Adenoviruses such as ColoAd1 which is an Ad11p/Ad3 chimeric group B adenovirus virus or conditionally replicating ones which are dependant upon tumour associated transcription factors or tumour-associated genotypic/phenotypic changes to allow replication.

Herpes simplex virus 1 (17+ strain) with both copies of the neurovirulence gene ICP34.5 gene removed from the virus in order to attenuate neurovirulence in mice and restrict tropism to transformed or malignant cells.

**Host/vector system**

Standard reporter genes such as luciferase, GFP (and its variants) and standard antibiotics

For Adeno virus work:
- Enzymes to increase spread of virus through solid tumour stroma
- Immune modulating agents
- Agents used to affect the immune system
- Prodrug activating enzymes such as E. coli nitroreductase (activated CB1954), cytosine deaminase/UPRT (activates 5-fluorocytosine) or Herpes virus thymidine kinase (activates gancyclovir)

Various promoters such as CMV, ubiquitin promoter or IRES or P2A sites to link expression of the transgene to that of specific virus proteins for strong ubiquitous expression.
### Tissue-specific and cancer-selective promoters.

For HSV work:
Antibodies for use as immune modulating agents.

Cytokines to modulate the tumour microenvironment such as interferon.

Vaccines consisting of a peptide antigen fused to co-stimulatory molecules.

### Evaluation of foreseeable effects

For Adenovirus work:
ColoAd1 has a wild-type Ad11p backbone with a chimeric E2 region and deletions in E3/E4 and was created by hyper-infection of HT20 colorectal carcinoma cells, with multiple adenovirus serotypes. The selection process involved the collection of progeny virus at short time points after infection. This favoured chimeras with the minimal genome necessary to permit replication in tumour cells (shorter genome faster replication). In comparison with Ad11, ColoAd1 is attenuated in normal cells through loss of genomic sequences. It is also further vulnerable to the immune system due to the absence of E3 genes.

Other conditionally replicating adenoviruses can be divided loosely into those that are dependent on tumour-associated transcription factors to regulate expression of key virus proteins, and those dependent on tumour-associated genotypic/phenotypic changes to complement functional deletions in the virus. Transgenes inserted into either E1 or E3 will render the virus either unable to replicate or more vulnerable to the immune system.

Wild type and conditionally replicating human adenovirus cannot be propagated in murine tissue. The performance of the viruses and combinations of viruses will be assessed by intravenous and intratumoural injection into nude and DCID mice that have been pre-implanted with human tumour xenografts. The Virus should replicate in the human tumour tissue but cease when the replication competent (or conditionally replicating) virus reaches a non-permissive cell (eg a mouse cell) replication of both viruses will cease.

For transgenes that are deemed to be harmless such as reporter genes, species specific antibodies and enzymes that have no damaging effect on tissues, strong ubiquitous promoters such as CMV may be used.

For transgenes with potential deleterious effects their expression will be carefully controlled using either tumour-specific promoters or by placing them under control of the adenovirus promoter. Such transgenes will only be employed in adenoviruses that are heavily attenuated and incapable of supporting a productive infection in humans or animals, for example in adenoviruses that have major deletions in their E3 regions and cannot resist rapid elimination by the immune system.

For HSV work:
Herpes simplex 1 with both copies of the neurovirulence gene ICP34.5 gene removed. ICP34.5 counteracts the interferon response in normal cells by causing inactivation of PKR. Many cancer cells have dysfunctional PKR signalling and thus an ICP34.5 disabled herpes virus is still capable of replicating selectively in tumours.

Antibodies for use as immune modulating agents. Antibodies used will be specific for murine antigens, therefore not pose a threat of interfering with the human immune system upon potential exposure.

Cytokines will be used to modulate the tumour microenvironment in an attempt to override immunosuppressive signals produced by tumour cells and associated Tregs and fibroblast cells. There is significant overlap between some cytokines/receptors between mice and humans, however, only cytokines with no cross reactivity between mice and humans will be used such that upon any potential exposure will not interfere with the human immune system.

Vaccines will consist of a peptide antigen fused to co-stimulatory molecules. In this case it is possible that mouse ligand could cross react with human receptor upon potential human exposure, however, any effects separate from ICP34.5 deleted HSV-1 should be against the cancer associated antigen only.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Elucidating the mechanism of chromosome segregation in Trypanosoma brucei

Faithful chromosome segregation is essential for the proliferation of all organisms. Although studies in conventional model eukaryotes have found that macromolecular kinetochore complexes assemble onto centromeric DNA to facilitate segregation, it is not known whether this mechanism applies to all eukaryotes. To uncover fundamental principles of eukaryotic segregation machinery, we study kinetochores in Trypanosoma brucei, an evolutionarily distant eukaryotic parasite. Using a localization-based screen and proteomics, we have identified 19 kinetochore proteins. We aim to characterize these proteins using various techniques both in vivo and in vitro to reveal the molecular mechanism of chromosome segregation in trypanosomes.

Trypanosoma brucei brucei. Procyclic forms of the parasites are non-infectious and T. brucei brucei strains are lysed by human serum. Use is mainly made of strains that have been engineered to express T7 polymerase and Tet repressor to facilitate inducible expression of transfected genes. Engineered genes are effectively silent in the absence of inducer.
Trypanosome vectors are based on a series of vectors constructed to provide prokaryotic tetracycline mediated inducible expression using either endogenous promoters or systems employing T7 polymerase and prokaryotic promoters/repressors.

**Origin & function**

Trypanosome genomic DNA is purified from Trypanosoma brucei brucei. Trypanosome genes/gene fragments will be expressed in E. coli/mammalian cells/insect cells to produce non-toxic recombinant products. Studies of gene function involve the targeted disruption of trypanosome genes through homologous recombination. In addition, RNAi gene knockdowns will be performed by expression of double-stranded RNA to endogenous genes via expression from opposing promoter vectors or as inverted repeat constructs. These are established technologies in trypanosomes. Trypanosome deletion mutants or RNAi cells, induced by tetracycline, are tested for phenotype during in vitro culture.

The main types of gene insert to be used are:

- Genes encoding kinetochore proteins that play a role in mediating the interaction between centromere DNA and spindle microtubules, as well as other mitotic proteins. Usually these genes will be tagged to provide epitope or other marking of the expressed proteins.
- Portions of genes arranged to produce double stranded RNA copies that will down regulate endogenous gene expression by means of RNA interference.
- Flanking sequences will be used to engineer gene targeting and knockouts.

**Evaluation of foreseeable effects**

The main focus of our work is genes that are likely to be important for chromosome segregation, cell cycle and nuclear organization. Final GMOs will contain one or more of the trypanosome genes of interest. In each expression system there is deliberate, in frame insertion of expressible DNA downstream of a strong promoter. However, the genes expressed are non toxic and will not increase the survival, replication or pathogenicity of the host strains.

Most experiments will not involve cross-species transfer. Some experiments will test putative homologous genes from other strains/species/genus for complementation of function or inactivation of function in trypanosomes. Given that the genes to be moved are involved in housekeeping functions and are not known (or likely to be) virulence genes, the likely outcome of movement of genes is loss of virulence, and in the case of movement into a non-pathogenic strain will not result in a gain of virulence.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

### Project Additional Information

**Purposes of the contained use**

Use of retro and lentivirus to elucidate the function of molecular events propagated in chromatin upon DNA damage detection, the influence these have on the execution of accurate DNA repair, and how defects in these events manifest in immune deficiency and cancer.

**Recipient or parental organism**

- E. coli K12 derivatives
- Mammalian cell lines such as 293 derivatives, U2OS, RPE, He La
- Primary cells

**Host/vector system**

- Adeno associated virus - replication defective
- Lentivirus - replication defective
- Retrovirus - replication defective

**Origin & function**

- Genes such as BRCA1, 53BP1, RIF1 and associated proteins thought to be involved in coordinating chromatin reorganisation during double strand break repair.
  
  RIF1 is thought to be the critical effector of 53BP1-dependent DNA repair by non-homologous end joining
  
  BRCA1 (Breast cancer 1 early onset gene) is responsible for repairing DNA and mutations of this gene are linked to an increase in risk of cancer.
  
  53BP1 (tumour suppressor p53 binding protein 1) mediates DNA repair and is underexpressed in some cancers
  
- Other genes expected to play a role in double stranded break repair
  
  WPRE (present in the lentiviral vectors) is a potential oncogene
  
- Reporter genes such as GFP, strep-Tag and FLAG
Standard antibiotic resistance genes

Evaluation of foreseeable effects

AAV virus - Wild type AAV are not thought to cause disease in human. Replication defective versions will be used. Genes required are separated onto 3 plasmids and a packaging cell line reducing the likelihood of recombination. The viral particles do not contain any of the viral genome but only the targeting construct comprising homology regions proximal to initiator/terminator sequences of the gene of interest coding sequence to an epitope tag, a selection marker, and recombination sites (loxP/frt) to facilitate the subsequent excision of selection markers if required. All transgene-expression related sequences of the gene to be tagged to facilitate accurate gene targeting. The transgene should integrate into a targetted region as opposed to remaining episomal. Expression of the tagging proteins is not expected to increase the hazard of the AAV.

Lentivirus - replication defective. The gene products required for viral particle generation are split onto 3 plasmids and a packaging cell line to reduce the possibility of recombination. The viral particles do not contain viral genes only cDNA or shRNA of interest and selection marker. Lentiviral particles randomly integrate.

Retrovirus - is replication defective and based on MoMLV (mouse leukemia virus). Essential viral genes are split between a shuttle vector and the packaging cell line to reduce the possibility of recombination. The viral particles do not contain viral genes only cDNA or shRNA of interest and selection marker.

Occasionally the genes to be over expressed/knocked out may be a tumour suppressor genes. Overexpression is not expected to be hazardous however knocking out the gene has the potential to be hazardous.

Expression of WPRE in the lentiviral vectors is potentially hazardous.

Generation and work with viral particles - Class 2

Transfected cell lines are not expected to be hazardous after initial round of integration

02/03/2022
This project aims to use two techniques of super-resolution microscopy (SIM and STORM, both available at the Department of Biochemistry) to characterize the localization of proteins required for cell and synthesis and cell division of S. aureus.

Recipient or parental organism
Staphylococcus aureus - Hazard group 2
strain RN4220: methicillin susceptible strain
strain NCTC8325-4: methicillin susceptible strains
strain COL: methicillin-resistant strain

Host/vector system
Genetically modified strains were created elsewhere using pMAD vector, pCNX (Derivative of the pCN51 vector) and pMGPII vector

Origin & function
Proteins involved in cell wall synthesis and division, such as PBP2 and PBP4 (involved in peptidoglycan biosynthesis), SpolIIIE and Slp (two DNA translocases required during cell division) and FtsZ and EzrA (two components of the divisome). If required other proteins will also be studied.

Fluorescent marker genes such as GFP, YFP and mCherry

Photswitchable and photoactivatable fluorescent fusions such as PAmCherry (red), PAGFP (green) and green-to-red photoswitchable mMaple.

Standard antibiotic resistance genes such as erythromycin, chloramphenicol and kanamycin.

Evaluation of foreseeable effects
Staphylococcus aureus are bacteria commonly carried on the skin or in the nose of healthy people without causing any disease. However in some cases can cause infections that are usually mild, superficial infections of the skin, however in some cases it does have the potential to cause serious life threatening illness.

Strains RN4220 and NCTC8325-4 are laboratory reference strains, susceptible to antibiotics normally used to control S. aureus infections. RN4220 has a mutation in the agr locus and NCTC8325-4 has a mutation the the sigmaB locus. Both mutations result in attenuated ability to cause infection. Strain COL is resistant to methicillin and
other beta-lactam antibiotics. However it is susceptible to a variety of antibiotics.

Addition of fluorescing genes is not expected to make the S. aureus more hazardous.

Deleting the genes of interest or mutating them is not expected to affect the pathogenicity of the bacterium.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration - Use of sharps is minimised in this project.

Degree of kill:
- Autoclaving, effectively 10% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

**Purposes of the contained use**

Use of replication defective lentiviral vectors to aid the study of cardiovascular disease

**Recipient or parental organism**

- Mammalian cells such as primary epicardium cells.
- Standard cell lines.
- Lentiviral production cells based on 293 cells and their derivatives

**Host/vector system**

02/03/2022  

Page 9131 of 15326
Standard replication defective lentiviral vectors which contain the minimal genes necessary split onto 2 or 3 separate plasmids (second or third generation vector systems).

In certain cases the Tet ON system will be used in the viral vectors so that the gene of interest will only be expressed in the presence of doxycycline enhancing the safety features.

### Origin & function

c-myc appears to play a central role in cell growth regulation and cell metabolism and its overexpression is often observed in cancerous cells. It is also one of four genes which when combined are used to create induced pluripotent stem cells.

WPRE - Woodchuck post regulatory response element which is known to enhance shRNA function by stabilizing and promoting nuclear export and also increase lentiviral titres by facilitating the packaging of the virus. However, there have been concerns about the use of WPRE as it has been reported that it may lead to tumourigenesis especially if it encodes the X protein.

Standard antibiotic resistance genes such as ampicillin, puromycin and hygromycin etc.

Commonly used reporter genes such as GFP, luciferase etc.

Overexpression or knockdown of key factors or small molecules to stimulate proliferation, migration, differentiation and maturation, with the potential to promote cardiovascular repair and regeneration.

Expression or knockdown of a number of these genes could have potentially deleterious effects although use of control measures to minimise percutaneous and inhalation exposure will reduce the risks to minimal.

### Evaluation of foreseeable effects

Rhomboids are intramembrane serine proteases that cleave membrane proteins within the bilayer and are involved in a wide range of biological processes. Mammalian rhomboid targets include thrombomodulin, ephrinB4 and EGF but Rhomboids are generally highly specific with a limited number of substrates.

iRhom molecules lack intramembrane protease activity but are required for inactivation of Tumour Necrosis Factor α Converting Enzyme (TACE) and thus secretion of TNFα and various EGFR ligands.

EGFR ligands, such as EGF, amphiregulin and HB-EGF will lead to activation of downstream signalling cascades such as the MAPK and JNK pathways leading to processes such as migration or proliferation. As such a precautionary approach will be taken.

The diversity of biological functions already known to depend on rhomboids is reflected in evidence that rhomboids play a role in a variety of diseases including cancer, parasite infection, Parkinson's disease and diabetes.

Standard fluorescent protein reporter genes, such as enhanced green fluorescent protein (EGFP), will be transduced into cells using lentiviral vectors, to provide positive controls with which to assess the efficiency of lentiviral transfer. Fluorescent proteins are a common investigative tool and no hazards are associated with their use.

The silencing of rhomboid and rhomboid related genes can be achieved using a Cas9 CRISPR-associated nuclease expressed under an EFS promoter which is guided to specific sites within the host genomes of human and mouse cells by a customizable sgRNA (synthetic single-guide RNA), under a U6 promoter, DNA double strand breaks, catalysed by Cas9, create frame shift insertion/deletion (indel) mutations that result in a loss-of-function allele.

Some concern has been raised with regards to the potential oncogenic nature of the WPRE which is present in many lentiviral vectors and therefore precautionary approach is adopted with these lentiviral particles.
Other risks from lentiviral particles is from their potential to integrate within a tumour supressor region of the genome however that will be minimised due to the lack of sharps within this project.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM

Project Containment
The project aims to investigate possible interactions between Streptococcus pyogenes, the agent responsible for group A streptococcal infections, and vessels/sinuses of the lymphatic system that may provide routes of entry, dissemination or sequestration in mucosal tissue and draining lymph nodes.

Streptococcus pyogenes causes human disease, ranging from simple (asymptomatic) colonisation of the throat, to pharyngitis, cellulitis, to necrotising soft tissue infection, and bacteremia with septic shock and death. It can also cause immunological sequellae such as rheumatic fever, the pathogenesis of which is unknown.

Recipient or parental organism

Streptococcus pyogenes causes human disease, ranging from simple (asymptomatic) colonisation of the throat, to pharyngitis, cellulitis, to necrotising soft tissue infection, and bacteremia with septic shock and death. It can also cause immunological sequellae such as rheumatic fever, the pathogenesis of which is unknown.

Host/vector system

pDL278 and derivatives. Confers SpectinomycinR
pGHost5 and derivatives. Confers Erythromycin R
pUCMUT and derivatives (gene targeting/knockout vector) Confers kanamycinR
pICL18 and derivatives including pICL18.LUX.

**Origin & function**

Short non-functional segments of putative S. pyogenes virulence genes to facilitate homologous recombination and mutagenesis of target genes.

Plasmids used for complementation will carry coding sequences of putative virulence factors that are missing from the host organisms eg superantigen genes spea, smez, mf; enzymes such as spycop; regulatory genes such as covRS.

Plasmids carrying reporter genes will include genes for fluorescent proteins such as gfp and other spectral variants; genes encoding bioluminescent systems (the luciferases are enzymes that produce light as a by-product of oxidation of a specific substrate, eg luxABCDE, gluc, lucff)

**Evaluation of foreseeable effects**
